Cisco ASA Series Command Reference

About This Guide

This preface includes the following sections:

Document Objectives

This guide contains the commands available for use with the ASA to protect your network from unauthorized use and to establish Virtual Private Networks (VPNs) to connect remote sites and users to your network.

You can also configure and monitor the ASA by using ASDM, a web-based GUI application. ASDM includes configuration wizards to guide you through some common configuration scenarios, and online Help for less common scenarios.

This guide applies to the Cisco ASA series. Throughout this guide, the term “ASA” applies generically to all supported models, unless specified otherwise.

Audience

This guide is for network managers who perform any of the following tasks:

- Manage network security
- Install and configure firewall/security appliances
- Configure VPNs
- Configure intrusion detection software

Use this guide with the CLI configuration guide.

Document Organization

- "Using the Command-Line Interface" introduces you to the ASA commands and access modes.
- Each chapter lists all commands in alphabetical order.
- "Cisco IOS Commands for the ASASM" lists the Cisco IOS commands that are used with the ASASM.

Document Conventions

The ASA command syntax descriptions use the following conventions:

Command descriptions use these conventions:

- Braces ({ }) indicate a required choice.
- Square brackets ([ ]) indicate optional elements.
- Vertical bars (|) separate alternative, mutually exclusive elements.
- **Boldface** indicates commands and keywords that are entered literally as shown.
- *Italics* indicate arguments for which you supply values.

Examples use these conventions:

- Examples depict screen displays and the command line in `screen` font.
- Information you need to enter in examples is shown in **`boldface screen`** font.
- Variables for which you must supply a value are shown in *`italic screen`* font.
- Examples might include output from different platforms; for example, you might not recognize an interface type in an example because it is not available on your platform. Differences should be minor.

Note Means *reader take note*. Notes contain helpful suggestions or references to material not covered in the manual.

Caution Means *reader be careful*. In this situation, you might do something that could result in equipment damage or loss of data.

Tip Means *reader take notice*. Tips include a useful hint or idea that may help you with an issue.

For information on modes, prompts, and syntax, see Using the Command-Line Interface.

Obtaining Documentation and Submitting a Service Request

For information on obtaining documentation, using the Cisco Bug Search Tool (BST), submitting a service request, and gathering additional information, see *What's New in Cisco Product Documentation* at: http://www.cisco.com/en/US/docs/general/whatsnew/whatsnew.html.

Subscribe to *What's New in Cisco Product Documentation*, which lists all new and revised Cisco technical documentation, as an RSS feed and deliver content directly to your desktop using a reader application. The RSS feeds are a free service.

Using the Command-Line Interface

This appendix describes how to use the CLI on the ASA and includes the following sections:

Note The CLI uses similar syntax and other conventions to the Cisco IOS CLI, but the ASA operating system is not a version of Cisco IOS software. Do not assume that a Cisco IOS CLI command works with or has the same function on the ASA.

Firewall Mode and Security Context Mode

The ASA runs in a combination of the following modes:

- Transparent firewall or routed firewall mode

  The firewall mode determines if the ASA runs as a Layer 2 or Layer 3 firewall.

- Multiple context or single context mode

  The security context mode determines if the ASA runs as a single device or as multiple security contexts, which act like virtual devices.

Some commands are only available in certain modes.

Command Modes and Prompts

The ASA CLI includes command modes. Some commands can only be entered in certain modes. For example, to enter commands that show sensitive information, you need to enter a password and enter a more privileged mode. Then, to ensure that configuration changes are not entered accidentally, you have to enter a configuration mode. All lower commands can be entered in higher modes, for example, you can enter a privileged EXEC command in global configuration mode.

Note The various types of prompts are all default prompts and when configured, they can be different.

- When you are in the system configuration or in single context mode, the prompt begins with the hostname:

  ```
  hostname
  ```

- When printing the prompt string, the prompt configuration is parsed and the configured keyword values are printed in the order in which you have set the **prompt** command. The keyword arguments can be any of the following and in any order: hostname, domain, context, priority, state.

  ```
  asa(config)# prompt hostname context priority state
  ```

- When you are within a context, the prompt begins with the hostname followed by the context name:

  ```
  hostname/context
  ```

The prompt changes depending on the access mode:

- User EXEC mode

  User EXEC mode lets you see minimum ASA settings. The user EXEC mode prompt appears as follows when you first access the ASA:

  ```
  hostname>

  hostname/context>
  ```

- Privileged EXEC mode

  Privileged EXEC mode lets you see all current settings up to your privilege level. Any user EXEC mode command will work in privileged EXEC mode. Enter the **enable** command in user EXEC mode, which requires a password, to start privileged EXEC mode. The prompt includes the number sign (#):

  ```
  hostname#

  hostname/context#
  ```

- Global configuration mode

  Global configuration mode lets you change the ASA configuration. All user EXEC, privileged EXEC, and global configuration commands are available in this mode. Enter the **configure terminal** command in privileged EXEC mode to start global configuration mode. The prompt changes to the following:

  ```
  hostname(config)#

  hostname/context(config)#
  ```

- Command-specific configuration modes

From global configuration mode, some commands enter a command-specific configuration mode. All user EXEC, privileged EXEC, global configuration, and command-specific configuration commands are available in this mode. For example, the **interface** command enters interface configuration mode. The prompt changes to the following:

```
hostname(config-if)#

hostname/context(config-if)#
```

Syntax Formatting

Command syntax descriptions use the conventions listed in Table i-1.

Table i-1 Syntax Conventions

Convention	Description
bold	Bold text indicates commands and keywords that you enter literally as shown.
italics	Italic text indicates arguments for which you supply values.
[x]	Square brackets enclose an optional element (keyword or argument).
|	A vertical bar indicates a choice within an optional or required set of keywords or arguments.
[x | y]	Square brackets enclosing keywords or arguments separated by a vertical bar indicate an optional choice.
{x | y}	Braces enclosing keywords or arguments separated by a vertical bar indicate a required choice.
[x {y | z}]	Nested sets of square brackets or braces indicate optional or required choices within optional or required elements. Braces and a vertical bar within square brackets indicate a required choice within an optional element.

Abbreviating Commands

You can abbreviate most commands down to the fewest unique characters for a command; for example, you can enter **wr t** to view the configuration instead of entering the full command **write terminal**, or you can enter **en** to start privileged mode and **conf t** to start configuration mode. In addition, you can enter **0** to represent **0.0.0.0**.

Command-Line Editing

The ASA uses the same command-line editing conventions as Cisco IOS software. You can view all previously entered commands with the **show history** command or individually with the up arrow or **^p** command. Once you have examined a previously entered command, you can move forward in the list with the down arrow or **^n** command. When you reach a command you wish to reuse, you can edit it or press the **Enter** key to start it. You can also delete the word to the left of the cursor with **^w**, or erase the line with **^u**.

The ASA permits up to 512 characters in a command; additional characters are ignored.

Command Completion

To complete a command or keyword after entering a partial string, press the **Tab** key. The ASA only completes the command or keyword if the partial string matches only one command or keyword. For example, if you enter **s** and press the **Tab** key, the ASA does not complete the command because it matches more than one command. However, if you enter **dis**, the **Tab** key completes the **disable** command.

Command Help

Help information is available from the command line by entering the following commands:

- **help** *command_name*

  Shows help for the specific command.

- *command_name* **?**

  Shows a list of arguments available.

- *string***?** (no space)

  Lists the possible commands that start with the string.

- **?** and **+?**

  Lists all commands available. If you enter **?**, the ASA shows only commands available for the current mode. To show all commands available, including those for lower modes, enter **+?**.

Note If you want to include a question mark (?) in a command string, you must press **Ctrl-V** before typing the question mark so that you do not inadvertently invoke CLI help.

Viewing the Running Configuration

To view the running configuration, use one of the following commands.

To filter the command output, see the "Filtering show and more Command Output" section on page xi.

Command	Purpose
show running-config [**all**] [*command*]	Shows the running configuration. If you specify **all**, then all default settings are shown as well. If you specify a *command*, then the output only includes related commands. **Note** Many passwords are shown as *****. To view the passwords in plain text, or in encrypted form if you have a master passphrase enabled (see the "Configuring the Master Passphrase" section on page 12-8), use the **more** command below.
more system:running-config	Shows the running configuration. Passwords are shown in plain text or in encrypted form if you have a master passphrase enabled (see the "Configuring the Master Passphrase" section on page 12-8).

Filtering show and more Command Output

You can use the vertical bar (|) with any **show** command and include a filter option and filtering expression. The filtering is performed by matching each output line with a regular expression, similar to Cisco IOS software. By selecting different filter options you can include or exclude all output that matches the expression. You can also display all output beginning with the line that matches the expression.

The syntax for using filtering options with the **show** command is as follows:

```
hostname# show command | {include | exclude | begin | grep [-v]} regexp
```

or

```
hostname# more system:running-config | {include | exclude | begin | grep [-v]} regexp
```

Note The **more** command can view the contents of any file, not just the running configuration; see the command reference guide for more information.

In this command string, the first vertical bar (|) is the operator and must be included in the command. This operator directs the output of the **show** command to the filter. In the syntax diagram, the other vertical bars (|) indicate alternative options and are not part of the command.

The **include** option includes all output lines that match the regular expression. The **grep** option without **-v** has the same effect. The **exclude** option excludes all output lines that match the regular expression. The **grep** option with **-v** has the same effect. The **begin** option shows all the output lines starting with the line that matches the regular expression.

Replace *regexp* with any Cisco IOS regular expression. The regular expression is not enclosed in quotes or double-quotes, so be careful with trailing white spaces, which will be taken as part of the regular expression.

When creating regular expressions, you can use any letter or number that you want to match. In addition, certain keyboard characters called *metacharacters* have special meaning when used in regular expressions.

Use **Ctrl+V** to escape all of the special characters in the CLI, such as a question mark (?) or a tab. For example, type **d[Ctrl+V]?g** to enter **d?g** in the configuration.

For a list of metacharacters, see Table 15-1 on page 15-15.

Command Output Paging

For commands such as **help** or **?**, **show**, **show xlate**, or other commands that provide long listings, you can determine if the information displays a screen and pauses, or lets the command run to completion. The **pager** command lets you choose the number of lines to display before the More prompt appears.

When paging is enabled, the following prompt appears:

```
<--- More --->
```

The More prompt uses syntax similar to the UNIX **more** command:

- To view another screen, press the **Space** bar.
- To view the next line, press the **Enter** key.
- To return to the command line, press the **q** key.

Adding Comments

You can precede a line with a colon (:) to create a comment. However, the comment only appears in the command history buffer and not in the configuration. Therefore, you can view the comment with the **show history** command or by pressing an arrow key to retrieve a previous command, but because the comment is not in the configuration, the **write terminal** command does not display it.

Text Configuration Files

This section describes how to format a text configuration file that you can download to the ASA, and includes the following topics:

How Commands Correspond with Lines in the Text File

The text configuration file includes lines that correspond with the commands described in this guide.

In examples, commands are preceded by a CLI prompt. The prompt in the following example is "hostname(config)#":

```
hostname(config)# context a
```

In the text configuration file you are not prompted to enter commands, so the prompt is omitted:

```
context a
```

Command-Specific Configuration Mode Commands

Command-specific configuration mode commands appear indented under the main command when entered at the command line. Your text file lines do not need to be indented, as long as the commands appear directly following the main command. For example, the following unindented text is read the same as indented text:

```
interface gigabitethernet0/0
nameif inside
interface gigabitethernet0/1
    nameif outside
```

Automatic Text Entries

When you download a configuration to the ASA, it inserts some lines automatically. For example, the ASA inserts lines for default settings or for the time the configuration was modified. You do not need to enter these automatic entries when you create your text file.

Line Order

For the most part, commands can be in any order in the file. However, some lines, such as ACEs, are processed in the order they appear, and the order can affect the function of the access list. Other commands might also have order requirements. For example, you must enter the **nameif** command for an interface first because many subsequent commands use the name of the interface. Also, commands in a command-specific configuration mode must directly follow the main command.

Commands Not Included in the Text Configuration

Some commands do not insert lines in the configuration. For example, a runtime command such as **show running-config** does not have a corresponding line in the text file.

Passwords

The login, enable, and user passwords are automatically encrypted before they are stored in the configuration. For example, the encrypted form of the password “cisco” might look like jMorNbK0514fadBh. You can copy the configuration passwords to another ASA in its encrypted form, but you cannot unencrypt the passwords yourself.

If you enter an unencrypted password in a text file, the ASA does not automatically encrypt it when you copy the configuration to the ASA. The ASA only encrypts it when you save the running configuration from the command line using the **copy running-config startup-config** or **write memory** command.

Multiple Security Context Files

For multiple security contexts, the entire configuration consists of the following multiple parts:

- The security context configurations
- The system configuration, which identifies basic settings for the ASA, including a list of contexts
- The admin context, which provides network interfaces for the system configuration

  The system configuration does not include any interfaces or network settings for itself. Rather, when the system needs to access network resources (such as downloading the contexts from the server), it uses a context that is designated as the admin context.

Each context is similar to a single context mode configuration. The system configuration differs from a context configuration in that the system configuration includes system-only commands (such as a list of all contexts) while other typical commands are not present (such as many interface parameters).

Supported Character Sets

The ASA CLI currently supports UTF-8 encoding only. UTF-8 is the particular encoding scheme for Unicode symbols, and has been designed to be compatible with an ASCII subset of symbols. ASCII characters are represented in UTF-8 as one-byte characters. All other characters are represented in UTF-8 as multibyte symbols.

The ASCII printable characters (0x20 to 0x7e) are fully supported. The printable ASCII characters are the same as ISO 8859-1. UTF-8 is a superset of ISO 8859-1, so the first 256 characters (0-255) are the same as ISO 8859-1. The ASA CLI supports up to 255 characters (multibyte characters) of ISO 8859-1.

aaa accounting command through accounting-server-group Commands

aaa accounting command

To send accounting messages to the TACACS+ accounting server when you enter any command other than **show** commands at the CLI, use the **aaa accounting command** command in global configuration mode. To disable support for command accounting, use the **no** form of this command.

aaa accounting command [**privilege** *level*] *tacacs+-server-tag*

no aaa accounting command [**privilege** *level*] *tacacs+-server-tag*

Syntax Description

privilege *level*	If you customize the command privilege level using the **privilege** command, you can limit which commands the ASA accounts for by specifying a minimum privilege level. The ASA does not account for commands that are below the minimum privilege level. **Note** If you enter a deprecated command and enabled the **privilege** keyword, then the ASA does not send accounting information for the deprecated command. If you want to account for deprecated commands, be sure to disable the **privilege** keyword. Many deprecated commands are still accepted at the CLI, and are often converted into the currently accepted command at the CLI; they are not included in CLI help or this guide.
tacacs+-server-tag	Specifies the server or group of TACACS+ servers to which accounting records are sent, as specified by the **aaa-server protocol** command.

Defaults

The default privilege level is 0.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

When you configure the **aaa accounting command** command, each command other than **show** commands entered by an administrator is recorded and sent to the accounting server or servers.

Examples

The following example specifies that accounting records will be generated for any supported command, and that these records are sent to the server from the group named adminserver:

```
hostname(config)# aaa accounting command adminserver
```

Related Commands

Command	Description
aaa accounting	Enables or disables TACACS+ or RADIUS user accounting (on a server designated by the **aaa-server** command).
clear configure aaa	Removes or resets the configured AAA accounting values.
show running-config aaa	Displays the AAA configuration.

aaa accounting console

To enable support for AAA accounting for administrative access, use the **aaa accounting console** command in global configuration mode. To disable support for aaa accounting for administrative access, use the **no** form of this command.

aaa accounting {**serial | telnet | ssh | enable**} **console** *server-tag*

no aaa accounting {**serial | telnet | ssh | enable**} **console** *server-tag*

Syntax Description

enable	Enables the generation of accounting records to mark the entry to and exit from privileged EXEC mode.
serial	Enables the generation of accounting records to mark the establishment and termination of admin sessions that are established via the serial console interface.
server-tag	Specifies the server group to which accounting records are sent, defined by the **aaa-server protocol** command. Valid server group protocols are RADIUS and TACACS+.
ssh	Enables the generation of accounting records to mark the establishment and termination of admin sessions created over SSH.
telnet	Enables the generation of accounting records to mark the establishment and termination of admin sessions created over Telnet.

Defaults

By default, AAA accounting for administrative access is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You must specify the name of the server group, previously specified in the **aaa-server** command.

Examples

The following example specifies that accounting records will be generated for enable access, and that these records are sent to the server named adminserver:

```
hostname(config)# aaa accounting enable console adminserver
```

Related Commands

Command	Description
aaa accounting match	Enables or disables TACACS+ or RADIUS user accounting (on a server designated by the **aaa-server** command),
aaa accounting command	Specifies that each command, or commands of a specified privilege level or higher, entered by an administrator/user is recorded and sent to the accounting server or servers.
clear configure aaa	Removes or resets the configured AAA accounting values.
show running-config aaa	Displays the AAA configuration.

aaa accounting include, exclude

To enable accounting for TCP or UDP connections through the ASA, use the **aaa accounting include** command in global configuration mode. To exclude addresses from accounting, use the **aaa accounting exclude** command. To disable accounting, use the **no** form of this command.

aaa accounting {**include** | **exclude**} *service interface_name inside_ip inside_mask* [*outside_ip outside_mask*] *server_tag*

no aaa accounting {**include** | **exclude**} *service interface_name inside_ip inside_mask* [*outside_ip outside_mask*] *server_tag*

Syntax Description

exclude	Excludes the specified service and address from accounting if it was already specified by an **include** command.
include	Specifies the services and IP addresses that require accounting. Traffic that is not specified by an **include** statement is not processed.
inside_ip	Specifies the IP address on the higher security interface. This address might be the source or the destination address, depending on the interface to which you apply this command. If you apply the command to the lower security interface, then this address is the destination address. If you apply the command to the higher security interface, then this address is the source address. Use 0 to mean all hosts.
inside_mask	Specifies the network mask for the inside IP address. Use 0 if the IP address is 0. Use 255.255.255.255 for a host.
interface_name	Specifies the interface name from which users require accounting.
outside_ip	(Optional) Specifies the IP address on the lower security interface. This address might be the source or the destination address, depending on the interface to which you apply this command. If you apply the command to the lower security interface, then this address is the source address. If you apply the command to the higher security interface, then this address is the destination address. Use 0 to mean all hosts.
outside_mask	(Optional) Specifies the network mask for the outside IP address. Use 0 if the IP address is 0. Use 255.255.255.255 for a host.
server_tag	Specifies the AAA server group defined by the **aaa-server host** command.
service	Specifies the services that require accounting. You can specify one of the following values: • **any** or **tcp/0** (specifies all TCP traffic) • ftp • http • **https** • **ssh** • telnet • **tcp/***port* • **udp/***port*

Defaults

By default, AAA accounting for administrative access is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The ASA can send accounting information to a RADIUS or TACACS+ server about any TCP or UDP traffic that passes through the ASA. If that traffic is also authenticated, then the AAA server can maintain accounting information by username. If the traffic is not authenticated, the AAA server can maintain accounting information by IP address. Accounting information includes when sessions start and stop, username, the number of bytes that pass through the ASA for the session, the service used, and the duration of each session.

Before you can use this command, you must first designate a AAA server with the **aaa-server** command.

To enable accounting for traffic that is specified by an ACL, use the **aaa accounting match** command. You cannot use the **match** command in the same configuration as the **include** and **exclude** commands. We suggest that you use the **match** command instead of the **include** and **exclude** commands; the **include** and **exclude** commands are not supported by ASDM.

You cannot use the **aaa accounting include** and **exclude** commands between same-security interfaces. For that scenario, you must use the **aaa accounting match** command.

Examples

The following example enables accounting on all TCP connections:

```
hostname(config)# aaa-server mygroup protocol tacacs+
hostname(config)# aaa-server mygroup (inside) host 192.168.10.10 thekey timeout 20
hostname(config)# aaa accounting include any inside 0 0 0 0 mygroup
```

Related Commands

Command	Description
aaa accounting match	Enables accounting for traffic specified by an ACL.
aaa accounting command	Enables accounting of administrative access.
aaa-server host	Configures the AAA server.
clear configure aaa	Clears the AAA configuration.
show running-config aaa	Displays the AAA configuration.

aaa accounting match

To enable accounting for TCP and UDP connections through the ASA, use the **aaa accounting match** command in global configuration mode. To disable accounting for traffic, use the **no** form of this command.

aaa accounting match *acl_name interface_name server_tag*

no aaa accounting match *acl_name interface_name server_tag*

Syntax Description

acl_name	Specifies the traffic that requires accounting by matching an ACL name. Permit entries in the ACL are accounted, while deny entries are exempt from accounting. This command is only supported for TCP and UDP traffic. A warning message is displayed if you enter this command and it references an ACL that permits other protocols.
interface_name	Specifies the interface name from which users require accounting.
server_tag	Specifies the AAA server group tag defined by the **aaa-server** command.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The ASA can send accounting information to a RADIUS or TACACS+ server about any TCP or UDP traffic that passes through the ASA. If that traffic is also authenticated, then the AAA server can maintain accounting information by username. If the traffic is not authenticated, the AAA server can maintain accounting information by IP address. Accounting information includes when sessions start and stop, username, the number of bytes that pass through the ASA for the session, the service used, and the duration of each session.

Before you can use this command, you must first designate a AAA server with the **aaa-server** command.

Accounting information is sent only to the active server in a server group unless you enable simultaneous accounting using the **accounting-mode** command in aaa-server protocol configuration mode.

You cannot use the **aaa accounting match** command in the same configuration as the **aaa accounting include** and **exclude** commands. We suggest that you use the **match** command instead of the **include** and **exclude** commands; the **include** and **exclude** commands are not supported by ASDM.

Examples

The following example enables accounting for traffic matching a specific ACL acl2:

```
hostname(config)# access-list acl12 extended permit tcp any any
hostname(config)# aaa accounting match acl2 outside radserver1
```

Related Commands

Command	Description
aaa accounting include, exclude	Enables accounting by specifying the IP addresses directly in the command.
access-list extended	Creates an ACL.
clear configure aaa	Removes AAA configuration.
show running-config aaa	Displays the AAA configuration.

aaa authentication console

To authenticate users who access the ASA CLI over a serial, SSH, HTTPS (ASDM), or Telnet connection, or to authenticate users who access privileged EXEC mode using the **enable** command, use the **aaa authentication console** command in global configuration mode. To disable authentication, use the **no** form of this command.

aaa authentication {**serial | enable | telnet | ssh | http**} **console** {**LOCAL |** *server_group* [**LOCAL**]}

no aaa authentication {**serial | enable | telnet | ssh | http**} **console** {**LOCAL |** *server_group* [**LOCAL**]}

Syntax Description

enable	Authenticates users who access privileged EXEC mode when they use the **enable** command.
http	Authenticates ASDM users who access the ASA over HTTPS. You only need to configure HTTPS authentication if you want to use a RADIUS or TACACS+ server. By default, ASDM uses the local database for authentication even if you do not configure this command.

LOCAL	Uses the local database for authentication. The **LOCAL** keyword is case sensitive. If the local database is empty, the following warning message appears:
	`Warning:local database is empty! Use 'username' command to define local users.`
	If the local database becomes empty when the **LOCAL** keyword is still present in the configuration, the following warning message appears:
	`Warning:Local user database is empty and there are still commands using 'LOCAL' for authentication.`

server-tag [**LOCAL**]	Specifies the AAA server group tag defined by the **aaa-server** command. HTTPS management authentication does not support the SDI protocol for a AAA server group. If you use the **LOCAL** keyword in addition to the *server-tag* argument, you can configure the ASA to use the local database as a fallback method if the AAA server is unavailable. The **LOCAL** keyword is case sensitive. We recommend that you use the same username and password in the local database as the AAA server because the ASA prompt does not give any indication which method is being used.
serial	Authenticates users who access the ASA using the serial console port.
ssh	Authenticates users who access the ASA using SSH.
telnet	Authenticates users who access the ASA using Telnet.

Defaults

By default, fallback to the local database is disabled.

If the **aaa authentication telnet console** command is not defined, you can gain access to the ASA CLI with the ASA login password (set with the **password** command).

If the **aaa authentication http console** command is not defined, you can gain access to the ASA (via ASDM) with no username and the ASA enable password (set with the **enable password** command). If the **aaa** commands are defined, but the HTTPS authentication requests a time out, which implies the AAA servers might be down or not available, you can gain access to the ASA using the default administrator username and the enable password. By default, the enable password is not set.

If the **aaa authentication ssh console** command is not defined, you can gain access to the ASA CLI with the username **pix** and with the ASA enable password (set with the **enable password** command). By default, the enable password is blank. This behavior differs from when you log in to the ASA without AAA configured; in that case, you use the login password (set by the **password** command).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Before the ASA can authenticate a Telnet or SSH user, you must first configure access to the ASA using the **telnet** or **ssh** commands. These commands identify the IP addresses that are allowed to communicate with the ASA.

Logging in to the Security Appliance

After you connect to the ASA, you log in and access user EXEC mode.

- If you do not enable any authentication for Telnet, you do not enter a username; you enter the login password (set with the **password** command). For SSH, you enter “pix” as the username, and enter the login password.
- If you enable Telnet or SSH authenticationusing this command, you enter the username and password as defined on the AAA server or local user database.

Accessing Privileged EXEC Mode

To enter privileged EXEC mode, enter the **enable** command or the **login** command (if you are using the local database only).

- If you do not configure enable authentication, enter the system enable password when you enter the **enable** command (set by the **enable password** command). However, if you do not use enable authentication, after you enter the **enable** command, you are no longer logged in as a particular user. To maintain your username, use enable authentication.
- If you configure enable authentication, the ASA prompts you for your username and password.

For authentication using the local database, you can use the **login** command, which maintains the username but requires no configuration to turn on authentication.

Accessing ASDM

By default, you can log into ASDM with a blank username and the enable password set by the **enable password** command. However, if you enter a username and password at the login screen (instead of leaving the username blank), ASDM checks the local database for a match.

Although you can configure HTTPS authentication using this command and specify the local database, that functionality is always enabled by default. You should only configure HTTPS authentication if you want to use a AAA server for authentication. HTTPS authentication does not support the SDI protocol for a AAA server group. The maximum username prompt for HTTPS authentication is 30 characters. The maximum password length is 16 characters.

No Support in the System Execution Space for AAA Commands

In multiple context mode, you cannot configure any AAA commands in the system configuration.

Number of Login Attempts Allowed

As the following table shows, the action of the prompts for authenticated access to the ASA CLI differ, depending on the option you choose with the **aaa authentication console** command.

Option	Number of Login Attempts Allowed
enable	Three tries before access is denied
serial	Continual until success
ssh	Three tries before access is denied
telnet	Continual until success
http	Continual until success

Limiting User CLI and ASDM Access

You can configure management authorization with the **aaa authorization exec** command to limit a local user, RADIUS, TACACS+, or LDAP user (if you map LDAP attributes to RADIUS attributes) from accessing the CLI, ASDM, or the **enable** command.

Note Serial access is not included in management authorization, so if you configure **aaa authentication serial console**, then any user who authenticates can access the console port.

To configure the user for management authorization, see the following requirements for each AAA server type or local user:

- RADIUS or LDAP (mapped) users—Configures the Service-Type attribute for one of the following values. (To map LDAP attributes, see the **ldap attribute-map** command.)
  - Service-Type 6 (Administrative)—Allows full access to any services specified by the **aaa authentication console** commands.
  - Service-Type 7 (NAS prompt)—Allows access to the CLI when you configure the **aaa authentication {telnet | ssh} console** command, but denies ASDM configuration access if you configure the **aaa authentication http console** command. ASDM monitoring access is allowed. If you configure **enable** authentication with the **aaa authentication enable console** command, the user cannot access privileged EXEC mode using the **enable** command.

  - Service-Type 5 (Outbound)—Denies management access. The user cannot use any services specified by the **aaa authentication console** commands (excluding the **serial** keyword; serial access is allowed). Remote access (IPSec and SSL) users can still authenticate and terminate their remote access sessions.

- TACACS+ users—Authorization is requested with "service=shell," and the server responds with PASS or FAIL.
  - PASS, privilege level 1—Allows full access to any services specified by the **aaa authentication console** commands.
  - PASS, privilege level 2 and higher—Allows access to the CLI when you configure the **aaa authentication {telnet | ssh} console** command, but denies ASDM configuration access if you configure the **aaa authentication http console** command. ASDM monitoring access is allowed. If you configure enable authentication with the **aaa authentication enable console** command, the user cannot access privileged EXEC mode using the **enable** command.
  - FAIL—Denies management access. The user cannot use any services specified by the **aaa authentication console** commands (excluding the **serial** keyword; serial access is allowed).
- Local users—Set the **service-type** command. By default, the **service-type** is **admin**, which allows full access to any services specified by the **aaa authentication console** commands.

Examples

The following example shows use of the **aaa authentication console** command for a Telnet connection to a RADIUS server with the server tag "radius":

```
hostname(config)# aaa authentication telnet console radius
```

The following example identifies the server group "AuthIn" for enable authentication:

```
hostname(config)# aaa authentication enable console AuthIn
```

The following example shows use of the **aaa authentication console** command with fallback to the LOCAL user database if all the servers in the group "svrgrp1" fail:

```
hostname(config)# aaa-server svrgrp1 protocol tacacs
hostname(config)# aaa authentication ssh console svrgrp1 LOCAL
```

Related Commands

Command	Description
aaa authentication	Enables or disables user authentication.
aaa-server host	Specifies the AAA server to use for user authentication.
clear configure aaa	Remove or resets the configured AAA accounting values.
ldap map-attributes	Maps LDAP attributes to RADIUS attributes that the ASA can understand.
service-type	Limits a local user CLI access.
show running-config aaa	Displays the AAA configuration.

aaa authentication include, exclude

To enable authentication for connections through the ASA, use the **aaa authentication include** command in global configuration mode. To disable authentication, use the **no** form of this command. To exclude addresses from authentication, use the **aaa authentication exclude** command. To not exclude addresses from authentication, use the **no** form of this command.

aaa authentication {include | exclude} *service interface_name inside_ip inside_mask* [*outside_ip outside_mask*] {*server_tag* | **LOCAL**}

no aaa authentication {include | exclude} *service interface_name inside_ip inside_mask* [*outside_ip outside_mask*] {*server_tag* | **LOCAL**}

Syntax Description

exclude	Excludes the specified service and address from authentication if it was already specified by an **include** command.
include	Specifies the services and IP addresses that require authentication. Traffic that is not specified by an **include** statement is not processed.
inside_ip	Specifies the IP address on the higher security interface. This address might be the source or the destination address, depending on the interface to which you apply this command. If you apply the command to the lower security interface, then this address is the destination address. If you apply the command to the higher security interface, then this address is the source address. Use 0 to mean all hosts.
inside_mask	Specifies the network mask for the inside IP address. Use 0 if the IP address is 0. Use 255.255.255.255 for a host.
interface_name	Specifies the interface name from which users require authentication.
LOCAL	Specifies the local user database.
outside_ip	(Optional) Specifies the IP address on the lower security interface. This address might be the source or the destination address, depending on the interface to which you apply this command. If you apply the command to the lower security interface, then this address is the source address. If you apply the command to the higher security interface, then this address is the destination address. Use 0 to mean all hosts.
outside_mask	(Optional) Specifies the network mask for the outside IP address. Use 0 if the IP address is 0. Use 255.255.255.255 for a host.

server_tag	Specifies the AAA server group defined by the **aaa-server** command.
service	Specifies the services that require authentication. You can specify one of the following values: • **any** or **tcp/0** (specifies all TCP traffic) • ftp • http • **https** • **ssh** • telnet • **tcp/***port*[**-***port*] • **udp/***port*[**-***port*] • **icmp/***type* • *protocol*[**/***port*[**-***port*]] Although you can configure the ASA to require authentication for network access to any protocol or service, users can authenticate directly with HTTP, HTTPS, Telnet, or FTP only. A user must first authenticate with one of these services before the ASA allows other traffic requiring authentication. See "Usage Guidelines" for more information.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To enable authentication for traffic that is specified by an ACL, use the **aaa authentication match** command. You cannot use the **match** command in the same configuration as the **include** and **exclude** commands. We suggest that you use the **match** command instead of the **include** and **exclude** commands; the **include** and **exclude** commands are not supported by ASDM.

You cannot use the **aaa authentication include** and **exclude** commands between same-security interfaces. For that scenario, you must use the **aaa authentication match** command.

TCP sessions might have their sequence numbers randomized even if you disable sequence randomization. This occurs when a AAA server proxies the TCP session to authenticate the user before permitting access.

One-Time Authentication

A user at a given IP address only needs to authenticate one time for all rules and types, until the authentication session expires. (See the **timeout uauth** command for timeout values.) For example, if you configure the ASA to authenticate Telnet and FTP, and a user first successfully authenticates for Telnet, then as long as the authentication session exists, the user does not also have to authenticate for FTP.

For HTTP or HTTPS authentication, once authenticated, a user never has to reauthenticate, no matter how low the **timeout uauth** command is set, because the browser caches the string "Basic=Uuhjksdkfhk==" in every subsequent connection to that particular site. This can be cleared only when the user exits *all* instances of the web browser and restarts. Flushing the cache is of no use.

Applications Required to Receive an Authentication Challenge

Although you can configure the ASA to require authentication for network access to any protocol or service, users can authenticate directly with HTTP, HTTPS, Telnet, or FTP only. A user must first authenticate with one of these services before the ASA allows other traffic requiring authentication.

The authentication ports that the ASA supports for AAA are fixed:

- Port 21 for FTP
- Port 23 for Telnet
- Port 80 for HTTP
- Port 443 for HTTPS

Security Appliance Authentication Prompts

For Telnet and FTP, the ASA generates an authentication prompt.

For HTTP, the ASA uses basic HTTP authentication by default, and provides an authentication prompt. You can optionally configure the ASA to redirect users to an internal web page where they can enter their username and password (configured with the **aaa authentication listener** command).

For HTTPS, the ASA generates a custom login screen. You can optionally configure the ASA to redirect users to an internal web page where they can enter their username and password (configured with the **aaa authentication listener** command).

Redirection is an improvement over the basic method because it provides an improved user experience when authenticating, and an identical user experience for HTTP and HTTPS in both Easy VPN and firewall modes. It also supports authenticating directly with the ASA.

You might want to continue to use basic HTTP authentication if: you do not want the ASA to open listening ports; if you use NAT on a router and you do not want to create a translation rule for the web page served by the ASA; basic HTTP authentication might work better with your network. For example non-browser applications, like when a URL is embedded in email, might be more compatible with basic authentication.

After you authenticate correctly, the ASA redirects you to your original destination. If the destination server also has its own authentication, the user enters another username and password. If you use basic HTTP authentication and need to enter another username and password for the destination server, then you need to configure the **virtual http** command.

Note If you use HTTP authentication without using the **aaa authentication secure-http-client** command, the username and password are sent from the client to the ASA in clear text. We recommend that you use the **aaa authentication secure-http-client** command whenever you enable HTTP authentication.

For FTP, a user has the option of entering the ASA username followed by an at sign (@) and then the FTP username (name1@name2). For the password, the user enters the ASA password followed by an at sign (@) and then the FTP password (password1@password2). For example, enter the following text.

```
name> asa1@partreq
password> letmein@he110
```

This feature is useful when you have cascaded firewalls that require multiple logins. You can separate several names and passwords by multiple at signs (@).

The number of login attempts allowed differs between the supported protocols:

Protocol	Number of Login Attempts Allowed
FTP	Incorrect password causes the connection to be dropped immediately.
HTTP HTTPS	Continual reprompting until successful login.
Telnet	Four tries before dropping the connection.

Static PAT and HTTP

For HTTP authentication, the ASA checks real ports when static PAT is configured. If it detects traffic destined for real port 80, regardless of the mapped port, the ASA intercepts the HTTP connection and enforces authentication.

For example, assume that outside TCP port 889 is translated to port 80 (www) and that any relevant ACLs permit the traffic:

```
static (inside,outside) tcp 10.48.66.155 889 192.168.123.10 www netmask 255.255.255.255
```

Then when users try to access 10.48.66.155 on port 889, the ASA intercepts the traffic and enforces HTTP authentication. Users see the HTTP authentication page in their web browsers before the ASA allows HTTP connection to complete.

If the local port is different than port 80, as in the following example:

```
static (inside,outside) tcp 10.48.66.155 889 192.168.123.10 111 netmask 255.255.255.255
```

Then users do not see the authentication page. Instead, the ASA sends an error message to the web browser indicating that the user must be authenticated before using the requested service.

Authenticating Directly with the ASA

If you do not want to allow HTTP, HTTPS, Telnet, or FTP through the ASA but want to authenticate other types of traffic, you can authenticate with the ASA directly using HTTP or HTTPS by configuring the **aaa authentication listener** command.

You can authenticate directly with the ASA at the following URLs when you enable AAA for the interface:

http://*interface_ip*[**:***port*]**/netaccess/connstatus.html**
https://*interface_ip*[**:***port*]**/netaccess/connstatus.html**

Alternatively, you can configure virtual Telnet (using the **virtual telnet** command). With virtual Telnet, the user Telnets to a given IP address configured on the ASA, and the ASA provides a Telnet prompt.

Examples

The following example includes for authentication TCP traffic on the outside interface, with an inside IP address of 192.168.0.0 and a netmask of 255.255.0.0, with an outside IP address of all hosts, and using a server group named tacacs+. The second command line excludes Telnet traffic on the outside interface with an inside address of 192.168.38.0, with an outside IP address of all hosts:

```
hostname(config)# aaa authentication include tcp/0 outside 192.168.0.0 255.255.0.0 0 0
tacacs+
hostname(config)# aaa authentication exclude telnet outside 192.168.38.0 255.255.255.0 0 0
tacacs+
```

The following examples demonstrate ways to use the *interface-name* parameter. The ASA has an inside network of 192.168.1.0, an outside network of 209.165.201.0 (subnet mask 255.255.255.224), and a perimeter network of 209.165.202.128 (subnet mask 255.255.255.224).

This example enables authentication for connections originated from the inside network to the outside network:

```
hostname(config)# aaa authentication include tcp/0 inside 192.168.1.0 255.255.255.0
209.165.201.0 255.255.255.224 tacacs+
```

This example enables authentication for connections originated from the inside network to the perimeter network:

```
hostname(config)#aaa authentication include tcp/0 inside 192.168.1.0 255.255.255.0
209.165.202.128 255.255.255.224 tacacs+
```

This example enables authentication for connections originated from the outside network to the inside network:

```
hostname(config)# aaa authentication include tcp/0 outside 192.168.1.0 255.255.255.0
209.165.201.0 255.255.255.224 tacacs+
```

This example enables authentication for connections originated from the outside network to the perimeter network:

```
hostname(config)# aaa authentication include tcp/0 outside 209.165.202.128 255.255.255.224
209.165.201.0 255.255.255.224 tacacs+
```

This example enables authentication for connections originated from the perimeter network to the outside network:

```
hostname(config)#aaa authentication include tcp/0 perimeter 209.165.202.128
255.255.255.224 209.165.201.0 255.255.255.224 tacacs+
```

Related Commands

Command	Description
aaa authentication console	Enables authentication for management access.
aaa authentication match	Enables user authentication for through traffic.
aaa authentication secure-http-client	Provides a secure method for user authentication to the ASA before allowing HTTP requests to traverse the ASA.

aaa-server	Configures group-related server attributes.
aaa-server host	Configures host-related attributes.

aaa authentication listener

To enable HTTP(S) listening ports to authenticate network users, use the **aaa authentication listener** command in global configuration mode. When you enable a listening port, the ASA serves an authentication page for direct connections and optionally for through traffic. To disable the listeners, use the **no** form of this command.

aaa authentication listener http[**s**] *interface_name* [**port** *portnum*] [**redirect**]

no aaa authentication listener http[**s**] *interface_name* [**port** *portnum*] [**redirect**]

Syntax Description

http[**s**]	Specifies the protocol that you want to listen for, either HTTP or HTTPS. Enter this command separately for each protocol.
interface_name	Specifies the interface on which you enable listeners.
port *portnum*	Specifies the port number that the ASA listens on for direct or redirected traffic; the defaults are 80 (HTTP) and 443 (HTTPS). You can use any port number and retain the same functionality, but be sure your direct authentication users know the port number; redirected traffic is sent to the correct port number automatically, but direct authenticators must specify the port number manually.
redirect	Redirects through traffic to an authentication web page served by the ASA. Without this keyword, only traffic directed to the ASA interface can access the authentication web pages.

Defaults

By default, no listener services are enabled, and HTTP connections use basic HTTP authentication. If you enable the listeners, the default ports are 80 (HTTP) and 443 (HTTPS).

If you are upgrading from 7.2(1), then the listeners are enabled on ports 1080 (HTTP) and 1443 (HTTPS). The **redirect** option is also enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.2(2)	This command was introduced.

Usage Guidelines

Without the **aaa authentication listener** command, when HTTP(S) users need to authenticate with the ASA after you configure the **aaa authentication match** or **aaa authentication include** command, the ASA uses basic HTTP authentication. For HTTPS, the ASA generates a custom login screen.

If you configure the **aaa authentication listener** command with the **redirect** keyword, the ASA redirects all HTTP(S) authentication requests to web pages served by the ASA.

Redirection is an improvement over the basic method because it provides an improved user experience when authenticating, and an identical user experience for HTTP and HTTPS in both Easy VPN and firewall modes. It also supports authenticating directly with the ASA.

You might want to continue to use basic HTTP authentication if: you do not want the ASA to open listening ports; if you use NAT on a router and you do not want to create a translation rule for the web page served by the ASA; basic HTTP authentication might work better with your network. For example non-browser applications, like when a URL is embedded in email, might be more compatible with basic authentication.

If you enter the **aaa authentication listener** command *without* the **redirect** option, then you only enable direct authentication with the ASA, while letting through traffic use basic HTTP authentication. The **redirect** option enables both direct and through-traffic authentication. Direct authentication is useful when you want to authenticate traffic types that do not support authentication challenges; you can have each user authenticate directly with the ASA before using any other services.

Note If you enable the **redirect** option, you cannot also configure static PAT for the same interface where you translate the interface IP address and the same port that is used for the listener; NAT succeds, but authentication fails. For example, the following configuration is unsupported:

```
hostname(config)# static (inside,outside) tcp interface www 192.168.0.50 www netmask
255.255.255.255
hostname(config)# aaa authentication listener http outside redirect
```

The following configuration is supported; the listener uses port 1080 instead of the default 80:

```
hostname(config)# static (inside,outside) tcp interface www 192.168.0.50 www netmask
255.255.255.255
hostname(config)# aaa authentication listener http outside port 1080 redirect
```

Examples

The following example configures the ASA to redirect HTTP and HTTPS connections to the default ports:

```
hostname(config)# aaa authentication http redirect
hostname(config)# aaa authentication https redirect
```

The following example allows authentication requests directly to the ASA; through traffic uses basic HTTP authentication:

```
hostname(config)# aaa authentication http
hostname(config)# aaa authentication https
```

The following example configures the ASA to redirect HTTP and HTTPS connections to non-default ports:

```
hostname(config)# aaa authentication http port 1100 redirect
hostname(config)# aaa authentication https port 1400 redirect
```

Related Commands

Command	Description
aaa authentication match	Configures user authentication for through traffic.

aaa authentication secure-http-client	Enables SSL and secure username and password exchange between HTTP clients and the ASA.
clear configure aaa	Removes the configured AAA configuration.
show running-config aaa	Displays the AAA configuration.
virtual http	Supports cascading HTTP authentications with basic HTTP authentication.

aaa authentication match

To enable authentication for connections through the ASA, use the **aaa authentication match** command in global configuration mode. To disable authentication, use the **no** form of this command.

aaa authentication match *acl_name interface_name* {*server_tag* | **LOCAL**} **user-identity**

no aaa authentication match *acl_name interface_name* {*server_tag* | **LOCAL**} **user-identity**

Syntax Description

acl_name	Specifies an extended ACL name.
interface_name	Specifies the interface name from which to authenticate users.
LOCAL	Specifies the local user database.
server_tag	Specifies the AAA server group tag defined by the **aaa-server** command.
user-identity	Specifies the user identity that is mapped to the identity firewall.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	The **user-identity** keyword was added.

Usage Guidelines

You cannot use the **aaa authentication match** command in the same configuration as the **include** and **exclude** commands. We suggest that you use the **match** command instead of the **include** and **exclude** commands; the **include** and **exclude** commands are not supported by ASDM.

TCP sessions might have their sequence numbers randomized even if you disable sequence randomization. This occurs when a AAA server proxies the TCP session to authenticate the user before permitting access.

One-Time Authentication

A user at a given IP address only needs to authenticate one time for all rules and types, until the authentication session expires. (See the **timeout uauth** command for timeout values.) For example, if you configure the ASA to authenticate Telnet and FTP, and a user first successfully authenticates for Telnet, then as long as the authentication session exists, the user does not also have to authenticate for FTP.

For HTTP or HTTPS authentication, once authenticated, a user never has to reauthenticate, no matter how low the **timeout uauth** command is set, because the browser caches the string "Basic=Uuhjksdkfhk==" in every subsequent connection to that particular site. This can be cleared only when the user exits *all* instances of the web browser and restarts. Flushing the cache is of no use.

Applications Required to Receive an Authentication Challenge

Although you can configure the ASA to require authentication for network access to any protocol or service, users can authenticate directly with HTTP, HTTPS, Telnet, or FTP only. A user must first authenticate with one of these services before the ASA allows other traffic requiring authentication.

The authentication ports that the ASA supports for AAA are fixed:

- Port 21 for FTP
- Port 23 for Telnet
- Port 80 for HTTP
- Port 443 for HTTPS (requires the **aaa authentication listener** command)

ASA Authentication Prompts

For Telnet and FTP, the ASA generates an authentication prompt.

For HTTP, the ASA uses basic HTTP authentication by default, and provides an authentication prompt. You can optionally configure the ASA to redirect users to an internal web page where they can enter their username and password (configured with the **aaa authentication listener** command).

For HTTPS, the ASA generates a custom login screen. You can optionally configure the ASA to redirect users to an internal web page where they can enter their username and password (configured with the **aaa authentication listener** command).

Redirection is an improvement over the basic method because it provides an improved user experience when authenticating, and an identical user experience for HTTP and HTTPS in both Easy VPN and firewall modes. It also supports authenticating directly with the ASA.

You might want to continue to use basic HTTP authentication if: you do not want the ASA to open listening ports; if you use NAT on a router and you do not want to create a translation rule for the web page served by the ASA; basic HTTP authentication might work better with your network. For example non-browser applications, like when a URL is embedded in email, might be more compatible with basic authentication.

After you authenticate correctly, the ASA redirects you to your original destination. If the destination server also has its own authentication, the user enters another username and password. If you use basic HTTP authentication and need to enter another username and password for the destination server, then you need to configure the **virtual http** command.

Note If you use HTTP authentication without using the **aaa authentication secure-http-client** command, the username and password are sent from the client to the ASA in clear text. We recommend that you use the **aaa authentication secure-http-client** command whenever you enable HTTP authentication.

For FTP, a user has the option of entering the ASA username followed by an at sign (@) and then the FTP username (name1@name2). For the password, the user enters the ASA password followed by an at sign (@) and then the FTP password (password1@password2). For example, enter the following text.

```
name> asa1@partreq
password> letmein@he110
```

This feature is useful when you have cascaded firewalls that require multiple logins. You can separate several names and passwords by multiple at signs (@).

The number of login attempts allowed differs between the supported protocols:

Protocol	Number of Login Attempts Allowed
FTP	Incorrect password causes the connection to be dropped immediately.
HTTP HTTPS	Continual reprompting until successful login.
Telnet	Four tries before dropping the connection.

Static PAT and HTTP

For HTTP authentication, the ASA checks real ports when static PAT is configured. If it detects traffic destined for real port 80, regardless of the mapped port, the ASA intercepts the HTTP connection and enforces authentication.

For example, assume that outside TCP port 889 is translated to port 80 (www) and that any relevant ACLs permit the traffic:

```
static (inside,outside) tcp 10.48.66.155 889 192.168.123.10 www netmask 255.255.255.255
```

Then when users try to access 10.48.66.155 on port 889, the ASA intercepts the traffic and enforces HTTP authentication. Users see the HTTP authentication page in their web browsers before the ASA allows HTTP connection to complete.

If the local port is different than port 80, as in the following example:

```
static (inside,outside) tcp 10.48.66.155 889 192.168.123.10 111 netmask 255.255.255.255
```

Then users do not see the authentication page. Instead, the ASA sends to the web browser an error message indicating that the user must be authenticated before using the requested service.

Authenticating Directly with the ASA

If you do not want to allow HTTP, HTTPS, Telnet, or FTP through the ASA but want to authenticate other types of traffic, you can authenticate with the ASA directly using HTTP or HTTPS by configuring the **aaa authentication listener** command.

You can authenticate directly with the ASA at the following URLs when you enable AAA for the interface:

http://*interface_ip*[**:***port*]**/netaccess/connstatus.html**
https://*interface_ip*[**:***port*]**/netaccess/connstatus.html**

Alternatively, you can configure virtual Telnet (using the **virtual telnet** command). With virtual Telnet, the user Telnets to a given IP address configured on the ASA, and the ASA provides a Telnet prompt.

Examples

The following set of examples illustrates how to use the **aaa authentication match** command:

```
hostname(config)# show access-list
access-list mylist permit tcp 10.0.0.0 255.255.255.0 192.168.2.0 255.255.255.0 (hitcnt=0)
access-list yourlist permit tcp any any (hitcnt=0)

hostname(config)# show running-config aaa
aaa authentication match mylist outbound TACACS+
```

In this context, the following command:

```
hostname(config)# aaa authentication match yourlist outbound tacacs
```

is equivalent to this command:

```
hostname(config)# aaa authentication include TCP/0 outbound 0.0.0.0 0.0.0.0 0.0.0.0
0.0.0.0 tacacs
```

The **aaa** command statement list is order-dependent between **access-list** command statements. If you enter the following command:

```
hostname(config)# aaa authentication match mylist outbound TACACS+
```

before this command:

```
hostname(config)# aaa authentication match yourlist outbound tacacs
```

the ASA tries to find a match in the **mylist access-list** command statement group before it tries to find a match in the **yourlist access-list** command statement group.

To enable authentication for connections through the ASA and match it to the Identity Firewall feature, enter the following command:

```
hostname(config)# aaa authenticate match access_list_name inside user-identity
```

Related Commands

Command	Description
aaa authorization	Enables user authorization services.
access-list extended	Creates an ACL.
clear configure aaa	Removes the configured AAA configuration.
show running-config aaa	Displays the AAA configuration.

aaa authentication secure-http-client

To enable SSL and secure username and password exchange between HTTP clients and the ASA, use the **aaa authentication secure-http-client** command in global configuration mode. To disable this function, use the **no** form of this command.

aaa authentication secure-http-client

no aaa authentication secure-http-client

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **aaa authentication secure-http-client** command offers a secure method for user authentication to the ASA before allowing user HTTP-based web requests to traverse the ASA. This command is used for HTTP cut-through proxy authentication through SSL.

The **aaa authentication secure-http-client** command has the following limitations:

- At runtime, a maximum of 16 HTTPS authentication processes is allowed. If all 16 HTTPS authentication processes are running, the 17th, new HTTPS connection requiring authentication is not allowed.
- When **uauth timeout 0** is configured (the **uauth timeout** is set to 0), HTTPS authentication might not work. If a browser initiates multiple TCP connections to load a web page after HTTPS authentication, the first connection is let through, but the subsequent connections trigger authentication. As a result, users are continuously presented with an authentication page, even if the correct username and password are entered each time. To work around this, set the **uauth timeout** to 1 second with the **timeout uauth 0:0:1** command. However, this workaround opens a 1-second window of opportunity that might allow non-authenticated users to go through the firewall if they are coming from the same source IP address.

- Because HTTPS authentication occurs on the SSL port 443, users must not configure an **access-list** command statement to block traffic from the HTTP client to HTTP server on port 443. Furthermore, if static PAT is configured for web traffic on port 80, it must also be configured for the SSL port. In the following example, the first line configures static PAT for web traffic and the second line must be added to support the HTTPS authentication configuration:

```
static (inside,outside) tcp 10.132.16.200 www 10.130.16.10 www
static (inside,outside) tcp 10.132.16.200 443 10.130.16.10 443
```

Examples

The following example configures HTTP traffic to be securely authenticated:

```
hostname(config)# aaa authentication secure-http-client
hostname(config)# aaa authentication include http...
```

where "..." represents your values for *authen_service if_name local_ip local_mask* [*foreign_ip foreign_mask*] *server_tag*.

The following command configures HTTPS traffic to be securely authenticated:

```
hostname (config)# aaa authentication include https...
```

where "..." represents your values for *authentication -service interface-name local-ip local-mask* [*foreign-ip foreign-mask*] *server-tag*.

Note The **aaa authentication secure-https-client** command is not needed for HTTPS traffic.

Related Commands

Command	Description
aaa authentication	Enables LOCAL, TACACS+, or RADIUS user authentication, on a server designated by the **aaa-server** command.
virtual telnet	Accesses the ASA virtual server.

aaa authorization command

To enable command authorization, use the **aaa authorization command** command in global configuration mode. To disable command authorization, use the **no** form of this command.

aaa authorization command {**LOCAL** | *tacacs+ server_tag* [**LOCAL**]}

no aaa authorization command {**LOCAL** | *tacacs+ server_tag* [**LOCAL**]}

Syntax Description

LOCAL	Enables local command privilege levels set by the **privilege** command. When a local, RADIUS, or LDAP (if you map LDAP attributes to RADIUS attributes) user authenticates for CLI access, the ASA places that user in the privilege level that is defined by the local database, RADIUS, or LDAP server. The user can access commands at the user privilege level and below. If you specify **LOCAL** after a TACACS+ server group tag, the local user database is used for command authorization only as a fallback when the TACACS+ server group is unavailable.
tacacs+ server_tag	Specifies a predefined server group tag for the TACACS+ authorization server. The AAA server group tag as defined by the **aaa-server** command.

Defaults

Fallback to the local database for authorization is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	Support added for fallback to LOCAL authorization when a TACACS+ server group is temporarily unavailable.
8.0(2)	Support for privilege levels defined on RADIUS or LDAP servers was added.

Usage Guidelines

The **aaa authorization command** command specifies whether command execution at the CLI is subject to authorization. By default when you log in, you can access user EXEC mode, which offers only a minimal number of commands. When you enter the **enable** command (or the **login** command when you use the local database), you can access privileged EXEC mode and advanced commands, including configuration commands. If you want to control the access to commands, the ASA lets you configure command authorization, where you can determine which commands are available to a user.

Supported Command Authorization Methods

You can use one of two command authorization methods:

- Local privilege levels—Configure the command privilege levels on the ASA. When a local, RADIUS, or LDAP (if you map LDAP attributes to RADIUS attributes) user authenticates for CLI access, the ASA places that user in the privilege level that is defined by the local database, RADIUS, or LDAP server. The user can access commands at the user privilege level and below. Note that all users access user EXEC mode when they first log in (commands at level 0 or 1). The user needs to authenticate again with the **enable** command to access privileged EXEC mode (commands at level 2 or higher), or they can log in with the **login** command (local database only).

Note You can use local command authorization without any users in the local database and without CLI or enable authentication. Instead, when you enter the **enable** command, you enter the system enable password, and the ASA places you in level 15. You can then create enable passwords for every level, so that when you enter **enable** *n* (2 to 15), the ASA places you in level *n*. These levels are not used unless you turn on local command authorization. (See the **enable** command for more information.)

- TACACS+ server privilege levels—On the TACACS+ server, configure the commands that a user or group can use after they authenticate for CLI access. Every command that a user enters at the CLI is checked with the TACACS+ server.

Security Contexts and Command Authorization

The following are important points to consider when implementing command authorization with multiple security contexts:

- AAA settings are discrete per context, not shared between contexts.

  When configuring command authorization, you must configure each security context separately. This provides you the opportunity to enforce different command authorizations for different security contexts.

  When switching between security contexts, administrators should be aware that the commands permitted for the username specified when they login may be different in the new context session or that command authorization may not be configured at all in the new context. Failure to understand that command authorizations may differ between security contexts could confuse an administrator. This behavior is further complicated by the next point.

- New context sessions started with the **changeto** command always use the default “enable_15” username as the administrator identity, regardless of what username was used in the previous context session. This behavior can lead to confusion if command authorization is not configured for the enable_15 user or if authorizations are different for the enable_15 user than for the user in the previous context session.

  This behavior also affects command accounting, which is useful only if you can accurately associate each command that is issued with a particular administrator. Because all administrators with permission to use the **changeto** command can use the enable_15 username in other contexts, command accounting records may not readily identify who was logged in as the enable_15 username. If you use different accounting servers for each context, tracking who was using the enable_15 username requires correlating the data from several servers.

  When configuring command authorization, consider the following:

  – An administrator with permission to use the **changeto** command effectively has permission to use all commands permitted to the enable_15 user in each of the other contexts.

– If you intend to authorize commands differently per context, ensure that in each context the enable_15 username is denied the use of commands that are also denied to administrators who are permitted to use the **changeto** command.

When switching between security contexts, administrators can exit privileged EXEC mode and enter the **enable** command again to use the username they need.

Note The system execution space does not support **aaa** commands; therefore, command authorization is not available in the system execution space.

Local Command Authorization Prerequisites

- Configure enable authentication for local, RADIUS, or LDAP authentication using the **aaa authentication enable console** command.

  Enable authentication is essential to maintain the username after the user accesses the **enable** command.

  Alternatively, you can use the **login** command (which is the same as the **enable** command with authentication), which requires no configuration. We do not recommend this option because it is not as secure as enable authentication.

  You can also use CLI authentication (**aaa authentication** {**ssh** | **telnet** | **serial**} **console**), but it is not required.

- You can use the **aaa authorization exec** command to enable support of administrative user privilege levels from RADIUS if RADIUS is used for authentication, but it is not required. This command also enables management authorization for local, RADIUS, LDAP (mapped), and TACACS+ users.
- See the following prerequisites for each user type:
  - Local database users—Configure each user in the local database at a privilege level from 0 to 15 using the **username** command.
  - RADIUS users—Configure the user with Cisco VSA CVPN3000-Privilege-Level with a value between 0 and 15.
  - LDAP users—Configure the user with a privilege level between 0 and 15, and then map the LDAP attribute to Cisco VAS CVPN3000-Privilege-Level using the **ldap map-attributes** command.
- See the **privilege** command for information about setting command privilege levels.

TACACS+ Command Authorization

If you enable TACACS+ command authorization, and a user enters a command at the CLI, the ASA sends the command and username to the TACACS+ server to determine if the command is authorized.

When configuring command authorization with a TACACS+ server, do not save your configuration until you are sure it works the way you want. If you get locked out because of a mistake, you can usually recover access by restarting the ASA.

Be sure that your TACACS+ system is completely stable and reliable. The necessary level of reliability typically requires that you have a fully redundant TACACS+ server system and fully redundant connectivity to the ASA. For example, in your TACACS+ server pool, include one server connected to interface 1, and another to interface 2. You can also configure local command authorization as a fallback method if the TACACS+ server is unavailable. In this case, you need to configure local users and command privilege levels.

See the CLI configuration guide for information about configuring the TACACS+ server.

TACACS+ Command Authorization Prerequisites

- Configure CLI authentication using the **aaa authentication** {**ssh** | **telnet** | **serial**} **console** command.
- Configure **enable** authentication using the **aaa authentication enable console** command.

Examples

The following example shows how to enable command authorization using a TACACS+ server group named tplus1:

```
hostname(config)# aaa authorization command tplus1
```

The following example shows how to configure administrative authorization to support fallback to the local user database if all servers in the tplus1 server group are unavailable.

```
hostname(config)# aaa authorization command tplus1 LOCAL
```

Related Commands

Command	Description
aaa authentication console	Enables CLI, ASDM, and enable authentication.
aaa authorization exec	Enables support of administrative user privilege levels from RADIUS.
aaa-server host	Configures host-related attributes.
aaa-server	Configures group-related server attributes.
enable	Enters privileged EXEC mode.
ldap map-attributes	Maps LDAP attributes to RADIUS attributes that the ASA can use.
login	Enters privileged EXEC mode using the local database for authentication.
service-type	Limits local database user CLI, ASDM, and enable access.
show running-config aaa	Displays the AAA configuration.

aaa authorization exec

To enable management authorization, use the **aaa authorization exec** command o in global configuration mode. To disable management authorization, use the **no** form of these commands.

aaa authorization exec {**authentication-server** | **LOCAL**}

no aaa authorization exec {**authentication-server** | **LOCAL**}

Syntax Description

authentication-server	Indicates that the authorization attributes will be retrieved from the server that was used to authenticate the user.
LOCAL	Indicates that the authorization attributes will be retrieved from the local user database of the ASA, regardless of how authentication is done.

Defaults

By default, this command is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
8.2(2)	The **LOCAL** option was added.

Usage Guidelines

When using the **aaa authorization exec** command, the service-type credentials of the user are checked before allowing console access.

When you disable management authorization with the **no aaa authorization exec** command, note the following:

- The service-type credentials of the user are not checked before allowing console access.
- If command authorization is configured, privilege-level attributes are still applied if they are found in the AAA server for RADIUS, LDAP, and TACACS+ users.

If you configure **aaa authentication console** commands to authenticate users when they access the CLI, ASDM, or the **enable** command, then the **aaa authorization exec** command can limit management access depending on the user configuration.

Note Serial access is not included in management authorization, so if you configure **aaa authentication serial console**, then any user who authenticates can access the console port.

To configure the user for management authorization, see the following requirements for each AAA server type or local user:

- LDAP mapped users—To map LDAP attributes, see the **ldap attribute-map** command.
- RADIUS users—Use the IETF RADIUS numeric **service-type** attribute, which maps to one of the following values:
  - Service-Type 5 (Outbound) denies management access. The user cannot use any services specified by the **aaa authentication console** commands (excluding the **serial** keyword; serial access is allowed). Remote access (IPsec and SSL) users can still authenticate and terminate their remote access sessions.
  - Service-Type 6 (Administrative) allows full access to any services specified by the **aaa authentication console** commands.
  - Service-Type 7 (NAS prompt) allows access to the CLI when you configure the **aaa authentication {telnet | ssh} console** command, but denies ASDM configuration access if you configure the **aaa authentication http console** command. ASDM monitoring access is allowed. If you configure **enable** authentication with the **aaa authentication enable console** command, the user cannot access privileged EXEC mode using the **enable** command.

Note The only recognized service-types are Login (1), Framed (2), Administrative (6), and NAS-Prompt (7). Using any other service-types results in denied access.

- TACACS+ users—Request authorization with the "service=shell" entry, and the server responds with PASS or FAIL, as follows:
  - PASS, privilege level 1 allows full access to any services specified by the **aaa authentication console** commands.
  - PASS, privilege level 2 and higher allows access to the CLI when you configure the **aaa authentication {telnet | ssh} console** command, but denies ASDM configuration access if you configure the **aaa authentication http console** command. ASDM monitoring access is allowed. If you configure enable authentication with the **aaa authentication enable console** command, the user cannot access privileged EXEC mode using the **enable** command.
  - FAIL denies management access. The user cannot use any services specified by the **aaa authentication console** commands (excluding the **serial** keyword; serial access is allowed).
- Local users—Set the **service-type** command, which is in the username configuration mode of the **username** command. By default, the **service-type** is **admin**, which allows full access to any services specified by the **aaa authentication console** commands.

Examples

The following example enables management authorization using the local database:

```
hostname(config)# aaa authorization exec LOCAL
```

Related Commands

Command	Description
aaa authentication console	Enables console authentication.
ldap attribute-map	Maps LDAP attributes.

service-type	Limits CLI access for a local user .
show running-config aaa	Displays the AAA configuration.

aaa authorization include, exclude

To enable authorization for connections through the ASA, use the **aaa authorization include** command in global configuration mode. To disable authorization, use the **no** form of this command. To exclude addresses from authorization, use the **aaa authorization exclude** command. To not exclude addresses from authorization, use the **no** form of this command.

aaa authorization {include | exclude} *service interface_name inside_ip inside_mask* [*outside_ip outside_mask*] *server_tag*

no aaa authorization {include | exclude} *service interface_name inside_ip inside_mask* [*outside_ip outside_mask*] *server_tag*

Syntax Description

exclude	Excludes the specified service and address from authorization if it was already specified by an **include** command.
include	Specifies the services and IP addresses that require authorization. Traffic that is not specified by an **include** statement is not processed.
inside_ip	Specifies the IP address on the higher security interface. This address might be the source or the destination address, depending on the interface to which you apply this command. If you apply the command to the lower security interface, then this address is the destination address. If you apply the command to the higher security interface, then this address is the source address. Use 0 to mean all hosts.
inside_mask	Specifies the network mask for the inside IP address. Use 0 if the IP address is 0. Use 255.255.255.255 for a host.
interface_name	Specifies the interface name from which users require authorization.
outside_ip	(Optional) Specifies the IP address on the lower security interface. This address might be the source or the destination address, depending on the interface to which you apply this command. If you apply the command to the lower security interface, then this address is the source address. If you apply the command to the higher security interface, then this address is the destination address. Use 0 to mean all hosts.
outside_mask	(Optional) Specifies the network mask for the outside IP address. Use 0 if the IP address is 0. Use 255.255.255.255 for a host.

server_tag	Specifies the AAA server group defined by the **aaa-server** command.
service	Specifies the services that require authorization. You can specify one of the following values: • **any** or **tcp/0** (specifies all TCP traffic) • ftp • http • **https** • **ssh** • telnet • **tcp/***port*[**-***port*] • **udp/***port*[**-***port*] • **icmp/***type* • *protocol*[**/***port*[**-***port*]] **Note** Specifying a port range might produce unexpected results at the authorization server. The ASA sends the port range to the server as a string, with the expectation that the server will parse it out into specific ports. Not all servers do this. In addition, you might want users to be authorized on specific services, which does not occur if a range is accepted.

Defaults

An IP address of **0** means "all hosts." Setting the local IP address to **0** lets the authorization server decide which hosts are authorized.

Fallback to the local database for authorization is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	The **exclude** parameter allows the user to specify a port to exclude to a specific host or hosts.

Usage Guidelines

To enable authorization for traffic that is specified by an ACL, use the **aaa authorization match** command. You cannot use the **match** command in the same configuration as the **include** and **exclude** commands. We suggest that you use the **match** command instead of the **include** and **exclude** commands; the **include** and **exclude** commands are not supported by ASDM.

You cannot use the **aaa authorization include** and **exclude** commands between same-security interfaces. For that scenario, you must use the **aaa authorization match** command.

You can configure the ASA to perform network access authorization with TACACS+. Authentication and authorization statements are independent; however, any unauthenticated traffic matched by an authorization statement will be denied. For authorization to succeed, a user must first authenticate with the ASA. Because a user at a given IP address only needs to authenticate one time for all rules and types, if the authentication session has not expired, authorization can occur even if the traffic is matched by an authentication statement.

After a user authenticates, the ASA checks the authorization rules for matching traffic. If the traffic matches the authorization statement, the ASA sends the username to the TACACS+ server. The TACACS+ server responds to the ASA with a permit or a deny for that traffic, based on the user profile. The ASA enforces the authorization rule in the response.

See the documentation for your TACACS+ server for information about configuring network access authorizations for a user.

For each IP address, one **aaa authorization include** command is permitted.

If the first attempt at authorization fails and a second attempt causes a timeout, use the **service resetinbound** command to reset the client that failed the authorization so that it will not retransmit any connections. An example authorization timeout message in Telnet follows.

```
Unable to connect to remote host: Connection timed out
```

Note Specifying a port range might produce unexpected results at the authorization server. The ASA sends the port range to the server as a string, with the expectation that the server will parse it out into specific ports. Not all servers do this. In addition, you might want users to be authorized on specific services, which does not occur if a range is accepted.

Examples

The following example uses the TACACS+ protocol:

```
hostname(config)# aaa-server tplus1 protocol tacacs+
hostname(config)# aaa-server tplus1 (inside) host 10.1.1.10 thekey timeout 20
hostname(config)# aaa authentication include any inside 0 0 0 0 tplus1
hostname(config)# aaa authorization include any inside 0 0 0 0
hostname(config)# aaa accounting include any inside 0 0 0 0 tplus1
hostname(config)# aaa authentication ssh console tplus1
```

In this example, the first command statement creates a server group named tplus1 and specifies the TACACS+ protocol for use with this group. The second command specifies that the authentication server with the IP address 10.1.1.10 resides on the inside interface and is in the tplus1 server group. The next three command statements specify that any users starting connections through the outside interface to any foreign host will be authenticated using the tplus1 server group, that the users who are successfully authenticated are authorized to use any service, and that all outbound connection information will be logged in the accounting database. The last command statement specifies that SSH access to the ASA console requires authentication from the tplus1 server group.

The following example enables authorization for DNS lookups from the outside interface:

```
hostname(config)# aaa authorization include udp/53 outside 0.0.0.0 0.0.0.0
```

The following example enables authorization of ICMP echo-reply packets arriving at the inside interface from inside hosts:

```
hostname(config)# aaa authorization include 1/0 inside 0.0.0.0 0.0.0.0
```

This means that users cannot ping external hosts if they have not been authenticated using Telnet, HTTP, or FTP.

The following example enables authorization only for ICMP echoes (pings) that arrive at the inside interface from an inside host:

```
hostname(config)# aaa authorization include 1/8 inside 0.0.0.0 0.0.0.0
```

Related Commands

Command	Description
aaa authorization command	Specifies whether or not command execution is subject to authorization, or configures administrative authorization to support fallback to the local user database if all servers in the specified server group are disabled.
aaa authorization match	Enables or disables the LOCAL or TACACS+ user authorization services for a specific access-list command name.
clear configure aaa	Removes or resets the configured AAA accounting values.
show running-config aaa	Displays the AAA configuration.

aaa authorization match

To enable authorization for connections through the ASA, use the **aaa authorization match** command in global configuration mode. To disable authorization, use the **no** form of this command.

aaa authorization match *acl_name interface_name server_tag*

no aaa authorization match *acl_name interface_name server_tag*

Syntax Description

acl_name	Specifies an extended ACL name. See the **access-list extended** command. The **permit** ACEs mark matching traffic for authorization, while **deny** entries exclude matching traffic from authorization.
interface_name	Specifies the interface name from which users require authentication.
server_tag	Specifies the AAA server group tag as defined by the **aaa-server** command.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You cannot use the **aaa authorization match** command in the same configuration as the **include** and **exclude** commands. We suggest that you use the **match** command instead of the **include** and **exclude** commands; the **include** and **exclude** commands are not supported by ASDM.

You can configure the ASA to perform network access authorization with TACACS+. RADIUS authorization with the **aaa authorization match** command only supports authorization of VPN management connections to the ASA.

Authentication and authorization statements are independent; however, any unauthenticated traffic matched by an authorization statement will be denied. For authorization to succeed, a user must first authenticate with the ASA. Because a user at a given IP address only needs to authenticate one time for all rules and types, if the authentication session has not expired, authorization can occur even if the traffic is matched by an authentication statement.

After a user authenticates, the ASA checks the authorization rules for matching traffic. If the traffic matches the authorization statement, the ASA sends the username to the TACACS+ server. The TACACS+ server responds to the ASA with a permit or a deny for that traffic, based on the user profile. The ASA enforces the authorization rule in the response.

See the documentation for your TACACS+ server for information about configuring network access authorizations for a user.

If the first attempt at authorization fails and a second attempt causes a timeout, use the **service resetinbound** command to reset the client that failed the authorization so that it will not retransmit any connections. An example authorization timeout message in Telnet follows.

```
Unable to connect to remote host: Connection timed out
```

Note Specifying a port range might produce unexpected results at the authorization server. The ASA sends the port range to the server as a string, with the expectation that the server will parse it out into specific ports. Not all servers do this. In addition, you might want users to be authorized on specific services, which does not occur if a range is accepted.

Examples

The following example uses the tplus1 server group with the **aaa** commands:

```
hostname(config)# aaa-server tplus1 protocol tacacs+
hostname(config)# aaa-server tplus1 (inside) host 10.1.1.10 thekey timeout 20
hostname(config)# aaa authentication include any inside 0 0 0 0 tplus1
hostname(config)# aaa accounting include any inside 0 0 0 0 tplus1
hostname(config)# aaa authorization match myacl inside tplus1
```

In this example, the first command statement defines the tplus1 server group as a TACACS+ group. The second command specifies that the authentication server with the IP address 10.1.1.10 resides on the inside interface and is in the tplus1 server group. The next two command statements specify that any connections traversing the inside interface to any foreign host are authenticated using the tplus1 server group, and that all these connections are logged in the accounting database. The last command statement specifies that any connections that match the ACEs in myacl are authorized by the AAA servers in the tplus1 server group.

Related Commands

Command	Description
aaa authorization	Enables or disables user authorization.
clear configure aaa	Resets all aaa configuration parameters to the default values.
clear uauth	Deletes AAA authorization and authentication caches for one user or all users, which forces users to reauthenticate the next time that they create a connection.
show running-config aaa	Displays the AAA configuration.
show uauth	Displays the username provided to the authorization server for authentication and authorization purposes, the IP address to which the username is bound, and whether the user is only authenticated or has cached services.

aaa local authentication attempts max-fail

To limit the number of consecutive failed local login attempts that the ASA allows any given user account (with the exception of users with a privilege level of 15; this feature does not affect level 15 users), use the **aaa local authentication attempts max-fail** command in global configuration mode. To disable this feature and allow an unlimited number of consecutive failed local login attempts, use the **no** form of this command.

aaa local authentication attempts max-fail *number*

Syntax Description

number	The maximum number of times a user can enter a wrong password before being locked out. This number can be in the range 1-16.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command only affects authentication with the local user database. If you omit this command, there is no limit on the number of times a user can enter an incorrect password.

After a user makes the configured number of attempts with the wrong password, the user is locked out and cannot log in successfully until the administrator unlocks the username. Locking or unlocking a username results in a syslog message.

Users with a privilege level of 15 are not affected by this command; they cannot be locked out.

The number of failed attempts resets to zero and the lockout status resets to No when the user successfully authenticates or when the ASA reboots.

Examples

The following example shows use of the **aaa local authentication attempts max-limits** command to set the maximum number of failed attempts allowed to 2:

```
hostname(config)# aaa local authentication attempts max-limits 2
```

Related Commands

Command	Description
clear aaa local user lockout	Clears the lockout status of the specified users and set their failed-attempts counter to 0.
clear aaa local user fail-attempts	Resets the number of failed user authentication attempts to zero without modifying the user locked-out status.
show aaa local user	Shows the list of usernames that are currently locked.

aaa mac-exempt

To specify the use of a predefined list of MAC addresses to exempt from authentication and authorization, use the **aaa mac-exempt** command in global configuration mode. To disable the use of a list of MAC addresses, use the **no** form of this command.

aaa mac-exempt match *id*

no aaa mac-exempt match *id*

Syntax Description

id	Specifies a MAC list number configured with the **mac-list** command.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can only add one **aaa mac-exempt** command. Configure the MAC list number using the **mac-list** command before using the **aaa mac-exempt** command. Permit entries in the MAC list exempt the MAC addresses from authentication and authorization, while deny entries require authentication and authorization for the MAC address, if enabled. Because you can only add one instance of the **aaa mac-exempt** command, be sure that the MAC list includes all the MAC addresses that you want to exempt.

Examples

The following example bypasses authentication for a single MAC address:

```
hostname(config)# mac-list abc permit 00a0.c95d.0282 ffff.ffff.ffff
hostname(config)# aaa mac-exempt match abc
```

The following entry bypasses authentication for all Cisco IP Phones, which have the hardware ID 0003.E3:

```
hostname(config)# mac-list acd permit 0003.E300.0000 FFFF.FF00.0000
hostname(config)# aaa mac-exempt match acd
```

The following example bypasses authentication for a a group of MAC addresses except for 00a0.c95d.02b2:

```
hostname(config)# mac-list 1 deny 00a0.c95d.0282 ffff.ffff.ffff
hostname(config)# mac-list 1 permit 00a0.c95d.0000 ffff.ffff.0000
hostname(config)# aaa mac-exempt match 1
```

Related Commands

Command	Description
aaa authentication	Enables user authentication.
aaa authorization	Enables user authorization services.
aaa mac-exempt	Exempts a list of MAC addresses from authentication and authorization.
show running-config mac-list	Displays a list of MAC addresses previously specified in the **mac-list** command.
mac-list	Specifies a list of MAC addresses to be used to exempt MAC addresses from authentication and/or authorization.

aaa proxy-limit

To limit the number of concurrent authentication attempts (at the same time) for a given IP address, use the **aaa proxy-limit** command in global configuration mode. To return to the default proxy-limit value, use the **no** form of this command.

aaa proxy-limit *proxy_limit*

aaa proxy-limit disable

no aaa proxy-limit

Syntax Description

disable	Specifies that no proxies are allowed.
proxy_limit	Specifies the number of concurrent proxy connections allowed per user, from 1 to 128.

Defaults

The default proxy-limit value is 16.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If a source address is a proxy server, consider excluding this IP address from authentication or increasing the number of allowable outstanding AAA requests.

For example, if two users were at the same IP address (perhaps connected to a terminal server) and both open a browser or connection and try to begin authenticating at exactly the same time, only one would be allowed, and the second would be blocked.

The first session from that IP address will be proxied and sent the auththentication request, while the other session would time out. This has nothing to do with how many connections a single username has.

Examples

The following example shows how to set the maximum number of outstanding authentication attempts (at the same time) for a given IP address:

```
hostname(config)# aaa proxy-limit 6
```

Related Commands

Command	Description
aaa authentication	Enables, disables, or views LOCAL, TACACS+, or RADIUS user authentication, on a server designated by the **aaa-server** command, or ASDM user authentication.
aaa authorization	Enables or disables LOCAL or TACACS+ user authorization services.
aaa-server host	Specifies a AAA server.
clear configure aaa	Removes or resets the configured AAA accounting values.
show running-config aaa	Displays the AAA configuration.

aaa-server

To create a AAA server group and configure AAA server parameters that are group-specific and common to all group hosts, use the **aaa-server** command in global configuration mode. To remove the designated group, use the **no** form of this command.

aaa-server *server-tag* **protocol** *server-protocol*

no aaa-server *server-tag* **protocol** *server-protocol*

Syntax Description

protocol *server-protocol*	Specifies the AAA protocol that the servers in the group support: • **http-form** • **kerberos** • **ldap** • **nt** • **radius** • **sdi** • **tacacs+**
server-tag	Specifies the server group name, which is matched by the name specified by the **aaa-server host** commands. Other AAA commands make reference to the AAA server group name.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.1(1)	The http-form protocol was added.
8.2(2)	The maximum number of AAA server groups was increased from 15 to 100 for single mode.
8.4(2)	The **ad-agent-mode** option in aaa-server group configuration mode was added.

Usage Guidelines

You can have up to 100 server groups in single mode or 4 server groups per context in multiple mode. Each group can have up to 15 servers in single mode or 4 servers in multiple mode. When a user logs in, the servers are accessed one at a time starting with the first server you specify in the configuration, until a server responds.

You control AAA server configuration by defining a AAA server group protocol with the **aaa-server** command, and then you add servers to the group using the **aaa-server host** command. When you enter the **aaa-server protocol** command, you enter aaa-server group configuration mode.

If you are using the RADIUS protocol and are in the aaa-server group configuration mode, note the following:

- To enable multi-session accounting for clientless SSL and AnyConnect sessions, enter the **interim-accounting-update** option. If you choose this option, interim accounting records are sent to the RADIUS server in addition to the start and stop records.
- To specify the shared secret between the ASA and the AD agent and indicate that a RADIUS server group includes AD agents that are not full-function RADIUS servers, enter the **ad-agent-mode** option. Only a RADIUS server group that has been configured using this option can be associated with user identity. As a result, the **test aaa-server** {**authentication** | **authorization**} *aaa-server-group* command is not available when a RADIUS server group that is not configured using the **ad-agent-mode** option is specified.

Examples

The following example shows the use of the **aaa-server** command to modify details of a TACACS+ server group configuration:

```
hostname(config)# aaa-server svrgrp1 protocol tacacs+
hostname(config-aaa-server-group)# accounting-mode simultaneous
hostname(config-aaa-server-group)# reactivation mode timed
hostname(config-aaa-server-group)# max-failed attempts 2
```

Related Commands

Command	Description
accounting-mode	Indicates whether accounting messages are sent to a single server (single mode) or sent to all servers in the group (simultaneous mode).
reactivation-mode	Specifes the method by which failed servers are reactivated.
max-failed-attempts	Specifies the number of failures that will be tolerated for any given server in the server group before that server is deactivated.
clear configure aaa-server	Removes all AAA server configurations.
show running-config aaa-server	Displays AAA server statistics for all AAA servers, for a particular server group, for a particular server within a particular group, or for a particular protocol.

aaa-server active, fail

To reactivate a AAA server that is marked failed, use the **aaa-server active** command in privileged EXEC mode. To fail an active server, use the **aaa-server fail** command in privileged EXEC mode.

aaa-server *server_tag* [**active | fail**] **host** {*server_ip* | *name*}

Syntax Description

active	Sets the server to an active state.
fail	Sets the server to a failed state.
host	Specifies the host IP address name or IP address.
name	Specifies the name of the server using either a name assigned locally using the **name** command or a DNS name. Maximum characters is 128 for DNS names and 63 characters for names assigned using the **name** command.
server_ip	Specifies the IP address of the AAA server.
server_tag	Specifies a symbolic name of the server group, which is matched by the name specified by the **aaa-server** command.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Without this command, servers in a group that failed remain in a failed state until all servers in the group fail, after which all are reactivated.

Examples

The following example shows the state for server 192.168.125.60 and manually reactivates it:

```
hostname# show aaa-server group1 host 192.68.125.60
Server Group:  group1
Server Protocol: RADIUS
Server Address:  192.68.125.60
Server port:  1645
Server status: FAILED. Server disabled at 11:10:08 UTC  Fri Aug 22
...
hostname# aaa-server active host 192.168.125.60
```

```
hostname# show aaa-server group1 host 192.68.125.60
Server Group:  group1
Server Protocol: RADIUS
Server Address:  192.68.125.60
Server port:  1645
Server status: ACTIVE (admin initiated). Last Transaction at 11:40:09 UTC  Fri Aug 22
...
```

Related Commands

Command	Description
aaa-server	Creates and modifies AAA server groups.
clear configure aaa-server	Removes all AAA-server configuration.
show running-config aaa-server	Displays AAA server statistics for all AAA servers, for a particular server group, for a particular server within a particular group, or for a particular protocol.

aaa-server host

To configure a AAA server as part of a AAA server group and to configure AAA server parameters that are host-specific, use the **aaa-server host** command in global configuration mode. To remove a host configuration, use the **no** form of this command.

aaa-server *server-tag* [(*interface-name*)] **host** {*server-ip* | *name*} [*key*] [**timeout** *seconds*]

no aaa-server *server-tag* [(*interface-name*)] **host** {*server-ip* | *name*} [*key*] [**timeout** *seconds*]

Syntax Description

(*interface-name*)	(Optional) Specifies the network interface where the authentication server resides. The parentheses are required in this parameter. If you do not specify an interface, the default is **inside**, if available.
key	(Optional) Specifies a case-sensitive, alphanumeric keyword of up to 127 characters that is the same value as the key on the RADIUS or TACACS+ server. Any characters entered past 127 are ignored. The key is used between the ASA and the server for encrypting data between them. the key must be the same on both the ASA and server systems. Spaces are not permitted in the key, but other special characters are allowed. You can add or modify the key using the **key** command in host mode.
name	Specifies the name of the server using either a name assigned locally using the **name** command or a DNS name. Maximum characters is 128 for DNS names and 63 characters for names assigned using the **name** command.
server-ip	Specifies the IP address of the AAA server.
server-tag	Specifies a symbolic name of the server group, which is matched by the name specified by the **aaa-server** command.
timeout *seconds*	(Optional) The timeout interval for the request. This is the time after which the ASA gives up on the request to the primary AAA server. If there is a standby AAA server, the ASA sends the request to the backup server. You can modify the timeout interval using the **timeout** command in host configuration mode.

Defaults

The default timeout value is 10 seconds.

The default interface is inside.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	Support for DNS names was added.
9.0(1)	Support for user identity was added.

Usage Guidelines

You control AAA server configuration by defining a AAA server group with the **aaa-server** command, and then you add servers to the group using the **aaa-server host** command. When you use the **aaa-server host** command, you enter the aaa-server host configuration mode, from which you can specify and manage host-specific AAA server connection data.

You can have up to 15 server groups in single mode or 4 server groups per context in multiple mode. Each group can have up to 16 servers in single mode or 4 servers in multiple mode. When a user logs in, the servers are accessed one at a time starting with the first server that you specify in the configuration, until a server responds.

Examples

The following example configures a Kerberos AAA server group named “watchdogs”, adds a AAA server to the group, and defines the Kerberos realm for the server:

Note Kerberos realm names use numbers and upper-case letters only. Although the ASA accepts lower-case letters for a realm name, it does not translate lower-case letters to upper-case letters. Be sure to use upper-case letters only.

```
hostname(config)# aaa-server watchdogs protocol kerberos
hostname(config-aaa-server-group)# exit
hostname(config)# aaa-server watchdogs host 192.168.3.4
hostname(config-aaa-server-host)# kerberos-realm EXAMPLE.COM
```

The following example configures an SDI AAA server group named “svrgrp1”, and then adds a AAA server to the group, sets the timeout interval to 6 seconds, sets the retry interval to 7 seconds, and configures the SDI version to version 5:

```
hostname(config)# aaa-server svrgrp1 protocol sdi
hostname(config-aaa-server-group)# exit
hostname(config)# aaa-server svrgrp1 host 192.168.3.4
hostname(config-aaa-server-host)# timeout 6
hostname(config-aaa-server-host)# retry-interval 7
hostname(config-aaa-server-host)# sdi-version sdi-5
```

The following example shows how to narrow down the search path to the targeted groups when you use the **aaa-server** *aaa_server_group_tag* command for LDAP search:

```
hostname(config)# aaa-server CISCO_AD_SERVER protocol ldap
hostname(config)# aaa-server CISCO_AD_SERVER host 10.1.1.1
hostname(config-aaa-server-host)# server-port 636
hostname(config-aaa-server-host)# ldap-base-dn DC=cisco,DC=com
hostname(config-aaa-server-host)# ldap-group-base-dn OU=Cisco Groups,DC=cisco,DC=com
hostname(config-aaa-server-host)# ldap-scope subtree
hostname(config-aaa-server-host)# ldap-login-password *
hostname(config-aaa-server-host)# ldap-login-dn CISCO\username1
hostname(config-aaa-server-host)# ldap-over-ssl enable
hostname(config-aaa-server-host)# server-type microsoft
```

Note When the **ldap-group-base-dn** command is specified, all groups must reside under it in the LDAP directory hierarchy and no group can reside outside this path.

The **ldap-group-base-dn** command takes effect only when at least one activated user-identity based policy exists.

The **server-type microsoft** command, which is not the default, must be configured.

The first **aaa-server** *aaa_server_group_tag* **host** command is used for LDAP operations.

Related Commands

Command	Description
aaa-server	Creates and modifies AAA server groups.
clear configure aaa-server	Removes all AAA server configurations.
show running-config aaa-server	Displays AAA server statistics for all AAA servers, for a particular server group, for a particular server within a particular group, or for a particular protocol.

absolute

To define an absolute time when a time range is in effect, use the **absolute** command in time-range configuration mode. To not specify a time for a time range, use the **no** form of this command.

absolute [**end** *time date*] [**start** *time date*]

no absolute

Syntax Description

date	(Optional) Specifies the date in the format, day month year; for example, 1 January 2006. The valid range of years is 1993 through 2035.
end	(Optional) Specifies the end of the time range.
start	(Optional) Specifies the start of the time range.
time	(Optional) Specifies the time in the format HH:MM. For example, 8:00 is 8:00 a.m. and 20:00 is 8:00 p.m.

Defaults

If no start time and date are specified, the permit or deny statement is in effect immediately and always on. Similarly, the maximum end time is 23:59 31 December 2035. If no end time and date are specified, the associated permit or deny statement is in effect indefinitely.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Time-range configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To implement a time-based ACL, use the **time-range** command to define specific times of the day and week. Then use the **access-list extended time-range** command to bind the time range to an ACL.

Examples

The following example activates an ACL at 8:00 a.m. on 1 January 2006:

```
hostname(config-time-range)# absolute start 8:00 1 January 2006

Because no end time and date are specified, the associated ACL is in effect indefinitely.
```

Related Commands

Command	Description
access-list extended	Configures a policy for permitting or denying IP traffic through the ASA.
default	Restores default settings for the **time-range** command **absolute** and **periodic** keywords.
periodic	Specifies a recurring (weekly) time range for functions that support the time-range feature.
time-range	Defines access control to the ASA based on time.

accept-subordinates

To configure the ASA to accept subordinate CA certificates if delivered during phase one IKE exchange when not previously installed on the device, use the **accept-subordinates** command in crypto ca trustpoint configuration mode. To restore the default setting, use the **no** form of the command.

accept-subordinates

no accept-subordinates

Syntax Description

This command has no arguments or keywords.

Defaults

The default setting is on (subordinate certificates are accepted).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca trustpoint configuration	•	•	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

During phase 1 processing, an IKE peer might pass both a subordinate certificate and an identity certificate. The subordinate certificate might not be installed on the ASA. This command lets an administrator support subordinate CA certificates that are not configured as trustpoints on the device without requiring that all subordinate CA certificates of all established trustpoints be acceptable; in other words, this command lets the device authenticate a certificate chain without installing the entire chain locally.

Examples

The following example enters crypto ca trustpoint configuration mode for trustpoint central, and allows the ASA to accept subordinate certificates for trustpoint central:

```
hostname(config)# crypto ca trustpoint central
hostname(ca-trustpoint)# accept-subordinates
hostname(ca-trustpoint)#
```

Related Commands

Command	Description
crypto ca trustpoint	Enters trustpoint configuration mode.
default enrollment	Returns enrollment parameters to their defaults.

access-group

To bind an ACL to a single interface, use the **access-group** command in global configuration mode. To unbind an ACL from the interface, use the **no** form of this command.

access-group *access-list* {**in | out**} **interface** *interface_name* [***per-user-override*** **|** ***control-plane***]

no access-group *access-list* {**in | out**} **interface** *interface_name*

To apply a single set of global rules to all interfaces with the single command, use the **access-group global** command in global configuration mode. To remove the global rules from all configured interfaces, use the **no** form of this command.

access-group *access-list* [**global**]

no access-group *access-list* **[global**]

Syntax Description

access-list	ACL *id.*
control-plane	(Optional) Specifies whether or not the rule is for to-the-box traffic. For example, you can use this option to block certain remote IP addresses from initiating a VPN session to the ASA by blocking ISAKMP. Access rules for to-the-box management traffic (defined by such commands as **http**, **ssh**, or **telnet**) have higher precedence than an ACL applied with the **control-plane** option. Therefore, such permitted management traffic will be allowed to come in even if explicitly denied by the to-the-box ACL.
global	(Optional) Applies an ACL to all configured interfaces.
in	Filters the inbound packets at the specified interface.
interface *interface-name*	Name of the network interface.
out	Filters the outbound packets at the specified interface.
per-user-override	(Optional) Allows downloadable user ACLs to override the ACL applied to the interface.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.3(1)	This command was modified to support global policies.

Usage Guidelines

Interface-specific access-group rules have higher priority that global rules, so at the time of packet classification, interface-specific rules are processed before global rules.

Usage Guidelines for Interface-specific Rules

The **access-group** command binds an ACL to an interface. The ACL is applied to traffic inbound to an interface. If you enter the **permit** option in an **access-list** command statement, the ASA continues to process the packet. If you enter the **deny** option in an **access-list** command statement, the ASA discards the packet and generates the following syslog message.

`%ASA-4-106019: IP packet from` *`source_addr`* `to` *`destination_addr`*`, protocol` *`protocol`* `received from interface` *`interface_name`* `deny by access-group` *`id`*

The **per-user-override** option allows downloaded ACLs to override the ACL applied to the interface. If the **per-user-override** option is not present, the ASA preserves the existing filtering behavior. When **per-user-override** is present, the ASA allows the **permit** or **deny** status from the per-user access-list (if one is downloaded) associated to a user to override the permit or deny status from the **access-group** command associated ACL. Additionally, the following rules are observed:

- At the time a packet arrives, if there is no per-user ACL associated with the packet, the interface ACL will be applied.
- The per-user ACL is governed by the timeout value specified by the **uauth** option of the **timeout** command but it can be overridden by the AAA per-user session timeout value.
- Existing ACL log behavior will be the same. For example, if user traffic is denied because of a per-user ACL, syslog message 109025 will be logged. If user traffic is permitted, no syslog message is generated. The log option in the per-user access-list will have no effect.

For VPN remote access traffic, the behavior depends on whether there is a **vpn-filter** applied in the group policy and whether you set the **per-user-override** option:

- No **per-user-override**, no **vpn-filter**—Traffic is matched against the interface ACL (per the default **no sysopt connection permit-vpn** command).
- No **per-user-override**, **vpn-filter**—Traffic is matched first against the interface ACL, then against the VPN filter.
- **per-user-override**, **vpn-filter**—Traffic is matched against the VPN filter only.

Always use the **access-list** command with the **access-group** command.

The **access-group** command binds an ACL to an interface. The **in** keyword applies the ACL to the traffic on the specified interface. The **out** keyword applies the ACL to the outbound traffic.

Note If all of the functional entries (the permit and deny statements) are removed from an ACL that is referenced by one or more **access-group** commands, the **access-group** commands are automatically removed from the configuration. The **access-group** command cannot reference empty ACLs or ACLs that contain only a remark.

Usage Guidelines for Global Rules

The **access-group global** command applies a single set of global rules on all traffic, no matter which interface the traffic arrives at the ASA.

Global rules for the **access-group global** command support extended ACLs only.

All global rules apply only to traffic in the ingress (input) direction. Global rules do not support egress (output) traffic.

Global rules for **access-group global** do not support the **control-plane** nor the **per-user-override** options that are supported in interface-specific access rules.

If global rules are configured in conjunction with interface access rules, then the interface access rule, which is specific, is processed before the global access rule, which is general.

Examples

The following example shows how to use the **access-group global** command to apply an ACL to all configured interfaces:

```
hostname(config)# access-list acl-1 extended permit ip host 10.1.2.2 host 10.2.2.2
hostname(config)# access-list acl-2 extended deny ip any any

hostname(config)# access-group acl-2
hostname(config)# access-group acl-1 in interface outside

hostname(config)# show run access-group acl-2
hostname(config)# access-group acl-1 in interface outside

hostname(config)# access-group acl-2 global
```

The preceding access-group configuration adds the following rules in the classification table (output from the **show asp table classify** command):

```
in  id=0xb1f90068, priority=13, domain=permit, deny=false
        hits=0, user_data=0xaece1ac0, cs_id=0x0, flags=0x0, protocol=0
        src ip=10.1.2.2, mask=255.255.255.255, port=0
        dst ip=10.2.2.2, mask=255.255.255.255, port=0, dscp=0x0
        input_ifc=outside, output_ifc=any
in  id=0xb1f2a250, priority=12, domain=permit, deny=true
        hits=0, user_data=0xaece1b40, cs_id=0x0, flags=0x0, protocol=0
        src ip=0.0.0.0, mask=0.0.0.0, port=0
        dst ip=0.0.0.0, mask=0.0.0.0, port=0, dscp=0x0
        input_ifc=any, output_ifc=any
in  id=0xb1f90100, priority=11, domain=permit, deny=true
        hits=0, user_data=0x5, cs_id=0x0, flags=0x0, protocol=0
        src ip=0.0.0.0, mask=0.0.0.0, port=0
        dst ip=0.0.0.0, mask=0.0.0.0, port=0, dscp=0x0
        input_ifc=outside, output_ifc=any
in  id=0xb1f2a3f8, priority=11, domain=permit, deny=true
        hits=0, user_data=0x5, cs_id=0x0, flags=0x0, protocol=0
        src ip=0.0.0.0, mask=0.0.0.0, port=0
        dst ip=0.0.0.0, mask=0.0.0.0, port=0, dscp=0x0
        input_ifc=any, output_ifc=any
```

The preceding rule passes traffic from 10.1.2.2 to 10.2.2.2 on the output interface and drops traffic from 10.1.1.10 to 10.2.2.20 on the output interface due to the global deny rule.

The following example allows global access to an HTTP server (with the IP address 10.2.2.2) in the DMZ from anywhere:

```
hostname(config)# access-list global_acl permit tcp any host 10.2.2.2 eq 80
hostname(config)# access-group global_acl global
```

The preceding rule permits the HTTP connection from outside host 10.1.2.2 to host 10.2.2.2, and it permits the HTTP connection from the inside host 192.168.0.0 to host 10.2.2.2.

Note If you have no global policy support, the preceding ACL must be applied to all applicable interfaces.

The following example shows how a global policy and an interface policy can be used together. The example allows access to a server (with the IP address 10.2.2.2) from any inside host, but it denies access to the server from any other host. The interface policy takes precedence.

```
hostname(config)# access-list inside_acl permit tcp any host 10.2.2.2 eq 23
hostname(config)# access-list global_acl deny ip any host 10.2.2.2
hostname(config)# access-group inside_acl in interface inside
hostname(config)# access-group global_acl global
```

The preceding rule denies the SSH connection from outside host 10.1.2.2 to host 10.2.2.2, and it permits the SSH connection from the inside host 192.168.0.0 to host 10.2.2..2.

The following example shows how NAT and the global access control policy work together. The example permits one HTTP connection from outside host 10.1.2.2 to host 10.2.2.2, permits another HTTP connection from inside host 192.168.0.0 to host 10.2.2.2, and denies (by implicit rule), one HTTP connection from outside host 10.255.255.255 to host 172.31.255.255.

```
hostname(config)# object network dmz-server host 10.1.1.2
hostname(config)# nat (any, any) static 10.2.2.2
hostname(config)# access-list global_acl permit tcp any host 10.2.2.2 eq 80
hostname(config)# access-group global_acl global
```

The following example shows how NAT and the global access control policy work together. The example permits one HTTP connection from host 10.1.1.1 to host 192.168.0.0, permits another HTTP connection from host 209.165.200.225 to host 172.16.0.0, and denies one HTTP connection from host 10.1.1.1 to host 172.16.0.0.

```
hostname(config)# object network 10.1.1.1 host 10.1.1.1
hostname(config)# object network 172.16.0.0 host 172.16.0.0
hostname(config)# object network 192.168.0.0 host 192.168.0.0
hostname(config)# nat (inside, any) source static 10.1.1.1 10.1.1.1 destination static
                  192.168.0.0 172.16.0.0
hostname(config)# access-list global_acl permit ip object 10.1.1.1 object 172.16.0.0
hostname(config)# access-list global_acl permit ip host 209.165.200.225 object 172.16.0.0
hostname(config)# access-list global_acl deny ip any 172.16.0.0
hostname(config)# access-group global_acl global
```

Related Commands

Command	Description
access-list extended	Creates an ACL or uses a downloadable ACL.
clear configure access-group	Removes access groups from all the interfaces.
show running-config access-group	Displays the current ACL bound to the interfaces.

access-list alert-interval

To specify the time interval between deny flow maximum messages, use the **access-list alert-interval** command in global configuration mode. To return to the default settings, use the **no** form of this command.

access-list alert-interval *secs*

no access-list alert-interval

Syntax Description

secs	Time interval between deny flow maximum message generation; valid values are from 1 to 3600 seconds. The default value is 300 seconds.

Defaults

The default is 300 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **access-list alert-interval** command sets the time interval for generating syslog message 106001, which alerts you that the ASA has reached a deny flow maximum. When the deny flow maximum is reached, another syslog message 106001 is generated if at least *secs* seconds have passed since the last syslog message 106001 was generated.

See the **access-list deny-flow-max** command for information about the deny flow maximum message generation.

Examples

The following example shows how to specify the time interval between deny flow maximum messages:

```
hostname(config)# access-list alert-interval 30
```

Related Commands

Command	Description
access-list deny-flow-max	Specifies the maximum number of concurrent deny flows that can be created.
access-list extended	Adds an ACL to the configuration and is used to configure policy for IP traffic through the ASA.
clear access-group	Clears an ACL counter.
clear configure access-list	Clears ACLs from the running configuration.
show access-list	Displays the ACL entries by number.

access-list deny-flow-max

To specify the maximum number of concurrent deny flows that can be created, use the **access-list deny-flow-max** command in global configuration mode. To return to the default settings, use the **no** form of this command.

access-list deny-flow-max

no access-list deny-flow-max

Syntax Description

This command has no arguments or keywords.

Defaults

The default is 4096 concurrent deny flows.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Syslog message 106101 is generated when the ASA has reached the maximum number, *n*, of ACL deny flows.

Examples

The following example shows how to specify the maximum number of concurrent deny flows that can be created:

```
hostname(config)# access-list deny-flow-max 256
```

Related Commands

Command	Description
access-list extended	Adds an ACL to the configuration and is used to configure policy for IP traffic through the ASA.
clear access-group	Clears an ACL counter.
clear configure access-list	Clears ACLs from the running configuration.

Command	Description
show access-list	Displays the ACL entries by number.
show running-config access-list	Displays the current running access list configuration.

access-list ethertype

To configure an ACL that controls traffic based on its EtherType, use the **access-list ethertype** command in global configuration mode. To remove the ACL, use the **no** form of this command.

access-list *id* **ethertype** {**deny** | **permit**} {**ipx** | **is-is** | **bpdu** | **mpls-unicast** | **mpls-multicast** | **any** | *hex_number*}

no access-list *id* **ethertype** {**deny** | **permit**} {**ipx** | **is-is** | **bpdu** | **mpls-unicast** | **mpls-multicast** | **any** | *hex_number*}

Syntax Description

any	Permits or denies all traffic.
bpdu	Permits or denies bridge protocol data units. By default, BPDUs are denied.
deny	Denies traffic.
hex_number	Permits or denies traffic with a particular EtherType, specified as a 16-bit hexadecimal number greater than or equal to 0x600.
id	Specifies the name or number of an ACL.
ipx	Permits or denies IPX.
is-is	Permits or denies IS-IS.
mpls-multicast	Permits or denies MPLS multicast.
mpls-unicast	Permits or denies MPLS unicast.
permit	Permits traffic.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	—	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.4(5), 9.1(2)	We added the **is-is** keyword.

Usage Guidelines

An EtherType ACL is made up of one or more Access Control Entries (ACEs) that specify an EtherType. An EtherType rule controls any EtherType identified by a 16-bit hexadecimal number, as well as selected traffic types.

Note For EtherType ACLs, the implicit deny at the end of the ACL does not affect IP traffic or ARPs; for example, if you allow EtherType 8037, the implicit deny at the end of the ACL does not now block any IP traffic that you previously allowed with an extended ACL (or implicitly allowed from a high security interface to a low security interface). However, if you explicitly deny all traffic with an EtherType ACE, then IP and ARP traffic is denied; only physical protocol traffic, such as auto-negotiation, is still allowed.

Supported EtherTypes and Other Traffic

An EtherType rule controls the following:

- EtherType identified by a 16-bit hexadecimal number, including common types IPX and MPLS unicast or multicast.
- Ethernet V2 frames.
- BPDUs, which are permitted by default. BPDUs are SNAP-encapsulated, and the ASA is designed to specifically handle BPDUs.
- Trunk port (Cisco proprietary) BPDUs. Trunk BPDUs have VLAN information inside the payload, so the ASA modifies the payload with the outgoing VLAN if you allow BPDUs.
- IS-IS

The following types of traffic are not supported:

- 802.3-formatted frames—These frames are not handled by the rule because they use a length field as opposed to a type field.

Access Rules for Returning Traffic

Because EtherTypes are connectionless, you need to apply the rule to both interfaces if you want traffic to pass in both directions.

Allowing MPLS

If you allow MPLS, ensure that Label Distribution Protocol and Tag Distribution Protocol TCP connections are established through the ASA by configuring both MPLS routers connected to the ASA to use the IP address on the ASA interface as the router-id for LDP or TDP sessions. (LDP and TDP allow MPLS routers to negotiate the labels (addresses) used to forward packets.)

On Cisco IOS routers, enter the appropriate command for your protocol, LDP or TDP. The interface is the interface connected to the ASA.

```
hostname(config)# mpls ldp router-id interface force
```

Or

```
hostname(config)# tag-switching tdp router-id interface force
```

Examples

The following example shows how to add an EtherType ACL:

```
hostname(config)# access-list ETHER ethertype permit ipx
hostname(config)# access-list ETHER ethertype permit bpdu
hostname(config)# access-list ETHER ethertype permit mpls-unicast
hostname(config)# access-group ETHER in interface inside
```

Related Commands

Command	Description
access-group	Binds the ACL to an interface.
clear access-group	Clears ACL counters.
clear configure access-list	Clears an ACL from the running configuration.
show access-list	Displays the ACL entries by number.
show running-config access-list	Displays the current running access-list configuration.

access-list extended

To add an Access Control Entry (ACE), use the **access-list extended** command in global configuration mode. To remove an ACE, use the **no** form of this command.

For any type of traffic, no ports:

access-list *access_list_name* [**line** *line_number*] **extended** {**deny** | **permit**} *protocol_argument* [*user_argument*] [*security_group_argument*] *source_address_argument* [*security_group_argument*] *dest_address_argument* [**log** [[*level*] [**interval** *secs*] | **disable** | **default**]] [**inactive** | **time-range** *time_range_name*]

no access-list *access_list_name* [**line** *line_number*] **extended** {**deny** | **permit**} *protocol_argument* [*user_argument*] [*security_group_argument*] *source_address_argument* [*security_group_argument*] *dest_address_argument* [**log** [[*level*] [**interval** *secs*] | **disable** | **default**]] [**inactive** | **time-range** *time_range_name*]

For TCP or UDP traffic, with ports:

access-list *access_list_name* [**line** *line_number*] **extended** {**deny** | **permit**} {**tcp** | **udp**} [*user_argument*] [*security_group_argument*] *source_address_argument* [*port_argument*] [*security_group_argument*] *dest_address_argument* [*port_argument*] [**log** [[*level*] [**interval** *secs*] | **disable** | **default**]] [**inactive** | **time-range** *time_range_name*]

no access-list *access_list_name* [**line** *line_number*] **extended** {**deny** | **permit**} {**tcp** | **udp**} [*user_argument*] [*security_group_argument*] *source_address_argument* [*port_argument*] [*security_group_argument*] *dest_address_argument* [*port_argument*] [**log** [[*level*] [**interval** *secs*] | **disable** | **default**]] [**inactive** | **time-range** *time_range_name*]

For ICMP traffic, with ICMP type:

access-list *access_list_name* [**line** *line_number*] **extended** {**deny** | **permit**} **icmp** [*user_argument*] [*security_group_argument*] *source_address_argument* [*security_group_argument*] *dest_address_argument* [*icmp_argument*] [**log** [[*level*] [**interval** *secs*] | **disable** | **default**]] [**inactive** | **time-range** *time_range_name*]

no access-list *access_list_name* [**line** *line_number*] **extended** {**deny** | **permit**} **icmp** [*user_argument*] [*security_group_argument*] *source_address_argument* [*security_group_argument*] *dest_address_argument* [*icmp_argument*] [**log** [[*level*] [**interval** *secs*] | **disable** | **default**]] [**inactive** | **time-range** *time_range_name*]

Syntax Description

access_list_name	Specifies the ACL ID, as a string or integer up to 241 characters in length. The ID is case-sensitive. **Tip** Use all capital letters to see the ACL ID better in your configuration.
default	(Optional) Sets logging to the default method, which is to generate system log message 106023 for each denied packet.

deny	Denies a packet if the conditions are matched. In the case of network access (the **access-group** command), this keyword prevents the packet from passing through the ASA. In the case of applying application inspection to a class map (the **class-map** and **inspect** commands), this keyword exempts the traffic from inspection. Some features do not allow deny ACEs to be used. See the command documentation for each feature that uses an ACL for more information.
dest_address_argument	Specifies the IP address or FQDN to which the packet is being sent. Available arguments include: • **host** *ip_address*—Specifies an IPv4 host address. • *dest_ip_address mask*—Specifies an IPv4 network address and subnet mask. When you specify a network mask, the method is different from the Cisco IOS software **access-list** command. The ASA uses a network mask (for example, 255.255.255.0 for a Class C mask). The Cisco IOS mask uses wildcard bits (for example, 0.0.0.255). • *ipv6-address*/*prefix-length*—Specifies an IPv6 host or network address and prefix. • **any**, **any4**, and **any6**—**any** specifies both IPv4 and IPv6 traffic; **any4** specifies only IPv4 traffic; and **any6** specifies any6 traffic. • **interface**—Specifies the interface address. You must specify the interface keyword instead of specifying the actual IP address in the ACL when the traffic source is a device interface. For example, you can use this option to block certain remote IP addresses from initiating a VPN session to the ASA by blocking ISAKMP. Any traffic originated from or destined to the ASA, itself, requires that you use the **access-group** command with the **control-plane** optional keyword. • **object** *nw_obj_id*—Specifies a network object created using the **object network** command. • **object-group** *nw_grp_id*—Specifies a network object group created using the **object-group network** command.
disable	(Optional) Disables logging for this ACE.
icmp_argument	(Optional) Specifies the ICMP type and code. • *icmp_type* [*icmp_code*]—Specifies the ICMP type by name or number, and the optional ICMP code for that type. If you do not specify the code, then all codes are used. • **object-group** *icmp_grp_id*—Specifies an ICMP object group created using the **object-group icmp** command.
inactive	(Optional) Disables an ACE. To reenable it, enter the entire ACE without the **inactive** keyword. This feature lets you keep a record of an inactive ACE in your configuration to make reenabling easier.
interval *secs*	(Optional) Specifies the log interval at which to generate system log message 106100. Valid values are from 1 to 600 seconds. The default is 300.
level	(Optional) Sets the system log message 106100 severity level from 0 to 7. The default level is 6 (informational).

line *line-num*	(Optional) Specifies the line number at which to insert the ACE. If you do not specify a line number, the ACE is added to the end of the ACL. The line number is not saved in the configuration; it only specifies where to insert the ACE.
log	(Optional) Sets logging options when a **ACE** matches a packet for network access (an ACL applied with the **access-group** command). If you enter the **log** keyword without any arguments, you enable system log message 106100 at the default level (6) and for the default interval (300 seconds). If you do not enter the **log** keyword, then the default system log message 106023 is generated.
permit	Permits a packet if the conditions are matched. In the case of network access (the **access-group** command), this keyword lets the packet pass through the ASA. In the case of applying application inspection to a class map (the **class-map** and **inspect** commands), this keyword applies inspection to the packet.
port_argument	(Optional) If you set the protocol to TCP or UDP, specifies the source and/or destination port. Available arguments include: • *operator port*—The *operator* can be one of the following: – **lt**—less than – **gt**—greater than – **eq**—equal to – **neq**—not equal to – **range**—an inclusive range of values. When you use this operator, specify two port numbers, for example: `range 100 200` The *port* can be the integer or name of a TCP or UDP port. DNS, Discard, Echo, Ident, NTP, RPC, SUNRPC, and Talk each require one definition for TCP and one for UDP. TACACS+ requires one definition for port 49 on TCP. • **object-group** *service_grp_id*—Specifies a service object group created using the **object-group service** command.
protocol_argument	Specifies the IP protocol. Available arguments include: • *name* or *number*—Specifies the protocol name or number. For example, UDP is 17, TCP is 6, and EGP is 47. Specify **ip** to apply to all protocols. • **object-group** *protocol_grp_id*—Specifies a protocol object group created using the **object-group protocol** command. • **object** *service_obj_id*—Specifies a service object created using the **object service** command. A TCP, UDP, or ICMP service object can include a protocol and a source and/or destination port or ICMP type and code, which are used when matching traffic to the ACE; you do not have to configure the port/type separately in the ACE. • **object-group** *service_grp_id*—Specifies a service object group created using the **object-group service** command.

security_group_argument	For use with the TrustSec feature, specifies the security group for which to match traffic in addition to the source or destination address. Available arguments include: • **object-group-security** *security_obj_grp_id*—Specifies a security object group created using the **object-group security** command. • **security-group** {**name** *security_grp_id* | **tag** *security_grp_tag*}—Specifies a security group name or tag.
source_address_argument	Specifies the IP address or FQDN from which the packet is being sent. Available arguments include: • **host** *ip_address*—Specifies an IPv4 host address. • *dest_ip_address mask*—Specifies an IPv4 network address and subnet mask. When you specify a network mask, the method is different from the Cisco IOS software **access-list** command. The ASA uses a network mask (for example, 255.255.255.0 for a Class C mask). The Cisco IOS mask uses wildcard bits (for example, 0.0.0.255). • *ipv6-address*/*prefix-length*—Specifies an IPv6 host or network address and prefix. • **any**, **any4**, and **any6**—**any** specifies both IPv4 and IPv6 traffic; **any4** specifies only IPv4 traffic; and **any6** specifies any6 traffic. • **interface**—Specifies the interface address. You must specify the interface keyword instead of specifying the actual IP address in the ACL when the traffic source is a device interface. For example, you can use this option to block certain remote IP addresses from initiating a VPN session to the ASA by blocking ISAKMP. Any traffic originated from or destined to the ASA, itself, requires that you use the **access-group** command with the **control-plane** optional keyword. • **object** *nw_obj_id*—Specifies a network object created using the **object network** command. • **object-group** *nw_grp_id*—Specifies a network object group created using the **object-group network** command.
tcp	Sets the protocol to TCP.
time-range *time_range_name*	(Optional) Schedules each ACE to be activated at specific times of the day and week by applying a time range to the ACE. See the **time-range** command for information about defining a time range.

udp	Sets the protocol to UDP.
user_argument	For use with the identity firewall feature, specifies the user or group for which to match traffic in addition to the source address. Available arguments include: • **object-group-user** *user_obj_grp_id*—Specifies a user object group created using the **object-group user** command. • **user** {[*domain_nickname*\]*name* | **any** | **none**}—Specifies a user name. Specify **any** to match all users with user credentials, or **none** to match users without user credentials. These options are especially useful for combining **access-group** and **aaa authentication match** policies. • **user-group** [*domain_nickname*\\]*user_group_name*—Specifies a user group name.

Defaults

- ACE logging generates system log message 106023 for denied packets. A **deny ACE** must be present to log denied packets.
- When the **log** keyword is specified, the default level for system log message 106100 is 6 (informational), and the default interval is 300 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.3(1)	When using NAT or PAT, mapped addresses and ports are no longer required in an ACL for several features. You should now always use the real, untranslated addresses and ports for these features. Using the real address and port means that if the NAT configuration changes, you do not need to change the ACLs. See the "Features That Use Real IP Addresses" section on page 1-74 for more information.
8.4(2)	You can now use identity firewall users and groups for the source and destination, in addition to the source or destination IP address. Support for **user**, **user-group**, and **object-group-user** were added for the source and destination.
9.0(1)	You can now use TrustSec security groups for the source and destination, in addition to the source or destination IP address. Support for **security-group** and **object-group-security** were added for the source or destination.

Release	Modification
9.0(1)	Support for IPv6 was added. The **any** keyword was changed to represent IPv4 and IPv6 traffic. The **any4** and **any6** keywords were added to represent IPv4-only and IPv6-only traffic, respectively. You can specify a mix of IPv4 and IPv6 addresses for the source and destination. If you use NAT to translate between IPv4 and IPv6, the actual packet will not include a mix of IPv4 and IPv6 addresses; however, for many features, the ACL always uses the real IP addresses and does not consider the NAT mapped addresses. The IPv6-specific ACLs are deprecated. Existing IPv6 ACLs are migrated to extended ACLs. See the release notes for more information about migration. For information about ACL migration, see the 9.0 release notes.
9.0(1)	Support for the ICMP code was added. When you specify **icmp** as the protocol, you can enter *icmp_type* [*icmp_code*].

Usage Guidelines

An ACL is made up of one or more ACEs with the same ACL ID. ACLs are used to control network access or to specify traffic for many features to act upon. Each ACE that you enter for a given ACL name is appended to the end of the ACL, unless you specify the line number in the ACE. To remove the entire ACL, use the **clear configure access-list** command.

Order of ACEs

The order of ACEs is important. When the ASA decides whether to forward or drop a packet, the ASA tests the packet with each ACE in the order in which the entries are listed. After a match is found, no more ACEs are checked. For example, if you create an ACE at the beginning of an ACL that explicitly permits all traffic, no further statements are ever checked.

Features That Use Real IP Addresses

Note For ACL migration information, see the *Cisco ASA 5500 Migration to Version 8.3 and Later.*

The following commands and features now use real IP addresses in the ACLs:

- **access-group** command
- Modular Policy Framework **match access-list** command
- Botnet Traffic Filter **dynamic-filter enable classify-list** command
- AAA **aaa ... match** commands
- WCCP

Features That Use Mapped IP Addresses

The following features use ACLs, but these ACLs will continue to use the mapped values as seen on an interface:

- IPsec ACLs
- **capture** command ACLs
- Per-user ACLs
- Routing protocol ACLs
- All other feature ACLs

Features That Do Not Support IDFW, FQDN, and TrustSec ACLs

The following features use ACLs, but cannot accept an ACL with IDFW, FQDN, or TrustSec values:

- **route-map** command
- VPN **crypto map** command
- VPN **group-policy** command, except for **vpn-filter**
- WCCP
- DAP

Examples

The following ACL allows all hosts (on the interface to which you apply the ACL) to go through the ASA:

```
hostname(config)# access-list ACL_IN extended permit ip any any
```

The following sample ACL prevents hosts on 192.168.1.0/24 from accessing the 209.165.201.0/27 network. All other addresses are permitted.

```
hostname(config)# access-list ACL_IN extended deny tcp 192.168.1.0 255.255.255.0
209.165.201.0 255.255.255.224
hostname(config)# access-list ACL_IN extended permit ip any any
```

If you want to restrict access to only some hosts, then enter a limited **permit ACE**. By default, all other traffic is denied unless explicitly permitted.

```
hostname(config)# access-list ACL_IN extended permit ip 192.168.1.0 255.255.255.0
209.165.201.0 255.255.255.224
```

The following ACL restricts all hosts (on the interface to which you apply the ACL) from accessing a website at address 209.165.201.29. All other traffic is allowed.

```
hostname(config)# access-list ACL_IN extended deny tcp any host 209.165.201.29 eq www
hostname(config)# access-list ACL_IN extended permit ip any any
```

The following ACL that uses object groups restricts several hosts on the inside network from accessing several web servers. All other traffic is allowed.

```
hostname(config-network)# access-list ACL_IN extended deny tcp object-group denied
object-group web eq www
hostname(config)# access-list ACL_IN extended permit ip any any
hostname(config)# access-group ACL_IN in interface inside
```

To temporarily disable an ACL that permits traffic from one group of network objects (A) to another group of network objects (B):

```
hostname(config)# access-list 104 permit ip host object-group A object-group B inactive
```

To implement a time-based ACL, use the **time-range** command to define specific times of the day and week. Then use the **access-list extended** command to bind the time range to an ACL. The following example binds an ACL named “Sales” to a time range named “New_York_Minute”:

```
hostname(config)# access-list Sales line 1 extended deny tcp host 209.165.200.225 host
209.165.201.1 time-range New_York_Minute
```

See the **time-range** command for more information about how to define a time range.

The following ACL allows any ICMP traffic:

```
hostname(config)# access-list abc extended permit icmp any any
```

The following ACL allows any ICMP traffic for the object group “obj_icmp_1”:

```
hostname(config)# access-list abc extended permit icmp any any object-group obj_icmp_1
```

The following ACL permits ICMP traffic with ICMP type 3 and ICMP code 4 from source host 10.0.0.0 to destination host 10.1.1.1. All other type of ICMP traffic is not be permitted.

```
hostname(config)# access-list abc extended permit icmp host 10.0.0.0 host 10.1.1.1 3 4
```

The following ACL permits ICMP traffic with ICMP type 3 and any ICMP code from source host 10.0.0.0 to destination host 10.1.1.1. All other type of ICMP traffic is not be permitted.

```
hostname(config)# access-list abc extended permit icmp host 10.0.0.0 host 10.1.1.1 3
```

Related Commands

Command	Description
access-group	Binds the ACL to an interface.
clear access-group	Clears an ACL counter.
clear configure access-list	Clears an ACL from the running configuration.
show access-list	Displays ACEs by number.
show running-config access-list	Displays the current running access list configuration.

access-list remark

To specify the text of a remark to add before or after an **access-list extended** command, use the **access-list remark** command in global configuration mode. To delete the remark, use the **no** form of this command.

access-list *id* [**line** *line-num*] **remark** *text*

no access-list *id* [**line** *line-num*] **remark** [*text*]

Syntax Description

id	Name of an ACL.
line *line-num*	(Optional) The line number at which to insert a remark or an access control element (ACE).
remark text	Text of the remark to add before or after an **access-list extended** command.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The remark text must contain at least one non-space character; an empty remark is not allowed. The remark text can be up to 100 characters long, including spaces and punctuation.

You cannot use the **access-group** command on an ACL that includes a remark only.

Examples

The following example shows how to specify the text of a remark to add before or after an **access-list** command:

```
hostname(config)# access-list 77 remark checklist
```

Related Commands

Command	Description
access-list extended	Adds an ACL to the configuration and is used to configure policy for IP traffic through the ASA.
clear access-group	Clears an ACL counter.
clear configure access-list	Clears ACLs from the running configuration.
show access-list	Displays the ACL entries by number.
show running-config access-list	Displays the current running access list configuration.

access-list rename

To rename an ACL, use the **access-list rename** command in global configuration mode.

access-list *id* **rename** *new_acl_id*

Syntax Description

id	Name of an existing ACL.
rename *new_acl_id*	Specifies the new ACL ID, as a string or integer up to 241 characters long. The ID is case-sensitive.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

If the ACL is renamed to the same name, the ASA will silently ignore the command.

Examples

The following example shows how to rename an ACL from TEST to OUTSIDE:

```
hostname(config)# access-list TEST rename OUTSIDE
```

Related Commands

Command	Description
access-list extended	Adds an ACL to the configuration and is used to configure policy for IP traffic through the ASA.
clear access-group	Clears an ACL counter.
clear configure access-list	Clears ACLs from the running configuration.
show access-list	Displays the ACL entries by number.
show running-config access-list	Displays the current running access-list configuration.

access-list standard

To add an ACL to identify the destination IP addresses of OSPF routes, which can be used in a route map for OSPF redistribution, use the **access-list standard** command in global configuration mode. To remove the ACL, use the **no** form of this command.

access-list *id* **standard** [**line** *line-num*] {**deny** | **permit**} {**any4** | **host** *ip_address* | *ip_address subnet_mask*}

no access-list *id* **standard** [**line** *line-num*] {**deny** | **permit**} {**any4** | **host** *ip_address* | *ip_address subnet_mask*}

Syntax Description

any4	Specifies access to anyone.
deny	Denies access if the conditions are matched.
host *ip_address*	(Optional) Specifies access to a host IP address.
id	Name or number of an ACL.
ip_address ip_mask	Specifies access to a specific IP address (optional) and subnet mask.
line *line-num*	(Optional) The line number at which to insert an ACE.
permit	Permits access if the conditions are matched.

Defaults

The defaults are as follows:

- The ASA denies all packets on the originating interface unless you specifically permit access.
- ACL logging generates system log message 106023 for denied packets—deny packets must be present to log denied packets.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

When used with the **access-group** command, the **deny** keyword does not allow a packet to traverse the ASA. By default, the ASA denies all packets on the originating interface unless you specifically permit access.

Use the following guidelines for specifying a source, local, or destination address:

- Use a 32-bit quantity in four-part, dotted-decimal format.

- Use the keyword **any** as an abbreviation for an address and mask of 0.0.0.0 0.0.0.0.
- Use the **host** *ip_address* option as an abbreviation for a mask of 255.255.255.255.

Examples

The following example shows how to deny IP traffic through the ASA:

```
hostname(config)# access-list 77 standard deny
```

The following example shows how to permit IP traffic through the ASA if conditions are matched:

```
hostname(config)# access-list 77 standard permit
```

The following example shows how to specify a destination address:

```
hostname(config)# access-list 77 standard permit host 10.1.10.123
```

Related Commands

Command	Description
access-group	Defines object groups that you can use to optimize your configuration.
clear access-group	Clears an ACL counter.
clear configure access-list	Clears ACLs from the running configuration.
show access-list	Displays the ACL entries by number.
show running-config access-list	Displays the current running access list configuration.

access-list webtype

To add an ACL to the configuration that supports filtering for clientless SSL VPN, use the **access-list webtype** command in global configuration mode. To remove the ACL, use the **no** form of this command.

access-list *id* **webtype** {**deny** | **permit**} **url** {*url_string* | **any**} [**log** {**disable** | **default** | **level**} [**interval** *secs*]] [**time_range** *name*]] [inactive]

no access-list *id* **webtype** {**deny** | **permit**} **url** {*url_string* | **any**} [**log** {**disable** | **default** | **level**} [**interval** *secs*]] [**time_range** *name*]] [inactive]

access-list *id* **webtype** {**deny** | **permit**} **tcp** [**host** *host_address* | *dest_address subnet_mask* | **any**] [*oper port* [*port*]] [**log** {**disable** | **default** | *level*} [**interval** *secs*] [**time_range** *name*]] [inactive]

no **access-list** *id* **webtype** {**deny** | **permit**} **tcp** [**host** *host_address* | *dest_address subnet_mask* | **any**] [*oper port* [*port*]] [**log** {**disable** | **default** | *level*} [**interval** *secs*] [**time_range** *name*]] [inactive]

Syntax Description

any	Specifies all IP addresses.
any	(Optional) Specifies all URLs.
deny	Denies access if the conditions are matched.
dest_address	Specifies a destination IP address.
host_address	Specifies a host IP address.
id	Specifies a name or number of an ACL.
inactive	Disables an ACE.
interval *secs*	(Optional) Specifies the time interval at which to generate system log message 106100; valid values are from 1 to 600 seconds.
log {**disable** | **default** | *level*}	(Optional) Specifies that system log message 106100 is generated for the ACE. See the **log** command for information.
oper	Compares *ip_address* ports. Possible operands include lt (less than), gt (greater than), eq (equal), neq (not equal), and range (inclusive range).
permit	Permits access if the conditions are matched.
port	Specifies the decimal number or name of a TCP or UDP port.
subnet mask	Specifies the subnet mask of the destination IP address.
time_range *name*	(Optional) Specifies a keyword for attaching the time-range option to this ACL element.
url	Specifies that a URL be used for filtering.
url_string	(Optional) Specifies the URL to be filtered.

Defaults

The defaults are as follows:

- The ASA denies all packets on the originating interface unless you specifically permit access.
- ACL logging generates syslog message 106023 for denied packets—deny packets must be present to log denied packets.

- When the **log** optional keyword is specified, the default level for syslog message 106100 is 6 (informational).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **access-list webtype** command is used to configure clientless SSL VPN filtering. The URL specified may be full or partial (no file specified), may include wildcards for the server, or may specify a port.

Valid protocol identifiers are: http, https, cifs, imap4, pop3, and smtp. The URL may also contain the keyword **any** to refer to any URL. An asterisk may be used to refer to a subcomponent of a DNS name.

If you disable an ACE with the inactive keyword, you can enable it again by entering the entire ACE without the **inactive** keyword. This feature enables you to keep a record of an inactive ACE in your configuration to make reenabling easier.

Examples

The following example shows how to deny access to a specific company URL:

```
hostname(config)# access-list acl_company webtype deny url http://*.example.com
```

The following example shows how to deny access to a specific file:

```
hostname(config)# access-list acl_file webtype deny url
https://www.example.com/dir/file.html
```

The following example shows how to deny HTTP access to any URL through port 8080:

```
hostname(config)# access-list acl_company webtype deny url http://my-server:8080/*
```

Related Commands

Command	Description
access-group	Defines object groups that you can use to optimize your configuration.
access-list ethertype	Configures an ACL that controls traffic based on its EtherType.
access-list extended	Adds an ACL to the configuration and configures policy for IP traffic through the ASA.
clear access-group	Clears an ACL counter.
show running-config access-list	Displays the access list configuration running on the ASA.

accounting-mode

To indicate whether accounting messages are sent to a single server (single mode) or sent to all servers in the group (simultaneous mode), use the **accounting-mode** command in aaa-server configuration mode. To remove the accounting mode specification, use the **no** form of this command.

accounting-mode {**simultaneous** | **single**}

Syntax Description

simultaneous	Sends accounting messages to all servers in the group.
single	Sends accounting messages to a single server.

Defaults

The default value is single mode.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the **single** keyword to send accounting messages to a single server. Use the **simultaneous** keyword to send accounting messages to all servers in the server group.

This command is meaningful only when the server group is used for accounting (RADIUS or TACACS+).

Examples

The following example shows the use of the **accounting-mode** command to send accounting messages to all servers in the group:

```
hostname(config)# aaa-server svrgrp1 protocol tacacs+
hostname(config-aaa-server-group)# accounting-mode simultaneous
hostname(config-aaa-server-group)# exit
hostname(config)#
```

Related Commands

Command	Description
aaa accounting	Enables or disables accounting services.

aaa-server protocol	Enters AAA server group configuration mode, so you can configure AAA server parameters that are group-specific and common to all hosts in the group.
clear configure aaa-server	Removes all AAA server configuration.
show running-config aaa-server	Displays AAA server statistics for all AAA servers, for a particular server group, for a particular server within a particular group, or for a particular protocol.

accounting-port

To specify the port number used for RADIUS accounting for this host, use the **accounting-port** command in aaa-server host configuration mode. To remove the authentication port specification, use the **no** form of this command.

accounting-port *port*

no accounting-port

Syntax Description

port	A port number for RADIUS accounting; the range of valid values is 1- 65535.

Defaults

By default, the device listens for RADIUS on port 1646 for accounting (in compliance with RFC 2058). If the port is not specified, the RADIUS accounting default port number (1646) is used.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server host configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command specifies the destination TCP/UDP port number of the remote RADIUS server hosts to which you want to send accounting records. If your RADIUS accounting server uses a port other than 1646, you must configure the ASA for the appropriate port before starting the RADIUS service with the **aaa-server** command.

This command is valid only for server groups that are configured for RADIUS.

Examples

The following example configures a RADIUS AAA server named “srvgrp1” on host “1.2.3.4”, sets a timeout of 9 seconds, sets a retry-interval of 7 seconds, and configures accounting port 2222.

```
hostname(config)# aaa-server svrgrp1 protocol radius
hostname(config-aaa-server-group)# aaa-server svrgrp1 host 1.2.3.4
hostname(config-aaa-server-host)# timeout 9
hostname(config-aaa-server-host)# retry-interval 7
hostname(config-aaa-server-host)# accountinq-port 2222
hostname(config-aaa-server-host)# exit
hostname(config)#
```

Related Commands

Command	Description
aaa accounting	Keeps a record of which network services a user has accessed.
aaa-server host	Enters aaa server host configuration mode, so you can configure AAA server parameters that are host-specific.
clear configure aaa-server	Removes all AAA command statements from the configuration.
show running-config aaa-server	Displays AAA server statistics for all AAA servers, for a particular server group, for a particular server within a particular group, or for a particular protocol.

accounting-server-group

To specify the AAA server group for sending accounting records, use the **accounting-server-group** command in various modes. To remove accounting servers from the configuration, use the **no** form of this command.

accounting-server-group *group_tag*

no accounting-server-group [*group_tag*]

Syntax Description

group_tag	Identifies the previously configured accounting server or group of servers. Use the **aaa-server** command to configure accounting servers.

Defaults

No accounting servers are configured by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Imap4s configuration	•	—	•	—	—
Pop3s configuration	•	—	•	—	—
Smtps configuration	•	—	•	—	—
Tunnel-group general-attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.1(1)	This command is available in tunnel-group general-attributes configuration mode, instead of webvpn configuration mode.

Usage Guidelines

The ASA uses accounting to keep track of the network resources that users access. If you enter this command in webvpn configuration mode, it is transformed to the same command in tunnel-group general-attributes configuration mode.

Examples

The following example entered in tunnel-group-general attributes configuration mode, configures an accounting server group named “aaa-server123” for an IPSec LAN-to-LAN tunnel group “xyz”:

```
hostname(config)# tunnel-group xyz type IPSec_L2L
hostname(config)# tunnel-group xyz general-attributes
hostname(config-tunnel-general)# accounting-server-group aaa-server123
hostname(config-tunnel-general)#
```

The following example shows how to configure POP3S e-mail proxy to use the set of accounting servers named POP3SSVRS:

```
hostname(config)# pop3s
hostname(config-pop3s)# accounting-server-group POP3SSVRS
```

Related Commands

Command	Description
aaa-server	Configures authentication, authorization, and accounting servers.

acl-netmask-convert through application-access hide-details Commands

acl-netmask-convert

To specify how the ASA treats netmasks received in a downloadable ACL from a RADIUS server that is accessed by using the **aaa-server host** command, use the **acl-netmask-convert** command in aaa-server host configuration mode . To remove the specified behavior for the ASA, use the **no** form of this command.

acl-netmask-convert {**auto-detect** | **standard** | **wildcard**}

no acl-netmask-convert

Syntax Description

auto-detect	Specifies that the ASA should attempt to determine the type of netmask expression used. If the ASA detects a wildcard netmask expression, it converts it to a standard netmask expression. See "Usage Guidelines" for more information about this keyword.
standard	Specifies that the ASA assumes downloadable ACLs received from the RADIUS server contain only standard netmask expressions. No translation from wildcard netmask expressions is performed.
wildcard	Specifies that the ASA assumes downloadable ACLs received from the RADIUS server contain only wildcard netmask expressions and converts them all to standard netmask expressions when the ACLs are downloaded.

Defaults

By default, no conversion from wildcard netmask expressions is performed.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server-host configuration	•	•	•	•	—

Command History

Release	Modification
7.0(4)	This command was introduced.

Usage Guidelines

Use the **acl-netmask-convert** command with the wildcard or auto-detect keywords when a RADIUS server provides downloadable ACLs that contain netmasks in wildcard format. The ASA expects downloadable ACLs to contain standard netmask expressions whereas Cisco VPN 3000 series concentrators expect downloadable ACLs to contain wildcard netmask expressions, which are the reverse of a standard netmas expression. A wildcard mask has ones in bit positions to ignore, zeros in bit positions to match.The **acl-netmask-convert** command helps minimize the effects of these differences upon how you configure downloadable ACLs on your RADIUS servers.

The **auto-detect** keyword is helpful when you are uncertain how the RADIUS server is configured; however, wildcard netmask expressions with "holes" in them cannot be unambiguously detected and converted. For example, the wildcard netmask 0.0.255.0 permits anything in the third octet and can be used validly on Cisco VPN 3000 series concentrators, but the ASA may not detect this expression as a wildcard netmask.

Examples

The following example configures a RADIUS AAA server named "srvgrp1" on host "192.168.3.4", enables conversion of downloadable ACL netmasks, sets a timeout of 9 seconds, sets a retry-interval of 7 seconds, and configures authentication port 1650:

```
hostname(config)# aaa-server svrgrp1 protocol radius
hostname(config-aaa-server-group)# aaa-server svrgrp1 host 192.168.3.4
hostname(config-aaa-server-host)# acl-netmask-convert wildcard
hostname(config-aaa-server-host)# timeout 9
hostname(config-aaa-server-host)# retry-interval 7
hostname(config-aaa-server-host)# authentication-port 1650
hostname(config-aaa-server-host)# exit
hostname(config)#
```

Related Commands

Command	Description
aaa authentication	Enables or disables LOCAL, TACACS+, or RADIUS user authentication, on a server designated by the **aaa-server** command, or ASDM user authentication.
aaa-server host	Enters aaa-server host configuration mode, so you can configure AAA server parameters that are host-specific.
clear configure aaa-server	Removes all AAA command statements from the configuration.
show running-config aaa-server	Displays AAA server statistics for all AAA servers, for a particular server group, for a particular server within a particular group, or for a particular protocol.

action

To either apply access policies to a session or teminate the session, use the **action** command in dynamic-access-policy-record configuration mode. To reset the session to apply an access policy to a session, use the **no** form of the command.

action {continue | terminate}

no action {continue | terminate}

Syntax Description

continue	Applies the access policies to the session.
terminate	Terminates the connection.

Defaults

The default value is continue.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Dynamic-access-policy-record configuration	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use the **continue** keyword to apply the access policies to the session in all of the selected DAP records. Use the **terminate** keyword to terminate the connection in any of the selected DAP records.

Examples

The following example shows how to terminate a session for the DAP policy Finance:

```
hostname (config)# config-dynamic-access-policy-record Finance
hostname(config-dynamic-access-policy-record)# action terminate
hostname(config-dynamic-access-policy-record)#
```

Related Commands

Command	Description
dynamic-access-policy-record	Creates a DAP record.
show running-config dynamic-access-policy-record [*name*]	Displays the running configuration for all DAP records, or for the named DAP record.

action-uri

To specify a web server URI to receive a username and password for single sign-on (SSO) authentication, use the **action-uri** command in aaa-server-host configuration mode. To reset the URI parameter value, use the **no** form of the command.

action-uri *string*

no action-uri

Note To configure SSO with the HTTP protocol correctly, you must have a thorough working knowledge of authentication and HTTP protocol exchanges.

Syntax Description

string	The URI for an authentication program. You can enter it on multiple lines. The maximum number of characters for each line is 255. The maximum number of characters for the complete URI is 2048 characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server-host configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

This is an SSO with HTTP Forms command. A URI or Uniform Resource Identifier is a compact string of characters that identifies a point of content on the Internet, whether it be a page of text, a video or sound clip, a still or animated image, or a software program. The most common form of URI is the web page address, which is a particular form or subset of URI called a URL.

The WebVPN server of the ASA can use a POST request to submit an SSO authentication request to an authenticating web server. To accomplish this, configure the ASA to pass a username and a password to an action URI on an authenticating web server using an HTTP POST request. The **action-uri** command specifies the location and name of the authentication program on the web server to which the ASA sends the POST request.

You can discover the action URI on the authenticating web server by connecting to the web server login page directly with a browser. The URL of the login web page displayed in your browser is the action URI for the authenticating web server.

For ease of entry, you can enter URIs on multiple, sequential lines. The ASA then concatenates the lines into the URI as you enter them. While the maximum characters per action-uri line is 255 characters, you can enter fewer characters on each line.

Note Any question mark in the string must be preceded by a CTRL-v escape sequence.

Examples

The following example specifies the URI on www.example.com:

http://www.example.com/auth/index.html/appdir/authc/forms/MCOlogin.fcc?TYPE=33554433&REALMOID=06-000a1311-a828-1185-ab41-8333b16a0008&GUID=&SMAUTHREASON=0&METHOD=GET&SMAGENTNAME=SM5FZmjnk3DRNwNjk2KcqVCFbIrNT9%2bJ0H0KPshFtg6rB1UV2PxkHqLw%3d%3d&TARGET=https%3A%2F%2Fauth.example.com

```
hostname(config)# aaa-server testgrp1 host www.example.com
hostname(config-aaa-server-host)# action-uri http://www.example.com/auth/index.htm
hostname(config-aaa-server-host)# action-uri l/appdir/authc/forms/MCOlogin.fcc?TYP
hostname(config-aaa-server-host)# action-uri 554433&REALMOID=06-000a1311-a828-1185
hostname(config-aaa-server-host)# action-uri -ab41-8333b16a0008&GUID=&SMAUTHREASON
hostname(config-aaa-server-host)# action-uri =0&METHOD=GET&SMAGENTNAME=$SM$5FZmjnk
hostname(config-aaa-server-host)# action-uri 3DRNwNjk2KcqVCFbIrNT9%2bJ0H0KPshFtg6r
hostname(config-aaa-server-host)# action-uri B1UV2PxkHqLw%3d%3d&TARGET=https%3A%2F
hostname(config-aaa-server-host)# action-uri %2Fauth.example.com
hostname(config-aaa-server-host)#
```

Note You must include the hostname and protocol in the action URI. In the preceding example, these are included in http://www.example.com at the start of the URI.

Related Commands

Command	Description
auth-cookie-name	Specifies a name for the authentication cookie.
hidden-parameter	Creates hidden parameters for exchange with the SSO server.
password-parameter	Specifies the name of the HTTP POST request parameter in which a user password must be submitted for SSO authentication.
start-url	Specifies the URL at which to retrieve a pre-login cookie.
user-parameter	Specifies the name of the HTTP POST request parameter in which a username must be submitted for SSO authentication.

activation-key

To enter a license activation key on the ASA, use the **activation-key** command in privileged EXEC mode.

activation-key [**noconfirm**] *activation_key* [**activate** | **deactivate**]

Syntax Description

activate	Activates a time-based activation key. **activate** is the default value. The last time-based key that you activate for a given feature is the active one.
activation_key	Applies an activation key to the ASA. The *activation_key* is a five-element hexadecimal string with one space between each element. The leading 0x specifier is optional; all values are assumed to be hexadecimal. You can install one permanent key, and multiple time-based keys. If you enter a new permanent key, it overwrites the already installed one.
deactivate	Deactivates a time-based activation key. The activation key is still installed on the ASA when you deactivate it, and you can activate it later using the **activate** keyword. If you enter a key for the first time, and specify **deactivate**, then the key is installed on the ASA in an inactive state.
noconfirm	(Optional) Enters an activation key without prompting you for confirmation.

Defaults

By default, your ASA ships with a license already installed. This license might be the Base License, to which you want to add more licenses, or it might already have all of your licenses installed, depending on what you ordered and what your vendor installed for you. See the **show activation-key** command to determine which licenses you have installed.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(5)	Increased the following limits: • ASA5510 Base license connections from 32000 to 5000; VLANs from 0 to 10. • ASA5510 Security Plus license connections from 64000 to 130000; VLANs from 10 to 25. • ASA5520 connections from 130000 to 280000; VLANs from 25 to 100. • ASA5540 connections from 280000 to 400000; VLANs from 100 to 200.
7.1(1)	SSL VPN licenses were introduced.
7.2(1)	A 5000-user SSL VPN license was introduced for the ASA 5550 and above.
7.2(2)	• The maximum number of VLANs for the Security Plus license on the ASA 5505 ASA was increased from 5 (3 fully functional; 1 failover; one restricted to a backup interface) to 20 fully functional interfaces. In addition, the number of trunk ports was increased from 1 to 8. • VLAN limits were increased for the ASA 5510 (from 10 to 50 for the Base license, and from 25 to 100 for the Security Plus license), the ASA 5520 (from 100 to 150), and the ASA 5550 (from 200 to 250).
7.2(3)	The ASA 5510 supports GE (Gigabit Ethernet) for port 0 and 1 with the Security Plus license. If you upgrade the license from Base to Security Plus, the capacity of the external Ethernet0/0 and Ethernet0/1 ports increases from the original FE (Fast Ethernet) (100 Mbps) to GE (1000 Mbps). The interface names will remain Ethernet 0/0 and Ethernet 0/1. Use the **speed** command to change the speed on the interface and use the **show interface** command to see what speed is currently configured for each interface.
8.0(2)	• The Advanced Endpoint Assessment license was introduced. • VPN load balancing is supported on the ASA 5510 Security Plus license.
8.0(3)	The AnyConnect for Mobile license was introduced.
8.0(4)/8.1(2)	Support for time-based licenses was introduced.
8.1(2)	The number of VLANs supported on the ASA 5580 increased from 100 to 250.
8.0(4)	The UC Proxy sessions license was introduced.
8.2(1)	• The Botnet Traffic Filter license was introduced. • The AnyConnect Essentials License was introduced. By default, the ASA uses the AnyConnect Essentials license, but you can disable it to use other licenses by using the **no anyconnect-essentials** command. • Shared licenses for SSL VPN were introduced.
8.2(2)	The Mobility Proxy no longer requires the UC Proxy license.

Release	Modification
8.3(1)	• Failover licenses no longer need to be identical on each unit. The license used for both units is the combined license from the primary and secondary units. • Time-based licenses are stackable. • The IME license was introduced. • You can install multiple time-based licenses, and have one license per feature active at a time. • You can activate or deactivate time-based licenses using **activate** or **deactivate** keywords.
8.4(1)	• For the ASA 5550 and ASA 5585-X with SSP-10, the maximum number of contexts was increased from 50 to 100. For the ASA 5580 and 5585-X with SSP-20 and higher, the maximum was increased from 50 to 250. • For the ASA 5580 and 5585-X, the maximum number of VLANs was increased from 250 to 1024. • We increased the firewall connection limits: – ASA 5580-20—1,000 K to 2,000 K. – ASA 5580-40—2,000 K to 4,000 K. – ASA 5585-X with SSP-10: 750 K to 1,000 K – ASA 5585-X with SSP-20: 1,000 K to 2,000 K – ASA 5585-X with SSP-40: 2,000 K to 4,000 K – ASA 5585-X with SSP-60: 2,000 K to 10,000 K • For the ASA 5580, the AnyConnect VPN session limit was increased from 5,000 to 10,000. • For the ASA 5580, the other VPN session limit was increased from 5,000 to 10,000. • IPsec remote access VPN using IKEv2 was added to the AnyConnect Essentials and AnyConnect Premium licenses. • Site-to-site sessions were added to the Other VPN license (formerly IPsec VPN). • For models available with No Payload Encryption (for example, the ASA 5585-X), the ASA software disables Unified Communications and VPN features, making the ASA available for export to certain countries.

Usage Guidelines

Obtaining an Activation Key

To obtain an activation key, you need a Product Authorization Key, which you can purchase from your Cisco account representative. You need to purchase a separate Product Activation Key for each feature license. For example, if you have the Base License, you can purchase separate keys for Advanced Endpoint Assessment and for additional SSL VPN sessions.

After obtaining the Product Authorization Keys, register them on Cisco.com at one of the following URLs.

- If you are a registered user of Cisco.com, go to the following website:

  http://www.cisco.com/go/license

- If you are not a registered user of Cisco.com, go to the following website:

  http://www.cisco.com/go/license/public

Context Mode Guidelines

- In multiple context mode, apply the activation key in the system execution space.
- Shared licenses are not supported in multiple context mode.

Failover Guidelines

- Shared licenses are not supported in Active/Active mode.
- Failover units do not require the same license on each unit.

  Older versions of ASA software required that the licenses match on each unit. Starting with Version 8.3(1), you no longer need to install identical licenses. Typically, you buy a license only for the primary unit; for Active/Standby failover, the secondary unit inherits the primary license when it becomes active. If you have licenses on both units, they combine into a single running failover cluster license.

- For the ASA 5505 and 5510, both units require the Security Plus license; the Base license does not support failover, so you cannot enable failover on a standby unit that only has the Base license.

Upgrade and Downgrade Guidelines

Your activation key remains compatible if you upgrade to the latest version from any previous version. However, you might have issues if you want to maintain downgrade capability:

- Downgrading to Version 8.1 or earlier—After you upgrade, if you activate additional feature licenses that were introduced *before 8.2*, then the activation key continues to be compatible with earlier versions if you downgrade. However if you activate feature licenses that were introduced in *8.2 or later*, then the activation key is not backwards compatible. If you have an incompatible license key, then see the following guidelines:
  - If you previously entered an activation key in an earlier version, then the ASA uses that key (without any of the new licenses you activated in Version 8.2 or later).
  - If you have a new system and do not have an earlier activation key, then you need to request a new activation key compatible with the earlier version.
- Downgrading to Version 8.2 or earlier—Version 8.3 introduced more robust time-based key usage as well as failover license changes:
  - If you have more than one time-based activation key active, when you downgrade, only the most recently activated time-based key can be active. Any other keys are made inactive.
  - If you have mismatched licenses on a failover pair, then downgrading will disable failover. Even if the keys are matching, the license used will no longer be a combined license.

Additional Guidelines and Limitations

- The activation key is not stored in your configuration file; it is stored as a hidden file in flash memory.

- The activation key is tied to the serial number of the device. Feature licenses cannot be transferred between devices (except in the case of a hardware failure). If you have to replace your device due to a hardware failure, contact the Cisco Licensing Team to have your existing license transferred to the new serial number. The Cisco Licensing Team will ask for the Product Authorization Key reference number and existing serial number.
- Once purchased, you cannot return a license for a refund or for an upgraded license.
- Although you can activate all license types, some features are incompatible with each other; for example, multiple context mode and VPN. In the case of the AnyConnect Essentials license, the license is incompatible with the following licenses: full SSL VPN license, shared SSL VPN license, and Advanced Endpoint Assessment license. By default, the AnyConnect Essentials license is used instead of the above licenses, but you can disable the AnyConnect Essentials license in the configuration to restore use of the other licenses using the **no anyconnect-essentials** command.
- Some permanent licenses require you to reload the ASA after you activate them. Table 2-1 lists the licenses that require reloading.

Table 2-1 Permanent License Reloading Requirements

Model	License Action Requiring Reload
ASA 5505 and ASA 5510	Changing between the Base and Security Plus license.
All models	Changing the Encryption license.
All models	Downgrading any permanent license (for example, going from 10 contexts to 2 contexts).

Examples

The following example shows how to change the activation key on the ASA:

```
hostname# activation-key 0xd11b3d48 0xa80a4c0a 0x48e0fd1c 0xb0443480 0x843fc490
```

The following is sample output from the **activation-key** command that shows output for failover when the new activation key is different than the old activation key:

```
hostname# activation-key 0xyadayada 0xyadayada 0xyadayada 0xyadayada 0xyadayada

Validating activation key. This may take a few minutes...
The following features available in the running permanent activation key are NOT available
in the new activation key:
Failover is different.
   running permanent activation key: Restricted (R)
   new activation key: Unrestricted (UR)
WARNING: The running activation key was not updated with the requested key.
Proceed with updating flash activation key? [y]
Flash permanent activation key was updated with the requested key.
```

The following is sample output from a license file:

```
Serial Number Entered: 123456789ja
Number of Virtual Firewalls Selected: 10
Formula One device: ASA 5520

Failover                       : Enabled

Related Commands

Command	Description
anyconnect-essentials	Enables or disables the Anyconnect Essentials license.
show activation-key	Shows the activation key.
show version	Shows the software version and activation key.

activex-relay

To incorporate applications that need ActiveX over the clientless portal, use the **activex-relay** command in group-policy webvpn configuration mode or username webvpn configuration mode. To inherit the **activex-relay** command from the default group policy, use the **no** form of this command.

activex-relay {**enable** | **disable**}

no activex-relay

Syntax Description

enable	Enables ActiveX on WebVPN sessions.
disable	Disables ActiveX on WebVPN sessions.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy webvpn configuration	•	—	•	—	—
Username webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use the **activex-relay enable** command to let users launch ActiveX from the WebVPN browser for any HTML content that has the object tags (such as images, audio, videos, JAVA applets, ActiveX, PDF, or flash). These applications use the WebVPN session to download and upload ActiveX controls. The ActiveX relay remains in force until the WebVPN session closes. If you plan to use something like Microsoft OWA 2007, you should disable ActiveX.

Note Because they have the same functionality, the **activex-relay enable** command generates smart tunnel logs even if smart tunnel is disabled.

The following example enables ActiveX controls on WebVPN sessions associated with a given group policy:

```
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# activex-relay enable
```

The following example disables ActiveX controls on WebVPN sessions associated with a given username:

```
hostname(config-username-policy)# webvpn
hostname(config-username-webvpn)# activex-relay disable
```

ad-agent-mode

To enables the AD Agent mode so that you can configure the Active Directory Agent for the Cisco Identify Firewall instance, use the **ad-agent-mode** command in global configuration mode.

ad-agent-mode

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

To configure the Active Directory Agent for the Identity Firewall, you must enter the **ad-agent-mode** command, which is a submode of the **aaa-server** command. Entering the **ad-agent-mode** command enters the aaa server group configuration mode.

Periodically or on-demand, the AD Agent monitors the Active Directory server security event log file via WMI for user login and logoff events. The AD Agent maintains a cache of user ID and IP address mappings. and notifies the ASA of changes.

Configure the primary and secondary AD Agents for the AD Agent Server Group. When the ASA detects that the primary AD Agent is not responding and a secondary agent is specified, the ASA switches to the secondary AD Agent. The Active Directory server for the AD agent uses RADIUS as the communication protocol; therefore, you should specify a key attribute for the shared secret between the ASA and AD Agent.

Examples

The following example shows how to enable **ad-agent-mode** while configuring the Active Directory Agent for the Identity Firewall:

```
hostname(config)# aaa-server adagent protocol radius
hostname(config)# ad-agent-mode
hostname(config-aaa-server-group)# aaa-server adagent (inside) host 192.168.1.101
hostname(config-aaa-server-host)# key mysecret
hostname(config-aaa-server-hostkey)# user-identity ad-agent aaa-server adagent
hostname(config-aaa-server-host)# test aaa-server ad-agent
```

Related Commands

Command	Description
aaa-server	Creates a AAA server group and configures AAA server parameters that are group-specific and common to all group hosts.
clear configure user-identity	Clears the configuration for the Identity Firewall feature.

address (dynamic-filter blacklist or whitelist)

To add an IP address to the Botnet Traffic Filter blacklist or whitelist, use the **address** command in dynamic-filter blacklist or whitelist configuration mode. To remove the address, use the **no** form of this command.

address *ip_address mask*

no address *ip_address mask*

Syntax Description

ip_address	Adds an IP address to the blacklist.
mask	Defines the subnet mask for the IP address. The *mask* can be for a single host or for a subnet.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Dynamic-filter blacklist or whitelist configuration	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

The static database lets you augment the dynamic database with domain names or IP addresses that you want to whitelist or blacklist. After you enter the dynamic-filter whitelist or blacklist configuration mode, you can manually enter domain names or IP addresses (host or subnet) that you want to tag as good names in a whitelist or bad names in a blacklist using the **address** and **name** commands.

You can enter this command multiple times for multiple entries. You can add up to 1000 blacklist and 1000 whitelist entries.

Examples

The following example creates entries for the blacklist and whitelist:

```
hostname(config)# dynamic-filter blacklist
hostname(config-llist)# name bad1.example.com
hostname(config-llist)# name bad2.example.com
hostname(config-llist)# address 10.1.1.1 255.255.255.0
hostname(config-llist)# dynamic-filter whitelist
hostname(config-llist)# name good.example.com
hostname(config-llist)# name great.example.com
```

```
hostname(config-llist)# name awesome.example.com
hostname(config-llist)# address 10.1.1.2 255.255.255.255
```

Related Commands

Command	Description
clear configure dynamic-filter	Clears the running Botnet Traffic Filter configuration.
clear dynamic-filter dns-snoop	Clears Botnet Traffic Filter DNS snooping data.
clear dynamic-filter reports	Clears Botnet Traffic filter report data.
clear dynamic-filter statistics	Clears Botnet Traffic filter statistics.
dns domain-lookup	Enables the ASA to send DNS requests to a DNS server to perform a name lookup for supported commands.
dns server-group	Identifies a DNS server for the ASA.
dynamic-filter blacklist	Edits the Botnet Traffic Filter blacklist.
dynamic-filter database fetch	Manually retrieves the Botnet Traffic Filter dynamic database.
dynamic-filter database find	Searches the dynamic database for a domain name or IP address.
dynamic-filter database purge	Manually deletes the Botnet Traffic Filter dynamic database.
dynamic-filter enable	Enables the Botnet Traffic Filter for a class of traffic or for all traffic if you do not specify an access list.
dynamic-filter updater-client enable	Enables downloading of the dynamic database.
dynamic-filter use-database	Enables use of the dynamic database.
dynamic-filter whitelist	Edits the Botnet Traffic Filter whitelist.
inspect dns dynamic-filter-snoop	Enables DNS inspection with Botnet Traffic Filter snooping.
name	Adds a name to the blacklist or whitelist.
show asp table dynamic-filter	Shows the Botnet Traffic Filter rules that are installed in the accelerated security path.
show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
show dynamic-filter dns-snoop	Shows the Botnet Traffic Filter DNS snooping summary, or with the **detail** keyword, the actual IP addresses and names.
show dynamic-filter reports	Generates reports of the top 10 botnet sites, ports, and infected hosts.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

address (media-termination)

To specify the address for a media termination instance to use for media connections to the Phone Proxy feature, use the **address** command in the media-termination configuration mode. To remove the address from the media termination configuration, use the **no** form of this command.

address *ip_address* [**interface** *intf_name*]

no address *ip_address* [**interface** *intf_name*]

Syntax Description

interface *intf_name*	Specifies the name of the interface for which the media termination address is used. Only one media-termination address can be configured per interface.
ip_address	Specifies the IP address to use for the media termination instance.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Media-termination configuration	•	—	•	—	—

Command History

Release	Modification
8.2(1)	The command was introduced.

Usage Guidelines

The ASA must have IP addresses for media termination that meet the following criteria:

- For the media termination instance, you can configure a global media-termination address for all interfaces or configure a media-termination address for different interfaces. However, you cannot use a global media-termination address and media-termination addresses configured for each interface at the same time.
- If you configure a media termination address for multiple interfaces, you must configure an address on each interface that the ASA uses when communicating with IP phones.
- The IP addresses are publicly routable addresses that are unused IP addresses within the address range on that interface.

See the CLI configuration guide for the complete list of prerequisites that you must follow when creating the media termination instance and configuring the media termination addresses.

Examples

The following example shows the use of the media-termination address command to specify the IP address to use for media connections:

```
hostname(config)# media-termination mediaterm1
hostname(config-media-termination)# address 192.0.2.25 interface inside
hostname(config-media-termination)# address 10.10.0.25 interface outside
```

Related Commands

Command	Description
phone-proxy	Configures the Phone Proxy instance.
media-termination	Configures the media termination instance to apply to a Phone Proxy instance.

address-pool (tunnel-group general attributes mode)

To specify a list of address pools for allocating addresses to remote clients, use the **address-pool** command in tunnel-group general-attributes configuration mode. To eliminate address pools, use the **no** form of this command.

address-pool [(*interface name*)] *address_pool1* [*...address_pool6*]

no address-pool [(*interface name*)] *address_pool1* [*...address_pool6*]

Syntax Description

address_pool	Specifies the name of the address pool configured with the **ip local pool** command. You can specify up to 6 local address pools.
interface name	(Optional) Specifies the interface to be used for the address pool.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Tunnel-group general-attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can enter multiples of each of these commands, one per interface. If an interface is not specified, then the command specifies the default for all interfaces that are not explicitly referenced.

The address-pools settings in the group-policy **address-pools** command override the local pool settings in the tunnel group **address-pool** command.

The order in which you specify the pools is significant. The ASA allocates addresses from these pools in the order in which the pools appear in this command.

Examples

The following example entered in config-tunnel-general configuration mode, specifies a list of address pools for allocating addresses to remote clients for an IPsec remote-access tunnel group test:

```
hostname(config)# tunnel-group test type remote-access
hostname(config)# tunnel-group test general
hostname(config-tunnel-general)# address-pool (inside) addrpool1 addrpool2 addrpool3
hostname(config-tunnel-general)#
```

Related Commands

Command	Description
ip local pool	Configures IP address pools to be used for VPN remote-access tunnels.
clear configure tunnel-group	Clears all configured tunnel groups.
show running-config tunnel-group	Shows the tunnel group configuration for all tunnel groups or for a particular tunnel group.
tunnel-group-map default-group	Associates the certificate map entries created using the **crypto ca certificate map** command with tunnel groups.

address-pools (group-policy attributes configuration mode)

To specify a list of address pools for allocating addresses to remote clients, use the **address-pools** command in group-policy attributes configuration mode. To remove the attribute from the group policy and enable inheritance from other sources of group policy, use the **no** form of this command.

address-pools value *address_pool1* [*...address_pool6*]

no address-pools value *address_pool1* [*...address_pool6*]

address-pools none

no address-pools none

Syntax Description

address_pool	Specifies the name of the address pool configured with the **ip local pool** command. You can specify up to 6 local address pools.
none	Specifies that no address pools are configured and disables inheritance from other sources of group policy.
value	Specifies a list of up to 6 address pools from which to assign addresses.

Defaults

By default, the address pool attribute allows inheritance.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The address pools settings in this command override the local pool settings in the group. You can specify a list of up to six local address pools to use for local address allocation.

The order in which you specify the pools is significant. The ASA allocates addresses from these pools in the order in which the pools appear in this command.

The command **address-pools none** disables this attribute from being inherited from other sources of policy, such as the DefaultGrpPolicy. The command **no address pools none** removes the **address-pools none** command from the configuration, restoring the default value, which is to allow inheritance.

Examples

The following example entered in config-general configuration mode, configures pool_1 and pool_20 as lists of address pools to use for allocating addresses to remote clients for GroupPolicy1:

```
hostname(config)# ip local pool pool_1 192.168.10.1-192.168.10.100 mask 255.255.0.0
hostname(config)# ip local pool pool_20 192.168.20.1-192.168.20.200 mask 255.255.0.0
hostname(config)# group-policy GroupPolicy1 attributes
hostname(config-group-policy)# address-pools value pool_1 pool_20
hostname(config-group-policy)#
```

Related Commands

Command	Description
ip local pool	Configures IP address pools to be used for VPN group policies.
clear configure group-policy	Clears all configured group policies.
show running-config group-policy	Shows the configuration for all group policies or for a particular group policy.

admin-context

To set the admin context for the system configuration, use the **admin-context** command in global configuration mode.

admin-context *name*

Syntax Description

name	Sets the name as a string up to 32 characters long. If you have not defined any contexts yet, then first specify the admin context name with this command. Then, the first context you add using the **context** command must be the specified admin context name. This name is case sensitive, so you can have two contexts named "customerA" and "CustomerA," for example. You can use letters, digits, or hyphens, but you cannot start or end the name with a hyphen. "System" or "Null" (in upper or lowercase letters) are reserved names, and cannot be used.

Defaults

For a new ASA in multiple context mode, the admin context is called "admin."

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can set any context to be the admin context, as long as the context configuration resides on the internal flash memory.

You cannot remove the current admin context, unless you remove all contexts using the **clear configure context** command.

The system configuration does not include any network interfaces or network settings for itself; rather, when the system needs to access network resources (such as downloading the ASA software or allowing remote management for an administrator), it uses one of the contexts that is designated as the admin context.

Examples

The following example sets the admin context to be "administrator":

```
hostname(config)# admin-context administrator
```

Related Commands

Command	Description
clear configure context	Removes all contexts from the system configuration.
context	Configures a context in the system configuration and enters context configuration mode.
show admin-context	Shows the current admin context name.

allocate-interface

To allocate interfaces to a security context, use the **allocate-interface** command in context configuration mode. To remove an interface from a context, use the **no** form of this command.

allocate-interface *physical_interface* [*map_name*] [**visible** | **invisible**]

no allocate-interface *physical_interface*

allocate-interface *physical_interface*.*subinterface*[-*physical_interface*.*subinterface*] [*map_name*[-*map_name*]] [**visible** | **invisible**]

no allocate-interface *physical_interface*.*subinterface*[-*physical_interface*.*subinterface*]

Syntax Description

invisible	(Default) Allows context users to only see the mapped name (if configured) in the **show interface** command.

map_name	(Optional) Sets a mapped name.
	
	The *map_name* is an alphanumeric alias for the interface that can be used within the context instead of the interface ID. If you do not specify a mapped name, the interface ID is used within the context. For security purposes, you might not want the context administrator to know which interfaces are being used by the context.
	
	A mapped name must start with a letter, end with a letter or digit, and have as interior characters only letters, digits, or an underscore. For example, you can use the following names:
	
	`int0`
	
	`inta`
	
	`int_0`
	
	For subinterfaces, you can specify a range of mapped names.
	
	See the "Usage Guidelines" section for more information about ranges.

physical_interface	Sets the interface ID, such as **gigabitethernet0/1**. See the **interface** command for accepted values. Do not include a space between the interface type and the port number.
subinterface	Sets the subinterface number. You can identify a range of subinterfaces.
visible	(Optional) Allows context users to see physical interface properties in the **show interface** command even if you set a mapped name.

Defaults

The interface ID is invisible in the **show interface** command output by default if you set a mapped name.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
	Routed	Transparent	Single	Multiple Context	System
Context configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can enter this command multiple times to specify different ranges. To change the mapped name or visible setting, reenter the command for a given interface ID, and set the new values; you do not need to enter the **no allocate-interface** command and start over. If you remove the **allocate-interface** command, the ASA removes any interface-related configuration in the context.

Transparent firewall mode allows only two interfaces to pass through traffic; however, on the ASA , you can use the dedicated management interface, Management 0/0, (either the physical interface or a subinterface) as a third interface for management traffic.

Note The management interface for transparent mode does not flood a packet out the interface when that packet is not in the MAC address table.

You can assign the same interfaces to multiple contexts in routed mode, if desired. Transparent mode does not allow shared interfaces.

If you specify a range of subinterfaces, you can specify a matching range of mapped names. Follow these guidelines for ranges:

- The mapped name must consist of an alphabetic portion followed by a numeric portion. The alphabetic portion of the mapped name must match for both ends of the range. For example, enter the following range:

  ```
  int0-int10
  ```

  If you enter **gigabitethernet0/1.1-gigabitethernet0/1.5 happy1-sad5**, for example, the command fails.

- The numeric portion of the mapped name must include the same quantity of numbers as the subinterface range. For example, both ranges include 100 interfaces:

  ```
  gigabitethernet0/0.100-gigabitethernet0/0.199 int1-int100
  ```

  If you enter **gigabitethernet0/0.100-gigabitethernet0/0.199 int1-int15**, for example, the command fails.

Examples

The following example shows gigabitethernet0/1.100, gigabitethernet0/1.200, and gigabitethernet0/2.300 through gigabitethernet0/1.305 assigned to the context. The mapped names are int1 through int8.

```
hostname(config-ctx)# allocate-interface gigabitethernet0/1.100 int1
```

```
hostname(config-ctx)# allocate-interface gigabitethernet0/1.200 int2
hostname(config-ctx)# allocate-interface gigabitethernet0/2.300-gigabitethernet0/2.305
int3-int8
```

Related Commands

Command	Description
context	Creates a security context in the system configuration and enters context configuration mode.
interface	Configures an interface and enters interface configuration mode.
show context	Shows a list of contexts (system execution space) or information about the current context.
show interface	Displays the runtime status and statistics of interfaces.
vlan	Assigns a VLAN ID to a subinterface.

allocate-ips

To allocate an IPS virtual sensor to a security context if you have the AIP SSM installed, use the **allocate-ips** command in context configuration mode. To remove a virtual sensor from a context, use the **no** form of this command.

allocate-ips *sensor_name* [*mapped_name*] [**default**]

no allocate-ips *sensor_name* [*mapped_name*] [**default**]

Syntax Description

default	(Optional) Sets one sensor per context as the default sensor; if the context configuration does not specify a sensor name, the context uses this default sensor. You can only configure one default sensor per context. If you want to change the default sensor, enter the **no allocate-ips** command to remove the current default sensor before you allocate a new default sensor. If you do not specify a sensor as the default, and the context configuration does not include a sensor name, then traffic uses the default sensor on the AIP SSM.
mapped_name	(Optional) Sets a mapped name as an alias for the sensor name that can be used within the context instead of the actual sensor name. If you do not specify a mapped name, the sensor name is used within the context. For security purposes, you might not want the context administrator to know which sensors are being used by the context. Or you might want to genericize the context configuration. For example, if you want all contexts to use sensors called “sensor1” and “sensor2,” then you can map the “highsec” and “lowsec” senors to sensor1 and sensor2 in context A, but map the “medsec” and “lowsec” sensors to sensor1 and sensor2 in context B.
sensor_name	Sets the sensor name configured on the AIP SSM. To view the sensors that are configured on the AIP SSM, enter **allocate-ips ?**. All available sensors are listed. You can also enter the **show ips** command. In the system execution space, the **show ips** command lists all available sensors; if you enter it in the context, it shows the sensors you already assigned to the context. If you specify a sensor name that does not yet exist on the AIP SSM, you get an error, but the **allocate-ips** command is entered as-is. Until you create a sensor of that name on the AIP SSM, the context assumes the sensor is down.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Context configuration	•	•	—	—	•

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

You can assign one or more IPS virtual sensors to each context. Then, when you configure the context to send traffic to the AIP SSM using the **ips** command, you can specify a sensor that is assigned to the context; you cannot specify a sensor that you did not assign to the context. If you do not assign any sensors to a context, then the default sensor configured on the AIP SSM is used. You can assign the same sensor to multiple contexts.

Note You do not need to be in multiple context mode to use virtual sensors; you can be in single mode and use different sensors for different traffic flows.

Examples

The following example assigns sensor1 and sensor2 to context A, and sensor1 and sensor3 to context B. Both contexts map the sensor names to "ips1" and "ips2." In context A, sensor1 is set as the default sensor, but in context B, no default is set so the default that is configured on the AIP SSM is used.

```
hostname(config-ctx)# context A
hostname(config-ctx)# allocate-interface gigabitethernet0/0.100 int1
hostname(config-ctx)# allocate-interface gigabitethernet0/0.102 int2
hostname(config-ctx)# allocate-interface gigabitethernet0/0.110-gigabitethernet0/0.115
int3-int8
hostname(config-ctx)# allocate-ips sensor1 ips1 default
hostname(config-ctx)# allocate-ips sensor2 ips2
hostname(config-ctx)# config-url ftp://user1:passw0rd@10.1.1.1/configlets/test.cfg
hostname(config-ctx)# member gold

hostname(config-ctx)# context sample
hostname(config-ctx)# allocate-interface gigabitethernet0/1.200 int1
hostname(config-ctx)# allocate-interface gigabitethernet0/1.212 int2
hostname(config-ctx)# allocate-interface gigabitethernet0/1.230-gigabitethernet0/1.235
int3-int8
hostname(config-ctx)# allocate-ips sensor1 ips1
hostname(config-ctx)# allocate-ips sensor3 ips2
hostname(config-ctx)# config-url ftp://user1:passw0rd@10.1.1.1/configlets/sample.cfg
hostname(config-ctx)# member silver
```

Related Commands

Command	Description
context	Creates a security context in the system configuration and enters context configuration mode.
ips	Diverts traffic to the AIP SSM for inspection.
show context	Shows a list of contexts (system execution space) or information about the current context.
show ips	Shows the virtual sensors configured on the AIP SSM.

allow-ssc-mgmt

To set an interface on the ASA 5505 to be the SSC management interface, use the **allow-ssc-mgmt** command in interface configuration mode. To unassign an interface, use the **no** form of this command.

allow-ssc-mgmt

no allow-ssc-mgmt

Syntax Description

This command has no arguments or keywords.

Command Default

This command is enabled in the factory default configuration for VLAN 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	—

Command History

Release	Modification
8.2(1)	We introduced this command.

Usage Guidelines

An SSC does not have any external interfaces. You can configure a VLAN as a management VLAN to allow access to an internal management IP address over the backplane. By default, VLAN 1 is enabled for the SSC management address. You can only assign one VLAN as the SSC management VLAN.

Do not configure NAT for the management address if you intend to access it using ASDM. For initial setup with ASDM, you need to access the real address. After initial setup (where you set the password in the SSC), you can configure NAT and supply ASDM with the translated address when you want to access the SSC.

Examples

The following example disables management access on VLAN 1, and enables it for VLAN 2:

```
hostname(config)# interface vlan 1
hostname(config-if)# no allow-ssc-mgmt
hostname(config-if)# interface vlan 2
hostname(config-if)# allow-ssc-mgmt
```

Related Commands

Command	Description
interface	Configures an interface.
ip address	Sets the management IP address for a bridge group.
nameif	Sets the interface name.
security-level	Sets the interface security level.
hw-module module ip	Configures the management IP address for the SSC.
hw-module module allow-ip	Sets the hosts that are allowed to access the management IP address.

always-on-vpn

To configure the behavior of the AnyConnect Always-On-VPN functionality, use the **always-on-vpn** command in group policy configuration mode.

always-on-vpn [**profile-setting** | **disable**]

Syntax Description

disable	Switches off the Always-On-VPN functionality.
profile-setting	Uses the **always-on-vpn** setting configured in the AnyConnect profile.

Command Default

Always-On-VPN functionality is switched off by default.

Command History

Release	Modification
8.3(1)	We introduced this command.

Usage Guidelines

To enable Always-On-VPN functionality for AnyConnect users, configure an AnyConnect profile in the profile editor. Then configure the group-policy attributes for the appropriate policy.

Examples

The following example disables management access on VLAN 1, and enables it for VLAN 2:

```
hostname(config)# group-policy <group policy> attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# always-on-vpn profile-setting
```

Related Commands

Command	Description
webvpn	Configures group policy for WebVPN.

anyconnect ask

To enable the ASA to prompt remote SSL VPN client users to download the client, use the **anyconnect ask** command in group policy webvpn or username webvpn configuration modes. To remove the command from the configuration, use the **no** form of the command.

anyconnect ask {**none** | **enable** [**default** {**webvpn** | **anyconnect**} **timeout** *value*]}

no anyconnect ask none [**default** {**webvpn** | **anyconnect**}]

Syntax Description

default anyconnect timeout *value*	Prompts the remote user to download the client or goes to the portal page for clientless connections, and waits the duration of *value* before taking the default action—downloading the client.
default webvpn timeout *value*	Prompts the remote user to download the client or goes to the portal page for clientless connections, and waits the duration of *value* before taking the default action—displaying the WebVPN portal page.
enable	Prompts the remote user to download the client or goes to the portal page for clientless connections and waits indefinitely for user response.
none	Immediately performs the default action.

Defaults

The default for this command is **anyconnect ask none default webvpn**. The ASA immediately displays the portal page for clientless connections.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group policy webvpn configuration	•	—	•	—	—
Username webvpn configuration	•	—	•	—	—

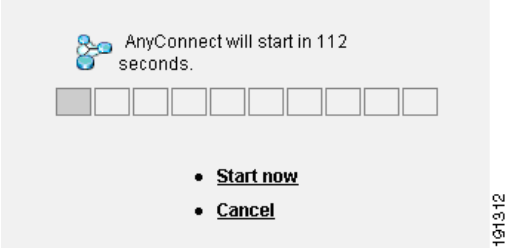
Command History

Release	Modification
8.0(2)	This command was introduced.
8.4(1)	The **anyconnect ask** command replaced the **svc ask** command.

Usage Guidelines

Figure 2-1 shows the prompt displayed to remote users when either the **default anyconnect timeout** *value* command or **default webvpn timeout** *value* command is configured:

Figure 2-1 Prompt Displayed to Remote Users for SSL VPN Client Download



Examples

The following example configures the ASA to prompt the remote user to download the client or go to the portal page and to wait 10 seconds for user response before downloading the client:

```
hostname(config-group-webvpn)# anyconnect ask enable default svc timeout 10
```

Related Commands

Command	Description
show webvpn anyconnect	Displays information about installed SSL VPN clients.
anyconnect	Enables or requires the SSL VPN client for a specific group or user.
anyconnect image	Specifies a client package file that the ASA expands in cache memory for downloading to remote PCs.

anyconnect-custom

To set or update the value of a custom attribute, use the **anyconnect-custom** command in Anyconnect-custom-attr configuration mode. To remove the value of a custom attribute, use the **no** form of this command.

anyconnect-custom *attr-name* **value** *attr-value*

anyconnect-custom *attr-name* **none**

no anyconnect-custom *attr-name*

Syntax Description

attr-name	The name of the attribute in the current group policy, as defined by the **anyconnnect custom-attr** command.
none	Immediately performs the default action.
value *attr-value*	A string containing the attribute value. The value is associated with the attribute name and passed to the client during connection setup. The maximum length is 450 characters.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Anyconnect-custom-attr configuration	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

This command sets the value of a custom attribute in a group policy. The *AnyConnect Administrator's Guide* lists which values are valid for the custom attributes that apply to that release. Custom attributes are created with the **anyconnect custom-attr** command.

Multiple instances of this command are supported to build a multiline value for an attribute. All data associated with a given attribute name is delivered to the client in the order that it is entered in the CLI. Individual lines of a multiline value can not be removed.

The **no** form of this command does not allow the **value** or **none** keywords.

If the data associated with an attribute name is entered in multiple CLI lines, it will be sent to the endpoint as a single concatenated string delimited by the newline character (\n).

Examples

The following example configures a custom attribute for an AnyConnect Deferred Update:

```
hostname(config-group-policy)# anyconnect-custom DeferredUpdateAllowed true
```

Related Commands

Command	Description
show run webvpn	Displays configuration information about WebVPN, including **anyconnect** commands.
show run group-policy	Displays configuration information about current group policies.
anyconnect custom-attr	Creates custom attributes.

anyconnect custom-attr

To create custom attributes, use the **anyconnect-custom-attr** command in Anyconnect-custom-attr configuration mode. To remove custom attributes, use the **no** form of this command.

[no] anyconnect-custom-attr *attr-name* **[description** *description***]**

Syntax Description

attr-name	The name of the attribute. This name is referenced in the group policy syntax and in the aggregate auth protocol messages. The maximum length is 32 characters.
description *description*	A free form description of attribute usage. This text appears in the command help when the custom attribute is referenced from the group-policy attribute configuration mode. The maximum length is 96 characters.
none	Immediately performs the default action.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Anyconnect-custom-attr configuration	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

This command creates custom attributes to support special AnyConnect features. After creating custom attributes for a particular feature, you add them to group policies, so that feature can be applied to VPN clients. This command guarantees that all of the defined attribute names are unique.

Some versions of AnyConnect use custom attributes to configure features. The release notes and *AnyConnect Administrator's Guide* for each version list any features that require custom attributes.

If you try to remove the definition of attribute that is being used in a group policy, an error message will be displayed, and the action will fail. If a user attempts to add an attribute that already exists as a custom attribute, any changes to the description will be incorporated, but the command will otherwise be ignored.

Examples

The following example configures a custom attribute for AnyConnect Deferred Update:

```
hostname(config-webvpn)# anyconnect DeferredUpdateAllowed description "Indicates if the deferred update feature is enabled or not"
```

Related Commands

Command	Description
show run webvpn	Displays configuration information about WebVPN, including **anyconnect** commands.
show run group-policy	Displays configuration information about current group policies.
anyconnect custom	Sets values of custom attributes.

anyconnect df-bit-ignore

To ignore the DF bit in packets that need fragmentation, use the **anyconnect-df-bit-ignore** command in group policy webvpn configuration mode. To acknowledge the DF bits that need fragmentation, use the **no** form of the command.

anyconnect df-bit-ignore {enable | none}

no anyconnect df-bit-ignore {enable | none}

Syntax Description

enable	Enables DF-bit ignore for AnyConnect client.
none	Disables DF-bit for AnyConnect client.

Defaults

By default, this option is not enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group policy webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.2(2)	The **svc df-bit-ignore** command was introduced.
8.4(3)	The **anyconnect df-bit-ignore** command replaced the **svc df-bit-ignore** command.

Examples

```
vmb-5520(config-group-webvpn)# anyconnect routing-filtering-ignore ?

config-group-webvpn mode commands/options:
  enable  Enable Routing/Filtering for AnyConnect Client
  none    Disable Routing/Filtering for AnyConnect Client
```

anyconnect dpd-interval

To enable Dead Peer Detection (DPD) on the ASA and to set the frequency that either the remote client or the ASA performs DPD over SSL VPN connections, use the **anyconnect dpd-interval** command in group policy webvpn or username webvpn configuration mode. To remove the command from the configuration and cause the value to be inherited, use the **no** form of the command.

anyconnect dpd-interval {[**gateway** {*seconds* | **none**}] | [**client** {*seconds* | **none**}]}

no anyconnect dpd-interval {[**gateway** {*seconds* | **none**}] | [**client** {*seconds* | **none**}]}

Syntax Description

client none	Disables the DPD that the client performs.
client *seconds*	Specifies the frequency, from 30 to 3600 seconds, for which the client performs DPD.
gateway none	Disables DPD that the ASA performs.
gateway *seconds*	Specifies the frequency, from 30 to 3600 seconds, for which the ASA performs DPD.

Defaults

The default is DPD is enabled and set to 30 seconds for both the ASA (gateway) and the client.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group policy webvpn configuration	•	—	•	—	—
Username webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.
8.0(3)	The default setting changed from disabled to 30 seconds for both the ASA (gateway) and the client.
8.4(1)	The **anyconnect dpd-interval** command replaced the **svc dpd-interval** command.

Examples

The following example shows how to configure the DPD frequency performed by the ASA (gateway) to 3000 seconds, and the DPD frequency performed by the client to 1000 seconds, for the existing group policy *sales*:

```
hostname(config)# group-policy sales attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# anyconnect dpd-interval gateway 3000
hostname(config-group-webvpn)# anyconnect dpd-interval client 1000
```

anyconnect dtls compression

To enable compression on low bandwidth links for a specific group or user, use the **anyconnect dtls compression** command in group policy webvpn or username webvpn configuration mode. To delete the configuration from the group, use the **no** form of the command.

anyconnect dtls compression {lzs | none}

no anyconnect dtls compression {lzs | none}

Syntax Description

lzs	Enables a stateless compression algorithm.
none	Disables compression.

Defaults

The default is to not enable AnyConnect compression.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group policy webvpn configuration	•	—	•	—	—
Username webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.4(2)	The **anyconnect dtls compression** command was introduced.

Examples

The following examples shows the sequence to disable compression:

```
asa# config terminal
asa(config)# group-policy DfltGrpPolicy attributes
asa(config-group-policy)# webvpn
asa(config-group-webvpn)# anyconnect ssl compression none
asa(config-group-webvpn)# anyconnect dtls compression none
```

anyconnect enable

To enable the ASA to download an AnyConnect client to remote computers or to connect to the ASA using the AnyConnect client with SSL or IKEv2, use the **anyconnect enable** command in webvpn configuration mode. To remove the command from the configuration, use the **no** form of the command.

anyconnect enable

no anyconnect enable

Defaults

The default for this command is disabled. The ASA does not download the client.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced as **svc enable**.
8.4(1)	The **anyconnect enable** command replaced the **svc enable** command.

Usage Guidelines

Entering the **no anyconnect enable** command does not terminate active sessions.

The **anyconnect enable** command must be issued after configuring the AnyConnect images with the **anyconnect image xyz** command. To use an AnyConnect client or AnyConnect weblaunch, **anyconnect enable** is required. If the **anyconnect enable** command is not issued with SSL or IKEv2, AnyConnect does not function as expected and times out with an IPsec VPN connection termination error. As a result, the **show webvpn svc** command does not consider the SSL VPN client to be enabled and does not list the installed AnyConnect packages.

Examples

In the following example shows how to enable the ASA to download the client:

```
hostname(config)# webvpn
hostname(config-webvpn)# anyconnect enable
```

Related Commands

Command	Description
anyconnect image	Specifies an AnyConnect SSL VPN client package file that the ASA expands in cache memory for downloading to remote PCs.
anyconnect modules	Specifies the names of modules that the AnyConnect SSL VPN Client requires for optional features.

anyconnect profiles	Specifies the name of the file used to store profiles that the ASA downloads to the Cisco AnyConnect SSL VPN client.
show webvpn anyconnect	Displays information about SSL VPN clients installed on the ASA and loaded in cache memory for downloading to remote PCs.
anyconnect localization	Specifies the package file used to store localization files that are downloaded to the Cisco AnyConnect VPN Client.

anyconnect firewall-rule

To establish a public or provide ACL firewall, use the **anyconnect firewall-rule** command in either group policy webvpn or username webvpn configuration mode.

anyconnect firewall-rule client interface {public | private} *ACL*

Syntax Description

ACL	Specifies the access control list
client interface	Specify client interface
private	Configure private interface rule
public	Configure public interface rule

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group policy webvpn configuration	•	—	•	—	—
Username webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.3(1)	This command was introduced.
8.4(1)	The **anyconnect firewall-rule** command replaced the **svc firewall-rule** command.
9.0(1)	The ACL in the command can now be a Unified Access Control rule that can specify both IPv4 and IPv6 addresses.

Usage Guidelines

To function as expected, this command requires a release of the AsyncOS for Web version 7.0 that provides AnyConnect Secure Mobility licensing support for the AnyConnect secure mobility client. It also requires an AnyConnect release that supports AnyConnect Secure Mobility, ASA 8.3, and ASDM 6.3.

The following notes clarify how the AnyConnect client uses the firewall:

- The source IP is not used for firewall rules. The client ignores the source IP information in the firewall rules sent from the ASA. The client determines the source IP depending on whether the rules are public or private. Public rules are applied to all interfaces on the client. Private rules are applied to the virtual adapter.

- The ASA supports many protocols for ACL rules. However, the AnyConnect firewall feature supports only TCP, UDP, ICMP, and IP. If the client receives a rule with a different protocol, it treats it as an invalid firewall rule, and then disables split tunneling and uses full tunneling for security reasons.

Be aware of the following differences in behavior for each operating system:

- For Windows computers, deny rules take precedence over allow rules in Windows Firewall. If the ASA pushes down an allow rule to the AnyConnect client, but the user has created a custom deny rule, the AnyConnect rule is not enforced.
- On Windows Vista, when a firewall rule is created, Vista takes the port number range as a comma-separated string (for example, from 1-300 or 5000-5300). The maximum number of ports allowed is 300. If you specify a number greater than 300 ports, the firewall rule is applied only to the first 300 ports.
- Windows users whose firewall service must be started by the AnyConnect client (not started automatically by the system) may experience a noticeable increase in the time it takes to establish a VPN connection.
- On Mac computers, the AnyConnect client applies rules sequentially in the same order that the ASA applies them. Global rules should always be last.
- For third-party firewalls, traffic is passed only if both the AnyConnect client firewall and the third-party firewall allow that traffic type. If the third-party firewall blocks a specify traffic type that the AnyConnect client allows, the client blocks the traffic.

For more information about the AnyConnect client firewall including ACL rule examples for local printing and tethered device support, see the *AnyConnect Administrator's Guide*.

Examples

The following example enables the ACL *AnyConnect_Client_Local_Print* as a public firewall:

```
hostname(config)# group-policy example_group attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# anyconnect firewall-rule client-interface public value
AnyConnect_Client_Local_Print
```

Related Commands

Command	Description
show webvpn anyconnect	Displays information about installed SSL VPN clients.
anyconnect	Enables or requires the SSL VPN client for a specific group or user.
anyconnect image	Specifies a client package file that the ASA expands in cache memory for downloading to remote PCs.

anyconnect image

To install or upgrade the AnyConnect distribution package and add it to the running configuration, use the **anyconnect image** command in webvpn configuration mode. To remove the AnyConnect distribution package from the running configuration, use the **no** form of the command.

anyconnect image *path order* [**regex** *expression*]

no anyconnect image *path order* [**regex** *expression*]

Syntax Description

order	With multiple client package files, specifies the order of the package files, from 1 to 65535. The ASA downloads portions of each client in the order you specify to the remote PC until it achieves a match with the operating system.
path	Specifies the path and filename of the AnyConnect package, up to 255 characters.
regex *expression*	Specifies a string that the ASA uses to match against the user-agent string passed by the browser.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced as **svc image**.
8.0(1)	The **regex** keyword was added.
8.4(1)	The **anyconnect image** command replaced the **svc image** command.

Usage Guidelines

Numbering the package files establishes the order in which the ASA downloads portions of them to the remote PC until it achieves a match with the operating system. It downloads the package file with the lowest number first. Therefore, you should assign the lowest number to the package file that matches the most commonly-encountered operating system used on remote PCs.

The default order is 1. If you do not specify the *order* argument, each time that you enter the **svc image** command, you overwrite the image that was previously considered number 1.

You can enter the **anyconnect image** command for each client package file in any order. For example, you can specify the package file to be downloaded second (*order* 2) before entering the **anyconnect image** command specifying the package file to be downloaded first (*order* 1).

For mobile users, you can decrease the connection time of the mobile device by using the **regex** keyword. When the browser connects to the ASA, it includes the user-agent string in the HTTP header. When the ASA receives the string, if the string matches an expression configured for an image, it immediately downloads that image without testing the other client images.

Note When using the standalone client, the **regex** command is ignored. It is used only for the web browser as a performance enhancement, and the regex string is not matched against any user or agent provided by the standalone client.

The ASA expands both AnyConnect client and Cisco Secure Desktop (CSD) package files in cache memory. For the ASA to successfully expand the package files, there must be enough cache memory to store the images and files of the package file.

If the ASA detects there is not enough cache memory to expand a package, it displays an error message to the console. The following example shows an error message reported after an attempt to install a package file with the **svc image** command:

```
hostname(config-webvpn)# anyconnect image disk0:/anyconnect-win-3.0.0520-k9.pkg
ERROR: File write error (check disk space)
ERROR: Unable to load SVC image - extraction failed
```

If this occurs when you attempt to install a package file, examine the amount of cache memory remaining and the size of any previously installed packages with the **dir cache:/** command in global configuration mode.

Note If your ASA has only the default internal flash memory size or the default DRAM size (for cache memory) you could have problems storing and loading multiple AnyConnect client packages on the ASA. Even if there is enough space in flash memory to hold the package files, the ASA could run out of cache memory when it unzips and loads the client images. For more information about the ASA memory requirements when deploying AnyConnect, and possibly upgrading the ASA memory, see the latest release notes for the Cisco ASA 5500 series.

Examples

The following example loads AnyConnect client package files for Windows, MAC, and Linux in that order:

```
hostname(config)# webvpn
hostname(config-webvpn)# anyconnect image disk0:/anyconnect-win-3.0.0527-k9.pkg 1
hostname(config-webvpn)# anyconnect image disk0:/anyconnect-macosx-i386-3.0.0414-k9.pkg 2
hostname(config-webvpn)# anyconnect image disk0:/anyconnect-linux-3.0.0414-k9.pkg 3
hostname(config-webvpn)
```

The following is sample output from the **show webvpn anyconnect** command, which displays the AnyConnect client packages loaded and their order:

```
hostname(config-webvpn)# show webvpn anyconnect
1. disk0:/anyconnect-win-3.0.0527-k9.pkg 1 dyn-regex=/Windows NT/
  CISCO STC win2k+
  3,0,0527
  Hostscan Version 3.0.0527
  Tue 10/19/2010 16:16:56.25

2. disk0:/anyconnect-macosx-i386-3.0.0414-k9.pkg 2 dyn-regex=/Intel Mac OS X/
  CISCO STC Darwin_i386
  3.0.0414
  Wed Oct 20 20:39:53 MDT 2010
```

```

3 AnyConnect Client(s) installed
hostname(config-webvpn)#
```

Related Commands

Command	Description
anyconnect modules	Specifies the names of modules that the AnyConnect SSL VPN Client requires for optional features.
anyconnect profiles	Specifies the name of the file used to store profiles that the ASA downloads to the Cisco AnyConnect SSL VPN client.
show webvpn anyconnect	Displays information about SSL VPN clients installed on the ASA and loaded in cache memory for downloading to remote PCs.
anyconnect localization	Specifies the package file used to store localization files that are downloaded to the Cisco AnyConnect VPN Client.

anyconnect keep-installer

Note This command does not apply to versions of AnyConnect after 2.5, but is still available for backward compatibility. Configuring the **anyconnect keep-installer** command does not affect AnyConnect 3.0 or later.

To enable the permanent installation of an SSL VPN client on a remote PC, use the **anyconnect keep-installer** command in group-policy webvpn or username webvpn configuration mode. To remove the command from the configuration and cause the value to be inherited, use the **no** form of this command.

anyconnect keep-installer {**installed** | **none**}

no anyconnect keep-installer {**installed** | **none**}

Syntax Description

installed	Disables the automatic uninstalling feature of the client. The client remains installed on the remote PC for future connections.
none	Specifies that the client uninstalls from the remote computer after the active connection terminates.

Defaults

The default is permanent installation of the client is enabled. The client remains on the remote computer at the end of the session.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group policy webvpn configuration	•	—	•	—	—
Username webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.
8.4(1)	The **anyconnect keep-installer** command replaced the **svc keep-installer** command.

Examples

In the following example, the user enters group policy webvpn configuration mode and configures the group policy to remove the client at the end of the session:

```
hostname(config-group-policy)#webvpn
hostname(config-group-webvpn)# anyconnect keep-installer none
hostname(config-group-webvpn)#
```

Related Commands

Command	Description
show webvpn anyconnect	Displays information about AnyConnect clients installed on the ASA and loaded in cache memory for downloading to remote PCs.
anyconnect	Enables or requires the SSL VPN client for a specific group or user.
anyconnect enable	Enables the ASA to download AnyConnect client files to remote PCs.
anyconnect image	Specifies an AnyConnect client package file that the ASA expands in cache memory for downloading to remote PCs.

anyconnect modules

To specify the names of modules that the AnyConnect SSL VPN Client requires for optional features, use the **anyconnect modules** command in group policy webvpn or username webvpn configuration mode. To remove the command from the configuration, use the **no** form of the command.

anyconnect modules {**none** | **value** *string*}

no anyconnect modules {**none** | **value** *string*}

Syntax Description

string	The name of the optional module, up to 256 characters. Separate multiple strings with commas.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group policy webvpn configuration	•	—	•	—	—
Username webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced as **svc modules**.
8.4(1)	The **anyconnect modules** command replaced the **svc modules** command.

Usage Guidelines

To minimize download time, the client only requests downloads (from the ASA) of modules that it needs for each feature that it supports. The **anyconnect modules** command enables the ASA to download these modules.

The following table shows the string values that represent AnyConnect Modules.

String representing AnyConnect Module	AnyConnect Module Name
dart	AnyConnect DART (Diagnostics and Reporting Tool)
nam	AnyConnect Network Access Manager
vpngina	AnyConnect SBL (Start Before Logon)
websecurity	AnyConnect Web Security Module
telemetry	AnyConnect Telemetry Module

posture	AnyConnect Posture Module
none	If you choose **none**, the ASA downloads the essential files with no optional modules. Existing modules are removed from the group policy.

Examples

In the following example, the user enters group-policy attributes mode for the group policy *PostureModuleGroup*, enters webvpn configuration mode for the group policy, and specifies the string *posture* and *telemetry* so that the AnyConnect Posture Module and AnyConnect Telemetry Module will be downloaded to the endpoint when it connects to the ASA.

```
hostname> en
Password:
hostname# config t
hostname(config)# group-policy PostureModuleGroup attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# anyconnect modules value posture,telemetry
hostname(config-group-webvpn)# write mem
Building configuration...
Cryptochecksum: 40975338 b918425d 083b391f 9e5a5c69

22055 bytes copied in 3.440 secs (7351 bytes/sec)
[OK]
hostname(config-group-webvpn)#
```

To remove a module from a group policy, resend the command specifying only the module values you want to keep. For example, this command removes the telemetry module:

```
hostname(config-group-webvpn)# anyconnect modules value posture
```

Related Commands

Command	Description
show webvpn anyconnect	Displays information about AnyConnect packages that are loaded in cache memory on the ASA and available for download.
anyconnect enable	Enables an AnyConnect client for a specific group or user.
anyconnect image	Specifies an AnyConnect client package file that the ASA expands in cache memory for downloading to remote PCs.

anyconnect mtu

To adjust the MTU size for SSL VPN connections established by the Cisco AnyConnect VPN Client, use the **anyconnect mtu** command in group policy webvpn or username webvpn configuration mode. To remove the command from the configuration, use the **no** form of the command.

anyconnect mtu *size*

no anyconnect mtu *size*

Syntax Description

size	The MTU size in bytes, from 256 to 1406 bytes.

Defaults

The default size is 1406 bytes.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group policy webvpn configuration	•	—	•	—	—
Username webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.
8.4(1)	The **anyconnect mtu** command replaced the **svc mtu** command.

Usage Guidelines

This command affects only the AnyConnect client. The Cisco SSL VPN Client is not capable of adjusting to different MTU sizes.

The default for this command in the default group policy is **no svc mtu**. The MTU size is adjusted automatically based on the MTU of the interface that the connection uses, minus the IP/UDP/DTLS overhead.

This command affects AnyConnect client connections established in only SSL and those established in SSL with DTLS.

The minimum MTU allowed on an IPv6 enabled interface is 1280 bytes; however, if IPsec is enabled on the interface, the MTU value should not be set below 1380 because of the overhead of IPsec encryption. Setting the interface below 1380 bytes may result in dropped packets.

Examples

The following example configures the MTU size to 500 bytes for the group policy *telecommuters*:

```
hostname(config)# group-policy telecommuters attributes
hostname(config-group-policy)# webvpn
```

```
hostname(config-group-webvpn)# anyconnect mtu 500
```

Related Commands

Command	Description
anyconnect keep-installer	Disables the automatic uninstalling feature of the client. After the initial download, the client remains on the remote PC after the connection terminates.
anyconnect ssl dtls	Enables DTLS for CVCs establishing SSL VPN connections.
show run webvpn	Displays configuration information about WebVPN, including **anyconnect** commands.

anyconnect profiles (group-policy or username attributes)

To specify a CVC profiles package downloaded to Cisco AnyConnect VPN Client (CVC) users, use the **anyconnect profiles** command in group policy webvpn or username attributes webvpn configuration mode. To remove the command from the configuration and cause the value it to be inherited, use the **no** form of the command.

anyconnect profiles {**value** *profile* | **none**}

no anyconnect profiles {**value** *profile* | **none** } **[type** *type*]

Syntax Description

value *profile*	The name of the profile.
none	The ASA does not download profiles.
type *type*	The user who corresponds to the standard AnyConnect profile or any alphanumeric value.

Defaults

The default is none. The ASA does not download profiles.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group policy webvpn configuration	•	—	•	—	—
Username webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.
8.3(1)	The optional type **value** was introduced.
8.4(1)	The **anyconnect profiles** command replaced the **svc profiles** command.

Usage Guidelines

This command, entered in group policy webvpn or username attributes webvpn configuration mode, enables the ASA to download profiles to CVC users on a group policy or username basis. To download a CVC profile to all CVC users, use this command from webvpn configuration mode.

A CVC profile is a group of configuration parameters that the CVC uses to configure the connection entries that appear in the CVC user interface, including the names and addresses of host computers. You can create and save profiles using the CVC user interface. You can also edit this file with a text editor and set advanced parameters that are not available through the user interface.

The CVC installation contains one profile template (cvcprofile.xml) that you can edit and use as a basis for creating other profile files. For more information about editing CVC profiles, see the *Cisco AnyConnect VPN Client Administrator Guide*.

Examples

In the following example, the user enters the **anyconnect profiles value** command, which displays the available profiles:

```
hostname(config-group-webvpn)# anyconnect profiles value ?

config-group-webvpn mode commands/options:
Available configured profile packages:
  engineering
  sales
```

Then the user configures the group policy to use the CVC profile sales:

```
hostname(config-group-webvpn)# anyconnect profiles sales
```

Related Commands

Command	Description
show webvpn anyconnect	Displays information about installed AnyConnect clients.
anyconnect	Enables or requires an SSL VPN client for a specific group or user.
anyconnect image	Specifies an AnyConnect client package file that the ASA expands in cache memory for downloading to remote PCs.

anyconnect profiles (webvpn)

To specify a file as a profiles package that the ASA loads in cache memory and makes available to group policies and username attributes of Cisco AnyConnect VPN Client (CVC) users, use the **anyconnect profiles** command in webvpn configuration mode. To remove the command from the configuration and cause the ASA to unload the package file from cache memory, use the **no** form of the command.

anyconnect profiles {*profile path*}

no anyconnect profiles {*profile path*}

Syntax Description

path	The path and filename of the profile file in flash memory of the ASA.
profile	The name of the profile to create in cache memory.

Defaults

The default is none. The ASA does not load a profiles package in cache memory.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.
8.4(1)	The **anyconnect profiles** command replaced the **svc profiles** command.

Usage Guidelines

A CVC profile is a group of configuration parameters that the CVC uses to configure the connection entries that appear in the CVC user interface, including the names and addresses of host computers. You can create and save profiles using the CVC user interface.

You can also edit this file with a text editor and set advanced parameters that are not available through the user interface. The CVC installation contains one profile template (cvcprofile.xml) that you can edit and use as a basis for creating other profile files. For more information about editing CVC profiles, see the *Cisco AnyConnect VPN Client Administrator Guide.*

After you create a new CVC profile and upload it to flash memory, identify the XML file to the ASA as a profile using the **anyconnect profiles** command in webvpn configuration mode. After you enter this command, files are loaded into cache memory on the ASA. Then you can specify the profile for a group or user with the **anyconnect profiles** command from group policy webvpn configuation or username attributes configuration mode.

Examples

In the following example, the user previously created two new profile files (sales_hosts.xml and engineering_hosts.xml) from the cvcprofile.xml file provided in the CVC installation and uploaded them to flash memory on the ASA.

Then the user identifies these files to the ASA as CVC profiles, specifying the names *sales* and *engineering*:

```
hostname(config-webvpn)# anyconnect profiles sales disk0:sales_hosts.xml
hostname(config-webvpn)# anyconnect profiles engineering disk0:engineering_hosts.xml
```

Entering the **dir cache:stc/profiles** command shows the profiles that have been loaded into cache memory:

```
hostname(config-webvpn)# dir cache:stc/profiles

Directory of cache:stc/profiles/

0      ----  774         11:54:41 Nov 22 2006  engineering.pkg
0      ----  774         11:54:29 Nov 22 2006  sales.pkg

2428928 bytes total (18219008 bytes free)
hostname(config-webvpn)#
```

These profiles are available to the **svc profiles** command in group policy webvpn configuration or username attributes configurate modes:

```
hostname(config)# group-policy sales attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# anyconnect profiles value ?

config-group-webvpn mode commands/options:
Available configured profile packages:
  engineering
  sales
```

Related Commands

Command	Description
show webvpn anyconnect	Displays information about installed AnyConnect clients.
anyconnect	Enables or requires the SSL VPN client for a specific group or user.
anyconnect image	Specifies an AnyConnect package file that the ASA expands in cache memory for downloading to remote PCs.

anyconnect routing-filtering-ignore

To notify the AnyConnect client that it should ignore routing and filtering rules, use the **anyconnect routing-filtering-ignore** command in group policy webvpn configuration mode. To turn off the notification of ignoring routing and filtering rules, use the **no** form of the command.

anyconnect routing-filtering-ignore {enable | none}

no anyconnect routing-filtering-ignore {enable | none}

Syntax Description

enable	Enables routing and filtering rules for AnyConnect client.
none	Disables routing and filtering rules for AnyConnect client.

Defaults

By default, this option is not enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group policy webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.2(3)	This command was introduced.
8.4(1)	The **anyconnect routing-filtering-ignore** command replaced the **svc routing-filtering-ignore** command.

Examples

```
vmb-5520(config-group-webvpn)# anyconnect routing-filtering-ignore ?

config-group-webvpn mode commands/options:
  enable  Enable Routing/Filtering for AnyConnect Client
  none    Disable Routing/Filtering for AnyConnect Client
```

anyconnect ssl compression

To enable compression of http data over an SSL VPN connection for a specific group or user, use the **anyconnect ssl compression** command in group policy webvpn or username webvpn configuration mode. To remove the command from the configuration and cause the value to be inherited, use the **no** form of the command.

anyconnect ssl compression {**deflate | lzs | none**}

no anyconnect ssl compression {**deflate | lzs | none**}

Syntax Description

deflate	Enables a deflate compression algorithm.
lzs	Enables a stateless compression algorithm.
none	Disables compression.

Defaults

By default, compression is set to none (disabled).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group policy webvpn configuration	•	—	•	—	—
Username webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.4(2)	The **anyconnect compression** command was introduced.

Usage Guidelines

For SSL VPN connections, the **compression** command configured from webvpn configuration mode overrides the **anyconnect ssl compression** command configured in group policy and username webvpn mode.

Examples

In the following example, SVC compression is disabled for the group policy sales:

```
hostname(config)# group-policy sales attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# anyconnect ssl compression none
```

Related Commands

Command	Description
anyconnect	Enables or requires the SSL VPN client for a specific group or user.
anyconnect keepalive	Specifies the frequency at which a client on a remote computer sends keepalive messages to the ASA over an SSL VPN connection.
anyconnect keep-installer	Disables the automatic uninstalling feature of the client. The client remains installed on the remote PC for future connections.
anyconnect rekey	Enables the client to perform a rekey on an SSL VPN connection.
compression	Enables compression for all SSL, WebVPN, and IPsec VPN connections.
show webvpn anyconnect	Displays information about installed SSL VPN clients.

anyconnect ssl df-bit-ignore

To enable the forced fragmentation of packets on an SSL VPN connection (allowing them to pass through the tunnel) for a specific group or user, use the **anyconnect ssl df-bit-ignore** command in the group policy webvpn or username webvpn configuration mode. To remove the command from the configuration and cause the value to be inherited, use the **no** form of this command.

anyconnect ssl df-bit-ignore {enable | disable}

no anyconnect ssl df-bit-ignore

Syntax Description

enable	Enable DF-bit ignore for AnyConnect with SSL.
disable	Disable DF-bit for AnyConnect with SSL.

Defaults

DF bit ignore is set to *disabled.*

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group policy webvpn configuration	•	—	•	—	—
Username webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.4(1)	The **anyconnect ssl df-bit-ignore** form of the command replaced **svc df-bit-ignore**.

Usage Guidelines

This feature allows the force fragmentation of packets that have the DF bit set, allowing them to pass through the tunnel. An example use case is for servers in your network that do not respond correctly to TCP MSS negotiations.

Examples

In the following example, DF bit ignore is enabled for the group policy sales:

```
hostname(config)# group-policy sales attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# anyconnect ssl df-bit-ignore enable
```

Related Commands

Command	Description
anyconnect	Enables or requires the SSL VPN client for a specific group or user.

anyconnect keepalive	Specifies the frequency at which a client on a remote computer sends keepalive messages to the ASA over an SSL VPN connection.
anyconnect keep-installer	Disables the automatic uninstalling feature of the client. The client remains installed on the remote PC for future connections.
anyconnect rekey	Enables the client to perform a rekey on an SSL VPN connection.

anyconnect ssl dtls enable

To enable Datagram Transport Layer Security (DTLS) connections on an interface for specific groups or users establishing SSL VPN connections with the Cisco AnyConnect VPN Client, use the **anyconnect ssl dtls enable** command in group policy webvpn or username attributes webvpn configuration mode. To remove the command from the configuration and cause the value to be inherited, use the **no** form of the command.

anyconnect ssl dtls enable *interface*

no anyconnect ssl dtls enable *interface*

Syntax Description

interface	The name of the interface.

Defaults

The default is enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group policy webvpn configuration	•	—	•	—	—
Username webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.
8.4(1)	The **anyconnect ssl dtls** command replaced the **svc dtls** command.

Usage Guidelines

Enabling DTLS allows the AnyConnect client establishing an SSL VPN connection to use two simultaneous tunnels—an SSL tunnel and a DTLS tunnel. Using DTLS avoids latency and bandwidth problems associated with some SSL connections and improves the performance of real-time applications that are sensitive to packet delays.

If you do not enable DTLS, AnyConnect client users establishing SSL VPN connections connect with an SSL tunnel only.

This command enables DTLS for specific groups or users. To enable DTLS for all AnyConnect client users, use the **anyconnect ssl dtls enable** command in webvpn configuration mode.

Examples

The following example enters group policy webvpn configuration mode for the group policy *sales* and enables DTLS:

```
hostname(config)# group-policy sales attributes
```

```
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# anyconnect ssl dtls enable
```

Related Commands

Command	Description
dtls port	Specifies a UDP port for DTLS.
anyconnect dtls	Enables DTLS for groups or users establishing SSL VPN connections.
vpn-tunnel-protocol	Specifies VPN protocols that the ASA allows for remote access, including SSL.

anyconnect ssl keepalive

To configure the frequency of keepalive messages which a remote client sends to the ASA over SSL VPN connections, use the **anyconnect ssl keepalive** command in group policy webvpn or username webvpn configuration modes. Use the **no** form of the command to remove the command from the configuration and cause the value to be inherited.

anyconnect ssl keepalive {**none** | *seconds*}

no anyconnect ssl keepalive {**none** | *seconds*}

Syntax Description

none	Disables keepalive messages.
seconds	Enables keepalive messages and specifies the frequency of the messages, from 15 to 600 seconds.

Defaults

The default is 20 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group policy webvpn configuration	•	—	•	—	—
Username webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.
8.0(3)	The default setting changed from disabled to 20 seconds.
8.4(1)	The **anyconnect ssl keepalive** command replaced the **svc keepalive** command.

Usage Guidelines

Both the Cisco SSL VPN Client (SVC) and the Cisco AnyConnect VPN Client can send keepalive messages when they establish SSL VPN connections to the ASA.

You can adjust the frequency of keepalive messages (specified in *seconds*) to ensure that an SSL VPN connection through a proxy, firewall, or NAT device remains open, even if the device limits the time that the connection can be idle.

Adjusting the frequency also ensures that the client does not disconnect and reconnect when the remote user is not actively running a socket-based application, such as Microsoft Outlook or Microsoft Internet Explorer.

Note Keepalives are enabled by default. If you disable keepalives, in the event of a failover event, SSL VPN client sessions are not carried over to the standby device.

Examples

In the following example, the user configures the ASA to enable the client to send keepalive messages, with a frequency of 300 seconds (5 minutes), for the existing group policy named *sales*:

```
hostname(config)# group-policy sales attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# anyconnect ssl keepalive 300
```

Related Commands

Command	Description
anyconnect	Enables or requires an SSL VPN client for a specific group or user.
anyconnect dpd-interval	Enables Dead Peer Detection (DPD) on the ASA, and sets the frequency in which either the client or the ASA performs DPD.
anyconnect keep-installer	Disables the automatic uninstalling feature of the client. The client remains installed on the remote PC for future connections.
anyconnect ssl rekey	Enables the client to perform a rekey on a session.

anyconnect ssl rekey

To enable a remote client to perform a rekey on an SSL VPN connection, use the **anyconnect ssl rekey** command in group-policy webvpn or username webvpn configuration mode. To remove the command from the configuration and cause the value to be inherited, use the **no** form of the command.

anyconnect ssl rekey {**method** {**ssl** | **new-tunnel**} | **time** *minutes* | **none**}

no anyconnect ssl rekey {**method** {**ssl** | **new-tunnel**} | **time** *minutes* | **none**}

Syntax Description

method ssl	Specifies that the client establishes a new tunnel during rekey.
method new-tunnel	Specifies that the client establishes a new tunnel during rekey.
method none	Disables rekey.
time *minutes*	Specifies the number of minutes from the start of the session until the rekey takes place, from 4 to 10080 (1 week).

Defaults

The default is none (disabled).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group policy webvpn configuration	•	—	•	—	—
Username webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced as **svc rekey**.
8.0(2)	The behavior of the **svc rekey method ssl** command changed to that of the **svc rekey method new-tunnel** command to prevent the possibility of a “man in the middle” attack.
8.4(1)	The **anyconnect ssl rekey** command replaced the **svc rekey** command.

Usage Guidelines

The Cisco AnyConnect Secure Mobility Client can perform a rekey on an SSL VPN connection to the ASA. Configuring the rekey method as **ssl** or **new-tunnel** specifies that the client establishes a new tunnel during rekey instead of the SSL renegotiation taking place during the rekey.

Examples

In the following example, the user specifies that remote clients belonging to the group policy *sales* renegotiate with SSL during rekey and rekey occurs 30 minutes after the session begins:

```
hostname(config)# group-policy sales attributes
```

```
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# anycoanynnect ssl rekey method ssl
hostname(config-group-webvpn)# anyconnect ssl rekey time 30
```

Related Commands

Command	Description
anyconnect enable	Enables or requires the AnyConnect Secure Mobility Client for a specific group or user.
anyconnect dpd-interval	Enables Dead Peer Detection (DPD) on the ASA, and sets the frequency that either the AnyConnect Secure Mobility Client or the ASA performs DPD.
anyconnect keepalive	Specifies the frequency at which an AnyConnect Secure Mobility Client on a remote computer sends keepalive messages to the ASA.
anyconnect keep-installer	Enables the permanent installation of an AnyConnect Secure Mobility Client onto a remote computer.

anyconnect-essentials

To enable AnyConnect Essentials on the ASA, use the **anyconnect-essentials** command in group policy webvpn configuration mode. To disable the use of AnyConnect Essentials and enable the premium AnyConnect client instead, use the **no** form of the command.

anyconnect-essentials

no anyconnect-essentials

Defaults

AnyConnect Essentials is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

Use this command to toggle between using the full AnyConnect SSL VPN client and the AnyConnect Essentials SSL VPN client, assuming that the full AnyConnect client license is installed. AnyConnect Essentials is a separately licensed SSL VPN client, entirely configured on the ASA, that provides the premium AnyConnect capability, with the following exceptions:

- No CSD (including HostScan/Vault/Cache Cleaner)
- No clientless SSL VPN

The AnyConnect Essentials client provides remote end users running Microsoft Windows Vista, Windows Mobile, Windows XP or Windows 2000, Linux, or Macintosh OS X, with the benefits of a Cisco SSL VPN client.

You enable or disable the AnyConnect Essentials license by using the **anyconnect-essentials** command, which is meaningful only after you have installed the AnyConnect Essentials license on the ASA. Without this license, this command returns the following error message:

```
ERROR: Command requires AnyConnect Essentials license
```

Note This command only enables or disables the use of AnyConnect Essentials. The AnyConnect Essentials *license* itself is not affected by the setting of the **anyconnect-essentials** command.

When the AnyConnect Essentials license is enabled, AnyConnect clients use Essentials mode, and Clientless SSL VPN access is disabled. When the AnyConnect Essentials license is disabled, AnyConnect clients use the full AnyConnect SSL VPN Client license.

If you have active clientless SSL VPN connections, and you enable the AnyConnect Essentials license, then all connections are logged off and will need to be reestablished.

Examples

In the following example, the user enters webvpn configuration mode and enables the AnyConnect Essentials VPN client:

```
hostname(config)# webvpn
hostname(config-webvpn)# anyconnect-essentials
```

apcf

To enable an Application Profile Customization Framework profile, use the **apcf** command in webvpn configuration mode. To disable a particular APCF script, use the **no** form of the command. To disable all APCF scripts, use the **no** form of the command without arguments.

apcf URL/filename.ext

no apcf [URL/filename.ext]

Syntax Description

filename.extension	Specifies the name of the APCF customization script. These scripts are always in XML format. The extension might be .xml, .txt, .doc or one of many others
URL	Specifies the location of the APCF profile to load and use on the ASA. Use one of the following URLs: http://, https://, tftp://, ftp://; flash:/, disk#:/' The URL might include a server, port, and path. If you provide only the filename, the default URL is flash:/. You can use the **copy** command to copy an APCF profile to flash memory.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The **apcf** command enables the ASA to handle non-standard web applications and web resources so that they render correctly over a WebVPN connection. An APCF profile contains a script that specifies when (pre, post), where (header, body, request, response), and which data to transform for a particular application.

You can use multiple APCF profiles on the ASA. When you do, the ASA applies each one of them in the order of oldest to newest.

We recommend that you use the APCF command only with the support of the Cisco TAC.

Examples

The following example shows how to enable an APCF named apcf1, located on flash memory at /apcf:

```
hostname(config)# webvpn
```

```
hostname(config-webvpn)# apcf flash:/apcf/apcf1.xml
hostname(config-webvpn)#
```

This example shows how to enable an APCF named apcf2.xml, located on an HTTPS server called myserver, port 1440 with the path /apcf:

```
hostname(config)# webvpn
hostname(config-webvpn)# apcf https://myserver:1440/apcf/apcf2.xml
hostname(config-webvpn)#
```

Related Commands

Command	Description
proxy-bypass	Configures minimal content rewriting for a particular application.
rewrite	Determines whether traffic travels through the ASA.
show running config webvpn apcf	Displays the APCF configuration.

appl-acl

To identify a previously configured webtype ACL to apply to a session, use the **appl-acl** command in dap webvpn configuration mode. To remove the attribute from the configuration, use the **no** form of the command. To remove all web-type ACLs, use the **no** form of the command without arguments.

appl-acl [*identifier***]**

no appl-acl [*identifier***]**

Syntax Description

identifier	The name of the previously configured webtype ACL. The maximum length is 240 characters.

Defaults

No default value or behaviors.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Dap webvpn configuration	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

To configure webtype ACLs, use the **access-list webtype** command in global configuration mode.

Use the **appl-acl** command multiple times to apply more than one webtype ACL to the DAP policy.

Examples

The following example shows how to apply the previously configured webtype ACL called newacl to the dynamic access policy:

```
hostname (config)# config-dynamic-access-policy-record Finance
hostname(config-dynamic-access-policy-record)# webvpn
hostname(config-dynamic-access-policy-record)# appl-acl newacl
```

Related Commands

Command	Description
dynamic-access-policy-record	Creates a DAP record.
access-list_webtype	Creates a web-type ACL.

application-access

To customize the Application Access fiels of the WebVPN Home page that is displayed to authenticated WebVPN users, and the Application Access window that is launched when the user selects an application, use the **application-access** command in customization configuration mode. To remove the command from the configuration and cause the value to be inherited, use the **no** form of this command.

application-access {**title** | **message** | **window**} {**text** | **style**} *value*

no application-access {**title** | **message** | **window**} {**text** | **style**} *value*

Syntax Description

message	Changes the message displayed under the title of the Application Access field.
style	Changes the style of the Application Access field.
text	Changes the text of the Application Access field.
title	Changes the title of the Application Access field.
value	The actual text to display (a maximum of 256 characters), or Cascading Style Sheet (CSS) parameters (a maximum of 256 characters).
window	Changes the Application Access window.

Defaults

The default title text of the Application Access field is “Application Access”.

The default title style of the Application Access field is:

background-color:#99CCCC;color:black;font-weight:bold;text-transform:uppercase

The default message text of the Application Access field is “Start Application Client”.

The default message style of the Application Access field is:

background-color:#99CCCC;color:maroon;font-size:smaller.

The default window text of the Application Access window is:

“Close this window when you finish using Application Access. Please wait for the table to be displayed before starting applications.”.

The default window style of the Application Access window is:

background-color:#99CCCC;color:black;font-weight:bold.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Customization configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

This command is accessed by using the **webvpn** command or the **tunnel-group webvpn-attributes** command.

The **style** option is expressed as any valid Cascading Style Sheet (CSS) parameter. Describing these parameters is beyond the scope of this document. For more information about CSS parameters, consult CSS specifications at the World Wide Web Consortium (W3C) website at www.w3.org. Appendix F of the CSS 2.1 Specification contains a convenient list of CSS parameters, and is available at www.w3.org/TR/CSS21/propidx.html.

The following tips can help you make the most common changes to the WebVPN pages—the page colors:

- You can use a comma-separated RGB value, an HTML color value, or the name of the color if recognized in HTML.
- RGB format is 0,0,0, a range of decimal numbers from 0 to 255 for each color (red, green, blue); the comma separated entry indicates the level of intensity of each color to combine with the others.
- HTML format is #000000, six digits in hexadecimal format; the first and second represent red, the third and fourth green, and the fifth and sixth represent blue.

Note To easily customize the WebVPN pages, we recommend that you use ASDM, which has convenient features for configuring style elements, including color swatches and preview capabilities.

Examples

The following example customizes the background color of the Application Access field to the RGB hexadecimal value 66FFFF, a shade of green:

```
F1-asa1(config)# webvpn
F1-asa1(config-webvpn)# customization cisco
F1-asa1(config-webvpn-custom)# application-access title style background-color:#66FFFF
```

Related Commands

Command	Description
application-access hide-details	Enables or disables the display of the application details in the Application Access window.
browse-networks	Customizes the Browse Networks field of the WebVPN Home page.
file-bookmarks	Customizes the File Bookmarks title or links on the WebVPN Home page.
web-applications	Customizes the Web Application field of the WebVPN Home page.
web-bookmarks	Customizes the Web Bookmarks title or links on the WebVPN Home page.

application-access hide-details

To hide application details that are displayed in the WebVPN Applications Access window, use the **application-access hide-details** command in customization configuration mode, which is accessed by using the **webvpn** command or the **tunnel-group webvpn-attributes** command. To remove the command from the configuration and cause the value to be inherited, use the **no** form of this command.

application-access hide-details {**enable | disable**}

no application-access [**hide-details** {**enable | disable**}]

Syntax Description

disable	Does not hide application details in the Application Access window.
enable	Hides application details in the Application Access window.

Defaults

The default is disabled. Application details appear in the Application Access window.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Customization configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Examples

The following example disables the appearance of the application details:

```
hostname(config)# webvpn
hostname(config-webvpn)# customization cisco
hostname(config-webvpn-custom)# application-access hide-details disable
```

Related Commands

Command	Description
application-access	Customizes the Application Access field of the WebVPN Home page.
browse-networks	Customizes the Browse Networks field of the WebVPN Home page.
web-applications	Customizes the Web Application field of the WebVPN Home page.

CHAPTER 3

area through auto-update timeout Commands

area

To create an OSPF v2 or OSPFv3 area, use the **area** command in router configuration mode. To remove the area, use the **no** form of this command.

area *area_id*

no area *area_id*

Syntax Description

area_id	The ID of the area being created. You can specify the identifier as either a decimal number or an IP address. Valid decimal values range from 0 to 4294967295.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	—	—
IPv6 router configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	We introduced this command.
9.0(1)	Support for OSPFv3 was added.

Usage Guidelines

The area that you create does not have any parameters set. Use the related **area** commands to set the area parameters.

Examples

The following example shows how to create an OSPF area with an area ID of 1:

```
hostname(config-router)# area 1
hostname(config-router)#
```

Related Commands

Command	Description
area nssa	Defines the area as a not-so-stubby area.
area stub	Defines the area as a stub area.

Command	Description
router ospf	Enters router configuration mode.
show running-config router	Displays the commands in the global router configuration.

area authentication

To enable authentication for an OSPFv2 area, use the **area authentication** command in router configuration mode. To disable area authentication, use the **no** form of this command.

area *area_id* **authentication** [**message-digest**]

no area *area_id* **authentication** [**message-digest**]

Syntax Description

area_id	The identifier of the area for which authentication is to be enabled. You can specify the identifier as either a decimal number or an IP address. Valid decimal values range from 0 to 4294967295.
message-digest	(Optional) Enables Message Digest 5 (MD5) authentication for the area specified by the *area_id*.

Defaults

Area authentication is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	We introduced this command.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

If the specified OSPFv2 area does not exist, it is created when this command is entered. Entering the **area authentication** command without the **message-digest** keyword enables simple password authentication. Including the **message-digest** keyword enables MD5 authentication.

Examples

The following example shows how to enable MD5 authentication for area 1:

```
hostname(config-router)# area 1 authentication message-digest
hostname(config-router)#
```

Related Commands

Command	Description
router ospf	Enters router configuration mode.
show running-config router	Displays the commands in the global router configuration.

area default-cost

To specify a cost for the default summary route sent into a stub or NSSA, use the **area default-cost** command in router configuration mode or IPv6 router configuration mode. To restore the default cost value, use the **no** form of this command.

area *area_id* **default-cost** *cost*

no area *area_id* **default-cost** *cost*

Syntax Description

area_id	The identifier of the stub or NSSA whose default cost is being changed. You can specify the identifier as either a decimal number or an IP address. Valid decimal values range from 0 to 4294967295.
cost	Specifies the cost for the default summary route that is used for a stub or NSSA. Valid values range from 0 to 65535

Defaults

The default value of *cost* is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	•	—
IPv6 router configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	We introduced this command.
9.0(1)	Multiple context mode and OSPFv3 are supported.

Usage Guidelines

If the specified area has not been previously defined using the **area** command, this command creates the area with the specified parameters.

Examples

The following example show how to specify a default cost for summary route sent into a stub or NSSA:

```
hostname(config-router)# area 1 default-cost 5
hostname(config-router)#
```

Related Commands

Command	Description
area nssa	Defines the area as a not-so-stubby area.
area stub	Defines the area as a stub area.
router ospf	Enters router configuration mode.
show running-config router	Displays the commands in the global router configuration.

area filter-list prefix

To filter prefixes advertised in Type 3 LSAs between OSPFv2 areas of an ABR, use the **area filter-list prefix** command in router configuration mode. To change or cancel the filter, use the **no** form of this command.

area *area_id* **filter-list prefix** *list_name* {**in** | **out**}

no area *area_id* **filter-list prefix** *list_name* {**in** | **out**}

Syntax Description

area_id	Identifies the area for which filtering is configured. You can specify the identifier as either a decimal number or an IP address. Valid decimal values range from 0 to 4294967295.
in	Applies the configured prefix list to prefixes advertised inbound to the specified area.
list_name	Specifies the name of a prefix list.
out	Applies the configured prefix list to prefixes advertised outbound from the specified area.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	We introduced this command.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

If the specified area has not been previously defined using the **area** command, this command creates the area with the specified parameters.

Only Type 3 LSAs can be filtered. If an ASBR has been configured in the private network, then it sends Type 5 LSAs (describing private networks) that are flooded to the entire AS including the public areas.

Examples

The following example filters prefixes that are sent from all other areas to area 1:

```
hostname(config-router)# area 1 filter-list prefix-list AREA_1 in
hostname(config-router)#
```

Related Commands

Command	Description
router ospf	Enters router configuration mode.
show running-config router	Displays the commands in the global router configuration.

area nssa

To configure an area as an NSSA, use the **area nssa** command in router configuration mode or IPv6 router configuration mode. To remove the NSSA designation from the area, use the **no** form of this command.

area *area_id* **nssa** [**no-redistribution**] [**default-information-originate** [**metric-type** {**1** | **2**}] [**metric** *value*]] [**no-summary**]

no area *area_id* **nssa** [**no-redistribution**] [**default-information-originate** [**metric-type** {**1** | **2**}] [**metric** *value*]] [**no-summary**]

Syntax Description

area_id	Identifies the area being designated as an NSSA. You can specify the identifier as either a decimal number or an IP address. Valid decimal values range from 0 to 4294967295.
default-information-originate	Used to generate a Type 7 default into the NSSA area. This keyword only takes effect on an NSSA ABR or an NSSA ASBR.
metric *metric_value*	(Optional) Specifies the OSPF default metric value. Valid values range from 0 to 16777214.
metric-type {**1** | **2**}	(Optional) the OSPF metric type for default routes. Valid values are the following: • **1**—type 1 • **2**—type 2. The default value is 2.
no-redistribution	(Optional) Used when the router is an NSSA ABR and you want the **redistribute** command to import routes only into the normal areas, but not into the NSSA area.
no-summary	(Optional) Allows an area to be a not-so-stubby area but not have summary routes injected into it.

Defaults

The defaults are as follows:

- No NSSA area is defined.
- The **metric-type** is 2.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	•	—
IPv6 router configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	We introduced this command.
9.0(1)	Multiple content mode and OSPFv3 are supported.

Usage Guidelines

If the specified area has not been previously defined using the **area** command, this command creates the area with the specified parameters.

If you configure one option for an area, and later specify another option, both options are set. For example, entering the following two command separately results in a single command with both options set in the configuration:

```
hostname(config-rtr)# area 1 nssa no-redistribution
hostname(config-rtr)# area area_id nssa default-information-originate
```

Examples

The following example shows how setting two options separately results in a single command in the configuration:

```
hostname(config-rtr)# area 1 nssa no-redistribution
hostname(config-rtr)# area 1 nssa default-information-originate
hostname(config-rtr)# exit
hostname(config-rtr)# show running-config router ospf 1
router ospf 1
 area 1 nssa no-redistribution default-information-originate
```

Related Commands

Command	Description
area stub	Defines the area as a stub area.
router ospf	Enters router configuration mode.
show running-config router	Displays the commands in the global router configuration.

area range (OSPFv2)

To consolidate and summarize routes at an area boundary, use the **area range** command in router configuration mode. To disable this function, use the **no** form of this command.

area *area_id* **range** *address mask* [**advertise | not-advertise**]

no area *area_id* **range** *address mask* [**advertise | not-advertise**]

Syntax Description

address	IP address of the subnet range.
advertise	(Optional) Sets the address range status to advertise and generates Type 3 summary link-state advertisements (LSAs).
area_id	Identifies the area for which the range is configured. You can specify the identifier as either a decimal number or an IP address. Valid decimal values range from 0 to 4294967295.
mask	IP address subnet mask.
not-advertise	(Optional) Sets the address range status to DoNotAdvertise. The Type 3 summary LSA is suppressed, and the component networks remain hidden from other networks.

Defaults

The address range status is set to advertise.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	We introduced this command.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

If the specified area has not been previously defined using the **area** command, this command creates the area with the specified parameters.

The **area range** command is used only with ABRs to consolidate or summarize routes for an area. The result is that a single summary route is advertised to other areas by the ABR. Routing information is condensed at area boundaries. External to the area, a single route is advertised for each address range. This behavior is called *route summarization*. You can configure multiple **area range** commands for an area. In this way, OSPF can summarize addresses for many different sets of address ranges.

The **no area** *area_id* **range** *ip_address netmask* **not-advertise** command removes only the **not-advertise** optional keyword.

Examples

The following example specifies one summary route to be advertised by the ABR to other areas for all subnets on network 10.0.0.0 and for all hosts on network 192.168.110.0:

```
hostname(config-router)# area 10.0.0.0 range 10.0.0.0 255.0.0.0
hostname(config-router)# area 0 range 192.168.110.0 255.255.255.0
hostname(config-router)#
```

Related Commands

Command	Description
router ospf	Enters router configuration mode.
show running-config router	Displays the commands in the global router configuration.

area range (OSPFv3)

To consolidate and summarize OSPFv3 routes at an area boundary, use the **area range** command in IPv6 router configuration mode. To disable this function, use the **no** form of this command.

area *area_id* **range** *ipv6-prefix/prefix-length* [**advertise | not-advertise**] [**cost** *cost*]

no area *area_id* **range** *ipv6-prefix/prefix-length* [**advertise | not-advertise**] [**cost** *cost*]

Syntax Description

advertise	(Optional) Sets the range status to advertise and generates Type 3 summary link-state advertisements (LSAs).
area_id	Specifies the identifier of the area for which routes are to be summarized. You can specify the identifier as either a decimal number or an IPv6 prefix.
cost *cost*	(Optional) Specifies the metric or cost for this summary route, which is used during OSPF SPF calculations to detemine the shortest paths to the destination. Valid values range from 0 to 16777215.
ipv6-prefix	Specifies the IPv6 prefix.
not-advertise	(Optional) Sets the range status to DoNotAdvertise. The Type 3 summary LSA is suppressed, and the component networks remain hidden from other networks.
prefix-length	Specifies the IPv6 prefix length.

Defaults

The range status is set to advertise by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
IPv6 router configuration	•	—	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

If the specified area has not been previously defined using the **area** command, this command creates the area with the specified parameters.

The **area range** command is used only with ABRs. It is used to consolidate or summarize routes for an area. The result is that a single summary route is advertised to other areas by the ABR. Routing information is condensed at area boundaries. External to the area, a single route is advertised for each

IPv6 prefix and prefix length. This behavior is called *route summarization*. You can configure multiple **area range** commands for an area. In this way, OSPFv3 can summarize routes for many different sets of IPv6 prefixes and prefix lengths.

Examples

The following example specifies one summary route to be advertised by the ABR to other areas for IPv6 prefix 2000:0:0:4::2 with the prefix-length 2001::/64:

```
hostname(config-router)# area 1 range 2000:0:0:4::2/2001::/64
hostname(config-router)#
```

Related Commands

Command	Description
ipv6 router ospf	Enters IPv6 router configuration mode for OSPFv3.
show running-config ipv6 router	Displays the IPv6 commands in the global router configuration.

area stub

To define an area as a stub area, use the **area stub** command in router configuration mode or IPv6 router configuration mode. To remove the stub area, use the **no** form of this command.

area *area_id* **stub** [**no-summary**]

no area *area_id* **stub** [**no-summary**]

Syntax Description

area_id	Identifies the stub area. You can specify the identifier as either a decimal number or an IP address. Valid decimal values range from 0 to 4294967295.
no-summary	Prevents an ABR from sending summary link advertisements into the stub area.

Defaults

The default behaviors are as follows:

- No stub areas are defined.
- Summary link advertisements are sent into the stub area.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	—	—
IPv6 router configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	We introduced this command.
9.0(1)	Support for OSPFv3 was added.

Usage Guidelines

The command is used only on an ABR attached to a stub or NSSA.

There are two stub area router configuration commands: the **area stub** and **area default-cost** commands. In all routers and access servers attached to the stub area, the area should be configured as a stub area using the **area stub** command. Use the **area default-cost** command only on an ABR attached to the stub area. The **area default-cost** command provides the metric for the summary default route generated by the ABR into the stub area.

Examples

The following example configures the specified area as a stub area:

```
hostname(config-rtr)# area 1 stub
```

```
hostname(config-rtr)#
```

Related Commands

Command	Description
area default-cost	Specifies a cost for the default summary route sent into a stub or NSSA.
area nssa	Defines the area as a not-so-stubby area.
router ospf	Enters router configuration mode.
show running-config router	Displays the commands in the global router configuration.

area virtual-link (OSPFv2)

To define an OSPF virtual link, use the **area virtual-link** command in router configuration mode. To reset the options or remove the virtual link, use the **no** form of this command.

area *area_id* **virtual-link** *router_id* [**authentication** [**message-digest | null**]] [**hello-interval** *seconds*] [**retransmit-interval** seconds] [**transmit-delay** *seconds*] [**dead-interval** *seconds* [[[[**authentication-key[0 | 8]** *key*] | [**message-digest-key** *key_id* **md5 [0 | 8]** *key*]]]]

no area *area_id* **virtual-link** *router_id* [**authentication** [**message-digest | null**]] [**hello-interval** *seconds*] [**retransmit-interval** seconds] [**transmit-delay** *seconds*] [**dead-interval** *seconds* [[[[**authentication-key [0 | 8]** *key*] | [**message-digest-key** *key_id* **md5 [0 | 8]** *key*]]]]

Syntax Description

area_id	Area ID of the transit area for the virtual link. You can specify the identifier as either a decimal number or an IP address. Valid decimal values range from 0 to 4294967295.
authentication	(Optional) Specifies the authentication type.
authentication-key [0 | 8]*key*	(Optional) Specifies an OSPF authentication password for use by neighboring routing devices.
dead-interval *seconds*	(Optional) Specifies the interval before declaring a neighboring routing device is down if no hello packets are received; valid values are from 1 to 65535 seconds.
hello-interval *seconds*	(Optional) Specifies the interval between hello packets sent on the interface; valid values are from 1 to 65535 seconds.
md5 [0 | 8] *key*	(Optional) Specifies an alphanumeric key up to 16 bytes.
message-digest	(Optional) Specifies that message digest authentication is used.
message-digest-key *key_id*	(Optional) Enables the Message Digest 5 (MD5) authentication and specifies the numerical authentication key ID number; valid values are from 1 to 255.
0	Specifies an unencrypted password will follow.
8	Specifies an encrypted password will follow.
null	(Optional) Specifies that no authentication is used. Overrides password or message digest authentication if configured for the OSPF area.
retransmit-interval *seconds*	(Optional) Specifies the time between LSA retransmissions for adjacent routers belonging to the interface; valid values are from 1 to 65535 seconds.
router_id	The router ID associated with the virtual link neighbor. The router ID is internally derived by each router from the interface IP addresses. This value must be entered in the format of an IP address. There is no default.
transmit-delay *seconds*	(Optional) Specifies the delay time between when OSPF receives a topology change and when it starts a shortest path first (SPF) calculation in seconds from 0 to 65535. The default is 5 seconds.

Note Single-digit passwords and passwords starting with a digit followed by a whitespace are no longer supported.

Defaults

The defaults are as follows:

- *area_id*: No area ID is predefined.
- *router_id*: No router ID is predefined.
- **hello-interval** *seconds*: 10 seconds.
- **retransmit-interval** *seconds*: 5 seconds.
- **transmit-delay** *seconds*: 1 second.
- **dead-interval** *seconds*: 40 seconds.
- **authentication-key [0 | 8]** *key*: No key is predefined.
- **message-digest-key** *key_id* **md5 [0 | 8]** *key*: No key is predefined.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	We introduced this command.

Usage Guidelines

In OSPF, all areas must be connected to a backbone area. If the connection to the backbone is lost, it can be repaired by establishing a virtual link.

The smaller the hello interval, the faster topological changes are detected, but more routing traffic ensues.

The setting of the retransmit interval should be conservative, or needless retransmissions occur. The value should be larger for serial lines and virtual links.

The transmit delay value should take into account the transmission and propagation delays for the interface.

The specified authentication key is used only when authentication is enabled for the backbone with the **area** *area_id* **authentication** command.

The two authentication schemes, simple text and MD5 authentication, are mutually exclusive. You can specify one or the other or neither. Any keywords and arguments you specify after **authentication-key [0 | 8]** *key* or **message-digest-key** *key_id* **md5[0 | 8]** *key* are ignored. Therefore, specify any optional arguments before such a keyword-argument combination.

If the authentication type is not specified for an interface, the interface uses the authentication type specified for the area. If no authentication type has been specified for the area, the area default is null authentication.

Note Each virtual link neighbor must include the transit area ID and the corresponding virtual link neighbor router ID for a virtual link to be properly configured. Use the **show ospf** command to see the router ID.

Examples

The following example establishes a virtual link with MD5 authentication:

```
hostname(config-rtr)# area 10.0.0.0 virtual-link 10.3.4.5 message-digest-key 3 md5 8
sa5721bk47
```

Related Commands

Command	Description
router ospf	Enters router configuration mode.
show ospf	Displays general information about the OSPF routing processes.
show running-config router	Displays the commands in the global router configuration.

area virtual-link (OSPFv3)

To define an OSPFv3 virtual link, use the **area virtual-link** command in IPv6 router configuration mode. To reset the options or remove the virtual link, use the **no** form of this command.

area *area_id* **virtual-link** *router_id* [**hello-interval** *seconds*] [**retransmit-interval** *seconds*] [**transmit-delay** *seconds*] [**dead-interval** *seconds* [**ttl-security hops** *hop-count*]

no area *area_id* **virtual-link** *router_id* [**hello-interval** *seconds*] [**retransmit-interval** *seconds*] [**transmit-delay** *seconds*] [**dead-interval** *seconds*] [**ttl-security hops** *hop-count*]

Syntax Description

area_id	Specifies the area ID of the transit area for the virtual link. You can specify the identifier as either a decimal number or valid IPv6 prefix. Valid decimal values range from 0 to 4294967295.
dead-interval *seconds*	(Optional) Specifies the time in seconds that hello packets are not seen before a neighbor indicates that the router is down. The dead interval in an unsigned integer value. As with the hello interval, this value must be the same for all routers and access servers that are attached to a common network. Valid values range from 1 to 8192 seconds.
hello-interval *seconds*	(Optional) Specifies the time in seconds between hello packets that the ASA sends on the interface. The hello interval is an unsigned integer value to be advertised in the hello packets. The value must be the same for all routers and access servers that are attached to a common network. Valid values range from 1 to 8192 seconds.
retransmit-interval *seconds*	(Optional) Specifies the time in seconds between LSA retransmissions for adjacent routers that belong to the interface. The retransmission interval is the expected round-trip delay between any two routers on the attached network. The value must be greater than the expected round-trip delay. Valid values range from 1 to 8192 seconds.
router_id	Specifies the router ID that is associated with the virtual link neighbor. The router ID appears in the **show ipv6 ospf** or **show ipv6 display** command.
transmit-delay *seconds*	(Optional) Specifies the estimated time in seconds that is required to send a link-state update packet on the interface. The integer value must be greater than zero. LSAs in the update packet have their age incremented by this amount before transmission. Valid values range from 1 to 8192 seconds.
ttl-security hops *hop-count*	(Optional) Configures the time-to-live (TTL) security on a virtual link. Valid values for the hop count range from 1 to 254.

Note Single-digit passwords and passwords starting with a digit followed by a white space are no longer supported.

Defaults

The defaults are as follows:

- *area_id*: No area ID is predefined.
- *router_id*: No router ID is predefined.

- **hello-interval**: 10 seconds.
- **retransmit-interval**: 5 seconds.
- **transmit-delay**: 1 second.
- **dead-interval**: 40 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
IPv6 router configuration	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

In OSPFv3, all areas must be connected to a backbone area. If the connection to the backbone is lost, it can be repaired by establishing a virtual link.

The smaller the hello interval, the faster topological changes are detected, but more routing traffic occurs.

The setting of the retransmission interval should be conservative, or unnecessary retransmissions occur. The value should be larger for serial lines and virtual links.

The transmit delay value should take into account the transmission and propagation delays for the interface.

Note Each virtual link neighbor must include the transit area ID and the corresponding virtual link neighbor router ID for a virtual link to be correctly configured. Use the **show ipv6 ospf** command to obtain the router ID.

Examples

The following example establishes a virtual link in OSPFv3:

```
hostname(config-if)# ipv6 router ospf 1
hostname(config-rtr)# log-adjacency-changes
hostname(config-rtr)# area 1 virtual-link 192.168.255.1 hello interval 5
```

Related Commandsi

Command	Description
ipv6 router ospf	Enters router configuration mode for OSPFv3.
show ipv6 ospf	Displays general information about the OSPFv3 routing processes.
show running-config ipv6 router	Displays the IPv6 commands in the global router configuration.

arp

To add a static ARP entry to the ARP table, use the **arp** command in global configuration mode. To remove the static entry, use the **no** form of this command.

arp *interface_name ip_address mac_address* [**alias**]

no arp *interface_name ip_address mac_address*

Syntax Description

alias	(Optional) Enables proxy ARP for this mapping. If the ASA receives an ARP request for the specified IP address, then it responds with the ASA MAC address. When the ASA receives traffic destined for the host belonging to the IP address, the ASA forwards the traffic to the host MAC address that you specify in this command. This keyword is useful if you have devices that do not perform ARP, for example. In transparent firewall mode, this keyword is ignored; the ASA does not perform proxy ARP.
interface_name	The interface attached to the host network.
ip_address	The host IP address.
mac_address	The host MAC address.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	We introduced this command.

Usage Guidelines

Although hosts identify a packet destination by an IP address, the actual delivery of the packet on Ethernet relies on the Ethernet MAC address. When a router or host wants to deliver a packet on a directly connected network, it sends an ARP request asking for the MAC address associated with the IP address, and then delivers the packet to the MAC address according to the ARP response. The host or router keeps an ARP table so it does not have to send ARP requests for every packet it needs to deliver. The ARP table is dynamically updated whenever ARP responses are sent on the network, and if an entry is not used for a period of time, it times out. If an entry is incorrect (for example, the MAC address changes for a given IP address), the entry times out before it can be updated.

A static ARP entry maps a MAC address to an IP address and identifies the interface through which the host is reached. Static ARP entries do not time out, and might help you solve a networking problem. In transparent firewall mode, the static ARP table is used with ARP inspection (see the **arp-inspection** command).

Note In transparent firewall mode, dynamic ARP entries are used for traffic to and from the ASA, such as management traffic.

Examples

The following example creates a static ARP entry for 10.1.1.1 with the MAC address 0009.7cbe.2100 on the outside interface:

```
hostname(config)# arp outside 10.1.1.1 0009.7cbe.2100
```

Related Commands

Command	Description
arp timeout	Sets the time before the ASA rebuilds the ARP table.
arp-inspection	For transparent firewall mode, inspects ARP packets to prevent ARP spoofing.
show arp	Shows the ARP table.
show arp statistics	Shows ARP statistics.
show running-config arp	Shows the current configuration of the ARP timeout.

arp permit-nonconnected

To enable the ARP cache to also include non-directly-connected subnets, use the **arp permit-nonconnected** command in global configuration mode. To disable non-connected subnets, use the **no** form of this command.

arp permit-nonconnected

no arp permit-nonconnected

Syntax Description

This command has no arguments or keywords.

Command Default

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.4(5), 9.0(1)	We introduced this command.

Usage Guidelines

The ASA ARP cache only contains entries from directly-connected subnets by default. This command lets you enable the ARP cache to also include non-directly-connected subnets. We do not recommend enabling this feature unless you know the security risks. This feature could facilitate denial of service (DoS) attack against the ASA; a user on any interface could send out many ARP replies and overload the ASA ARP table with false entries.

You may want to use this feature if you use:

- Secondary subnets.
- Proxy ARP on adjacent routes for traffic forwarding.

Examples

The following example enables non-connected subnets:

```
hostname(config)# arp permit non-connected
```

Related Commands

Command	Description
arp	Adds a static ARP entry.

arp-inspection

To enable ARP inspection for transparent firewall mode, use the **arp-inspection** command in global configuration mode. To disable ARP inspection, use the **no** form of this command.

arp-inspection *interface_name* **enable** [**flood** | **no-flood**]

no arp-inspection *interface_name* **enable**

Syntax Description

enable	Enables ARP inspection.
flood	(Default) Specifies that packets that do not match any element of a static ARP entry are flooded out all interfaces except the originating interface. If there is a mismatch between the MAC address, the IP address, or the interface, then the ASA drops the packet. **Note** The management-specific interface, if present, never floods packets even if this parameter is set to flood.
interface_name	The interface on which you want to enable ARP inspection.
no-flood	(Optional) Specifies that packets that do not exactly match a static ARP entry are dropped.

Defaults

By default, ARP inspection is disabled on all interfaces; all ARP packets are allowed through the ASA. When you enable ARP inspection, the default is to flood non-matching ARP packets.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	—	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Configure static ARP entries using the **arp** command before you enable ARP inspection.

ARP inspection checks all ARP packets against static ARP entries (see the **arp** command) and blocks mismatched packets. This feature prevents ARP spoofing.

When you enable ARP inspection, the ASA compares the MAC address, IP address, and source interface in all ARP packets to static entries in the ARP table, and takes the following actions:

- If the IP address, MAC address, and source interface match an ARP entry, the packet is passed through.

- If there is a mismatch between the MAC address, the IP address, or the interface, then the ASA drops the packet.
- If the ARP packet does not match any entries in the static ARP table, then you can set the ASA to either forward the packet out all interfaces (flood), or to drop the packet.

Note The dedicated management interface, if present, never floods packets even if this parameter is set to flood.

ARP inspection prevents malicious users from impersonating other hosts or routers (known as ARP spoofing). ARP spoofing can enable a "man-in-the-middle" attack. For example, a host sends an ARP request to the gateway router; the gateway router responds with the gateway router MAC address. The attacker, however, sends another ARP response to the host with the attacker MAC address instead of the router MAC address. The attacker can then intercept all the host traffic before forwarding it on to the router.

ARP inspection ensures that an attacker cannot send an ARP response with the attacker MAC address, provided the correct MAC address and the associated IP address are in the static ARP table.

Note In transparent firewall mode, dynamic ARP entries are used for traffic to and from the ASA, such as management traffic.

Examples

The following example enables ARP inspection on the outside interface and sets the ASA to drop any ARP packets that do not match the static ARP entry:

```
hostname(config)# arp outside 209.165.200.225 0009.7cbe.2100
hostname(config)# arp-inspection outside enable no-flood
```

Related Commands

Command	Description
arp	Adds a static ARP entry.
clear configure arp-inspection	Clears the ARP inspection configuration.
firewall transparent	Sets the firewall mode to transparent.
show arp statistics	Shows ARP statistics.
show running-config arp	Shows the current configuration of the ARP timeout.

arp timeout

To set the time before the ASA rebuilds the ARP table, use the **arp timeout** command in global configuration mode. To restore the default timeout, use the **no** form of this command.

arp timeout *seconds*

no arp timeout *seconds*

Syntax Description

seconds	The number of seconds between ARP table rebuilds, from 60 to 4294967.

Defaults

The default value is 14,400 seconds (4 hours).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	We introduced this command.

Usage Guidelines

Rebuilding the ARP table automatically updates new host information and removes old host information. You might want to reduce the timeout because the host information changes frequently.

Examples

The following example changes the ARP timeout to 5,000 seconds:

```
hostname(config)# arp timeout 5000
```

Related Commands

Command	Description
arp	Adds a static ARP entry.
arp-inspection	For transparent firewall mode, inspects ARP packets to prevent ARP spoofing.
show arp statistics	Shows ARP statistics.
show running-config arp timeout	Shows the current configuration of the ARP timeout.

asdm disconnect

To terminate an active ASDM session, use the **asdm disconnect** command in privileged EXEC mode.

asdm disconnect *session*

Syntax Description

session	The session ID of the active ASDM session to be terminated.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from the **pdm disconnect** command to the **asdm disconnect** command.

Usage Guidelines

Use the **show asdm sessions** command to display a list of active ASDM sessions and their associated session IDs. Use the **asdm disconnect** command to terminate a specific session.

When you terminate an ASDM session, any remaining active ASDM sessions keep their associated session ID. For example, if there are three active ASDM sessions with the session IDs of 0, 1, and 2, and you terminate session 1, the remaining active ASDM sessions keep the session IDs 0 and 2. The next new ASDM session in this example would be assigned a session ID of 1, and any new sessions after that would begin with the session ID 3.

Examples

The following example terminates an ASDM session with a session ID of 0. The **show asdm sessions** commands display the active ASDM sessions before and after the **asdm disconnect** command is entered.

```
hostname# show asdm sessions

0 192.168.1.1
1 192.168.1.2
hostname# asdm disconnect 0
hostname# show asdm sessions

1 192.168.1.2
```

Related Commands

Command	Description
show asdm sessions	Displays a list of active ASDM sessions and their associated session ID.

asdm disconnect log_session

To terminate an active ASDM logging session, use the **asdm disconnect log_session** command in privileged EXEC mode.

asdm disconnect log_session *session*

Syntax Description

session	The session ID of the active ASDM logging session to be terminated.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the **show asdm log_sessions** command to display a list of active ASDM logging sessions and their associated session IDs. Use the **asdm disconnect log_session** command to terminate a specific logging session.

Each active ASDM session has one or more associated ASDM logging sessions. ASDM uses the logging session to retrieve syslog messages from the ASA. Terminating a log session may have an adverse effect on the active ASDM session. To terminate an unwanted ASDM session, use the **asdm disconnect** command.

Note Because each ASDM session has at least one ASDM logging session, the output for the **show asdm sessions** and **show asdm log_sessions** may appear to be the same.

When you terminate an ASDM logging session, any remaining active ASDM logging sessions keep their associated session ID. For example, if there are three active ASDM logging sessions with the session IDs of 0, 1, and 2, and you terminate session 1, the remaining active ASDM logging sessions keep the session IDs 0 and 2. The next new ASDM logging session in this example would be assigned a session ID of 1, and any new logging sessions after that would begin with the session ID 3.

Examples

The following example terminates an ASDM session with a session ID of 0. The **show asdm log_sessions** commands display the active ASDM sessions before and after the **asdm disconnect log_sessions** command is entered.

```
hostname# show asdm log_sessions

0 192.168.1.1
1 192.168.1.2
hostname# asdm disconnect 0
hostname# show asdm log_sessions

1 192.168.1.2
```

Related Commands

Command	Description
show asdm log_sessions	Displays a list of active ASDM logging sessions and their associated session ID.

asdm history enable

To enable ASDM history tracking, use the **asdm history enable** command in global configuration mode. To disable ASDM history tracking, use the **no** form of this command.

asdm history enable

no asdm history enable

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was changed from the **pdm history enable** command to the **asdm history enable** command.

Usage Guidelines

The information obtained by enabling ASDM history tracking is stored in the ASDM history buffer. You can view this information using the **show asdm history** command. The history information is used by ASDM for device monitoring.

Examples

The following example enables ASDM history tracking:

```
hostname(config)# asdm history enable
hostname(config)#
```

Related Commands

Command	Description
show asdm history	Displays the contents of the ASDM history buffer.

asdm image

To specify the location of the ASDM software image in flash memory, use the **asdm image** command in global configuration mode. To remove the image location, use the **no** form of this command.

asdm image *url*

no asdm image [*url*]

Syntax Description

url	Sets the location of the ASDM image in flash memory. See the following URL syntax: • **disk0:/**[*path*/]*filename* For the ASA 5500 series, this URL indicates the internal flash memory. You can also use **flash** instead of **disk0**; they are aliased. • **disk1:/**[*path*/]*filename* For the ASA 5500 series, this URL indicates the external flash memory card. • **flash:/**[*path*/]*filename* This URL indicates the internal flash memory.

Defaults

If you do not include this command in your startup configuration, the ASA uses the first ASDM image it finds at startup. It searches the root directory of internal Flash memory and then external flash memory. The ASA then inserts the **asdm image** command into the running configuration if it discovered an image.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can store more than one ASDM software image in flash memory. If you enter the **asdm image** command to specify a new ASDM software image while there are active ASDM sessions, the new command does not disrupt the active sessions; active ASDM sessions continue to use the ASDM software image they started with. New ASDM sessions use the new software image. If you enter the **no asdm image** command, the command is removed from the configuration. However, you can still access ASDM from the ASA using the last-configured image location.

If you do not include this command in your startup configuration, the ASA uses the first ASDM image it finds at startup. It searches the root directory of internal flash memory and then external flash memory. The ASA then inserts the **asdm image** command into the running configuration if it discovered an image. Be sure to save the running configuration to the startup configuration using the **write memory** command. If you do not save the **asdm image** command to the startup configuration, every time you reboot, the ASA searches for an ASDM image and inserts the **asdm image** command into your running configuration. If you are using Auto Update, the automatic addition of this command at startup causes the configuration on the ASA not to match the configuration on the Auto Update Server. This mismatch causes the ASA to download the configuration from the Auto Update Server. To avoid unnecessary Auto Update activity, save the **asdm image** command to the startup configuration.

Examples

The following example sets the ASDM image to asdm.bin:

```
hostname(config)# asdm image flash:/asdm.bin
hostname(config)#
```

Related Commands

Command	Description
show asdm image	Displays the current ASDM image file.
boot	Sets the software image and startup configuration files.

asdm location

Caution Do not manually configure this command. ASDM adds **asdm location** commands to the running configuration and uses them for internal communication. This command is included in the documentation for informational purposes only.

asdm location *ip_addr netmask if_name*

asdm location *ipv6_addr/prefix if_name*

Syntax Description

if_name	The name of the highest security interface. If you have multiple interfaces at the highest security, then an arbitrary interface name is chosen. This interface name is not used, but is a required parameter.
ip_addr	The IP address used internally by ASDM to define the network topology.
ipv6_addr/prefix	The IPv6 address and prefix used internally by ASDM to define the network topology.
netmask	The subnet mask for *ip_addr*.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from the **pdm location** command to the **asdm location** command.

Usage Guidelines

Do not manually configure or remove this command.

asp load-balance per-packet

For multicore ASAs, to change the load balancing behavior, use the **asp load-balance per-packet** command in global configuration mode. To restore the default load-balancing mechanism, use the **no** form of this command.

asp load-balance per-packet

no asp load-balance per-packet

Syntax Description

This command has no arguments or keywords.

Command Default

By default, the load-balancing mechanism favors many interfaces. The default behavior is to allow only one core to receive packets from an interface receive ring at a time.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
8.1(1)	We introduced this command.

Usage Guidelines

The default behavior is optimized for scenarios where packets are received uniformly on all interface rings. The per-packet behavior is optimized for scenarios where traffic is asymmetrically distributed on interface receive rings. Performance on the ASAs with multiple cores can vary depending on the number of processors, the number of interface receive rings, and the nature of the traffic passing through. Using the **asp load-balance per-packet** command allows multiple cores to work simultaneously on packets received from a single interface receive ring. This command provides for parallel processing if the packets received are spread over many independent connections. Note that this command can cause additional queuing overhead for packets from the same and related connections because these packets are processed by one core.

If the system drops packets, and the **show cpu** command output is far less than 100%, then this command may help your throughput if the packets belong to many unrelated connections. The CPU usage is a good indicator of how many cores are effectively being used.

For example on the ASA 5580-40, which includes 8 cores, if two cores are used, then the **show cpu** command output will be 25%; four cores will be 50%; and six cores will be 75%.

Examples

The following example enables per-packet load balancing:

```
hostname(config)# asp load-balance per-packet
```

Related Commands

Command	Description
show asp load-balance	Displays a histogram of the load balancer queue sizes.

asr-group

To specify an asymmetrical routing interface group ID, use the **asr-group** command in interface configuration mode. To remove the ID, use the **no** form of this command.

asr-group *group_id*

no asr-group *group_id*

Syntax Description

group_id	The asymmetric routing group ID. Valid values are from 1 to 32.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	—	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

When Active/Active failover is enabled, you may encounter situations where load balancing causes the return traffic for outbound connections to be routed through an active context on the peer unit, in which the context for the outbound connection is in the standby group.

The **asr-group** command causes incoming packets to be reclassified with the interface of the same ASR group if a flow with the incoming interface cannot be found. If reclassification finds a flow with another interface, and the associated context is in standby state, then the packet is forwarded to the active unit for processing.

Stateful Failover must be enabled for this command to take effect.

You can view ASR statistics using the **show interface detail** command. These statistics include the number of ASR packets sent, received, and dropped on an interface.

Note No two interfaces in the same context should be configured in the same ASR group.

Examples

The following example assigns the selected interfaces to the asymmetric routing group 1.

Context ctx1 configuration:

```
hostname/ctx1(config)# interface Ethernet2
```

```
hostname/ctx1(config-if)# nameif outside
hostname/ctx1(config-if)# ip address 192.168.1.11 255.255.255.0 standby 192.168.1.21
hostname/ctx1(config-if)# asr-group 1
```

Context ctx2 configuration:

```
hostname/ctx2(config)# interface Ethernet3
hostname/ctx2(config-if)# nameif outside
hostname/ctx2(config-if)# ip address 192.168.1.31 255.255.255.0 standby 192.168.1.41
hostname/ctx2(config-if)# asr-group 1
```

Related Commands

Command	Description
interface	Enters interface configuration mode.
show interface	Displays interface statistics.

assertion-consumer-url

To identify the URL that the security device accesses to contact the assertion consumer service, use the **assertion-consumer-url** command in the webvpn configuration mode for that specific SAML-type SSO server. To remove the URL from the assertion, use the **no** form of this command.

assertion-consumer-url *url*

no assertion-consumer-url [*url*]

Syntax Description

url	Specifies the URL of the assertion consumer service used by the SAML-type SSO server. The URL must start with either http:// or https:// and must be less than 255 alphanumeric characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Single sign-on (SSO) support, available only for WebVPN, lets users access different secure services on different servers without entering a username and password more than once. The ASA currently supports the SAML POST-type SSO server and the SiteMinder-type of SSO server.

This command applies only to SAML-type SSO servers.

If the URL begins with HTTPS, the requirement is to install the root certificate for the assertion consumer service SSL certificate.

Examples

The following example specifies the assertion consumer URL for a SAML-type SSO server:

```
hostname(config-webvpn)# sso server myhostname type saml-v1.1-post
hostname(config-webvpn-sso-saml# assertion-consumer-url https://saml-server/postconsumer
hostname(config-webvpn-sso-saml#
```

Related Commands

Command	Description
issuer	Specifies the SAML-type SSO server security device name.
request-timeout	Specifies the number of seconds before a failed SSO authentication attempt times out.
show webvpn sso-server	Displays the operating statistics for all SSO servers configured on the security device.
sso-server	Creates a WebVPN SSO server.
trustpoint	Specifies a trustpoint name that contains the certificate to use to sign the SAML-type browser assertion.

attribute

To specify attribute value pairs that the ASA writes to the DAP attribute database, enter the **attribute** command in dap test attributes mode.

attribute *name value*

Syntax Description

name	Specifies a well-known attribute name, or an attribute that incorporates a "label" tag. The label tag corresponds to the endpoint ID that you configure for file, registry, process, antivirus, antispyware, and personal firewall endpoint attributes in the DAP record.
value	The value assigned to the AAA attribute.

Command Default

No default value or behaviors.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
DAP attributes configuration	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use this command multiple times to enter multiple attribute value pairs.

Normally the ASA retrieves user authorization attributes from the AAA server and retrieves endpoint attributes from Cisco Secure Desktop, Host Scan, CNA or NAC. For the test command, you specify the user authorization and endpoint attributes in this attributes mode. The ASA writes them to an attribute database that the DAP subsystem references when evaluating the AAA selection attributes and endpoint selection attributes for a DAP record.

Examples

The following example assumes that ASA selects two DAP records if the authenticated user is a member of the SAP group and has antivirus software installed on the endpoint system. The endpoint ID for the antivirus software endpoint rule is *nav*.

The DAP records have the following policy attributes:

DAP Record 1	DAP Record 2
action = continue	action = continue
port-forward = enable hostlist1	url-list = links2
—	url-entry = enable

```
hostname # test dynamic-access-policy attributes
hostname(config-dap-test-attr)# attribute aaa.ldap.memberof SAP
hostname(config-dap-test-attr)# attribute endpoint.av.nav.exists true
hostname(config-dap-test-attr)# exit

hostname # test dynamic-access-policy execute
Policy Attributes:
action = continue
port-forward = enable hostlist1
url-list = links2
url-entry = enable

hostname #
```

Related Commandsl

Command	Description
display	Displays current attribute lists.
dynamic-access-policy-record	Creates a DAP record.
test dynamic-access-policy attributes	Enters attributes.
test dynamic-access-policy execute	Executes the logic that generates the DAP and displays the resulting access policies to the console.

auth-cookie-name

To specify the name of an authentication cookie, use the **auth-cookie-name** command in aaa-server host configuration mode. This is an SSO with HTTP Forms command.

auth-cookie-name

Syntax Description

name	The name of the authentication cookie. The maximum name size is 128 characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server host configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The WebVPN server of the ASA uses an HTTP POST request to submit a single sign-on (SSO) authentication request to an SSO server. If authentication succeeds, the authenticating web server passes back an authentication cookie to the client browser. The client browser then authenticates to other web servers in the SSO domain by presenting the authentication cookie. The **auth-cookie-name** command configuresthe name of the authentication cookie to be used for SSO by the ASA.

A typical authentication cookie format is Set-Cookie: *cookie name=cookie value* [;*cookie attributes*]. In the following authentication cookie example, SMSESSION is the name that would be configured with the **auth-cookie-name** command:

```
Set-Cookie:
SMSESSION=yN4Yp5hHVNDgs4FT8dn7+Rwev41hsE49XlKc+1twie0gqnjbhkTkUnR8XWP3hvDH6PZPbHIHtWLDKTa8
ngDB/lbYTjIxrbDx8WPWwaG3CxVa3adOxHFR8yjD55GevK3ZF4ujgU1lhO6fta0dSSOSepWvnsCb7IFxCw+MGiw0o8
8uHa2t4l+SillqfJvcpuXfiIAO06D/dapWriHjNoi4llJOgCst33wEhxFxcWy2UWxs4EZSjsI5GyBnefSQTPVfma5d
c/emWor9vWr0HnTQaHP5rg5dTNqunkDEdMIHfbeP3F90cZejVzihM6igiS6P/CEJAjE;Domain=.example.com;Pa
th=/
```

Examples

The following example specifies the authentication cookie name of SMSESSION for the authentication cookie received from a web server named example.com:

```
hostname(config)# aaa-server testgrp1 host example.com
hostname(config-aaa-server-host)# auth-cookie-name SMSESSION
hostname(config-aaa-server-host)#
```

Related Commands

Command	Description
action-uri	Specifies a web server URI to receive a username and password for single sign-on authentication.
hidden-parameter	Creates hidden parameters for exchange with the authenticating web server.
password-parameter	Specifies the name of the HTTP POST request parameter in which a user password must be submitted for SSO authentication.
start-url	Specifies the URL at which to retrieve a pre-login cookie.
user-parameter	Specifies that a username parameter must be submitted as part of the HTTP POST request used for SSO authentication.

authenticated-session-username

To specify which authentication username to associate with the session when double authentication is enabled, use the **authenticated-session-username** command in tunnel-group general-attributes mode. To remove the attribute from the configuration, use the **no** form of this command.

authenticated-session-username {**primary** | **secondary**}

no authenticated-session-username

Syntax Description

primary	Uses the username from the primary authentication server.
secondary	Uses the username from the secondary authentication server.

Defaults

The default value is **primary**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Tunnel-group general-attributes configuration	•	—	•	—	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

This command is meaningful only when double authentication is enabled. The **authenticated-session-username** command selects the authentication server from which the ASA extracts the username to associate with the session.

Examples

The following example, entered in global configuration mode, creates an IPsec remote access tunnel group named remotegrp and specifies the use of the username from the secondary authentication server for the connection:

```
hostname(config)# tunnel-group remotegrp type ipsec_ra
hostname(config)# tunnel-group remotegrp general-attributes
hostname(config-tunnel-webvpn)# authenticated-session-username secondary
hostname(config-tunnel-webvpn)#
```

Related Commands

Command	Description
pre-fill-username	Enables the prefill username feature.
show running-config tunnel-group	Shows the indicated tunnel-group configuration.
tunnel-group general-attributes	Specifies the general attributes for the named tunnel group.
username-from-certificate	Specifies the field in a certificate to use as the username for authorization.

authentication-attr-from-server

To specify which authentication server authorization attributes to apply to the connection when double authentication is enabled, use the **authentication-attr-from-server** command in tunnel-group general-attributes mode. To remove the attribute from the configuration, use the **no** form of this command.

authentication-attr-from-server {**primary** | **secondary**}

no authentication-attr-from-server

Syntax Description

primary	Uses the primary authentication server.
secondary	Uses the secondary authentication server.

Defaults

The default value is **primary**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group general-attributes configuration	•	—	•	—	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

This command is meaningful only when double authentication is enabled. The **authentication-attr-from-server** command selects the authentication server from which the ASA extracts the authorization attributes to be applied to the connection.

Examples

The following example, entered in global configuration mode, creates an IPsec remote access tunnel group named remotegrp and specifies that the authorization attributes to be applied to the connection must come from the secondary authentication server:

```
hostname(config)# tunnel-group remotegrp type ipsec_ra
hostname(config)# tunnel-group remotegrp general-attributes
hostname(config-tunnel-webvpn)# authentication-attr-from-server secondary
hostname(config-tunnel-webvpn)#
```

Related Commands

Command	Description
pre-fill-username	Enables the prefill username feature.
show running-config tunnel-group	Shows the indicated tunnel-group configuration.
tunnel-group general-attributes	Specifies the general attributes for the named tunnel group.
username-from-certificate	Specifies the field in a certificate to use as the username for authorization.

authentication-certificate

To request a certificate from a WebVPN client establing a connection, use the **authentication-certificate** command in webvpn configuration mode. To cancel the requirement for a client certificate, use the **no** form of this command.

authentication-certificate *interface-name*

no authentication-certificate [*interface-name*]

Syntax Description

interface-name	The name of the interface used to establish the connection. Available interfaces names are: • **inside** Name of interface GigabitEthernet0/1 • **outside** Name of interface GigabitEthernet0/0

Defaults

If you omit the **authentication-certificate** command, client certificate authentication is disabled. If you do not specify an interface name with the **authentication-certificate** command, the default interface name is **inside**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

For this command to take effect, WebVPN must already be enabled on the corresponding interface. An interface is configured and named with the **interface**, **IP address**, and **nameif** commands.

This command applies only to WebVPN client connections; however, the ability to specify client certificate authentication for management connections with the **http authentication-certificate** command is available on all platforms, including those that do not support WebVPN.

The ASA validates certificates using the PKI trustpoints. If a certificate does not pass validation, then one of the following actions occurs:

If:	Then:
The local CA embedded in the ASA is not enabled.	The ASA closes the SSL connection.
The local CA is enabled, and AAA authentication is not enabled.	The ASA redirects the client to the certificate enrollment page for the local CA to obtain a certificate.
Both the local CA and AAA authentication are enabled.	The client is redirected to a AAA authentication page. If configured, the client also is presented with a link to the enrollment page for the local CA.

Examples

The following example configures certificate authentication for WebVPN user connections on the outside interface:

```
hostname(config)# webvpn
hostname(config-webvpn)# authentication-certificate outside
hostname(config-webvpn)#
```

Related Commands

Command	Description
authentication (tunnel-group webvpn configuration mode)	Specifies that the members of a tunnel group must use a digital certificate for authentication.
http authentication-certificate	Specifies authentication by means of certificate for ASDM management connections to the ASA.
interface	Configures the interface used to establish the connection
show running-config ssl	Displays the current set of configured SSL commands.
ssl trust-point	Configures the SSL certificate trustpoint.

authentication-exclude

To enable end users to browse to configured links without logging in to clientless SSL VPN, enter the **authentication-exclude** command in webvpn configuration mode. Use this command multiple times to permit acccess to multiple sites.

authentication-exclude *url-fnmatch*

Syntax Description

url-fnmatch	Identifies the link to exempt from the requirement to log in to a clientless SSL VPN.

Command Default

Disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

This feature is useful when you require some internal resources to be available for public use via SSL VPN.

You need to distribute information about the links to end users in an SSL VPN-mangled form, for example, by browsing to these resources using SSL VPN and copying the resulting URLs into the information about links that you distribute.

Examples

The following example shows how to exempt two sites from authentication requirements:

```
hostname(config)# webvpn
hostname(config-webvpn)# authentication-exclude http://www.example.com/public/*
hostname(config-webvpn)# authentication-exclude *example.html
hostname(config-webvpn)# hostname #
```

authentication

To configure the authentication method for WebVPN and e-mail proxies, use the **authentication** command in various modes. To restore the default method, use the **no** form of this command. The ASA authenticates users to verify their identity.

authentication {[**aaa**] [**certificate**] [**mailhost**] [**piggyback**]}

no authentication [**aaa**] [**certificate**] [**mailhost**] [**piggyback**]

Syntax Description

aaa	Provides a username and password that the ASA checks with a previously configured AAA server.
certificate	Provides a certificate during SSL negotiation.
mailhost	Authenticates via the remote mail server for SMTPS only. For IMAP4S and POP3S, mailhost authentication is mandatory and not displayed as a configurable option.
piggyback	Requires that an HTTPS WebVPN session already exist. Piggyback authentication is available for e-mail proxies only.

Defaults

The following table shows the default authentication methods for WebVPN and e-mail proxies:

Protocol	Default Authentication Method
IMAP4S	Mailhost (required)
POP3S	Mailhost (required)
SMTPS	AAA
WebVPN	AAA

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Imap4s configuration	•	—	•	—	—
Pop3s configuration	•	—	•	—	—
Smtps configuration	•	—	•	—	—
Webvpn configuration	•		•		

Command History

Release	Modification
8.0(2)	This command was introduced.

Release	Modification
7.1(1)	This command was deprecated in webvpn configuration mode and moved to tunnel-group webvpn-attributes configuration mode for WebVPN.
8.0(2)	This command was modified to reflect changes to certificate authentication requirements.

Usage Guidelines

At least one authentication method is required. For WebVPN, for example, you can specify AAA authentication, certificate authentication, or both. You can enter these commands in either order.

WebVPN certificate authentication requires that HTTPS user certificates be required for the respective interfaces. That is, for this selection to be operational, before you can specify certificate authentication, you must have specified the interface in an **authentication-certificate** command.

If you enter this command in webvpn configuration mode, it is transformed into the same command in tunnel-group webvpn-attributes configuration mode.

For WebVPN, you can require both AAA and certificate authentication. In this case, users must provide both a certificate and a username and password. For e-mail proxy authentication, you can require more than one authentication method. Specifying the command again overwrites the current configuration.

Examples

The following example shows how to require that WebVPN users provide certificates for authentication:

```
hostname(config)# webvpn
hostname(config-webvpn)# authentication certificate
```

Related Commands

Command	Description
authentication-certificate	Requests a certificate from a WebVPN client establishing a connection.
show running-config	Displays the current tunnel group configuration.
clear configure aaa	Removes or resets the configured AAA values.
show running-config aaa	Displays the AAA configuration.

authentication eap-proxy

For L2TP over IPsec connections, to enable EAP and permit the ASA to proxy the PPP authentication process to an external RADIUS authentication server, use the **authentication eap-proxy** command in tunnel-group ppp-attributes configuration mode. To return the command to its default setting (permit CHAP and MS-CHAP), use the **no** form of this command.

authentication eap-proxy

no authentication eap-proxy

Syntax Description

This command has no keywords or arguments.

Defaults

By default, EAP is not a permitted authentication protocol.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group ppp-attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

You can apply this attribute only to the L2TP or IPsec tunnel group type.

Examples

The following example entered in config-ppp configuration mode, permits EAP for PPP connections for the tunnel group named ppremotegrp:

```
hostname(config)# tunnel-group ppremotegrp type IPSec/IPSec
hostname(config)# tunnel-group ppremotegrp ppp-attributes
hostname(config-ppp)# authentication eap
hostname(config-ppp)#
```

Related Commands

Command	Description
clear configure tunnel-group	Clears all configured tunnel groups.

Command	Description
show running-config tunnel-group	Shows the indicated certificate map entry.
tunnel-group-map default-group	Associates the certificate map entries created using the **crypto ca certificate map** command with tunnel groups.

authentication key eigrp

To enable authentication of EIGRP packets and specify the authentication key, use the **authentication key eigrp** command in interface configuration mode. To disable EIGRP authentication, use the **no** form of this command.

authentication key eigrp *as-number key* **key-id** *key-id*

no authentication key eigrp *as-number*

Syntax Description

as-number	The autonomous system number of the EIGRP process being authenticated. This must be the same value as configured for the EIGRP routing process.
key	Key to authenticate EIGRP updates. The key can contain up to 16 characters.
key-id *key-id*	Key identification value; valid values range from 1 to 255.

Defaults

EIGRP authentication is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

You must configure both the **authentication mode eigrp** and the **authentication key eigrp** commands on an interface to enable EIGRP message authentication. Use the **show running-config interface** command to view the **authentication** commands configured on an interface.

Examples

The following examples shows EIGRP authentication configured on interface GigabitEthernet0/3:

```
hostname(config)# interface Gigabit0/3
hostname(config-if)# authentication mode eigrp md5
hostname(config-if)# authentication key eigrp 100 thisismykey key_id 5
```

Related Commands

Command	Description
authentication mode eigrp	Specifies the type of authentication used for EIGRP authentication.

authentication mode eigrp

To specify the type of authentication used for EIGRP authentication, use the **authentication mode eigrp** command in interface configuration mode. To restore the default authentication method, use the **no** form of this command.

authentication mode eigrp *as-num* **md5**

no authentication mode eigrp *as-num* **md5**

Syntax Description

as-num	The autonomous system number of the EIGRP routing process.
md5	Uses MD5 for EIGRP message authentication.

Defaults

No authentication is provided by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

You must configure both the **authentication mode eigrp** and the **authentication key eigrp** commands on an interface to enable EIGRP message authentication. Use the **show running-config interface** command to view the **authentication** commands configured on an interface.

Examples

The following examples shows EIGRP authentication configured on interface GigabitEthernet0/3:

```
hostname(config)# interface GigabitEthernet0/3
hostname(config-if)# authentication mode eigrp 100 md5
hostname(config-if)# authentication key eigrp 100 thisismykey key_id 5
```

Related Commands

Command	Description
authentication key eigrp	Enables authentication of EIGRP packets and specifies the authentication key.

authentication ms-chap-v1

For L2TP over IPsec connections, to enable Microsoft CHAP, Version 1 authentication for PPP, use the **authentication ms-chap-v1** command in tunnel-group ppp-attributes configuration mode.To return the command to its default setting (permit CHAP and MS-CHAP), use the **no** form of this command. To disable Microsoft CHAP, Version 1, use the **no** form of this command.

authentication ms-chap-v1

no authentication ms-chap-v1

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group ppp-attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

You can apply this attribute only to the L2TP or IPsec tunnel-group type. This protocol is similar to CHAP, but more secure in that the server stores and compares only encrypted passwords rather than cleartext passwords as in CHAP. This protocol also generates a key for data encryption by MPPE.

Related Commands

Command	Description
clear configure tunnel-group	Clears the entire tunnel-group database or just the specified tunnel group.
show running-config tunnel-group	Displays the currently running tunnel-group configuration for a specified tunnel group or for all tunnel groups.
tunnel-group	Creates and manages the database of connection-specific records for IPsec and WebVPN tunnels.

authentication ms-chap-v2

For L2TP over IPsec connections, to enable Microsoft CHAP, Version 2 authentication for PPP, use the **authentication ms-chap-v1** command in tunnel-group ppp-attributes configuration mode. To return the command to its default setting (permit CHAP and MS-CHAP), use the **no** form of this command.

authentication ms-chap-v2

no authentication ms-chap-v2

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group ppp-attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

You can apply this attribute only to the L2TP or IPsec tunnel-group type.

This protocol is similar to CHAP but more secure in that the server stores and compares only encrypted passwords rather than clear text passwords as in CHAP. This protocol also generates a key for data encryption by MPPE.

Related Commands

Command	Description
clear configure tunnel-group	Clears the entire tunnel group database or just the specified tunnel group.
show running-config tunnel-group	Displays the currently running tunnel-group configuration for a specified tunnel group or for all tunnel groups.
tunnel-group	Creates and manages the database of connection-specific records for IPsec and WebVPN tunnels.

authentication pap

For L2TP over IPsec connections, to permit PAP authentiation for PPP, use the **authentication pap** command in tunnel-group ppp-attributes configuration mode. To return the command to its default setting (permit CHAP and MS-CHAP), use the **no** form of this command.

authentication pap

no authentication pap

Syntax Description

This command has no keywords or arguments.

Defaults

By default, PAP is not a permitted authentication protocol.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group ppp-attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

You can apply this attribute only to the L2TP or IPsec tunnel group type.

This protocol passes the clear text username and password during authentication and is not secure.

Examples

The following example entered in config-ppp configuration mode, permits PAP for PPP connections for a tunnel group named ppremotegrps:

```
hostname(config)# tunnel-group ppremotegrp type IPSec/IPSec
hostname(config)# tunnel-group ppremotegrp ppp-attributes
hostname(config-ppp)# authentication pap
hostname(config-ppp)#
```

Related Commands

Command	Description
clear configure tunnel-group	Clears all configured tunnel groups.

Command	Description
show running-config tunnel-group	Shows the indicated certificate map entry.
tunnel-group-map default-group	Associates the certificate map entries created using the **crypto ca certificate map** command with tunnel groups.

authentication-certificate

To request a certificate from a WebVPN client establishing a connection, use the **authentication-certificate** command in webvpn configuration mode. To cancel the requirement for a client certificate, use the **no** form of this command.

authentication-certificate *interface-name*

no authentication-certificate [*interface-name*]

Syntax Description

interface-name	The name of the interface used to establish the connection. Available interfaces names are: • **inside** Name of interface GigabitEthernet0/1 • **outside** Name of interface GigabitEthernet0/0

Defaults

If you omit the **authentication-certificate** command, client certificate authentication is disabled. If you do not specify an interface name with the **authentication-certificate** command, the default interface-name is **inside**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

For this command to take effect, WebVPN must already be enabled on the corresponding interface. An interface is configured and named with the **interface**, **IP address**, and **nameif** commands.

This command applies only to WebVPN client connections; however, the ability to specify client certificate authentication for management connections with the **http authentication-certificate** command is available on all platforms, including the platforms that do not support WebVPN.

The ASA validates certificates with the PKI trustpoints. If a certificate does not pass validation, then one of the following actions occurs:

If:	Then:
The local CA embedded in the ASA is not enabled.	The ASA closes the SSL connection.
The local CA is enabled, and AAA authentication is not enabled.	The ASA redirects the client to the certificate enrollment page for the local CA to obtain a certificate.
Both the local CA and AAA authentication are enabled.	The client is redirected to a AAA authentication page. If configured, the client also is presented with a link to the enrollment page for the local CA.

Examples

The following example configures certificate authentication for WebVPN user connections on the outside interface:

```
hostname(config)# webvpn
hostname(config-webvpn)# authentication-certificate outside
hostname(config-webvpn)#
```

Related Commands

Command	Description
authentication (tunnel-group webvpn configuration mode)	Specifies that the members of a tunnel group must use a digital certificate for authentication.
http authentication-certificate	Specifies authentication by means of certificate for ASDM management connections to the ASA.
interface	Configures the interface used to establish the connection.
show running-config ssl	Displays the current set of configured SSL commands.
ssl trust-point	Configures the SSL certificate trustpoint.

authentication-port

To specify the port number used for RADIUS authentication for this host, use the **authentication-port** command in aaa-server configuration host configuration mode. To remove the authentication port specification, use the **no** form of this command.

authentication-port *port*

no authentication-port

Syntax Description

port	A port number, in the range 1-65535, for RADIUS authentication.

Defaults

By default, the device listens for RADIUS on port 1645 (in compliance with RFC 2058). If the port is not specified, the RADIUS authentication default port number 1645 is used.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server host configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	Semantic change to the command to support the specification of server ports on a per-host basis for server groups that contain RADIUS servers.

Usage Guidelines

This command specifies the destination TCP/UDP port number of the remote RADIUS server hosts to which you want to assign authentication functions. If your RADIUS authentication server uses a port other than 1645, you must configure the ASA for the appropriate port before starting the RADIUS service with the **aaa-server** command.

This command is valid only for server groups that are configured for RADIUS.

Examples

The following example configures a RADIUS AAA server named “srvgrp1” on host “1.2.3.4”, sets a timeout of 9 seconds, sets a retry interval of 7 seconds, and configures authentication port 1650.

```
hostname(config)# aaa-server svrgrp1 protocol radius
hostname(config-aaa-server-group)# aaa-server svrgrp1 host 1.2.3.4
hostname(config-aaa-server-host)# timeout 9
hostname(config-aaa-server-host)# retry-interval 7
hostname(config-aaa-server-host)# authentication-port 1650
hostname(config-aaa-server-host)# exit
hostname(config)#
```

Related Commands

Command	Description
aaa authentication	Enables or disables LOCAL, TACACS+, or RADIUS user authentication on a server designated by the **aaa-server** command or by ASDM user authentication.
aaa-server host	Enters aaa-server host configuration mode, so you can configure AAA server parameters that are host-specific.
clear configure aaa-server	Removes all AAA command statements from the configuration.
show running-config aaa-server	Displays AAA server statistics for all AAA servers, for a particular server group, for a particular server within a particular group, or for a particular protocol.

authentication-server-group (imap4s, pop3s, smtps)

To specify the set of authentication servers to use for e-mail proxies, use the **authentication-server-group** command in various modes. To remove authentication servers from the configuration, use the **no** form of this command.

authentication-server-group *group_tag*

no authentication-server-group

Syntax Description

group_tag	Identifies the previously configured authentication server or group of servers.

Defaults

No authentication servers are configured by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Imap4s configuration	•	—	•	—	—
Pop3s configuration	•	—	•	—	—
Smtps configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The ASA authenticates users to verify their identity.

If you configure AAA authentication, you must configure this attribute as well. Otherwise, authentication always fails.

Use the **aaa-server** command to configure authentication servers.

Examples

The following example shows how to configure an IMAP4S e-mail proxy to use the set of authentication servers named “IMAP4SSVRS”:

```
hostname(config)# imap4s
hostname(config-imap4s)# authentication-server-group IMAP4SSVRS
```

Related Commands

Command	Description
aaa-server host	Configures authentication, authorization, and accounting servers.

authentication-server-group (tunnel-group general-attributes)

To specify the AAA server group to use for user authentication for a tunnel group, use the **authentication-server-group** command in tunnel-group general-attributes configuration mode. To return this attribute to the default, use the **no** form of this command.

authentication-server-group [(*interface_name*)] *server_group* [**LOCAL**]

no authentication-server-group [(*interface_name*)] *server_group*

Syntax Description

interface_name	(Optional) Specifies the interface at which the IPsec tunnel terminates.
LOCAL	(Optional) Requires authentication with the local user database if all of the servers in the server group have been deactivated due to communication failures.
server_group	Identifies the previously configured authentication server or group of servers.

Defaults

The default setting for the server-group in this command is **LOCAL**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group general-attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.1(1)	This command was deprecated in webvpn configuration mode and moved to tunnel-group general-attributes configuration mode.
8.0(2)	This command was enhanced to allow per-interface authentication for IPsec connections.

Usage Guidelines

You can apply this attribute to all tunnel-group types.

Use the **aaa-server** command to configure authentication servers and the **aaa-server-host** command to add servers to a previously configured AAA server group.

Examples

The following example entered in config-general configuration mode, configures an authentication server group named aaa-server456 for an IPsec remote access tunnel group named remotegrp:

```
hostname(config)# tunnel-group remotegrp type ipsec-ra
```

```
hostname(config)# tunnel-group remotegrp general-attributes
hostname(config-tunnel-general)# authentication-server-group aaa-server456
hostname(config-tunnel-general)#
```

Related Commands

Command	Description
aaa-server	Creates a AAA server group and configures AAA server parameters that are group-specific and common to all group hosts.
aaa-server host	Adds servers to a previously configured AAA server group and configures host-specific AAA server parameters.
clear configure tunnel-group	Clears all configured tunnel groups.
show running-config tunnel-group	Shows the tunnel group configuration for all tunnel groups or for a particular tunnel group.

authorization-required

To require users to authorize successfully prior to connecting, use the **authorization-required** command in various modes. To remove the attribute from the configuration, use the **no** form of this command.

authorization-required

no authorization-required

Syntax Description

This command has no arguments or keywords.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Imap4s configuration	•	—	•	—	—
Pop3s configuration	•	—	•	—	—
Smtps configuration	•	—	•	—	—
Tunnel-group general-attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.1(1)	This command was deprecated in webvpn configuration mode and moved to tunnel-group general-attributes configuration mode.
7.2(1)	Replaced the webvpn configuration mode with the imap4s, pop3s, and smtps configuration modes.

Examples

The following example, entered in global configuration mode, requires authorization based on the complete DN for users connecting through a remote access tunnel group named remotegrp. The first command configures the tunnel-group type as ipsec_ra (IPsec remote access) for the remote group named remotegrp. The second command enters tunnel-group general-attributes configuration mode for the specified tunnel group, and the last command specifies that authorization is required for the named tunnel group.

```
hostname(config)# tunnel-group remotegrp type ipsec_ra
hostname(config)# tunnel-group remotegrp general-attributes
hostname(config-tunnel-general)# authorization-required
hostname(config-tunnel-general)#
```

Related Commands

Command	Description
authorization-dn-attributes	Specifies the primary and secondary subject DN fields to use as the username for authorization.
clear configure tunnel-group	Clears all configured tunnel groups.
show running-config tunnel-group	Shows the indicated certificate map entry.
tunnel-group general-attributes	Specifies the general attributes for the named tunnel group.

authorization-server-group

To specify the set of authorization servers to use with WebVPN and e-mail proxies, use the **authorization-server-group** command in various modes. To remove authorization servers from the configuration, use the **no** form of this command.

authorization-server-group *group_tag*

no authorization-server-group

Syntax Description

group_tag	Identifies the previously configured authorization server or group of servers. Use the **aaa-server** command to configure authorization servers.

Defaults

No authorization servers are configured by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Imap4s configuration	•	—	•	—	—
Pop3s configuration	•	—	•	—	—
Smtps configuration	•	—	•	—	—
Tunnel-group general-attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.1(1)	This command was deprecated in webvpn configuration mode and moved to tunnel-group general-attributes configuration mode.

Usage Guidelines

The ASA uses authorization to verify the level of access to network resources that users are permitted.

If you enter this command in webvpn configuration mode, it is transformed into the same command in tunnel-group general-attributes mode.

When VPN authorization is defined as LOCAL, the attributes configured in the default group policy DfltGrpPolicy are enforced.

Examples

The following example shows how to configure POP3S e-mail proxy to use the set of authorization servers named “POP3Spermit”:

```
hostname(config)# pop3s
hostname(config-pop3s)# authorization-server-group POP3Spermit
```

The following example entered in tunnel-general configuration mode, configures an authorization server group named “aaa-server78” for an IPsec remote-access tunnel group named “remotegrp”:

```
hostname(config)# tunnel-group remotegrp type ipsec-ra
hostname(config)# tunnel-group remotegrp general-attributes
hostname(config-tunnel-general)# authorization-server-group aaa-server78
hostname(config-tunnel-general)#
```

Related Commands

Command	Description
aaa-server host	Configures authentication, authorization, and accounting servers.
clear configure tunnel-group	Clears all configured tunnel groups.
show running-config tunnel-group	Shows the tunnel group configuration for all tunnel groups or for a particular tunnel group.
tunnel-group general-attributes	Specifies the general attributes for the named tunnel group.

auth-prompt

To specify or change the AAA challenge text for through-the-ASA user sessions, use the **auth-prompt** command in global configuration mode. To remove the authentication challenge text, use the **no** form of this command.

auth-prompt prompt [**prompt** | **accept** | **reject**] *string*

no auth-prompt prompt [**prompt** | **accept** | **reject**]

Syntax Description

accept	If a user authentication via Telnet is accepted, displays the prompt *string*.
prompt	The AAA challenge prompt string follows this keyword.
reject	If a user authentication via Telnet is rejected, displays the prompt *string*.
string	A string of up to 235 alphanumeric characters or 31 words, limited by whichever maximum is first reached. Special characters, spaces, and punctuation characters are permitted. Entering a question mark or pressing the **Enter** key ends the string. (The question mark appears in the string.)

Defaults

If you do not specify an authentication prompt:

- FTP users see `FTP authentication`.
- HTTP users see `HTTP Authentication`.
- Telnet users see no challenge text.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	Minor semantic changes.

Usage Guidelines

The **auth-prompt** command lets you specify the AAA challenge text for HTTP, FTP, and Telnet access through the ASA when requiring user authentication from TACACS+ or RADIUS servers. This text is primarily for cosmetic purposes and displays above the username and password prompts that users see when logging in.

If user authentication occurs from Telnet, you can use the **accept** and **reject** options to display different status prompts to indicate that the authentication attempt is accepted or rejected by the AAA server.

If the AAA server authenticates the user, the ASA displays the **auth-prompt accept** text, if specified, to the user; otherwise, it displays the **reject** text, if specified. Authentication of HTTP and FTP sessions displays only the challenge text at the prompt. The **accept** and **reject** text do not appear.

Note Microsoft Internet Explorer displays up to 37 characters in an authentication prompt. Telnet and FTP display up to 235 characters in an authentication prompt.

Examples

The following example sets the authentication prompt to the string "Please enter your username and password.":

```
hostname(config)# auth-prompt prompt Please enter your username and password
```

After this string is added to the configuration, users see the following:

```
Please enter your username and password
User Name:
Password:
```

For Telnet users, you can also provide separate messages to display when the ASA accepts or rejects the authentication attempt; for example:

```
hostname(config)# auth-prompt reject Authentication failed. Try again.
hostname(config)# auth-prompt accept Authentication succeeded.
```

The following example sets the authentication prompt for a successful authentication to the string, "You're OK."

```
hostname(config)# auth-prompt accept You're OK.
```

After successfully authenticating, the user sees the following message:

```
You're OK.
```

Related Commands

Command	Description
clear configure auth-prompt	Removes the previously specified authentication prompt challenge text and reverts to the default value, if any.
show running-config auth-prompt	Displays the current authentication prompt challenge text.

auto-signon

To configure the ASA to automatically pass user login credentials for clientless SSL VPN connections on to internal servers, use the **auto-signon** command in any of three modes: webvpn configuration, webvpn group configuration, or webvpn username configuration mode. To disable auto-signon to a particular server, use the **no** form of this command with the original **ip**, **uri**, and **auth-type** arguments. To disable auto-signon to all servers, use the **no** form of this command without arguments.

auto-signon allow {**ip** *ip-address ip-mask* | **uri** *resource-mask*} **auth-type** {**basic** | **ftp** | **ntlm** | **all**}

no auto-signon [**allow** {**ip** *ip-address ip-mask* | **uri** *resource-mask*} **auth-type** {**basic** | **ftp** | **ntlm** | **all**}]

Syntax Description

all	Specifies both the NTLM and HTTP Basic authentication methods.
allow	Enables authentication to a particular server.
auth-type	Enables selection of an authentication method.
basic	Specifies the HTTP Basic authentication method.
ftp	Ftp and cifs authentication type.
ip	Specifies that an IP address and mask identifies the servers to be authenticated to.
ip-address	In conjunction with *ip-mask*, identifies the IP address range of the servers to be authenticated to.
ip-mask	In conjunction with *ip-address*, identifies the IP address range of the servers to be authenticated to.
ntlm	Specifies the NTLMv1 authentication method.
resource-mask	Identifies the URI mask of the servers to be authenticated to.
uri	Specifies that a URI mask identifies the servers to be authenticated to.

Defaults

By default, this feature is disabled for all servers.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration (global)	•	—	•	—	—
Webvpn group policy configuration	•	—	•	—	—
Webvpn username configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.
8.0(1)	NTLMv2 support was added. The **ntlm** keyword includes both NTLMv1 and NTLMv2.

Usage Guidelines

The **auto-signon** command is a single sign-on method for clientless SSL VPN users. It passes the login credentials (username and password) to internal servers for authentication using NTLM authentication, HTTP Basic authentication, or both. Multiple auto-signon commands can be entered and are processed according to the input order (early commands take precedence).

You can use the auto-signon feature in three modes: webvpn configuration group-policy, webvpn configuration, or webvpn username configuration mode. The typical precedence behavior applies, where username supersedes group, and group supersedes global. The mode you choose depends on the desired scope of authentication:

Mode	Scope
Webvpn configuration	All WebVPN users globally
Webvpn group configuration	A subset of WebVPN users defined by a group policy
Webvpn username configuration	An individual WebVPN user

Examples

The following example configures auto-signon for all clientless users, using NTLM authentication, to servers with IP addresses ranging from 10.1.1.0 to 10.1.1.255:

```
hostname(config)# webvpn
hostname(config-webvpn)# auto-signon allow ip 10.1.1.0 255.255.255.0 auth-type ntlm
```

The following example configures auto-signon for all clientless users, using HTTP Basic authentication, to servers defined by the URI mask https://*.example.com/*:

```
hostname(config)# webvpn
hostname(config-webvpn)# auto-signon allow uri https://*.example.com/* auth-type basic
```

The following example configures auto-signon for clientless users ExamplePolicy group policy, using either HTTP Basic or NTLM authentication, to servers defined by the URI mask https://*.example.com/*:

```
hostname(config)# group-policy ExamplePolicy attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# auto-signon allow uri https://*.example.com/* auth-type all
```

The following example configures auto-signon for a user named Anyuser, using HTTP Basic authentication, to servers with IP addresses ranging from 10.1.1.0 to 10.1.1.255:

```
hostname(config)# username Anyuser attributes
hostname(config-username)# webvpn
hostname(config-username-webvpn)# auto-signon allow ip 10.1.1.0 255.255.255.0 auth-type
basic
```

Related Commands

Command	Description
show running-config webvpn auto-signon	Displays auto-signon assignments of the running configuration.

auto-summary

To enable the automatic summarization of subnet routes into network-level routes, use the **auto-summary** command in router configuration mode. To disable route summarization, use the **no** form of this command.

auto-summary

no auto-summary

Syntax Description

This command has no arguments or keywords.

Defaults

Route summarization is enabled for RIP Version 1, RIP Version 2, and EIGRP.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.
8.0(2)	Support for EIGRP was added.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

Route summarization reduces the amount of routing information in the routing tables.

RIP Version 1 always uses automatic summarization. You cannot disable automatic summarization for RIP Version 1.

If you are using RIP Version 2, you can turn off automatic summarization by specifying the **no auto-summary** command. Disable automatic summarization if you must perform routing between disconnected subnets. When automatic summarization is disabled, subnets are advertised.

EIGRP summary routes are given an administrative distance value of 5. You cannot configure this value.

Only the **no** form of this command appears in the running configuration.

Examples

The following example disables RIP route summarization:

```
hostname(config)# router rip
hostname(config-router)# network 10.0.0.0
hostname(config-router)# version 2
hostname(config-router)# no auto-summary
```

The following example disables automatic EIGRP route summarization:

```
hostname(config)# router eigrp 100
hostname(config-router)# network 10.0.0.0
hostname(config-router)# no auto-summary
```

Related Commands

Command	Description
clear configure router	Clears all **router** commands and router configuration mode commands from the running configuration.
router eigrp	Enables the EIGRP routing process and enters EIGRP router configuration mode.
router rip	Enables the RIP routing process and enters RIP router configuration mode.
show running-config router	Displays the **router** commands and router configuration mode commands in the running configuration.

auto-update device-id

To configure the ASA device ID for use with an Auto Update Server, use the **auto-update device-id** command in global configuration mode. To remove the device ID, use the **no** form of this command.

auto-update device-id [**hardware-serial** | **hostname** | **ipaddress** [*if_name*] | **mac-address** [*if_name*] | **string** *text*]

no auto-update device-id [**hardware-serial** | **hostname** | **ipaddress** [*if_name*] | **mac-address** [*if_name*] | **string** *text*]

Syntax Description

hardware-serial	Uses the hardware serial number of the ASA to uniquely identify the device.
hostname	Uses the hostname of the ASA to uniquely identify the device.
ipaddress [*if_name*]	Uses the IP address of the ASA to uniquely identify the ASA. By default, the ASA uses the interface used to communicate with the Auto Update Server. If you want to use a different IP address, specify the *if_name* option.
mac-address [*if_name*]	Uses the MAC address of the ASA to uniquely identify the ASA. By default, the ASA uses the MAC address of the interface used to communicate with the Auto Update Server. If you want to use a different MAC address, specify the *if_name* option.
string *text*	Specifies the text string to uniquely identify the device to the Auto Update Server.

Defaults

The default ID is the hostname.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example sets the device ID to the serial number:

```
hostname(config)# auto-update device-id hardware-serial
```

Related Commands

auto-update poll-period	Sets how often the ASA checks for updates from an Auto Update Server.
auto-update server	Identifies the Auto Update Server.
auto-update timeout	Stops traffic from passing through the ASA if the Auto Update Server is not contacted within the timeout period.
clear configure auto-update	Clears the Auto Update Server configuration.
show running-config auto-update	Shows the Auto Update Server configuration.

auto-update poll-at

To schedule a specific time for the ASA to poll the Auto Update Server, use the **auto-update poll-at** command in global configuration mode. To remove all specified scheduling times for the ASA to poll the Auto Update Server, use the **no** form of this command.

auto-update poll-at *days-of-the-week time* [**randomize** *minutes*] [*retry_count* [*retry_period*]]

no auto-update poll-at *days-of-the-week time* [**randomize** *minutes*] [*retry_count* [*retry_period*]]

Syntax Description

days-of-the-week	Any single day or combination of days: Monday, Tuesday, Wednesday, Thursday, Friday, Saturday and Sunday. Other possible values are daily (Monday through Sunday), weekdays (Monday through Friday) and weekend (Saturday and Sunday).
randomize *minutes*	Specifies the period to randomize the poll time following the specified start time. from from 1 to 1439 minutes.
retry_count	Specifies how many times to try reconnecting to the Auto Update Server if the first attempt fails. The default is 0.
retry_period	Specifies how long to wait between connection attempts. The default is 5 minutes. The range is from 1 and 35791 minutes.
time	Specifies the time in the format HH:MM at which to start the poll. For example, 8:00 is 8:00 AM and 20:00 is 8:00 PM.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The **auto-update poll-at** command specifies a time at which to poll for updates. If you enable the **randomize** option, the polling occurs at a random time within the range of the first *time* option and the specified number of minutes. The **auto-update poll-at** and **auto-update poll-period** commands are mutually exclusive. Only one of them can be configured.

Examples

In the following example, the ASA polls the Auto Update Server every Friday and Saturday night at a random time between 10:00 p.m. and 11:00 p.m. If the ASA is unable to contact the server, it tries two more times every 10 minutes.

```
hostname(config)# auto-update poll-at Friday Saturday 22:00 randomize 60 2 10
hostname(config)# auto-update server http://192.168.1.114/aus/autoupdate.asp
```

Related Commands

auto-update device-id	Sets the ASA device ID for use with an Auto Update Server.
auto-update poll-period	Sets how often the ASA checks for updates from an Auto Update Server.
auto-update timeout	Stops traffic from passing through the ASA if the Auto Update Server is not contacted within the timeout period.
clear configure auto-update	Clears the Auto Update Server configuration.
management-access	Enables access to an internal management interface on the ASA.
show running-config auto-update	Shows the Auto Update Server configuration.

auto-update poll-period

To configure how often the ASA checks for updates from an Auto Update Server, use the **auto-update poll-period** command in global configuration mode. To reset the parameters to the defaults, use the **no** form of this command.

auto-update poll-period *poll_period* [*retry_count* [*retry_period*]]

no auto-update poll-period *poll_period* [*retry_count* [*retry_period*]]

Syntax Description

poll_period	Specifies how often, in minutes, to poll an Auto Update Server, between 1 and 35791. The default is 720 minutes (12 hours).
retry_count	Specifies how many times to try reconnecting to the Auto Update Server if the first attempt fails. The default is 0.
retry_period	Specifies how long to wait, in minutes, between connection attempts, between 1 and 35791. The default is 5 minutes.

Defaults

The default poll period is 720 minutes (12 hours).

The default number of times to try reconnecting to the Auto Update Server if the first attempt fails is 0.

The default period to wait between connection attempts is 5 minutes.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **auto-update poll-at** and **auto-update poll-period** commands are mutually exclusive. Only one of them can be configured.

Examples

The following example sets the poll period to 360 minutes, the retries to 1, and the retry period to 3 minutes:

```
hostname(config)# auto-update poll-period 360 1 3
```

Related Commands

auto-update device-id	Sets the ASA device ID for use with an Auto Update Server.
auto-update server	Identifies the Auto Update Server.
auto-update timeout	Stops traffic from passing through the ASA if the Auto Update Server is not contacted within the timeout period.
clear configure auto-update	Clears the Auto Update Server configuration.
show running-config auto-update	Shows the Auto Update Server configuration.

auto-update server

To identify the Auto Update Server, use the **auto-update server** command in global configuration mode. To remove the server, use the **no** form of this command.

auto-update server *url* [**source** *interface*] [*verify-certificate*]

no auto-update server *url* [**source** *interface*] [*verify-certificate*]

Syntax Description

source *interface*	Specifies which interface for the source IP address to use when sending requests to the Auto Update Server.
url	Specifies the location of the Auto Update Server using the following syntax: **http**[**s**]**:**[[*user:password@*]*location* [:*port*]] **/** *pathname*
verify_certificate	Verifies the certificate returned by the Auto Update Server.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	The command was modified to add support for multiple servers.

Usage Guidelines

The ASA periodically contacts the Auto Update Server for any configuration, operating system, and ASDM updates.

You can configure multiple servers to work with auto-update. When checking for updates, a connection is made to the first server, but if that fails, then the next server is contacted. This process continues until all the servers have been tried. If all of them fail to connect, then a retry starting with the first server is attempted if the auto-update poll period has been configured to retry the connection.

For auto-update functionality to work correctly, you must use the **boot system configuration** command and ensure that it specifies a valid boot image. In addition, you must use the **asdm image** command with auto-update to update the ASDM software image.

If the interface specified in the **source** *interface* argument is the same interface specified with the **management-access** command, requests to the Auto Update Server are sent over the VPN tunnel.

Examples

The following example sets the Auto Update Server URL and specifies the interface as outside:

```
hostname(config)# auto-update server http://10.1.1.1:1741/ source outside
```

Related Commands

auto-update device-id	Sets the ASA device ID for use with an Auto Update Server.
auto-update poll-period	Sets how often the ASA checks for updates from an Auto Update Server.
auto-update timeout	Stops traffic from passing through the ASA if the Auto Update Server is not contacted within the timeout period.
clear configure auto-update	Clears the Auto Update Server configuration.
management-access	Enables access to an internal management interface on the ASA.
show running-config auto-update	Shows the Auto Update Server configuration.

auto-update timeout

To set a timeout period in which to contact the Auto Update Server, use the **auto-update timeout** command in global configuration mode. To remove the timeout, use the **no** form of this command.

auto-update timeout [*period*]

no auto-update timeout [*period*]

Syntax Description

period	Specifies the timeout period in minutes between 1 and 35791. The default is 0, which means there is no timeout. You cannot set the timeout to 0; use the **no** form of the command to reset it to 0.

Defaults

The default timeout is 0, which sets the ASA to never time out.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

A timeout condition is reported with syslog message 201008.

If the Auto Update Server has not been contacted for the timeout period, the ASA stops all traffic going through it. Set a timeout to ensure that the ASA has the most recent image and configuration.

Examples

The following example sets the timeout to 24 hours:

```
hostname(config)# auto-update timeout 1440
```

Related Commands

auto-update device-id	Sets the ASA device ID for use with an Auto Update Server.
auto-update poll-period	Sets how often the ASA checks for updates from an Auto Update Server.
auto-update server	Identifies the Auto Update Server.

clear configure auto-update	Clears the Auto Update Server configuration.
show running-config auto-update	Shows the Auto Update Server configuration.

backup interface through browse-networks Commands

backup interface

For models with a built-in switch, such as the ASA 5505, use the **backup interface** command in interface configuration mode to identify a VLAN interface as a backup interface, for example, to an ISP. To restore normal operation, use the **no** form of this command.

backup interface vlan *number*

no backup interface vlan *number*

Syntax Description

vlan *number*	Specifies the VLAN ID of the backup interface.

Defaults

By default, the **backup interface** command is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.
7.2(2)	The Security Plus license no longer limits the number of VLAN interfaces to 3 for normal traffic, 1 for a backup interface, and 1 for failover; you can now configure up to 20 interfaces without any other limitations. Therefore ,the **backup interface** command is not required to enable more than 3 interfaces.

Usage Guidelines

This command can be entered in the interface configuration mode for a VLAN interface only. This command blocks all through traffic on the identified backup interface unless the default route through the primary interface goes down.

When you configure Easy VPN with the **backup interface** command, if the backup interface becomes the primary, then the ASA moves the VPN rules to the new primary interface. See the **show interface** command to view the state of the backup interface.

Be sure to configure default routes on both the primary and backup interfaces so that the backup interface can be used when the primary fails. For example, you can configure two default routes: one for the primary interface with a lower administrative distance, and one for the backup interface with a higher distance. See the **dhcp client route distance** command to override the administrative distance for default routes acquired from a DHCP server. To configure dual ISP support, see the **sla monitor** and **track rtr** commands for more information.

You cannot configure a backup interface when the **management-only** command is already configured on the interface.

Examples

The following example configures four VLAN interfaces. The backup-isp interface only allows through traffic when the primary interface is down. The **route** commands create default routes for the primary and backup interfaces, with the backup route at a lower administrative distance.

```
hostname(config)# interface vlan 100
hostname(config-if)# nameif outside
hostname(config-if)# security-level 0
hostname(config-if)# ip address 10.1.1.1 255.255.255.0
hostname(config-if)# backup interface vlan 400
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 200
hostname(config-if)# nameif inside
hostname(config-if)# security-level 100
hostname(config-if)# ip address 10.2.1.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 300
hostname(config-if)# nameif dmz
hostname(config-if)# security-level 50
hostname(config-if)# ip address 10.3.1.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 400
hostname(config-if)# nameif backup-isp
hostname(config-if)# security-level 50
hostname(config-if)# ip address 10.1.2.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config)# interface ethernet 0/0
hostname(config-if)# switchport access vlan 100
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/1
hostname(config-if)# switchport access vlan 200
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/2
hostname(config-if)# switchport access vlan 300
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/3
hostname(config-if)# switchport access vlan 400
hostname(config-if)# no shutdown

hostname(config-if)# route outside 0 0 10.1.1.2 1
hostname(config)# route backup-isp 0 0 10.1.2.2 2
```

Related Commands

Command	Description
forward interface	Restricts an interface from initiating traffic to another interface.
interface vlan	Creates a VLAN interface and enters interface configuration mode.
dhcp client route distance	Overrides the administrative distance for default routes acquired from a DHCP server.
sla monitor	Creates an SLA monitoring operation for static route tracking.
track rtr	Tracks the state of an SLA monitoring operation.

backup-servers

To configure backup servers, use the **backup-servers** command in group-policy configuration mode. To remove a backup server, use the **no** form of this command.

backup-servers {*server1 server2. . . . server10* | **clear-client-config** | **keep-client-config**}

no backup-servers [*server1 server2. . . . server10* | **clear-client-config** | **keep-client-config**]

Syntax Description

clear-client-config	Specifies that the client uses no backup servers. The ASA pushes a null server list.
keep-client-config	Specifies that the ASA sends no backup server information to the client. The client uses its own backup server list, if configured.
server1 server 2.... server10	Provides a space delimited, priority-ordered list of servers for the VPN client to use when the primary ASA is unavailable. Identifies servers by IP address or hostname. The list can be 500 characters long, but can contain only 10 entries.

Defaults

Backup servers do not exist until you configure them, either on the client or on the primary ASA.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To remove the backup-servers attribute from the running configuration, use the **no** form of this command without arguments. This enables inheritance of a value for backup servers from another group policy.

IPsec backup servers let a VPN client connect to the central site when the primary ASA is unavailable. When you configure backup servers, the ASA pushes the server list to the client as the IPsec tunnel is established.

Configure backup servers either on the client or on the primary ASA. If you configure backup servers on the ASA, it pushes the backup server policy to the clients in the group, replacing the backup server list on the client if one is configured.

Note If you are using hostnames, it is wise to have backup DNS and WINS servers on a separate network from that of the primary DNS and WINS servers. Otherwise, if clients behind a hardware client obtain DNS and WINS information from the hardware client via DHCP, the connection to the primary server is lost, and the backup servers have different DNS and WINS information, clients cannot be updated until the DHCP lease expires. In addition, if you use hostnames and the DNS server is unavailable, significant delays can occur.

Examples

The following example shows how to configure backup servers with IP addresses 10.10.10.1 and 192.168.10.14, for the group policy named "FirstGroup":

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# backup-servers 10.10.10.1 192.168.10.14
```

banner

To configure the ASDM, session, login, or message-of-the-day banner, use the **banner** command in global configuration mode. To remove all lines from the banner keyword specified (**exec**, **login**, or **motd**), use the **no** form of this command.

banner {**asdm | exec | login | motd** *text*}

[no] banner {**asdm | exec | login | motd** [*text*]}

Syntax Description

asdm	Configures the system to display a banner after you successfully log in to ASDM. The user is prompted to either continue to complete login, or to disconnect. This option lets you require users to accept the terms of a written policy before connecting.
exec	Configures the system to display a banner before displaying the enable prompt.
login	Configures the system to display a banner before the password login prompt when accessing the ASA using Telnet or a serial console.
motd	Configures the system to display a message-of-the-day banner when you first connect.
text	Line of message text to display.

Defaults

The default is no banner.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.2(4)/8.0(3)	The **asdm** keyword was added.
9.0(1)	The **banner login** command supports serial console connections.

Usage Guidelines

The **banner** command configures a banner to display for the keyword specified. The *text* string consists of all characters following the first white space (space) until the end of the line (carriage return or line feed [LF]). Spaces in the text are preserved. However, you cannot enter tabs through the CLI.

Subsequent *text* entries are added to the end of an existing banner unless the banner is cleared first.

Note The tokens $(domain) and $(hostname) are replaced with the hostname and domain name of the ASA. When you enter a $(system) token in a context configuration, the context uses the banner configured in the system configuration.

Multiple lines in a banner are handled by entering a new banner command for each line that you want to add. Each line is then appended to the end of the existing banner.

Note The maximum length of the authorization prompt for banners is 235 characters or 31 words, whichever limitation is reached first.

When accessing the ASA through Telnet or SSH, the session closes if there is not enough system memory available to process the banner messages or if a TCP write error occurs. Only the **exec** and **motd** banners support access to the ASA through SSH. The login banner does not support SSHv1 clients or SSH clients that do not pass the username as part of the initial connection.

To replace a banner, use the **no banner** command before adding the new lines.

Use the **no banner** {**exec | login | motd**} command to remove all the lines for the banner keyword specified.

The **no banner** command does not selectively delete text strings, so any *text* that you enter at the end of the **no banner** command is ignored.

Examples

The following example shows how to configure the **asdm**, **exec**, **login**, and **motd** banners:

```
hostname(config)# banner asdm You successfully logged in to ASDM
hostname(config)# banner motd Think on These Things
hostname(config)# banner exec Enter your password carefully
hostname(config)# banner login Enter your password to log in
hostname(config)# show running-config banner
asdm:
You successfully logged in to ASDM

exec:
Enter your password carefully

login:
Enter your password to log in

motd:
Think on These Things
```

The following example shows how to add a second line to the **motd** banner:

```
hostname(config)# banner motd and Enjoy Today
hostname(config)# show running-config banner motd
Think on These Things and Enjoy Today
```

Related Commands

Command	Description
clear configure banner	Removes all banners.
show running-config banner	Displays all banners.

banner (group-policy)

To display a banner or welcome text on remote clients when they connect, use the **banner** command in group-policy configuration mode. To delete a banner, use the **no** form of this command.

banner {**value** *banner_string* | **none**}

no banner

Note If you configure multiple banners under a VPN group policy, and you delete any one of the banners, all banners are deleted.

Syntax Description

none	Sets a banner with a null value, thereby disallowing a banner. Prevents inheriting a banner from a default or specified group policy.
value *banner_string*	Constitutes the banner text. Maximum string size is 500 characters. Use the "\n" sequence to insert a carriage return.

Defaults

There is no default banner.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To prevent inheriting a banner, use the **banner none** command.

The IPsec VPN client supports full HTML for the banner. However, the clientless portal and the AnyConnect client support partial HTML. To ensure the banner displays correctly to remote users, follow these guidelines:

- For IPsec client users, use the /n tag.
- For AnyConnect client users, use the <BR> tag.
- For clientless users, use the <BR> tag.

Examples

The following example shows how to create a banner for the group policy named “FirstGroup”:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# banner value Welcome to Cisco Systems 7.0.
```

blocks

To allocate additional memory to block diagnostics (displayed by the **show blocks** command), use the **blocks** command in privileged EXEC mode. To set the value back to the default, use the **no** form of this command.

blocks queue history enable [*memory_size*]

no blocks queue history enable [*memory_size*]

Syntax Description

memory_size	(Optional) Sets the memory size for block diagnostics in bytes, instead of applying the dynamic value. If this value is greater than free memory, an error message appears and the value is not accepted. If this value is greater than 50% of free memory, a warning message appears, but the value is accepted.

Defaults

The default memory assigned to track block diagnostics is 2136 bytes.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To view the currently allocated memory, enter the **show blocks queue history** command.

If you reload the ASA, the memory allocation returns to the default.

The amount of memory allocated will be at most 150 KB, but never more than 50% of free memory. Optionally, you can specify the memory size manually.

Examples

The following example increases the memory size for block diagnostics:

```
hostname# blocks queue history enable
```

The following example increases the memory size to 3000 bytes:

```
hostname# blocks queue history enable 3000
```

The following example attempts to increase the memory size to 3000 bytes, but the value is more than the available free memory:

```
hostname# blocks queue history enable 3000
ERROR: memory size exceeds current free memory
```

The following example increases the memory size to 3000 bytes, but the value is more than 50% of the free memory:

```
hostname# blocks queue history enable 3000
WARNING: memory size exceeds 50% of current free memory
```

Related Commands

Command	Description
clear blocks	Clears the system buffer statistics.
show blocks	Shows the system buffer usage.

boot

To specify which image the system uses at the next reload and which configuration file the system uses at startup, use the **boot** command in global configuration mode. To restore the default value, use the **no** form of this command.

boot {**config** | **system**} *url*

no boot {**config** | **system**} *url*

Syntax Description

config	Specifies which configuration file to use when the system is loaded.
system	Specifies which image file to use when the system is loaded.
url	Sets the location of the image or configuration. In multiple context mode, all remote URLs must be accessible from the admin context. See the following URL syntax: • **disk0:/**[*path*/]*filename* For the ASA, this URL indicates the internal flash memory. You can also use **flash** instead of **disk0**; they are aliased. • **disk1:/**[*path*/]*filename* For the ASA, this URL indicates the external flash memory card. This option is not available for the ASA Services Module. • **flash:/**[*path*/]*filename* This URL indicates the internal flash memory. • **tftp://**[*user*[**:***password*]@]*server*[:*port*]**/**[*path*/]*filename*[**;int=***interface_name*] Specify the interface name if you want to override the route to the server address. This option is available for the **boot system** command for the ASA 5500 series only; the **boot config** command requires the startup configuration to be on the flash memory. Only one **boot system tftp:** command can be configured, and it must be the first one configured.

Defaults

If the **boot config** command is not specified, the startup configuration file will be saved to a hidden location, and used only with commands that use it, such as the **show startup-config** command and the **copy startup-config** command.

For the **boot system** command, there are no defaults. If you do not specify a location, the ASA searches only the internal flash memory for the first valid image to boot. If no valid image is found, no system image will be loaded, and the ASA will boot loop until you break into the ROMMON or Monitor mode.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

When you save this command to the startup configuration using the **write memory** command, you also save the settings to the BOOT and CONFIG_FILE environment variables, which the ASA uses to determine the startup configuration and software image to boot when it restarts.

You can enter up to four **boot system** command entries, to specify different images to boot from in order, and the ASA will boot the first valid image it finds.

If you want to use a startup configuration file at the new location that is different from the current running configuration, then be sure to copy the startup configuration file to the new location after you save the running configuration. Otherwise, the running configuration will overwrite the new startup configuration when you save it.

Tip The ASDM image file is specified by the **asdm image** command.

Examples

The following example specifies that at startup the ASA should load a configuration file called configuration.txt:

```
hostname(config)# boot config disk0:/configuration.txt
```

Related Commands

Command	Description
asdm image	Specifies the ASDM software image.
show bootvar	Displays boot file and configuration environment variables.

border style

To customize the border of the WebVPN Home page that is displayed to authenticated WebVPN users, use the **border style** command in customization configuration mode. To remove the command from the configuration and cause the value to be inherited, use the **no** form of this command.

border style *value*

no border style *value*

Syntax Description

value	Specifies the Cascading Style Sheet (CSS) parameters to use. The maximum number of characters allowed is 256.

Defaults

The default style of the border is background-color:#669999;color:white.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Customization configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The **style** option is expressed as any valid Cascading Style Sheet (CSS) parameters. Describing these parameters is beyond the scope of this document. For more information about CSS parameters, consult CSS specifications at the World Wide Web Consortium (W3C) website at www.w3.org. Appendix F of the CSS 2.1 Specification contains a convenient list of CSS parameters, and is available at www.w3.org/TR/CSS21/propidx.html.

Here are some tips for making the most common changes to the WebVPN pages—the page colors:

- You can use a comma-separated RGB value, an HTML color value, or the name of the color if recognized in HTML.
- RGB format is 0,0,0, a range of decimal numbers from 0 to 255 for each color (red, green, blue); the comma-separated entry indicates the level of intensity of each color to combine with the others.
- HTML format is #000000, six digits in hexadecimal format; the first and second represent red, the third and fourth green, and the fifth and sixth represent blue.

Note To easily customize the WebVPN pages, we recommend that you use ASDM, which has convenient features for configuring style elements, including color swatches and preview capabilities.

Examples

The following example customizes the background color of the border to the RGB color #66FFFF, a shade of green:

```
hostname(config)# webvpn
hostname(config-webvpn)# customization cisco
hostname(config-webvpn-custom)# border style background-color:66FFFF
```

Related Commands

Command	Description
application-access	Customizes the Application Access box of the WebVPN Home page.
browse-networks	Customizes the Browse Networks box of the WebVPN Home page.
web-bookmarks	Customizes the Web Bookmarks title or links on the WebVPN Home page.
file-bookmarks	Customizes the File Bookmarks title or links on the WebVPN Home page.

bridge-group

To assign an interface to a bridge group in transparent firewall mode, use the **bridge-group** command in interface configuration mode. To unassign an interface, use the **no** form of this command. A transparent firewall connects the same network on its interfaces. Up to four interfaces can belong to a bridge group.

bridge-group *number*

no bridge-group *number*

Syntax Description

number	Specifies an integer between 1 and 100.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	—	•	•	•	—

Command History

Release	Modification
8.4(1)	We introduced this command.

Usage Guidelines

You can configure up to eight bridge groups of four interfaces each. You can only assign four interfaces to a bridge group. You cannot assign the same interface to more than one bridge group.

Assign a management IP address to the bridge group using the **interface bvi** command and then the **ip address** command.

Each bridge group connects to a separate network. Bridge group traffic is isolated from other bridge groups; traffic is not routed to another bridge group within the ASA, and traffic must exit the ASA before it is routed by an external router back to another bridge group in the ASA.

You might want to use more than one bridge group if you do not want the overhead of security contexts, or want to maximize your use of security contexts. Although the bridging functions are separate for each bridge group, many other functions are shared between all bridge groups. For example, all bridge groups share a syslog server or AAA server configuration. For complete security policy separation, use security contexts with one bridge group in each context.

Examples

The following example assigns GigabitEthernet 1/1 to bridge group 1:

```
hostname(config)# interface gigabitethernet 1/1
```

```
hostname(config-if)# bridge-group 1
```

Related Commands

Command	Description
interface	Configures an interface.
interface bvi	Enters the interface configuration mode for a bridge group so you can set the management IP address.
ip address	Sets the management IP address for a bridge group.
nameif	Sets the interface name.
security-level	Sets the interface security level.

browse-networks

To customize the Browse Networks box of the WebVPN Home page that is displayed to authenticated WebVPN users, use the **browse-networks** command in webvpn customization configuration mode. To remove the command from the configuration and cause the value to be inherited, use the **no** form of this command.

browse-networks {**title** | **message** | **dropdown**} {**text** | **style**} *value*

no browse-networks [{**title** | **message** | **dropdown**} {**text** | **style**} *value*]

Syntax Description

dropdown	Specifies a change to the drop-down list.
message	Specifies youa change to the message displayed under the title.
style	Specifies a change to the style.
text	Specifies a change to the text.
title	Specifies a change to the title.
value	Indicates the actual text to display. The maximum number of characters allowed is 256. This value applies to Cascading Style Sheet (CSS) parameters also.

Defaults

The default title text is “Browse Networks”.

The default title style is:

background-color:#99CCCC;color:black;font-weight:bold;text-transform:uppercase

The default message text is “Enter Network Path”.

The default message style is:

background-color:#99CCCC;color:maroon;font-size:smaller.

The default dropdown text is “File Folder Bookmarks”.

The default dropdown style is:

border:1px solid black;font-weight:bold;color:black;font-size:80%.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn customization configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The **style** option is expressed as any valid Cascading Style Sheet (CSS) parameters. Describing these parameters is beyond the scope of this document. For more information about CSS parameters, consult CSS specifications at the World Wide Web Consortium (W3C) website at www.w3.org. Appendix F of the CSS 2.1 Specification contains a convenient list of CSS parameters, and is available at www.w3.org/TR/CSS21/propidx.html.

Here are some tips for making the most common changes to the WebVPN pages—the page colors:

- You can use a comma-separated RGB value, an HTML color value, or the name of the color if recognized in HTML.
- RGB format is 0,0,0, a range of decimal numbers from 0 to 255 for each color (red, green, blue); the comma separated entry indicates the level of intensity of each color to combine with the others.
- HTML format is #000000, six digits in hexadecimal format; the first and second represent red, the third and fourth green, and the fifth and sixth represent blue.

Note To easily customize the WebVPN pages, we recommend that you use ASDM, which has convenient features for configuring style elements, including color swatches and preview capabilities.

Examples

The following example changes the title to “Browse Corporate Networks”, and the text within the style to blue:

```
F1-asa1(config)# webvpn
F1-asa1(config-webvpn)# customization cisco
F1-asa1(config-webvpn-custom)# browse-networks title text Browse Corporate Networks
F1-asa1(config-webvpn-custom)# browse-networks title style color:blue
```

Related Commands

Command	Description
application-access	Customizes the Application Access box of the WebVPN Home page.
file-bookmarks	Customizes the File Bookmarks title or links on the WebVPN Home page.
web-applications	Customizes the Web Application box of the WebVPN Home page.
web-bookmarks	Customizes the Web Bookmarks title or links on the WebVPN Home page.

CHAPTER 5

cache through clear compression Commands

cache

To enter cache mode and set values for caching attributes, enter the **cache** command in webvpn configuration mode. To remove all cache related commands from the configuration and reset them to their default values, enter the **no** form of this command.

cache

no cache

Defaults

Enabled with default settings for each cache attribute.

Command Modes

The following table shows the modes in which you enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Caching stores frequently reused objects in the system cache, which reduces the need to perform repeated rewriting and compressing of content. It reduces traffic between WebVPN and both the remote servers and end-user browsers, so that many applications run much more efficiently.

Examples

The following example shows how to enter cache mode:

```
hostname(config)# webvpn
hostname(config-webvpn)# cache
hostname(config-webvpn-cache)#
```

Related Commands

Command	Description
cache-static-content	Caches content not subject to rewriting.
disable	Disables caching.
expiry-time	Configures the expiration time for caching objects without revalidating them.
lmfactor	Sets a revalidation policy for caching objects that have only the last-modified timestamp.
max-object-size	Defines the maximum size of an object to cache.
min-object-size	Defines the minimum sizze of an object to cache.

cache-time

To specify in minutes how long to allow a CRL to remain in the cache before considering it stale, use the **cache-time** command in ca-crl configuration mode, which is accessible from crypto ca trustpoint configuration mode. To return to the default value, use the **no** form of this command.

cache-time *refresh-time*

no cache-time

Syntax Description

refresh-time	Specifies the number of minutes to allow a CRL to remain in the cache. The range is 1 - 1440 minutes. If the NextUpdate field is not present in the CRL, the CRL is not cached.

Defaults

The default setting is 60 minutes.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca-crl configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example enters ca-crl configuration mode, and specifies a cache time refresh value of 10 minutes for trustpoint central:

```
hostname(configure)# crypto ca trustpoint central
hostname(ca-trustpoint)# crl configure
hostname(ca-crl)# cache-time 10
hostname(ca-crl)#
```

Related Commands

Command	Description
crl configure	Enters crl configuration mode.
crypto ca trustpoint	Enters trustpoint configuration mode.
enforcenextupdate	Specifies how to handle the NextUpdate CRL field in a certificate.

call-agent

To specify a group of call agents, use the **call-agent** command in mgcp map configuration mode. To remove the configuration, use the **no** form of this command.

call-agent *ip_address group_id*

no call-agent *ip_address group_id*

Syntax Description

group_id	The ID of the call agent group, from 0 to 2147483647.
ip_address	The IP address of the gateway.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Mgcp map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the **call-agent** command to specify a group of call agents that can manage one or more gateways. The call agent group information is used to open connections for call agents in the group (other than the one to which a gateway sends a command) so that any of the call agents can send the response. Call agents with the same *group_id* belong to the same group. A call agent may belong to more than one group.

Examples

The following example allows call agents 10.10.11.5 and 10.10.11.6 to control gateway 10.10.10.115, and allows call agents 10.10.11.7 and 10.10.11.8 to control both gateways 10.10.10.116 and 10.10.10.117:

```
hostname(config)# mgcp-map mgcp_inbound
hostname(config-mgcp-map)# call-agent 10.10.11.5 101
hostname(config-mgcp-map)# call-agent 10.10.11.6 101
hostname(config-mgcp-map)# call-agent 10.10.11.7 102
hostname(config-mgcp-map)# call-agent 10.10.11.8 102
hostname(config-mgcp-map)# gateway 10.10.10.115 101
hostname(config-mgcp-map)# gateway 10.10.10.116 102
hostname(config-mgcp-map)# gateway 10.10.10.117 102
```

Related Commands

Commands	Description
debug mgcp	Enables the display of debugging information for MGCP.
mgcp-map	Defines an MGCP map and enables MGCP map configuration mode.
show mgcp	Displays MGCP configuration and session information.

call-duration-limit

To configure the call duration for an H.323 call, use the **call-duration-limit** command in parameters configuration mode. To disable this feature, use the **no** form of this command.

call-duration-limit *hh:mm:ss*

no call-duration-limit *hh:mm:ss*

Syntax Description

hh:mm:ss	Specifies the duration in hours, minutes, and seconds.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to configure the call duration for an H.323 call:

```
hostname(config)# policy-map type inspect h323 h323_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# call-duration-limit 0:1:0
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3 or 4 policy map.
show running-config policy-map	Displays all current policy map configurations.

call-party-numbers

To enforce sending call party numbers during an H.323 call setup, use the **call-party-numbers** command in parameters configuration mode. To disable this feature, use the **no** form of this command.

call-party-numbers

no call-party-numbers

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to enforce call party numbers during call setup for an H.323 call:

```
hostname(config)# policy-map type inspect h323 h323_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# call-party-numbers
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3 or 4 policy map.
show running-config policy-map	Displays all current policy map configurations.

call-home

To enter call home configuration mode, use the **call-home** command in global configuration mode.

call-home

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
8.2(2)	This command was introduced.

Usage Guidelines

After you enter the **call-home** command, the prompt changes to hostname (cfg-call-home)#, and you have access to the following Call Home configuration commands:

- [**no**] **alert-group** {**group name** | **all**}—Enables or disables the Smart Call Home group. The default is enabled for all alert-groups.
  group name: Syslog, diagnostic, environment, inventory, configuration, snapshot, threat, telemetry, test.
- [**no**] **contact-e-mail-addr e-mail-address**—Specifies the customer contact e-mail address. This field is required.
  e-mail-address: A customer e-mail address of up to 127 characters.
- [**no**] **contact-name contact name**—Specifies the customer name.
  e-mail-address: A customer name of up to 127 characters.
- **copy profile src-profile-name dest-profile-name**—Copies the content of an existing profile (**src-profile-name**) to a new profile (**dest-profile-name**).
  src-profile-name: An existing profile name of up to 23 characters.
  dest-profile-name: A new profile name of up to 23 characters.
- **rename profile src-profile-name dest-profile-name**—Changes the name of an existing profile.
  src-profile-name: An existing profile name of up to 23 characters.
  dest-profile-name: A new profile name of up to 23 characters.
- **no configuration all**—Clears the Smart Call-home configuration.
  [**no**] **customer-id customer-id-string**—Specifies the customer ID.
  customer-id-string: A customer ID of up to 64 characters. This field is required for XML format messages.

- [**no**] **event-queue-size queue_size**—Specifies the event queue size.
  queue-size: The number of events from 5-60. The default is 10.
- [**no**] **mail-server ip-address | name priority 1-100 all**—Specifies the SMTP mail server. Customers can specify up to five mail servers. At least one mail server is required for using e-mail transport for Smart Call Home messages.
  ip-address: The IPv4 or IPv6 address of the mail server.
  name: The hostname of the mail server.
  1-100: The priority of the mail server. The lower the number, the higher the priority.
- [**no**] **phone-number phone-number-string**—Specifies the customer phone number. This field is optional.
  phone-number-string: The phone number.
- [**no**] **rate-limit msg-count**—Specifies the number of messages that Smart Call Home can send per minute.
  msg-count: The number of messages per minute. The default is 10.
- [**no**] **sender** {**from e-mail-address | reply-to e-mail-address**} —Specifies the from/reply-to e-mail address of an e-mail message. This field is optional.
  e-mail-address: The from and reply-to e-mail address.
- [**no**] **site-id site-id-string**—Specifies the customer site ID. This field is optional.
  site-id-string: A site ID to identify the location of the customer.
- [**no**] **street-address street-address**—Specifies the customer address. This field is optional.
  street-address: A free-format string of up to 255 characters.
- [**no**] **alert-group-config environment**—Enters environment group configuration mode.
  [**no**] **threshold** {**cpu | memory**} **low-high**—Specifies the environmental resource threshold.
  low, high: Valid values are 0-100. The default is 85-90.
- [**no**] **alert-group-config snapshot**—Enters snapshot group configuration mode.
  system, user: To run the CLI in sysem or user context (available only in multimode).
- [**no**] **add-command "cli command"** [{**system | user**}] —Specifies CLI commands to capture in the snapshot group.
  cli command: The CLI command to be entered.
  system, user: To run the CLI in the system or in user context (available only in multiple mode). If both the system and user are not specified, the CLI will be run in both the system and user contexts. The default is the user context.
- [**no**] **profile profile-name | no profile all**—Creates, deletes, or edits a profile. Enters profile configuration mode and changes the prompt to hostname (cfg-call-home-profile)#.
  profile-name: A profile name of up to 20 characters.
- [**no**] **active**—Enables or disables a profile. The default is enabled.
  no destination address {**e-mail | http**} **all | [no] destination** {**address** {**e-mail | http**} **e-mail-address | http-url** [**msg-format short-text | long-text | xml**] **| message-size-limit max-size | preferred-msg-format short-text | long-text | xml | transport-method e-mail | http**}—Configures the destination, message size, message format, and transport method for the Smart Call Home message receiver. The default message format is XML, and the default enabled transport method is e-mail.
  e-mail-address: The e-mail address of the Smart Call Home receiver, which can be up to 100 characters.
  http-url: The HTTP or HTTPS URL.
  max-size: The maximum message size in bytes. 0 means no limit. The default is 5 MB.

- [**no**] **subscribe-to-alert-group alert-group-name** [**severity** {**catastrophic** | **disaster** | **emergencies** | **alert** | **critical** | **errors** | **warning** | **notifications** | **informational** | **debugging**}]—Subscribes to events of a group with a specified severity level.
  alert-group-name: Syslog, diagnostic, environment, or threat are valid values.
- [**no**] **subscribe-to-alert-group syslog** [{**severity** {**catastrophic** | **disaster** | **emergencies** | **alert** | **critical** | **errors** | **warning** | **notifications** | **informational** | **debugging**} | **message start** [**-end**]}]—Subscribes to syslogs with a severity level or message ID.
  start-[**end**]: One syslog message ID or a range of syslog message IDs.
- [**no**] **subscribe-to-alert-group inventory** [**periodic** {**daily** | **monthly day_of_month** | **weekly day_of_week** [**hh:mm**]]—Subscribes to inventory events.
  day_of_month: Day of the month, 1-31.
  day_of_week: Day of the week (Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday).
  hh, mm: Hours and minutes of a day, in 24-hour time.
- [**no**] **subscribe-to-alert-group configuration** [**export full** | **minimum**] [**periodic** {**daily** | **monthly day_of_month** | **weekly day_of_week** [**hh:mm**]]—Subscribes to configuration events.
  full: Configuration to export the running configuration, startup configurtion, feature list, number of elements in an access list, and the context name in multimode.
  minimum: Configuration to export-only feature list, number of elements in an access list, and the context name in multimode.
  day_of_month: Day of the month, 1-31.
  day_of_week: Day of the week (Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday).
  hh, mm: Hours and minutes of a day, in 24-hour time.
- [**no**] **subscribe-to-alert-group telemetry periodic** {**hourly** | **daily** | **monthly day_of_month** | **weekly day_of_week** [**hh:mm**]—Subscribes to telemetry periodic events.
  day_of_month: Day of the month, 1-31.
  day_of_week: Day of the week (Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday).
  hh, mm: Hours and minutes of a day, in 24-hour time.
- [**no**] **subscribe-to-alert-group snapshot periodic** {**interval minutes** | **hourly** [**mm**] | **daily** | **monthly day_of_month** |**weekly day_of_week** [**hh:mm**]}—Subscribes to snapshot periodic events.
  minutes: The interval in minutes.
  day_of_month: Day of the month, 1-31.
  day_of_week: Day of the week (Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday).
  hh, mm: Hours and minutes of a day, in 24-hour time.

Note Call-home HTTPS messages can only be sent over a specified source interface on the VRF using the **ip http client source-interface** command, independent of the **vrf** command described here.

Examples

The following example show how to configure contact information:

```
hostname(config)# call-home
hostname(cfg-call-home)# contact-e-mail-addr username@example.com
hostname(cfg-call-home)# customer-id Customer1234
hostname(cfg-call-home)# phone-number +1-800-555-0199
hostname(cfg-call-home)# site-id Site1
hostname(cfg-call-home)# street-address "1234 Any Street, Any city, Any state, 12345"
```

The following example shows how to configure the Call Home message rate-limit threshold:

```
hostname(config)# call-home
hostname(cfg-call-home)# rate-limit 50
```

The following example shows how to set the Call Home message rate-limit threshold to the default setting:

```
hostname(config)# call-home
hostname(cfg-call-home)# default rate-limit
```

The following example shows how to create a new destination profile with the same configuration settings as an existing profile:

```
hostname(config)# call-home
hostname(cfg-call-home)# copy profile profile1 profile1a
```

The following example shows how to configure the general e-mail parameters, including a primary and secondary e-mail server:

```
hostname(config)# call-home
hostname(cfg-call-home)# mail-server smtp.example.com priority 1
hostname(cfg-call-home)# mail-server 192.168.0.1 priority 2
hostname(cfg-call-home)# sender from username@example.com
hostname(cfg-call-home)# sender reply-to username@example.com
```

Related Commands

Command	Description
alert-group	Enables an alert group.
profile	Enters call-home profile configuration mode.
show call-home	Displays Call Home configuration information.

call-home send

To execute a CLI command and e-mail the command output to a specified address, use the **call-home send** command in privileged EXEC mode.

call-home send cli command [**email** *email*] [**service-number** *service number*]

Syntax Description

cli-command	Specifies the CLI command to be executed. The command output is sent by e-mail.
email *email*	Specifies the e-mail address to which the CLI command output is sent. If no e-mail address is specified, the command output is sent to the Cisco TAC at attach@cisco.com.
service-number *service number*	Specifies an active TAC case number to which the command output pertains. This number is required only if no e-mail address (or a TAC e-mail address) is specified, and will appear in the e-mail subject line.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
8.2(2)	This command was introduced.

Usage Guidelines

This command causes the specified CLI command to be executed on the system. The specified CLI command must be enclosed in quotes (“”), and can be any **run** or **show** command, including commands for all modules.

The command output is then sent by e-mail to the specified e-mail address. If no e-mail address is specified, the command output is sent to the Cisco TAC at attach@cisco.com. The e-mail is sent in long text format with the service number, if specified, in the subject line.

Examples

The following example shows how to send a CLI command and have the command output e-mailed:

```
hostname# call-home send "show diagnostic result module all" email support@example.com
```

Related Commands

call-home	Enters call home configuration mode.
call-home test	Sends a Call Home test message that you define.

service call-home	Enables or disables Call Home.
show call-home	Displays call-home configuration information.

call-home send alert-group

To send a specific alert group message, use the **call-home send alert-group** command in privileged EXEC mode.

call-home send alert-group {**configuration** | **telemetry** | **inventory** | **group snapshot**} [**profile** *profile-name*]

Syntax Description

configuration	Sends the configuration alert-group message to the destination profile.
group snapshot	Sends the snapshot group.
inventory	Sends the inventory call-home message.
profile *profile-name*	(Optional) Specifies the name of the destination profile.
telemetry	Sends the diagnostic alert-group message to the destination profile for a specific module, slot/subslot, or slot/bay number.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.2(2)	This command was introduced.

Usage Guidelines

If you do not specify the **profile** *profile-name*, the message is sent to all subscribed destination profiles.

Only the configuration, diagnostic, and inventory alert groups can be manually sent. The destination profile need not be subscribed to the alert group.

Examples

The following example shows how to send the configuration alert-group message to the destination profile:

```
hostname# call-home send alert-group configuration
```

The following example shows how to send the diagnostic alert-group message to the destination profile for a specific module, slot/subslot, or slot/bay number:

```
hostname# call-home send alert-group diagnostic module 3 5/2
```

The following example shows how to send the diagnostic alert-group message to all destination profiles for a specific module, slot/subslot, or slot/bay number:

```
hostname# call-home send alert-group diagnostic module 3 5/2 profile Ciscotac1
```

This example shows how to send the inventory call-home message:

```
hostname# call-home send alert-group inventory
```

Related Commands

call-home	Enters call home configuration mode.
call-home test	Sends a Call Home test message that you define.
service call-home	Enables or disables Call Home.
show call-home	Displays call-home configuration information.

call-home test

To manually send a Call Home test message using the configuration of a profile, use the **call-home test** command in privileged EXEC mode.

call-home test [“*test-message*”] **profile** *profile-name*

Syntax Description

profile *profile-name*	Specifies the name of the destination profile.
“*test-message*”	(Optional) Test message text.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.2(2)	This command was introduced.

Usage Guidelines

This command sends a test message to the specified destination profile. If you enter test message text, you must enclose the text in quotes (“”) if it contains spaces. If you do not enter a message, a default message is sent.

Examples

The following example shows how to manually send a Call Home test message:

```
hostname# call-home test “test of the day” profile Ciscotac1
```

Related Commands

call-home	Enters call home configuration mode.
call-home send alert-group	Sends a specific alert group message.
service call-home	Enables or disables Call Home.
show call-home	Displays Call Home configuration information.

capture

To enable packet capture capabilities for packet sniffing and network fault isolation, use the **capture** command in privileged EXEC mode. To disable packet capture capabilities, use the **no** form of this command.

[**cluster exec**] **capture** *capture_name* [**type** {**asp-drop all** [*drop-code*] | **tls-proxy** | **raw-data** | **lacp** | **isakmp** [**ikev1** | **ikev2**] | **webvpn user** *webvpn-user*}] [**access-list** *access_list_name*] [**interface asa_dataplane**] [**buffer** *buf_size*] [**ethernet-type** *type*] [**interface** *interface_name*] [**reinject-hide**] [**packet-length** *bytes*] [**circular-buffer**] [**trace** *trace_count*] [**real-time**] [**trace**] [**match** *prot* {**host** *source-ip* | *source-ip mask* | **any**}{**host** *destination-ip* | *destination-ip mask* | **any**} [*operator* **port**]

[**cluster exec**] **no capture** *capture_name* [**type** {**asp-drop all** [*drop-code*] | **tls-proxy** | **raw-data** | **lacp** | **isakmp** [**ikev1** | **ikev2**] | **webvpn user** *webvpn-user*}] [**access-list** *access_list_name*] [**asa_dataplane**] [**buffer** *buf_size*] [**ethernet-type** *type*] [**interface** *interface_name*] [**reinject-hide**] [**packet-length** *bytes*] [**circular-buffer**] [**trace** *trace_count*] [**real-time**] [**trace**] [**match** *prot* {**host** *source-ip* | *source-ip mask* | **any**}{**host** *destination-ip* | *destination-ip mask* | **any**} [*operator* **port**]

Syntax Description

access-list *access_list_name*	(Optional) Captures traffic that matches an access list. In multiple context mode, this is only available within a context.
any	Specifies any IP address instead of a single IP address and mask.
all	Captures all the packets that the ASA drops
asa_dataplane	Captures packets on the ASA backplane that pass between the ASA and the ASA CX module.
asp-drop *drop-code*	(Optional) Captures packets dropped by the accelerated security path. The *drop-code* specifies the type of traffic that is dropped by the accelerated security path. See the **show asp drop frame** command for a list of drop codes. If you do not enter the *drop-code* argument, then all dropped packets are captured. You can enter this keyword with the **packet-length**, **circular-buffer**, and **buffer** keywords, but not with the **interface** or **ethernet-type** keyword. In a cluster, dropped forwarded data packets from one unit to another are also captured. In multiple context mode, when this option is issued in system context, all dropped data packets are captured; when this option is issued in a user context, only dropped data packets that enter from interfaces belonging to the user context are captured.
buffer *buf_size*	(Optional) Defines the buffer size used to store the packet in bytes. Once the byte buffer is full, packet capture stops. When used in a cluster, this is the per-unit size, not the sum of all units.
capture_name	Specifies the name of the packet capture. Use the same name on multiple **capture** statements to capture multiple types of traffic. When you view the capture configuration using the **show capture** command, all options are combined on one line.
circular-buffer	(Optional) Overwrites the buffer, starting from the beginning, when the buffer is full.
cluster exec	(Optional) Used only in a clustering deployment as a wrapper CLI prefix and can be used with the **capture** and **show capture** commands. Enables you to issue the **capture** command in one unit and run the command in all the other units at the same time.

ethernet-type *type*	(Optional) Selects an Ethernet type to capture. Supported Ethernet types include 8021Q, ARP, IP, IP6, IPX, LACP, PPPOED, PPPOES, RARP, and VLAN. An exception occurs with the 802.1Q or VLAN type. The 802.1Q tag is automatically skipped and the inner Ethernet type is used for matching.
host *ip*	Specifies the single IP address of the host to which the packet is being sent.
interface *interface_name*	Sets the name of the interface on which to use packet capture. You must configure an interface for any packets to be captured. You can configure multiple interfaces using multiple **capture** commands with the same name. To capture packets on the dataplane of an ASA, you can use the **interface** keyword with “asa_dataplane” as the interface name.You can specify “cluster” as the interface name to capture the traffic on the cluster control link interface. The interface names "cluster" and "asa-dataplane" are fixed and not configurable. If the type **lacp** capture is configured, the interface name is the physical name.
ikev1/ikev2	Captures only IKEv1 or IKEv2 protocol information.
isakmp	(Optional) Captures ISAKMP traffic for VPN connections. The ISAKMP subsystem does not have access to the upper layer protocols. The capture is a pseudo capture, with the physical, IP, and UDP layers combined together to satisfy a PCAP parser. The peer addresses are obtained from the SA exchange and are stored in the IP layer.
lacp	(Optional) Captures LACP traffic. If configured, the interface name is the physical interface name. The **trace**, **match**, and **access-list** keywords cannot be used together with the **lacp** keyword.
mask	The subnet mask for the IP address. When you specify a network mask, the method is different from the Cisco IOS software **access-list** command. The ASA uses a network mask (for example, 255.255.255.0 for a Class C mask). The Cisco IOS mask uses wildcard bits (for example, 0.0.0.255).
match *prot*	Specifies the packets that match the five-tuple to allow filtering of those packets to be captured. You can use this keyword up to three times on one line.
operator	(Optional) Matches the port numbers used by the source or destination. The permitted operators are as follows: • **lt—**less than • **gt—**greater than • **eq—**equal to • **neq**—not equal to • **range**—range
packet-length *bytes*	(Optional) Sets the maximum number of bytes of each packet to store in the capture buffer.
port	(Optional) If you set the protocol to **tcp** or **udp**, specifies the integer or name of a TCP or UDP port.
raw-data	(Optional) Captures inbound and outbound packets on one or more interfaces.
real-time	Displays the captured packets continuously in real-time. To terminate real-time packet capture, enter **Ctrl + c.** To permanently remove the capture, use the **no** form of this command. This option applies only to **raw-data** and **asp-drop** captures. This option is not supported when you use the **cluster exec capture** command.
reinject-hide	(Optional) Specifies that no reinjected packets will be captured. Applies only in a clustering environment.

tls-proxy	(Optional) Captures decrypted inbound and outbound data from TLS proxy on one or more interfaces.
trace *trace_count*	(Optional) Captures packet trace information, and the number of packets to capture. This option is used with an access list to insert trace packets into the data path to determine whether or not the packet has been processed as expected.
type	(Optional) Specifies the type of data captured.
user *webvpn-user*	(Optional) Specifies a username for a WebVPN capture.
webvpn	(Optional) Captures WebVPN data for a specific WebVPN connection.

Defaults

The defaults are as follows:

- The default **type** is **raw-data**.
- The default **buffer** *size* is 512 KB.
- The default Ethernet type is IP packets.
- The default **packet-length** is 1518 bytes.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
6.2(1)	This command was introduced.
7.0(1)	This command was modified to include the following keywords: **type asp-drop**, **type isakmp**, **type raw-data**, and **type webvpn**.
7.0(8)	Added the **all** option to capture all packets that the ASA drops**.**
7.2(1)	This command was modified to include the following options: **trace** *trace_count,* **match** *prot,* **real-time, host** *ip,* **any**, *mask,* and *operator.*
8.0(2)	This command was modified to update the path to capture contents.
8.4(1)	The new **type** keywords **ikev1** and **ikev2** were added.
8.4(2)	Additional detail was added to the output for IDS.
8.4(4.1)	The **asa_dataplane** option was added to support traffic over the backplane to the ASA CX module.
9.0(1)	The **cluster, cluster exec,** and **reinject-hide** keywords were added. The new **type** option **lacp** was added. Support for multiple-context mode was added for ISAKMP.
9.1(3)	Supports filtering of packets captured on the ASA CX backplane with the **asa_dataplane** option.

Usage Guidelines

Capturing packets is useful when troubleshooting connectivity problems or monitoring suspicious activity. You can create multiple captures. To view the packet capture, use the **show capture** *name* command. To save the capture to a file, use the **copy capture** command. Use the **https://***ASA-ip-address***/***admin***/capture/***capture_name*[**/pcap**] command to see the packet capture information with a web browser. If you specify the **pcap** optional keyword, then a libpcap-format file is downloaded to the web browser and can be saved using the web browser. (A libcap file can be viewed with TCPDUMP or Ethereal.)

If you copy the buffer contents to a TFTP server in ASCII format, you will see only the headers, not the details and hexadecimal dump of the packets. To see the details and hexadecimal dump, you need to transfer the buffer in PCAP format and read it with TCPDUMP or Ethereal.

Note Enabling WebVPN capture affects the performance of the ASA. Be sure to disable the capture after you generate the capture files that you need for troubleshooting.

Entering **no capture** without optional keywords deletes the capture. If the **access-list** optional keyword is specified, the access list is removed from the capture and the capture is preserved. If the **interface** keyword is specified, the capture is detached from the specified interface and the capture is preserved. Enter the **no capture** command with either the **access-list** or **interface** optional keyword unless you want to clear the capture itself.

You cannot perform any operations on a capture while the real-time display is in progress. Using the **real-time** keyword with a slow console connection may result in an excessive number of non-displayed packets because of performance considerations. The fixed limit of the buffer is 1000 packets. If the buffer fills up, a counter is maintained of the captured packets. If you open another session, you can disable the real-time display be entering the **no capture real-time** command.

Note The **capture** command is not saved to the running configuration, and is not copied to the standby unit during failover.

The ASA is capable of tracking all IP traffic that flows across it and of capturing all the IP traffic that is destined to it, including all the management traffic (such as SSH and Telnet traffic).

The ASA architecture consists of three different sets of processors for packet processing; this architecture poses certain restrictions on the capability of the capture feature. Typically most of the packet forwarding functionality in the ASA is handled by the two front-end network processors, and packets are sent to the control-plane general-purpose processor only if they need application inspection. The packets are sent to the session management path network processor only if there is a session miss in the accelerated path processor.

Because all the packets that are forwarded or dropped by the ASA hits the two front-end network processors, the packet capture feature is implemented in these network processors. So all the packets that hit the ASA can be captured by these front end processors, if an appropriate capture is configured for those traffic interfaces. On the ingress side, the packets are captured the moment the packet hits the ASA interfaces, and on the egress side the packets are captured just before they are sent out on the wire.

After you have performed cluster-wide capture, to copy the same capture file from all units in the cluster at the same time to a TFTP server, enter the following command on the master unit:

```
hostname# cluster exec copy /pcap capture: cap_name tftp://location/path/filename.pcap
```

Multiple PCAP files, one from each unit, are copied to the TFTP server. The destination capture file name is automatically attached with the unit name, such as filename_A.pcap, filename_B.pcap, and so on. In this example, A and B are cluster unit names.

Note A different destination name is generated if you add the unit name at the end of the filename.

The following are some of the limitations of the capture feature. Most of the limitations are caused by the distributed nature of the ASA architecture and by the hardware accelerators that are being used in the ASA.

- You can only capture IP traffic; you cannot capture non-IP packets such as ARPs.
- For cluster control link capture in multiple context mode, only the packet that is associated with the context sent in the cluster control link is captured.
- In multicontext mode, the **copy capture** command is available only in the system space. The syntax is as follows:

  copy /pcap capture:*Context-name*/*in-cap* **tftp**:

  Where *in-cap* is the capture configured in the context *context-name*
- The **cluster exec capture realtime** command is not supported. The following error message appears:

  ```
  Error: Real-time capture can not be run in cluster exec mode.
  ```
- For a shared VLAN, the following guidelines apply:
  - You can only configure one capture for the VLAN; if you configure a capture in multiple contexts on the shared VLAN, then only the last capture that was configured is used.
  - If you remove the last-configured (active) capture, no captures become active, even if you have previously configured a capture in another context; you must remove and readd the capture to make it active.
  - All traffic that enters the interface to which the capture is attached (and that matches the capture access list) is captured, including traffic to other contexts on the shared VLAN.
  - Therefore, if you enable a capture in Context A for a VLAN that is also used by Context B, both Context A and Context B ingress traffic are captured.
- For egress traffic, only the traffic of the context with the active capture is captured. The only exception is when you do not enable the ICMP inspection (therefore the ICMP traffic does not have a session in the accelerated path). In this case, both ingress and egress ICMP traffic for all contexts on the shared VLAN is captured.
- Configuring a capture typically involves configuring an access list that matches the traffic that needs to be captured. After an access list that matches the traffic pattern is configured, then you need to define a capture and associate this access list to the capture, along with the interface on which the capture needs to be configured. Note that a capture only works if an access list and an interface are associated with a capture for capturing IPv4 traffic. The access list is not required for IPv6 traffic.
- For the ASA CX module traffic, captured packets contain an additional AFBP header that your PCAP viewer might not understand; be sure to use the appropriate plugin to view these packets.
- If there is no ingress interface and therefore no global interface, packets sent on the ASA CX backplane are treated as control packets in the system context. These packets bypass the access list check and are always captured. This behavior applies in both single mode and multiple context mode.

Examples

To capture a packet, enter the following command:

```
hostname# capture captest interface inside
```

```
hostname# capture captest interface outside
```

On a web browser, you can view the content of the **capture** command that was issued, named "captest," at the following location:

```
https://171.69.38.95/admin/capture/captest
```

To download a libpcap file (that web browsers use) to a local machine, enter the following command:

```
https://171.69.38.95/capture/http/pcap
```

The following example shows that the traffic is captured from an outside host at 171.71.69.234 to an inside HTTP server:

```
hostname# access-list http permit tcp host 10.120.56.15 eq http host 171.71.69.234
hostname# access-list http permit tcp host 171.71.69.234 host 10.120.56.15 eq http
hostname# capture http access-list http packet-length 74 interface inside
```

The following example shows how to capture ARP packets:

```
hostname# capture arp ethernet-type arp interface outside
```

The following example inserts five tracer packets into the data stream, where *access-list 101* defines traffic that matches TCP protocol FTP:

```
hostname# capture ftptrace interface outside access-list 101 trace 5
```

To view the traced packets and information about packet processing in an easily readable manner, use the **show capture ftptrace** command.

The following example shows how to display captured packets in real-time:

```
hostname# capture test interface outside real-time
Warning: Using this option with a slow console connection may result in an excess amount
of non-displayed packets due to performance limitations.
Use ctrl-c to terminate real-time capture.

10 packets displayed
12 packets not displayed due to performance limitations
```

The following example shows how to configure an extended access list that matches the IPv4 traffic that needs to be captured:

```
hostname (config)# access-list capture extended permit ip any any
```

The following examples shows how to configure the capture:

```
hostname (config)# capture name access-list acl_name interface interface_name
```

By default, configuring a capture creates a linear capture buffer of size 512 KB. You can optionally configure a circular buffer. By default, only 68 bytes of the packets are captured in the buffer. You can optionally change this value.

The following example creates a capture called "ip-capture" using the capture access list previously configured that is applied to the outside interface:

```
hostname (config)# capture ip-capture access-list capture interface outside
```

The following example shows how to view the capture:

```
hostname (config)# show capture name
```

The following example shows how to end the capture, but retain the buffer:

```
hostname (config)# no capture name access-list acl_name interface interface_name
```

The following example shows how to end the capture and delete the buffer:

```
hostname (config)# no capture name
```

The following example shows how to filter traffic captured on the ASA CX backplane in single mode:

```
hostname# capture x interface asa_dataplane access-list any4
hostname# capture y interface asa_dataplane match ip any any
```

Note Control packets are captured in the single mode even though you have specified the access list.

The following examples show how to filter traffic captured on the ASA CX backplane in multiple context mode:

Usage in user context:

```
hostname (contextA)# capture x interface asa_dataplane access-list any4
hostname (contextA)# capture y interface asa_dataplane match ip any any
```

Usage in system context:

```
hostname# capture z interface asa_dataplane
```

Note In multiple context mode, the **access-list** and **match** options are not available in the system context.

Capture for Clustering

To enable capture on all units in the cluster, you can add the **cluster exec** keywords in front of each of these commands.

The following example shows how to create an LACP capture for the clustering environment:

```
hostname (config)# capture lacp type lacp interface gigabitEthernet0/0
```

The following example shows how to create a capture for control path packets in the clustering link:

```
hostname (config)# cap cp interface cluster match udp any eq 49495 any
hostname (config)# cap cp interface cluster match udp any any eq 49495
```

The following example shows how to create a capture for data path packets in the clustering link:

```
hostname (config)# access-list cc1 extended permit udp any any eq 4193
hostname (config)# access-list cc1 extended permit udp any eq 4193 any
hostname (config)# capture dp interface cluster access-list ccl
```

The following example shows how to capture data path traffic through the cluster:

```
hostname (config)# capture abc interface inside match tcp host 1.1.1.1 host 2.2.2.2 eq www
hostname (config)# capture abc interface inside match dup host 1.1.1.1 any
hostname (config)# capture abc interface inside access-list xxx
```

The following example shows how to capture logical update messages for flows that match the real source to the real destination, and capture packets forwarded over CCL that match the real source to the real destination:

```
hostname (config)# access-list dp permit real src real dst
```

The following example shows how to capture a certain type of data plane message, such as icmp echo request/response, that is forwarded from one ASA to another ASA using the **match** keyword or the access list for the message type:

```
hostname (config)# capture capture_name interface cluster access-list match icmp any any
```

The following example shows how to create a capture by using access list 103 on a cluster control link in a clustering environment:

```
hostname (config)# access-list 103 permit ip A B
hostname (config)# capture example1 interface cluster
```

In the previous example, if A and B are IP addresses for the CCL interface, only the packets that are sent between these two units are captured.

If A and B are IP addresses for through-device traffic, then the following is true:

- Forwarded packets are captured as usual, provided the source and destination IP addresses are matched with the access list.
- The data path logic update message is captured provided it is for the flow between A and B or for an access list (for example, access-list 103). The capture matches the five-tuple of the embedded flow.
- Although the source and destination addresses in the UDP packet are CCL addresses, if this packet is to update a flow that is associated with addresses A and B, it is also captured. That is, as long as addresses A and B that are embedded in the packet are matched, it is also captured.

Related Commands

Command	Description
clear capture	Clears the capture buffer.
copy capture	Copies a capture file to a server.
show capture	Displays the capture configuration when no options are specified.

cd

To change the current working directory to the one specified, use the **cd** command in privileged EXEC mode.

cd [**disk0: | disk1: | flash:**] [*path*]

Syntax Description

disk0:	Specifies the internal flash memory, followed by a colon.
disk1:	Specifies the removable, external flash memory card, followed by a colon.
flash:	Specifies the internal flash memory, followed by a colon. In the ASA 5500 series, the **flash** keyword is aliased to **disk0**.
path	(Optional) The absolute path of the directory to change to.

Defaults

If you do not specify a directory, the directory is changed to the root directory.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to change to the “config” directory:

```
hostname# cd flash:/config/
```

Related Commands

Command	Description
pwd	Displays the current working directory.

cdp-url

To specify the CDP to be included in certificates issued by the local CA, use the **cdp-url** command in ca server configuration mode. To revert to the default CDP, use the **no** form of this command.

[no] cdp-url *url*

Syntax Description

url	Specifies the URL where a validating party obtains revocation status for certificates issued by the local CA. The URL must be less than 500 alphanumeric characters.

Defaults

The default CDP URL is that of the ASA that includes the local CA. The default URL is in the format: http://hostname.domain/+CSCOCA+/asa_ca.crl.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca server configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The CDP is an extension that can be included in issued certificates to specify the location where a validating party can obtain revocation status for the certificate. Only one CDP can be configured at a time.

Note If a CDP URL is specified, it is the responsibility of the administrator to maintain access to the current CRL from that location.

Examples

The following example configures a CDP at 10.10.10.12 for certificates issued by the local CA server:

```
hostname(config)# crypto ca server
hostname(config-ca-server)# cdp-url http://10.10.10.12/ca/crl
hostname(config-ca-server)#
```

Related Commands

Command	Description
crypto ca server	Provides access to ca server configuration mode CLI command set, which allows you to configure and manage a local CA.
crypto ca server crl issue	Forces the issuance of a CRL.
crypto ca server revoke	Marks a certificate issued by a local CA server as revoked in the certificate database and CRL.
crypto ca server unrevoke	Unrevokes a previously revoked certificate issued by a local CA server.
lifetime crl	Specifies the lifetime of the certificate revocation list.

certificate

To add the indicated certificate, use the **certificate** command in crypto ca certificate chain configuration mode. To delete the certificate, use the **no** form of this command.

certificate [**ca** | **ra-encrypt** | **ra-sign** | **ra-general**] *certificate-serial-number*

no certificate *certificate-serial-number*

Syntax Description

ca	Indicates that the certificate is a CA issuing certificate.
certificate-serial-number	Specifies the serial number of the certificate in hexadecimal format ending with the word "quit."
ra-encrypt	Indicates that the certificate is an RA key encipherment certificate used in SCEP.
ra-general	Indicates that the certificate is an RA certificate used for digital signing and key encipherment in SCEP messaging.
ra-sign	Indicates that the certificate is an RA digital signature certificate used in SCEP messaging.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca certificate chain configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

When this command is issued, the ASA interprets the data included with it as the certificate in hexadecimal format. A **quit** string indicates the end of the certificate.

A CA is an authority in a network that issues and manages security credentials and public key for message encryption. As part of a public key infrastructure, a CA checks with a RA to verify information provided by the requestor of a digital certificate. If the RA verifies the requestor information, the CA can then issue a certificate.

Examples

The following example adds a CA certificate with the serial number 29573D5FF010FE25B45:

```
hostname(config)# crypto ca trustpoint central
```

```
hostname(ca-trustpoint)# crypto ca certificate chain central
hostname(ca-cert-chain)# certificate ca 29573D5FF010FE25B45
  30820345 308202EF A0030201 02021029 572A3FF2 96EF854F D0D6732F E25B4530

Related Commands

Command	Description
clear configure crypto map	Clears all configuration for all crypto maps.
show running-config crypto map	Displays the crypto map configuration.
crypto ca certificate chain	Enters certificate crypto ca certificate chain mode.
crypto ca trustpoint	Enters ca trustpoint mode.
show running-config crypto map	Displays all configuration for all the crypto maps.

certificate-group-map

To associate a rule entry from a certificate map with a tunnel group, use the **certificate-group-map** command in webvpn configuration mode. To clear current tunnel-group map associations, use the **no** form of this command.

certificate-group-map *certificate_map_name index tunnel_group_name*

no certificate-group-map

Syntax Description

certificate_map_name	The name of a certificate map.
index	The numeric identifier for a map entry in the certificate map. The index value can be in the range of 1-65535.
tunnel_group_name	The name of the tunnel group chosen if the map entry matches the certificate. The *tunnel-group name* must already exist.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

With the **certificate-group-map** command in effect, if a certificate received from a WebVPN client corresponds to a map entry, the resulting tunnel group is associated with the connection, overriding any tunnel group choice made by the user.

Multiple instances of the **certificate-group-map** command allow multiple mappings.

Examples

The following example shows how to associate rule 6 for a tunnel group named tgl:

```
hostname(config)# webvpn
hostname(config-webvpn)# certificate-group-map map1 6 tg1
hostname(config-webvpn)#
```

Related Commands

Command	Description
crypto ca certificate map	Enters ca certificate map configuration mode for configuring rules based on the certificate issuer and subject distinguished names (DNs).
tunnel-group-map	Configures the policy and rules by which certificate-based IKE sessions are mapped to tunnel groups.

chain

To enable sending a certificate chain, use the **chain** command in tunnel-group ipsec-attributes configuration mode. To return this command to the default, use the **no** form of this command.

chain

no chain

Syntax Description

This command has no arguments or keywords.

Defaults

The default setting for this command is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group ipsec-attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can apply this attribute to all IPsec tunnel group types.

Entering this command includes the root certificate and any subordinate CA certificates in the transmission.

Examples

The following example entered in tunnel-group-ipsec attributes configuration mode, enables sending a chain for an IPSec LAN-to-LAN tunnel group with the IP address of 209.165.200.225, which includes the root certificate and any subordinate CA certificates:

```
hostname(config)# tunnel-group 209.165.200.225 type IPSec_L2L
hostname(config)# tunnel-group 209.165.200.225 ipsec-attributes
hostname(config-tunnel-ipsec)# chain
hostname(config-tunnel-ipsec)#
```

Related Commands

Command	Description
clear-configure tunnel-group	Clears all configured tunnel groups.
show running-config tunnel-group	Shows the current tunnel group configuration.
tunnel-group ipsec-attributes	Configures the tunnel-group ipsec-attributes for this group.

change-password

To enable users to change their own account passwords, use the **change-password** command in privileged EXEC mode.

change-password [**/silent**] [**old-password** *old-password* [**new-password** *new-password*]]

Syntax Description

new-password *new-password*	Specifies the new password.
old-password *old-password*	Reauthenticates the user.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	—	•
Global configuration	•	•	•	—	•

Command History

Release	Modification
8.4(4.1)	This command was introduced.

Usage Guidelines

If users omit the passwords, the ASA prompts them for input. When users enter the **change-password** command, they are asked to save their running configuration. After a user has successfully changed the password, a message appears to remind the user to save configuration changes.

Examples

The following example changes a user account password:

```
hostname# change-password old-password myoldpassword000 new password mynewpassword123
```

Related Commands

Command	Description
show run password-policy	Shows the password policy for the current context.
clear configure password-policy	Resets password policy for the current context to the default value.
clear configure username	Removes a username from a user account.

changeto

To change between security contexts and the system, use the **changeto** command in privileged EXEC mode.

changeto {**system** | **context** *name*}

Syntax Description

context *name*	Changes to the context with the specified name.
system	Changes to the system execution space.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If you log into the system execution space or the admin context, you can change between contexts and perform configuration and monitoring tasks within each context. The "running" configuration that you edit in configuration mode, or that is used in the **copy** or **write** commands, depends on which execution space you are in. When you are in the system execution space, the running configuration consists only of the system configuration; when you are in a context execution space, the running configuration consists only of that context. For example, you cannot view all running configurations (system plus all contexts) by entering the **show running-config** command. Only the current configuration appears.

Examples

The following example changes between contexts and the system in privileged EXEC mode:

```
hostname/admin# changeto system
hostname# changeto context customerA
hostname/customerA#
```

The following example changes between the system and the admin context in interface configuration mode. When you change between execution spaces, and you are in a configuration mode, the mode changes to the global configuration mode in the new execution space.

```
hostname(config-if)# changeto context admin
hostname/admin(config)#
```

Related Commands

Command	Description
admin-context	Sets a context to be the admin context.
context	Creates a security context in the system configuration and enters context configuration mode.
show context	Shows a list of contexts (system execution space) or information about the current context.

channel-group

To assign a physical interface to an EtherChannel, use the **channel-group** command in interface configuration mode. To unassaign the interface, use the **no** form of this command.

channel-group *channel_id* **mode** {**active** | **passive** | **on**} [**vss-id** {**1** | **2**}]

no channel-group *channel_id*

Syntax Description

channel_id	Specifies the EtherChannel to which you want to assign this interface, between 1 and 48.
vss-id {**1** | **2**}	(Optional) With clustering, if you are connecting the ASA to two switches in a VSS or vPC, then configure the **vss-id** keyword to identify to which switch this interface is connected (1 or 2). You must also use the **port-channel span-cluster vss-load-balance** command for the port-channel interface.
mode {**active** | **passive** | **on**}	You can configure each physical interface in an EtherChannel to be: • Active—Sends and receives Link Aggregation Control Protocol (LACP) updates. An active EtherChannel can establish connectivity with either an active or a passive EtherChannel. You should use the active mode unless you need to minimize the amount of LACP traffic. • Passive—Receives LACP updates. A passive EtherChannel can only establish connectivity with an active EtherChannel. • On—The EtherChannel is always on, and LACP is not used. An “on” EtherChannel can only establish a connection with another “on” EtherChannel.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	•

Command History

Release	Modification
8.4(1)	We introduced this command.
9.0(1)	We added the **vss-id** keyword to support ASA clustering and spanned EtherChannels.

Usage Guidelines

Each channel group can have eight active interfaces. Note that you can assign up to 16 interfaces to a channel group. While only eight interfaces can be active, the remaining interfaces can act as standby links in case of interface failure.

All interfaces in the channel group must be the same type and speed. The first interface added to the channel group determines the correct type and speed.

If the port-channel interface for this channel ID does not yet exist in the configuration, one will be added:

interface port-channel *channel_id*

The Link Aggregation Control Protocol (LACP) aggregates interfaces by exchanging the Link Aggregation Control Protocol Data Units (LACPDUs) between two network devices. LACP coordinates the automatic addition and deletion of links to the EtherChannel without user intervention. It also handles misconfigurations and checks that both ends of member interfaces are connected to the correct channel group. "On" mode cannot use standby interfaces in the channel group when an interface goes down, and the connectivity and configurations are not checked.

ASA Clustering

You can include multiple interfaces per ASA in a spanned EtherChannel. Multiple interfaces per ASA are especially useful for connecting to both switches in a VSS or vPC. If you are connecting the ASA to two switches in a VSS or vPC, then you should enable VSS load balancing by using the **vss-load-balance** keyword. This feature ensures that the physical link connections between the ASAs to the VSS (or vPC) pair are balanced. You must configure the **vss-id** keyword in the **channel-group** command for each member interface before enabling load balancing.

Examples

The following example assigns interfaces to channel group 1:

```
hostname(config)# interface GigabitEthernet0/0
hostname(config-if)# channel-group 1 mode active
hostname(config-if)# interface GigabitEthernet0/1
hostname(config-if)# channel-group 1 mode active
hostname(config-if)# interface GigabitEthernet0/2
hostname(config-if)# channel-group 1 mode passive
```

Related Commands

Command	Description
interface port-channel	Configures an EtherChannel.
lacp max-bundle	Specifies the maximum number of active interfaces allowed in the channel group.
lacp port-priority	Sets the priority for a physical interface in the channel group.
lacp system-priority	Sets the LACP system priority.
port-channel load-balance	Configures the load-balancing algorithm.
port-channel min-bundle	Specifies the minimum number of active interfaces required for the port-channel interface to become active.
show lacp	Displays LACP information such as traffic statistics, system identifier and neighbor details.

Command	Description
show port-channel	Displays EtherChannel information in a detailed and one-line summary form. This command also displays the port and port-channel information.
show port-channel load-balance	Displays port-channel load-balance information along with the hash result and member interface selected for a given set of parameters.

character-encoding

To specify the global character encoding in WebVPN portal pages, use the **character-encoding** command in webvpn configuration mode. To remove the value of the character-encoding attribute, use the **no** form of this command.

character-encoding *charset*

no character-encoding *charset*

Syntax Description

charset	String consisting of up to 40 characters, and equal to one of the valid character sets identified in http://www.iana.org/assignments/character-sets. You can use either the name or the alias of a character set listed on that page. Examples include iso-8859-1, shift_jis, and ibm850. The string is case-insensitive. The command interpreter converts upper case to lower case in the ASA configuration.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Character encoding, also called “character coding” and “a character set,” is the pairing of raw data (such as 0s and 1s) and characters to represent the data. The language determines the character encoding method to use. Some languages use the same method, while others do not. Usually, the geographic region determines the default encoding method used by the browser, but the user can change this. The browser can also detect the encoding specified on the page, and render the document accordingly. The character-encoding attribute lets the user specify the value of the character-encoding method into the WebVPN portal page to ensure that the browser renders it correctly, regardless of the region in which the user is using the browser, or any changes made to the browser.

The character-encoding attribute is a global setting that, by default, all WebVPN portal pages inherit. However, the user can override the file-encoding attribute for Common Internet File System (CIFS) servers that use character encoding that differs from the value of the character-encoding attribute. Use different file-encoding values for CIFS servers that require different character encodings.

The WebVPN portal pages downloaded from the CIFS server to the WebVPN user encode the value of the WebVPN file-encoding attribute identifying the server, or if one does not, they inherit the value of the character-encoding attribute. The remote user browser maps this value to an entry in its character encoding set to determine the proper character set to use. The WebVPN portal pages do not specify a value if WebVPN configuration does not specify a file-encoding entry for the CIFS server and the character-encoding attribute is not set. The remote browser uses its own default encoding if the WebVPN portal page does not specify the character encoding or if it specifies a character encoding value that the browser does not support.

The mapping of CIFS servers to their appropriate character encoding, globally with the webvpn character-encoding attribute, and individually with file-encoding overrides, provides for the accurate handling and display of CIFS pages when the correct rendering of file names or directory paths, as well as pages, is an issue.

Note The character-encoding and file-encoding values do not exclude the font family to be used by the browser. The user needs to complement the setting of one these values with the **page style** command in webvpn customization command mode to replace the font family if you are using Japanese Shift_JIS character encoding, as shown in the following example, or enter the **no page style** command in webvpn customization command mode to remove the font family.

The encoding type set on the remote browser determines the character set for WebVPN portal pages when this attribute does not have a value.

Examples

The following example sets the character-encoding attribute to support Japanese Shift_JIS characters, removes the font family, and retains the default background color:

```
hostname(config)# webvpn
hostname(config-webvpn)# character-encoding shift_jis
F1-asa1(config-webvpn)# customization DfltCustomization
F1-asa1(config-webvpn-custom)# page style background-color:white
F1-asa1(config-webvpn-custom)#
```

Related Commands

Command	Description
debug webvpn cifs	Displays debugging messages about the CIFS server.
file-encoding	Specifies CIFS servers and associated character encoding to override the value of this attribute.
show running-config [all] webvpn	Displays the running configuration for WebVPN. Use the **all** keyword to include the default configuration.

checkheaps

To configure checkheaps verification intervals, use the **checkheaps** command in global configuration mode. To set the value to the default, use the **no** form of this command.

checkheaps {check-interval | validate-checksum} *seconds*

no checkheaps {check-interval | validate-checksum} [*seconds*]

Syntax Description

check-interval	Sets the buffer verification interval. The buffer verification process checks the sanity of the heap (allocated and freed memory buffers). During each invocation of the process, the ASA checks the entire heap, validating each memory buffer. If there is a discrepancy, the ASA issues either an "allocated buffer error" or a "free buffer error." If there is an error, the ASA dumps traceback information when possible and reloads.
seconds	Sets the interval in seconds between 1 and 2147483.
validate-checksum	Sets the code space checksum validation interval. When the ASA first boots up, the ASA calculates a hash of the entire code. Later, during the periodic check, the ASA generates a new hash and compares it to the original. If there is a mismatch, the ASA issues a "text checksum checkheaps error." If there is an error, the ASA dumps traceback information when possible and reloads.

Defaults

The default intervals are 60 seconds each.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Checkheaps is a periodic process that verifies the sanity of the heap memory buffers (dynamic memory is allocated from the system heap memory region) and the integrity of the code region.

Examples

The following example sets the buffer allocation interval to 200 seconds and the code space checksum interval to 500 seconds:

```
hostname(config)# checkheaps check-interval 200
hostname(config)# checkheaps validate-checksum 500
```

Related Commands

Command	Description
show checkheaps	Shows checkheaps statistics.

check-retransmission

To prevent against TCP retransmission style attacks, use the **check-retransmission** command in tcp-map configuration mode. To remove this specification, use the **no** form of this command.

check-retransmission

no check-retransmission

Syntax Description

This command has no arguments or keywords.

Defaults

The default is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tcp-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **tcp-map** command is used along with the Modular Policy Framework infrastructure. Define the class of traffic using the **class-map** command and customize the TCP inspection with **tcp-map** commands. Apply the new TCP map using the **policy-map** command. Activate TCP inspection with **service-policy** commands.

Use the **tcp-map** command to enter tcp-map configuration mode. To prevent against TCP retransmission style attacks that arise from end-system interpretation of inconsistent retransmissions, use the **check-retransmission** command in tcp-map configuration mode.

The ASA will make efforts to verify if the data in retransmits are the same as the original. If the data does not match, then the connection is dropped by the ASA. When this feature is enabled, packets on the TCP connection are only allowed in order. For more details, see the **queue-limit** command.

Examples

The following example enables the TCP check-retransmission feature on all TCP flows:

```
hostname(config)# access-list TCP extended permit tcp any any
hostname(config)# tcp-map tmap
hostname(config-tcp-map)# check-retransmission
hostname(config)# class-map cmap
hostname(config-cmap)# match access-list TCP
hostname(config)# policy-map pmap
hostname(config-pmap)# class cmap
```

```
hostname(config-pmap)# set connection advanced-options tmap
hostname(config)# service-policy pmap global
```

Related Commands

Command	Description
class	Specifies a class map to use for traffic classification.
help	Shows syntax help for the **policy-map**, **class**, and **description** commands.
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
set connection	Configures connection values.
tcp-map	Creates a TCP map and allows access to tcp-map configuration mode.

checksum-verification

To enable or disable TCP checksum verification, use the **checksum-verification** command in tcp-map configuration mode. To remove this specification, use the **no** form of this command.

checksum-verification

no checksum-verification

Syntax Description

This command has no arguments or keywords.

Defaults

Checksum verification is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tcp-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **tcp-map** command is used along with the Modular Policy Framework infrastructure. Define the class of traffic using the **class-map** command and customize the TCP inspection with **tcp-map** commands. Apply the new TCP map using the **policy-map** command. Activate TCP inspection with **service-policy** commands.

Use the **tcp-map** command to enter tcp-map configuration mode. Use the **checksum-verification** command in tcp-map configuration mode to enable TCP checksum verification. If the check fails, the packet is dropped.

Examples

The following example enables TCP checksum verification on TCP connections from 10.0.0.0 to 20.0.0.0:

```
hostname(config)# access-list TCP1 extended permit tcp 10.0.0.0 255.0.0.0 20.0.0.0
255.0.0.0
hostname(config)# tcp-map tmap
hostname(config-tcp-map)# checksum-verification

hostname(config)# class-map cmap
hostname(config-cmap)# match access-list TCP1

hostname(config)# policy-map pmap
hostname(config-pmap)# class cmap
```

```
hostname(config-pmap)# set connection advanced-options tmap

hostname(config)# service-policy pmap global
```

Related Commands

Command	Description
class	Specifies a class map to use for traffic classification.
help	Shows syntax help for the **policy-map**, **class**, and **description** commands.
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
set connection	Configures connection values.
tcp-map	Creates a TCP map and allows access to tcp-map configuration mode.

cipc security-mode authenticated

To force Cisco IP Communicator (CIPC) softphones to operate in authenticated mode when CIPC softphones are deployed in a voice and data VLAN scenario, use the **cipc security-mode authenticated** command in phone-proxy configuration mode. To turn off this command when CIPC softphones support encryption, use the **no** form of this command.

cipc security-mode authenticated

no cipc security-mode authenticated

Syntax Description

This command has no arguments or keywords.

Defaults

Be default, this command is disabled via the no form of the command.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Phone-proxy configuration	•	—	•	—	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Usage Guidelines

Separating voice and data traffic by using VLANs is a security best practice to hide voice streams from security threats that attempt to penetrate the data VLAN. However, Cisco IP Communicator (CIPC) softphone applications must connect to their respective IP phones, which reside on the voice VLAN. This requirement makes segregating voice and data VLANs an issue because the SIP and SCCP protocols dynamically negotiate the RTP/RTCP ports on a wide range of ports. This dynamic negotiation requires that a range of ports be open between the two VLANs.

Note Earlier versions of CIPC that do not support Authenticated mode are not supported with the Phone Proxy.

To allow CIPC softphones on the data VLAN to connect to their respective IP phones on the voice VLAN without requiring access between the VLANs on a wide range of ports, you can configure the Phone Proxy with the **cipc security-mode authenticated** command.

This command allows the Phone Proxy to look for CIPC configuration files and force CIPC softphones to be in authenticated mode rather than encrypted mode, because current versions of CIPC do not support encrypted mode.

When this command is enabled, the Phone Proxy parses the phones configuration file to determine if the phone is a CIPC softphone and changes the security mode to authenticated. Additionally, CIPC softphones support authenticated mode only while the Phone Proxy, by default, forces all phones to be in encrypted mode.

Examples

The following example shows the use of the **cipc security-mode authenticated** command to force Cisco IP Communicator (CIPC) softphones to operate in authenticated mode when CIPC softphones are deployed in a voice and data VLAN scenario:

```
hostname(config)# phone-proxy asa_phone_proxy
hostname(config-phone-proxy)#cipc security-mode authenticated
```

Related Commands

Command	Description
phone-proxy	Configures the Phone Proxy instance.

clacp system-mac

To manually configure the cLACP system ID on the master unit in an ASA cluster, use the **clacp system-mac** command in cluster group configuration mode. To retsore the default setting, use the **no** form of this command.

clacp system-mac {*mac_address* | **auto**} [**system-priority** *number*]

no clacp system-mac {*mac_address* | **auto**} [**system-priority** *number*]

Syntax Description

mac_address	Manually sets the system ID in the form *H.H.H*, where H is a 16-bit hexadecimal digit. For example, the MAC address 00-0A-00-00-AA-AA is entered as 000A.0000.AAAA.
auto	Auto-generates the system ID.
system-priority *number*	Sets the system priority, between 1 and 65535. The priority is used to decide which unit is in charge of making a bundling decision. By default, the ASA uses priority 1, which is the highest priority. The priority needs to be higher than the priority on the switch.

Command Default

By default, the system-mac is auto-generated (**auto**).

By default, the system-priority is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Cluster group configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

When using spanned EtherChannels, the ASA uses cLACP to negotiate the EtherChannel with the neighbor switch. ASAs in a cluster collaborate in cLACP negotiation so that they appear as a single (virtual) device to the switch. One parameter in cLACP negotiation is a system ID, which is in the format of a MAC address. All ASAs use the same system ID: auto-generated by the master unit (the default) and replicated to all slaves; or manually specified in this command. You might want to manually configure the MAC address for troubleshooting purposes, for example, so you can use an easily identified MAC address. Typically, you would use the auto-generated MAC address.

This command is not part of the bootstrap configuration, and is replicated from the master unit to the slave units. However, you cannot change this value after you enable clustering.

Examples

The following example manually configures a system ID:

```
cluster group pod1
    local-unit unit1
    cluster-interface port-channel1 ip 192.168.1.1 255.255.255.0
    priority 1
    key chuntheunavoidable
    health-check
    clacp system-mac 000a.0000.aaaa
    enable noconfirm
```

Related Commands

Command	Description
cluster group	Configures cluster parameters.

class (global)

To create a resource class to which to assign a security context, use the **class** command in global configuration mode. To remove a class, use the **no** form of this command.

class *name*

no class *name*

Syntax Description

name	Specifies the name as a string up to 20 characters long. To set the limits for the default class, enter **default** for the name.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	—	—	•

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

By default, all security contexts have unlimited access to the resources of the ASA, except where maximum limits per context are enforced. However, if you find that one or more contexts use too many resources, and they cause other contexts to be denied connections, for example, then you can configure resource management to limit the use of resources per context.

The ASA manages resources by assigning contexts to resource classes. Each context uses the resource limits set by the class.

When you create a class, the ASA does not set aside a portion of the resources for each context assigned to the class; rather, the ASA sets the maximum limit for a context. If you oversubscribe resources, or allow some resources to be unlimited, a few contexts can "use up" those resources, potentially affecting service to other contexts. See the **limit-resource** command to set the resources for the class.

All contexts belong to the default class if they are not assigned to another class; you do not have to actively assign a context to the default class.

If a context belongs to a class other than the default class, those class settings always override the default class settings. However, if the other class has any settings that are not defined, then the member context uses the default class for those limits. For example, if you create a class with a 2 percent limit for all concurrent connections, but no other limits, then all other limits are inherited from the default class. Conversely, if you create a class with limits for all resources, the class uses no settings from the default class.

By default, the default class provides unlimited access to resources for all contexts, except for the following limits, which are by default set to the maximum allowed per context:

- Telnet sessions—5 sessions.
- SSH sessions—5 sessions.
- MAC addresses—65,535 entries.

Examples

The following example sets the default class limit for conns to 10 percent instead of unlimited:

```
hostname(config)# class default
hostname(config-class)# limit-resource conns 10%
```

All other resources remain at unlimited.

To add a class called gold, enter the following commands:

```
hostname(config)# class gold
hostname(config-class)# limit-resource mac-addresses 10000
hostname(config-class)# limit-resource conns 15%
hostname(config-class)# limit-resource rate conns 1000
hostname(config-class)# limit-resource rate inspects 500
hostname(config-class)# limit-resource hosts 9000
hostname(config-class)# limit-resource asdm 5
hostname(config-class)# limit-resource ssh 5
hostname(config-class)# limit-resource rate syslogs 5000
hostname(config-class)# limit-resource telnet 5
hostname(config-class)# limit-resource xlates 36000
hostname(config-class)# limit-resource routes 5000
```

Related Commands

Command	Description
clear configure class	Clears the class configuration.
context	Configures a security context.
limit-resource	Sets the resource limit for a class.
member	Assigns a context to a resource class.
show class	Shows the contexts assigned to a class.

class (policy-map)

To assign a class map to a policy map where you can assign actions to the class map traffic, use the **class** command in policy-map configuration mode. To remove a class map from a policy map, use the **no** form of this command.

class *classmap_name*

no class *classmap_name*

Syntax Description

classmap_name	Specifies the name for the class map. For a Layer 3/4 policy map (the **policy-map** command), you must specify a Layer 3/4 class map name (the **class-map** or **class-map type management** command). For an inspection policy map (the **policy-map type inspect** command), you must specify an inspection class map name (the **class-map type inspect** command).

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Policy-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To use the **class** command, use the Modular Policy Framework. To use a class in a Layer 3/4 policy map, enter the following commands:

1. **class-map**—Identify the traffic on which you want to perform actions.
2. **policy-map**—Identify the actions associated with each class map.
   a. **class**—Identify the class map on which you want to perform actions.
   b. *commands for supported features*—For a given class map, you can configure many actions for various features, including QoS, application inspection, CSC or AIP SSM, TCP and UDP connections limits and timeout, and TCP normalization. See the CLI configuration guide for more details about the commands available for each feature.
3. **service-policy**—Assigns the policy map to an interface or globally.

To use a class in an inspection policy map, enter the following commands:

1. **class-map type inspect**—Identify the traffic on which you want to perform actions.

2. **policy-map type inspect**—Identify the actions associated with each class map.
   a. **class**—Identify the inspection class map on which you want to perform actions.
   b. *commands for application types*—See the CLI configuration guide for commands available for each application type. Actions supported in class configuration mode of an inspection policy map include:
   – Dropping a packet
   – Dropping a connection
   – Resetting a connection
   – Logging
   – Rate-limiting of messages
   – Masking content
   c. **parameters**—Configure parameters that affect the inspection engine. The CLI enters parameters configuration mode. See the CLI configuration guide for available commands.
3. **class-map**—Identify the traffic on which you want to perform actions.
4. **policy-map**—Identify the actions associated with each class map.
   a. **class**—Identify the Layer 3/4 class map on which you want to perform actions.
   b. **inspect** *application inspect_policy_map*—Enables application inspection, and calls an inspection policy map to perform special actions.
5. **service-policy**—Assigns the policy map to an interface or globally.

The configuration always includes a class map called **class-default** that matches all traffic. At the end of every Layer 3/4 policy map, the configuration includes the **class-default** class map with no actions defined. You can optionally use this class map when you want to match all traffic, and do not want to bother creating another class map. In fact, some features are only configurable for the **class-default** class map, such as the **shape** command.

Including the **class-default** class map, up to 63 **class** and **match** commands can be configured in a policy map.

Examples

The following is an example of a **policy-map** command for connection policy that includes the **class** command. It limits the number of connections allowed to the web server 10.1.1.1:

```
hostname(config)# access-list http-server permit tcp any host 10.1.1.1
hostname(config)# class-map http-server
hostname(config-cmap)# match access-list http-server

hostname(config)# policy-map global-policy
hostname(config-pmap)# description This policy map defines a policy concerning connection
to http server.
hostname(config-pmap)# class http-server
hostname(config-pmap-c)# set connection conn-max 256
```

The following example shows how multi-match works in a policy map:

```
hostname(config)# class-map inspection_default
hostname(config-cmap)# match default-inspection-traffic
hostname(config)# class-map http_traffic
hostname(config-cmap)# match port tcp eq 80

hostname(config)# policy-map outside_policy
hostname(config-pmap)# class inspection_default
```

```
hostname(config-pmap-c)# inspect http http_map
hostname(config-pmap-c)# inspect sip
hostname(config-pmap)# class http_traffic
hostname(config-pmap-c)# set connection timeout tcp 0:10:0
```

The following example shows how traffic matches the first available class map, and will not match any subsequent class maps that specify actions in the same feature domain:

```
hostname(config)# class-map telnet_traffic
hostname(config-cmap)# match port tcp eq 23
hostname(config)# class-map ftp_traffic
hostname(config-cmap)# match port tcp eq 21
hostname(config)# class-map tcp_traffic
hostname(config-cmap)# match port tcp range 1 65535
hostname(config)# class-map udp_traffic
hostname(config-cmap)# match port udp range 0 65535
hostname(config)# policy-map global_policy
hostname(config-pmap)# class telnet_traffic
hostname(config-pmap-c)# set connection timeout tcp 0:0:0
hostname(config-pmap-c)# set connection conn-max 100
hostname(config-pmap)# class ftp_traffic
hostname(config-pmap-c)# set connection timeout tcp 0:5:0
hostname(config-pmap-c)# set connection conn-max 50
hostname(config-pmap)# class tcp_traffic
hostname(config-pmap-c)# set connection timeout tcp 2:0:0
hostname(config-pmap-c)# set connection conn-max 2000
```

When a Telnet connection is initiated, it matches **class telnet_traffic**. Similarly, if an FTP connection is initiated, it matches **class ftp_traffic**. For any TCP connection other than Telnet and FTP, it will match **class tcp_traffic**. Even though a Telnet or FTP connection can match **class tcp_traffic**, the ASA does not make this match because they previously matched other classes.

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
class-map type management	Creates a Layer 3/4 class map for management traffic.
clear configure policy-map	Removes all policy map configuration, except for any policy map that is in use in a **service-policy** command.
match	Defines the traffic-matching parameters.
policy-map	Configures a policy; that is, an association of one or more traffic classes, each with one or more actions.

class-map

When using the Modular Policy Framework, identify Layer 3 or 4 traffic to which you want to apply actions by using the **class-map** command (without the **type** keyword) in global configuration mode. To delete a class map, use the **no** form of this command.

class-map *class_map_name*

no class-map *class_map_name*

Syntax Description

class_map_name	Specifies the class map name up to 40 characters in length. The names "class-default" and any name that begins with "_internal" or "_default" are reserved. All types of class maps use the same name space, so you cannot resuse a name already used by another type of class map.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This type of class map is for Layer 3/4 through traffic only. For management traffic destined to the ASA, see the **class-map type management** command.

A Layer 3/4 class map identifies Layer 3 and 4 traffic to which you want to apply actions. You can create multiple Layer 3/4 class maps for each Layer 3/4 policy map.

Default Class Maps

The configuration includes a default Layer 3/4 class map that the ASA uses in the default global policy. It is called **inspection_default** and matches the default inspection traffic:

```
class-map inspection_default
 match default-inspection-traffic
```

Another class map that exists in the default configuration is called class-default, and it matches all traffic:

```
class-map class-default
 match any
```

This class map appears at the end of all Layer 3/4 policy maps and essentially tells the ASA to not perform any actions on all other traffic. You can use the class-default class map if desired, rather than making your own **match any** class map. In fact, some features are only available for class-default, such as QoS traffic shaping.

Maximum Class Maps

The maximum number of class maps of all types is 255 in single mode or per context in multiple mode. Class maps include the following types:

- **class-map**
- **class-map type management**
- **class-map type inspection**
- **class-map type regex**
- **match** commands in policy-map type inspect configuration mode

This limit also includes default class maps of all types.

Configuration Overview

Configuring Modular Policy Framework consists of four tasks:

1. Identify the Layer 3 and 4 traffic to which you want to apply actions using the **class-map** or **class-map type management** command.
2. (Application inspection only) Define special actions for application inspection traffic using the **policy-map type inspect** command.
3. Apply actions to the Layer 3 and 4 traffic using the **policy-map** command.
4. Activate the actions on an interface using the **service-policy** command.

Use the **class-map** command to enter class-map configuration mode. From class-map configuration mode, you can define the traffic to include in the class using the **match** command. A Layer 3/4 class map contains, at most, one **match** command (with the exception of the **match tunnel-group** and **match default-inspection-traffic** commands) that identifies the traffic included in the class map.

Examples

The following example creates four Layer 3/4 class maps:

```
hostname(config)# access-list udp permit udp any any
hostname(config)# access-list tcp permit tcp any any
hostname(config)# access-list host_foo permit ip any 10.1.1.1 255.255.255.255

hostname(config)# class-map all_udp
hostname(config-cmap)# description "This class-map matches all UDP traffic"
hostname(config-cmap)# match access-list udp

hostname(config-cmap)# class-map all_tcp
hostname(config-cmap)# description "This class-map matches all TCP traffic"
hostname(config-cmap)# match access-list tcp

hostname(config-cmap)# class-map all_http
hostname(config-cmap)# description "This class-map matches all HTTP traffic"
hostname(config-cmap)# match port tcp eq http

hostname(config-cmap)# class-map to_server
hostname(config-cmap)# description "This class-map matches all traffic to server 10.1.1.1"
hostname(config-cmap)# match access-list host_foo
```

Related Commands

Command	Description
class-map type management	Creates a class map for traffic to the ASA.
policy-map	Creates a policy map by associating the traffic class with one or more actions.
policy-map type inspect	Defines special actions for application inspection.
service-policy	Creates a security policy by associating the policy map with one or more interfaces.
show running-config class-map	Displays the information about the class map configuration.

class-map type inspect

When using the Modular Policy Framework, match criteria that is specific to an inspection application by using the **class-map type inspect** command in global configuration mode. To delete an inspection class map, use the **no** form of this command.

class-map type inspect *application* [**match-all | match-any]** *class_map_name*

no class-map [**type inspect** *application* [**match-all | match-any**]] *class_map_name*

Syntax Description

application	Specifies the type of application traffic you want to match. Available types include: • **dns** • **ftp** • **h323** • **http** • **im** • **scansafe** • **sip**
class_map_name	Specifies the class map name up to 40 characters in length. The names "class-default" and any name that begins with "_internal" or "_default" are reserved. All types of class maps use the same name space, so you cannot resuse a name already used by another type of class map.
match-all	(Optional) Specifies that traffic must match all criteria to match the class map. **match-all** is the default if you do not specify an option.
match-any	(Optional) Specifies that traffic can match one or more criteria to match the class map.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.
8.0(2)	The **match-any** keyword was added.

Usage Guidelines

Modular Policy Framework lets you configure special actions for many application inspections. When you enable an inspection engine in the Layer 3/4 policy map, you can also optionally enable actions as defined in an *inspection policy map* (see the **policy-map type inspect** command).

In the inspection policy map, you can identify the traffic you want to act upon by creating an inspection class map. The class map contains one or more **match** commands. (You can alternatively use **match** commands directly in the inspection policy map if you want to pair a single criterion with an action). You can match criteria that is specific to an application. For example, for DNS traffic, you can match the domain name in a DNS query.

A class map groups multiple traffic matches (in a match-all class map), or lets you match any of a list of matches (in a match-any class map). The difference between creating a class map and defining the traffic match directly in the inspection policy map is that the class map lets you group multiple match commands, and you can reuse class maps. For the traffic that you identify in this class map, you can specify actions such as dropping, resetting, and/or logging the connection in the inspection policy map.

The maximum number of class maps of all types is 255 in single mode or per context in multiple mode. Class maps include the following types:

- **class-map**
- **class-map type management**
- **class-map type inspection**
- **class-map type regex**
- **match** commands in policy-map type inspect configuration mode

This limit also includes default class maps of all types. See the **class-map** command for more information.

Examples

The following example creates an HTTP class map that must match all criteria:

```
hostname(config-cmap)# class-map type inspect http match-all http-traffic
hostname(config-cmap)# match req-resp content-type mismatch
hostname(config-cmap)# match request body length gt 1000
hostname(config-cmap)# match not request uri regex class URLs
```

The following example creates an HTTP class map that can match any of the criteria:

```
hostname(config-cmap)# class-map type inspect http match-any monitor-http
hostname(config-cmap)# match request method get
hostname(config-cmap)# match request method put
hostname(config-cmap)# match request method post
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map for through traffic.
policy-map	Creates a policy map by associating the traffic class with one or more actions.
policy-map type inspect	Defines special actions for application inspection.
service-policy	Creates a security policy by associating the policy map with one or more interfaces.
show running-config class-map	Displays the information about the class map configuration.

class-map type management

When using the Modular Policy Framework, identify Layer 3 or 4 management traffic destined for the ASA to which you want to apply actions by using the **class-map type management** command in global configuration mode. To delete a class map, use the **no** form of this command.

class-map type management *class_map_name*

no class-map type management *class_map_name*

Syntax Description

class_map_name	Specifies the class map name up to 40 characters in length. The names "class-default" and any name that begins with "_internal" or "_default" are reserved. All types of class maps use the same name space, so you cannot resuse a name already used by another type of class map.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.
8.0(2)	The s**et connection** command is now available for a Layer 3/4 management class map, for to-the-ASA management traffic. Only the **conn-max** and **embryonic-conn-max** keywords are available.

Usage Guidelines

This type of class map is for management traffic only. For through traffic, see the **class-map** command (without the **type** keyword).

For management traffic to the ASA, you might want to perform actions specific to this kind of traffic. The types of actions available for a management class map in the policy map are specialized for management traffic. For example, this type of class map lets you inspect RADIUS accounting traffic and set connection limits.

A Layer 3/4 class map identifies Layer 3 and 4 traffic to which you want to apply actions. The maximum number of class maps of all types is 255 in single mode or per context in multiple mode.

You can create multiple Layer 3/4 class maps (management or through traffic) for each Layer 3/4 policy map.

Configuring Modular Policy Framework consists of four tasks:

1. Identify the Layer 3 and 4 traffic to which you want to apply actions using the **class-map** and **class-map type management** commands.
2. (Application inspection only) Define special actions for application inspection traffic using the **policy-map type inspect** command.
3. Apply actions to the Layer 3 and 4 traffic using the **policy-map** command.
4. Activate the actions on an interface using the **service-policy** command.

Use the **class-map type management** command to enter class-map configuration mode. From class-map configuration mode, you can define the traffic to include in the class using the **match** command. You can specify a management class map that can match an access list or TCP or UDP ports. A Layer 3/4 class map contains, at most, one **match** command that identifies the traffic included in the class map.

The maximum number of class maps of all types is 255 in single mode or per context in multiple mode. Class maps include the following types:

- **class-map**
- **class-map type management**
- **class-map type inspection**
- **class-map type regex**
- **match** commands in policy-map type inspect configuration mode

This limit also includes default class maps of all types. See the **class-map** command for more information.

Examples

The following example creates a Layer 3/4 management class map:

```
hostname(config)# class-map type management radius_acct
hostname(config-cmap)# match port tcp eq 10000
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map for through traffic.
policy-map	Creates a policy map by associating the traffic class with one or more actions.
policy-map type inspect	Defines special actions for application inspection.
service-policy	Creates a security policy by associating the policy map with one or more interfaces.
show running-config class-map	Displays the information about the class map configuration.

class-map type regex

When using the Modular Policy Framework, group regular expressions for use with matching text by using the **class-map type regex** command in global configuration mode. To delete a regular expression class map, use the **no** form of this command.

class-map type regex match-any *class_map_name*

no class-map [**type regex match-any**] *class_map_name*

Syntax Description

class_map_name	Specifies the class map name up to 40 characters in length. The names "class-default" and any name that begins with "_internal" or "_default" are reserved. All types of class maps use the same name space, so you cannot resuse a name already used by another type of class map.
match-any	Specifies that the traffic matches the class map if it matches only one of the regular expressions. **match-any** is the only option.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Modular Policy Framework lets you configure special actions for many application inspections. When you enable an inspection engine in the Layer 3/4 policy map, you can also optionally enable actions as defined in an *inspection policy map* (see the **policy-map type inspect** command).

In the inspection policy map, you can identify the traffic you want to act upon by creating an inspection class map containing one or more **match** commands or you can use **match** commands directly in the inspection policy map. Some **match** commands let you identify text in a packet using a regular expression; for example, you can match URL strings inside HTTP packets. You can group regular expressions in a regular expression class map.

Before you create a regular expression class map, create the regular expressions using the **regex** command. Then, identify the named regular expressions in class-map configuration mode using the **match regex** command.

The maximum number of class maps of all types is 255 in single mode or per context in multiple mode. Class maps include the following types:

- **class-map**
- **class-map type management**
- **class-map type inspection**
- **class-map type regex**
- **match** commands in policy-map type inspect configuration mode

This limit also includes default class maps of all types. See the **class-map** command for more information.

Examples

The following example creates two regular expressions, and adds them to a regular expression class map. Traffic matches the class map if it includes the string “example.com” or “example2.com.”

```
hostname(config)# regex url_example example\.com
hostname(config)# regex url_example2 example2\.com
hostname(config)# class-map type regex match-any URLs
hostname(config-cmap)# match regex url_example
hostname(config-cmap)# match regex url_example2
```

Related Commands

Command	Description
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a policy map by associating the traffic class with one or more actions.
policy-map type inspect	Defines special actions for application inspection.
service-policy	Creates a security policy by associating the policy map with one or more interfaces.
regex	Creates a regular expression.

clear aaa kerberos

To clear all Kerberos ticket information on the ASA, use the **clear aaa kerberos** command in webvpn configuration mode.

[**cluster exec**] **clear aaa kerberos** [**username** *user* | **host** *ip* | *hostname*]

Syntax Description

cluster exec	(Optional) In a clustering environment, enables you to issue the **clear aaa kerberos** command in one unit and run the command in all the other units at the same time.
host	Specifies the specific host that you want to clear from the Kerberos ticket.
hostname	Specifies the hostname.
ip	Specifies the IP address for the host.
username	Specifies the specific user that you want to clear from the Kerberos ticket.

Defaults

No defaults exist for this command.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.4(1)	This command was introduced.
9.0(1)	The **cluster exec** option was added.

Usage Guidelines

Use the **clear aaa kerberos** command in webvpn configuration mode to clear all the Kerberos tickets cached on the ASA. The **username** and **host** keywords are used to clear the Kerberos tickets of a specific user or host.

Examples

The following example shows the usage of the **clear aaa kerberos** command:

```
hostname(config)# clear aaa kerberos
```

Related Commands

Command	Description
show aaa kerberos	Displays all the Kerberos tickets cached on the ASA.

clear aaa local user fail-attempts

To reset the number of failed user authentication attempts to zero without modifying the user locked-out status, use the **clear aaa local user fail-attempts** command in privileged EXEC mode.

[**cluster exec**] **clear aaa local user authentication fail-attempts** {**username** *name* | **all**}

Syntax Description

all	Resets the failed-attempts counter to 0 for all users.
cluster exec	(Optional) In a clustering environment, enables you to issue the **clear aaa local user authentication fail-attempts** command in one unit and run the command in all the other units at the same time.
name	Specifies a specific username for which the failed-attempts counter is reset to 0.
username	Indicates that the following parameter is a username, for which the failed-attempts counter is reset to 0.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	The **cluster exec** option was added.

Usage Guidelines

Use this command if a user fails to authenticate after a few attempts.

After the configured number of failed authentication attempts, the user is locked out of the system and cannot successfully log in until either a system administrator unlocks the username or the system reboots. The number of failed attempts resets to zero and the lockout status resets to No when the user successfully authenticates, or when the ASA reboots. In addition, the system resets the counter to zero when the configuration has recently been modified.

Locking or unlocking a username results in a system log message. A system administrator with a privilege level of 15 cannot be locked out.

Examples

The following example shows use of the **clear aaa local user authentication fail-attempts** command to reset the failed-attempts counter to 0 for the username anyuser:

```
hostname(config)# clear aaa local user authentication fail-attempts username anyuser
hostname(config)#
```

The following example shows use of the **clear aaa local user authentication fail-attempts** command to reset the failed-attempts counter to 0 for all users:

```
hostname(config)# clear aaa local user authentication fail-attempts all
hostname(config)#
```

Related Commands

Command	Description
aaa local authentication attempts max-fail	Configures a limit on the number of failed user authentication attempts allowed.
clear aaa local user lockout	Resets the number of failed user authentication attempts to zero without modifying the locked-out status of the user.
show aaa local user [locked]	Shows the list of usernames that are currently locked.

clear aaa local user lockout

To clear the lockout status of the specified users and set their failed-attempts counter to 0, use the **clear aaa local user lockout** command in privileged EXEC mode.

[**cluster exec**] **clear aaa local user lockout** {**username** *name* | **all**}

Syntax Description

all	Resets the failed-attempts counter to 0 for all users.
cluster exec	(Optional) In a clustering environment, enables you to issue the **clear aaa local user lockout** command in one unit and run the command in all the other units at the same time.
name	Specifies a specific username for which the failed-attempts counter is reset to 0.
username	Indicates that the following parameter is a username, for which the failed-attempts counter is reset to 0.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	The **cluster exec** option was added.

Usage Guidelines

You can specify a single user by using the **username** option or all users with the **all** option.

This command affects only the status of users that are locked out.

The administrator cannot be locked out of the device.

Locking or unlocking a username results in a syslog message.

Examples

The following example shows use of the **clear aaa local user lockout** command to clear the lockout condition and reset the failed-attempts counter to 0 for the username anyuser:

```
hostname(config)# clear aaa local user lockout username anyuser
hostname(config)#
```

Related Commands

Command	Description
aaa local authentication attempts max-fail	Configures a limit on the number of failed user authentication attempts allowed.
clear aaa local user fail-attempts	Resets the number of failed user authentication attempts to zero without modifying the locked-out status of the user.
show aaa local user [locked]	Shows the list of usernames that are currently locked.

clear aaa-server statistics

To reset the statistics for AAA servers, use the **clear aaa-server statistics** command in privilged EXEC mode.

clear aaa-server statistics [**LOCAL** | *groupname* [**host** *hostname*] | **protocol** *protocol*]

Syntax Description

groupname	(Optional) Clears statistics for servers in a group.
host *hostname*	(Optional) Clears statistics for a particular server in the group.
LOCAL	(Optional) Clears statistics for the LOCAL user database.
protocol *protocol*	(Optional) Clears statistics for servers of the specificed protocol: • **kerberos** • **ldap** • **nt** • **radius** • **sdi** • **tacacs+**

Defaults

Remove all AAA server statistics across all groups.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was modified to adhere to CLI guidelines. In the protocol values, **nt** replaces the older **nt-domain**, and **sdi** replaces the older **rsa-ace**.

Examples

The following example shows how to reset the AAA statistics for a specific server in a group:

```
hostname(config)# clear aaa-server statistics svrgrp1 host 1.2.3.4
```

The following example shows how to reset the AAA statistics for an entire server group:

```
hostname(config)# clear aaa-server statistics svrgrp1
```

The following example shows how to reset the AAA statistics for all server groups:

```
hostname(config)# clear aaa-server statistics
```

The following example shows how to reset the AAA statistics for a particular protocol (in this case, TACACS+):

```
hostname(config)# clear aaa-server statistics protocol tacacs+
```

Related Commands

Command	Description
aaa-server protocol	Specifies and manages the grouping of AAA server connection data.
clear configure aaa-server	Removes all nondefault AAA server groups or clear the specified group.
show aaa-server	Displays AAA server statistics.
show running-config aaa-server	Displays the current AAA server configuration values.

clear access-list

To clear an access-list counter, use the **clear access-list** command in global configuration mode.

clear access-list *id* **counters**

Syntax Description

counters	Clears access list counters.
id	Name or number of an access list.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

When you enter the **clear access-list** command, you must specify the *id* of an access list to clear the counters.

Examples

The following example shows how to clear a specific access list counter:

```
hostname# clear access-list inbound counters
```

Related Commands

Command	Description
access-list extended	Adds an access list to the configuration and configures policy for IP traffic through the firewall.
access-list standard	Adds an access list to identify the destination IP addresses of OSPF routes, which can be used in a route map for OSPF redistribution.
clear configure access-list	Clears an access list from the running configuration.
show access-list	Displays the access list entries by number.
show running-config access-list	Displays the access list configuration that is running on the adaptive security appliance.

clear arp

To clear dynamic ARP entries or ARP statistics, use the **clear arp** command in privileged EXEC mode.

clear arp [**statistics**]

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example clears all ARP statistics:

```
hostname# clear arp statistics
```

Related Commands

Command	Description
arp	Adds a static ARP entry.
arp-inspection	For transparent firewall mode, inspects ARP packets to prevent ARP spoofing.
show arp statistics	Shows ARP statistics.
show running-config arp	Shows the current configuration of the ARP timeout.

clear asp drop

To clear accelerated security path (ASP) drop statistics, use the **clear asp drop** command in privileged EXEC mode.

clear asp drop [**flow** *type* | **frame** *type*]

Syntax Description

flow	(Optional) Clears the dropped flow statistics.
frame	(Optional) Clears the dropped packet statistics.
type	(Optional) Clears the dropped flow or packets statistics for a particular process.

Defaults

By default, this command clears all drop statistics.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Process types include the following:

```
acl-drop
audit-failure
closed-by-inspection
conn-limit-exceeded
fin-timeout
flow-reclaimed
fo-primary-closed
fo-standby
fo_rep_err
host-removed
inspect-fail
ips-fail-close
ips-request
ipsec-spoof-detect
loopback
mcast-entry-removed
mcast-intrf-removed
mgmt-lockdown
nat-failed
nat-rpf-failed
need-ike
```

```
no-ipv6-ipsec
non_tcp_syn
out-of-memory
parent-closed
pinhole-timeout
recurse
reinject-punt
reset-by-ips
reset-in
reset-oout
shunned
syn-timeout
tcp-fins
tcp-intecept-no-response
tcp-intercept-kill
tcp-intercept-unexpected
tcpnorm-invalid-syn
tcpnorm-rexmit-bad
tcpnorm-win-variation
timeout
tunnel-pending
tunnel-torn-down
xlate-removed
```

Examples

The following example clears all drop statistics:

```
hostname# clear asp drop
```

Related Commands

Command	Description
show asp drop	Shows the accelerated security path counters for dropped packets.

clear asp table

To clear the hit counters in ASP ARP tables, ASP classify tables, or both, use the **clear asp table** command in privileged EXEC mode.

clear asp table [**arp** | **classify**]

Syntax Description

arp	Clears the hits counters in ASP ARP tables only.
classify	Clears the hits counters in ASP classify tables only

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.2(4)	This command was introduced.

Usage Guidelines

Only two options, **arp** and **classify**, have hits in the **clear asp table** command.

Examples

The following example clears all ASP table statistics:

```
hostname# clear asp table

Warning: hits counters in asp arp and classify tables are cleared, which might impact the
hits statistic of other modules and output of other "show" commands! hostname#clear asp
table arp
Warning: hits counters in asp arp table are cleared, which might impact the hits statistic
of other modules and output of other "show" commands! hostname#clear asp table classify
Warning: hits counters in classify tables are cleared, which might impact the hits
statistic of other modules and output of other "show" commands! hostname(config)# clear
asp table
Warning: hits counters in asp tables are cleared, which might impact the hits statistics
of other modules and output of other "show" commands! hostname# sh asp table arp

Context: single_vf, Interface: inside 10.1.1.11 Active 00e0.8146.5212 hits 0

Context: single_vf, Interface: identity :: Active 0000.0000.0000 hits 0 0.0.0.0 Active
0000.0000.0000 hits 0
```

Related Commands

Command	Description
show asp table arp	Shows the contents of the accelerated security path, which might help you troubleshoot a problem.

clear asp table filter

To clear the hit counters for the ASP filter table entries, use the **clear asp table filter** command in privileged EXEC mode.

clear asp table filter [**access-list** *acl-name*]

Syntax Description

acl-name	Clears the hit counters only for a specified access list.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
8.2(2)	This command was introduced.

Usage Guidelines

Only the **access-list** option has hits in the **clear asp table filter** command.

Examples

The following example clears all ASP filter table statistics:

```
hostname# clear asp table filter
```

Related Commands

Command	Description
show asp table arp	Shows the contents of the accelerated security path, which might help you troubleshoot a problem.

clear blocks

To reset the packet buffer counters such as the low watermark and history information, use the **clear blocks** command in privileged EXEC mode.

clear blocks

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Resets the low watermark counters to the current available blocks in each pool. Addtionally, this command clears the history information stored during the last buffer allocation failure.

Examples

The following example clears the blocks:

```
hostname# clear blocks
```

Related Commands

Command	Description
blocks	Increases the memory assigned to block diagnostics.
show blocks	Shows the system buffer utilization.

clear-button

To customize the Clear button of the WebVPN page login field that is displayed to WebVPN users when they connect to the ASA, use the **clear-button** command in customization configuration mode. To remove the command from the configuration and cause the value to be inherited, use the **no** form of this command.

clear-button {**text** | **style**} *value*

no clear-button [{**text** | **style**}] *value*

Syntax Description

style	Specifies you are changing the style.
text	Specifies you are changing the text.
value	The actual text to display or Cascading Style Sheet (CSS) parameters, each with a maximum of 256 characters allowed.

Defaults

The default text is “Clear”.

The default style is border:1px solid black;background-color:white;font-weight:bold;font-size:80%.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Customization configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The **style** option is expressed as any valid Cascading Style Sheet (CSS) parameters. Describing these parameters is beyond the scope of this document. For more information about CSS parameters, consult CSS specifications at the World Wide Web Consortium (W3C) website at www.w3.org. Appendix F of the CSS 2.1 Specification contains a convenient list of CSS parameters, and is available at www.w3.org/TR/CSS21/propidx.html.

Here are some tips for making the most common changes to the WebVPN pages—the page colors:

- You can use a comma-separated RGB value, an HTML color value, or the name of the color if recognized in HTML.
- RGB format is 0,0,0, a range of decimal numbers from 0 to 255 for each color (red, green, blue); the comma separated entry indicates the level of intensity of each color to combine with the others.
- HTML format is #000000, six digits in hexadecimal format; the first and second represent red, the third and fourth green, and the fifth and sixth represent blue.

Note To easily customize the WebVPN pages, we recommend that you use ASDM, which has convenient features for configuring style elements, including color swatches and preview capabilities.

Examples

The following example changes the default background color of the Clear button from black to blue:

```
hostname(config)# webvpn
hostname(config-webvpn)# customization cisco
hostname(config-webvpn-custom)# clear-button style background-color:blue
```

Related Commands

Command	Description
group-prompt	Customizes the group prompt of the WebVPN page Login field.
login-button	Customizes the login button of the WebVPN page Login field.
login-title	Customizes the title of the WebVPN page Login field.
password-prompt	Customizes the password prompt of the WebVPN page Login field.
username-prompt	Customizes the username prompt of the WebVPN page Login field.

clear capture

To clear the capture buffer, use the **clear capture** *capture_name* command in privileged EXEC configuration mode.

clear capture *capture_name*

Syntax Description

capture_name	Name of the packet capture.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The shortened form of the **clear capture** (for example, **cl cap** or **clear cap**) is not supported to prevent accidental destruction of all the packet captures.

Examples

This example shows how to clear the capture buffer for the capture buffer “example”:

```
hostname(config)# clear capture example
```

Related Commands

Command	Description
capture	Enables packet capture capabilities for packet sniffing and network fault isolation.
show capture	Displays the capture configuration when no options are specified.

clear cluster info

To clear cluster statistics, use the **clear cluster info** command in privileged EXEC mode.

clear cluster info {trace | transport}

Syntax Description

trace	Clears cluster event trace information.
transport	Clears cluster transport statistics.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

To view cluster statistics, use the **show cluster info** command.

Examples

The following example clears cluster event trace information:

```
hostname# clear cluster info trace
```

Related Commands

Command	Description
show cluster info	Shows cluster statistics.

clear compression

To clear compression statistics for all SVC and WebVPN connections, use the **clear compression** command in privileged EXEC mode.

clear compression {**all** | **svc** | **http-comp**}

Syntax Description

all	Clears all compressions statistics.
http-comp	Clears HTTP-COMP statistics.
svc	Clears SVC compression statistics.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•		—

Command History

Release	Modification
7.1(1)	This command was introduced.

Examples

The following example, clears the compression configuration for the user:

```
hostname# clear configure compression
```

Related Commands

Command	Description
compression	Enables compression for all SVC and WebVPN connections.
svc compression	Enables compression of data over an SVC connection for a specific group or user.

CHAPTER 6

clear configure through clear configure http Commands

clear configure

To clear the running configuration, use the **clear configure** command in global configuration mode.

clear configure {**primary** | **secondary** | **all** | *command*}

Syntax Description

all	Clears the entire running configuration.
command	Clears the configuration for a specified command. For more information, see individual entries in this guide for each **clear configure** *command* command.
primary	Clears commands related to connectivity, including the following commands: • **tftp-server** • **shun** • **route** • **ip address** • **mtu** • **failover** • **monitor-interface** • **boot**
secondary	Clears commands not related to connectivity (that are cleared using the **primary** keyword).

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
8.2(2)	Support for password encryption has been added.

Usage Guidelines

When you enter this command in a security context, you clear only the context configuration. If you enter this command in the system execution space, you clear the system running configuration as well as all context running configurations. Because you cleared all context entries in the system configuration (see the **context** command), the contexts are no longer running, and you cannot change to a context execution space.

Before clearing the configuration, make sure you save any changes to the **boot config** command (which specifies the startup configuration location) to the startup configuration; if you changed the startup configuration location only in the running configuration, then when you restart, the configuration loads from the default location.

Note When you enter the **clear configure all** command, the master pass phrase used in password encryption is not removed. For more information about the master pass phrase, see the **config key password-encryption** command.

Examples

The following example clears the entire running configuration:

```
hostname(config)# clear configure all
```

Related Commands

Command	Description
configure http	Merges a configuration file from the specified HTTP(S) URL with the running configuration.
configure memory	Merges the startup configuration with the running configuration.
configure net	Merges a configuration file from the specified TFTP URL with the running configuration.
configure factory-default	Adds commands you enter at the CLI to the running configuration.
show running-config	Shows the running configuration.

clear configure aaa

To clear the AAA configuration, use the **clear configure aaa** command in global configuration mode.

clear configure aaa

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was modified for consistency within the CLI.

Usage Guidelines

The **clear configure aaa** command removes the AAA command statements from the configuration. This command also resets the AAA parameters to their default values, if any.

There is no undo.

Examples

The following example clears the AAA configuration:

```
hostname(config)# clear configure aaa
```

Related Commands

Command	Description
aaa accounting	Enables, disables, or views recordkeeping of which network services a user has accessed.
aaa authentication	Enables or views LOCAL, TACACS+, or RADIUS user authentication, on a server designated by the **aaa-server** command, or for ASDM user authentication.
aaa authorization	Enables or disables user authorization for a LOCAL or a TACACS+ server designated by the **aaa-server** command, or for ASDM user authentication.
show running-config aaa	Displays the AAA configuration.

clear configure aaa-server

To remove all AAA server groups or to clear the specified group, use the **clear configure aaa-server** command in global configuration mode.

clear configure aaa-server [*server-tag*]

clear configure aaa-server [*server-tag*] **host** *server-ip*

Syntax Description

server-ip	The IP address of the AAA server.
server-tag	(Optional) Symbolic name of the server group to be cleared.

Defaults

Remove all AAA server groups.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can specify a particular AAA server group or, by default, all AAA server groups.

Use the **host** keyword to specify a particular server within a server group.

This command also resets the AAA server parameters to their default values, if any.

Examples

The following example removes AAA server group svrgrp1:

```
hostname(config)# aaa-server svrgrp1 protocol sdi
hostname(config)# aaa-server svrgrp1 host 10.2.3.4
hostname(config-aaa-server)# timeout 9
hostname(config-aaa-server)# retry 7
hostname(config-aaa-server)# sdi-version sdi-5
hostname(config-aaa-server)# exit
```

Given the preceding configuration, the following example shows how to remove a specific server from a group:

```
hostname(config)# clear config aaa-server svrgrp1 host 1.2.3.4
```

The following example shows how to remove a server group:

```
hostname(config)# clear config aaa-server svrgrp1
```

The following example shows how to remove all server groups:

```
hostname(config)# clear config aaa-server
```

Related Commands

Command	Description
aaa-server host	Specifies and manages host-specific AAA server connection data.
aaa-server protocol	Allows you to configure AAA server parameters that are group-specific and common to all hosts.
show running-config aaa	Displasy the current maximum number of concurrent proxy connections allowed per user, along with other AAA configuration values.

clear configure access-group

To remove access groups from all the interfaces, use the **clear configure access-group** command in global configuration mode.

clear configure access-group

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	Added the **configure** keyword.

Examples

The following example shows how to remove all access groups:

```
hostname(config)# clear configure access-group
```

Related Commands

Command	Description
access-group	Binds an access list to an interface.
show running-config access-group	Displays the current access group configuration.

clear configure access-list

To clear an access list from the running configuration, use the **clear configure access list** command in global configuration mode.

clear configure access-list [*id*]

Syntax Description

id	(Optional) Name or number of an access list.

Defaults

All the access lists are cleared from the running configuration.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **clear configure access-list** command automatically unbinds an access list from a **crypto map** command or interface. The unbinding of an access list from a **crypto map** command can lead to a condition that discards all packets because the **crypto map** commands referencing the access list are incomplete. To correct the condition, either define other **access-list** commands to complete the **crypto map** commands or remove the **crypto map** commands that pertain to the **access-list** command. See the **crypto map client** command for more information.

Examples

The following example shows how to clear the access lists from the running configuration:

```
hostname(config)# clear configure access-list
```

Related Commands

Command	Description
access-list extended	Adds an access list to the configuration and configures policy for IP traffic through the firewall.
access-list standard	Adds an access list to identify the destination IP addresses of OSPF routes, which can be used in a route map for OSPF redistribution.
clear access-list	Clears access list counters.

Command	Description
show access-list	Displays counters for an access list.
show running-config access-list	Displays the access list configuration running on the ASA.

clear configure alias

To remove all **alias** commands from the configuration, use the **clear configure alias** command in global configuration mode.

clear configure alias

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to remove all **alias** commands from the configuration:

```
hostname(config)# clear configure alias
```

Related Commands

Command	Description
alias	Translates one address into another.
show running-config alias	Displays the overlapping addresses with dual NAT commands in the configuration.

clear configure arp

To clear static ARP entries added by the **arp** command, use the **clear configure arp** command in global configuration mode.

clear configure arp

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	—	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example clears static ARP entries from the configuration:

```
hostname(config)# clear configure arp
```

Related Commands

Command	Description
arp	Adds a static ARP entry.
arp-inspection	For transparent firewall mode, inspects ARP packets to prevent ARP spoofing.
firewall transparent	Sets the firewall mode to transparent.
show arp statistics	Shows ARP statistics.
show running-config arp	Shows the current configuration of the ARP timeout.

clear configure arp-inspection

To clear the ARP inspection configuration, use the **clear configure arp-inspection** command in global configuration mode.

clear configure arp-inspection

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	—	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example clears the ARP inspection configuration:

```
hostname(config)# clear configure arp-inspection
```

Related Commands

Command	Description
arp	Adds a static ARP entry.
arp-inspection	For transparent firewall mode, inspects ARP packets to prevent ARP spoofing.
firewall transparent	Sets the firewall mode to transparent.
show arp statistics	Shows ARP statistics.
show running-config arp	Shows the current configuration of the ARP timeout.

clear configure asdm

To remove all **asdm** commands from the running configuration, use the **clear configure asdm** command in global configuration mode.

clear configure asdm [**location** | **group** | **image**]

Syntax Description

group	(Optional) Clears only the **asdm group** commands from the running configuration.
image	(Optional) Clears only the **asdm image** command from the running configuration.
location	(Optional) Clears only the **asdm location** commands from the running configuration.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was changed from the **clear pdm** command to the **clear configure asdm** command.

Usage Guidelines

To view the **asdm** commands in the running configuration, use the **show running-config asdm** command.

Clearing the **asdm image** command from the configuration disables ASDM access. Clearing the **asdm location** and **asdm group** commands from the configuration causes ASDM to regenerate those commands the next time ASDM is accessed, but may disrupt active ASDM sessions.

Note On ASAs running in multiple context mode, the **clear configure asdm image** command is only available in the system execution space, while the **clear configure asdm group** and **clear configure asdm location** commands are only available in the user contexts.

Examples

The following example clears the **asdm group** commands from the running configuration:

```
hostname(config)# clear configure asdm group
```

```
hostname(config)#
```

Related Commands

Command	Description
asdm group	Used by ASDM to associate object group names with interfaces.
asdm image	Specifies the ASDM image file.
asdm location	Used by ASDM to record IP address to interface associations.
show running-config asdm	Displays the **asdm** commands in the running configuration.

clear configure auth-prompt

To remove the previously specified authentication prompt challenge text and revert to the default value, if any, use the **clear configure auth-prompt** command in global configuration mode.

clear configure auth-prompt

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was modified to conform with CLI standards.

Usage Guidelines

After you clear the authentication prompt, the prompt users see when they log in depends on the protocol they use:

- Users who log in using HTTP see `HTTP Authentication`.
- Users who log in using FTP see `FTP Authentication`.
- Users who log in using Telnet see no prompt.

Examples

The following example shows how to clear the auth-prompt:

```
hostname(config)# clear configure auth-prompt
```

Related Commands

auth-prompt	Sets the user authorization prompts.
show running-config auth-prompt	Displays the user authorization prompts.

clear configure banner

To remove all the banners, use the **clear configure banner** command in global configuration mode.

clear configure banner

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to clear banners:

```
hostname(config)# clear configure banner
```

Related Commands

Command	Description
banner	Configures the session, login, or message-of-the-day banner.
show running-config banner	Displays all banners.

clear configure boot

To restore the default boot file and configuration file that the system uses at startup, use the **clear configure boot** command in global configuration mode.

clear configure boot

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

This example shows how to restore the default configuration file:

```
hostname(config)# clear configure boot
```

Related Commands

Command	Description
boot	Configures the session, login, or message-of-the-day banner.
show bootvar	Displays boot file and configuration environment variables.

clear configure ca certificate map

To remove all certificate map entries or to remove a specified certificate map entry, use the **clear configure ca configurate map** command in global configuration mode.

clear configure ca certificate map [*sequence-number*]

Syntax Description

sequence-number	(Optional) Specifies a number for the certificate map rule that you are removing. The range is 1 through 65535.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example removes all certificate map entries.

```
hostname(config)# clear configure ca certificate map
hostname(config)#
```

Related Commands+

Command	Description
crypto ca certificate map	Enters ca certificate map configuration mode.

clear configure class

To clear the resource class configuration, use the **clear configure class** command in global configuration mode.

clear configure class

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	—	—	•

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example clears the class configuration:

```
hostname(config)# clear configure class
```

Related Commands

Command	Description
class	Configures a resource class.
context	Configures a security context.
limit-resource	Sets the resource limit for a class.
member	Assigns a context to a resource class.
show class	Shows the contexts assigned to a class.

clear configure class-map

To remove all class maps, use the **clear configure class-map** command in global configuration mode.

clear configure class-map [**type** {**management** | **regex** | **inspect** [*protocol*]}

Syntax Description

inspect	(Optional) Clears inspection class maps.
management	(Optional) Clears management class maps.
protocol	(Optional) Specifies the type of application map you want to clear. Available types include: • **dns** • **ftp** • **h323** • **http** • **im** • **p2p-donkey** • **sip**
regex	(Optional) Clears regular expression class maps.
type	(Optional) Specifies the type of class map you want to clear. To clear Layer 3/4 class maps, do not specify the type.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To clear the class map for a specific class map name, use the **no** form of the **class-map** command.

Examples

The following example shows how to clear all configured class maps:

```
hostname(config)# clear configure class-map
```

Related Commands

Command	Description
class-map	Applies a traffic class to an interface.
show running-config class-map	Displays the information about the class map configuration.

clear configure client-update

To remove from the configuration the ability to force a client update, use the **clear configure client-update** command in global configuration mode or tunnel-group ipsec-attributes configuration mode.

clear configure client-update

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—
Tunnel-group ipsec-attributes configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.1(1)	Added tunnel-group ipsec-attributes configuration mode.
9.0(1)	Support for multiple context mode was added.

Examples

The following example entered in global configuration mode, removes the client-update capability from the configuration:

```
hostname(config)# clear configure client-update
hostname(config)#
```

The following example entered in tunnel-group ipsec-attributes configuration mode, removes the client-update capability from the configuration of the tunnel group named test:

```
hostname(config)# tunnel-group test ipsec-attributes
hostname(config-tunnel-ipsec)# clear configure client-update
hostname(config-tunnel-ipsec)#
```

Related Commands

Command	Description
client-update	Configures client update.
show running-config client-update	Shows the current client-update configuration.

clear configure clock

To clear the clock configuration, use the **clear configure clock** command in global configuration mode.

clear configure clock

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was changed from **clear clock**.

Usage Guidelines

This command clears all **clock** configuration commands. The **clock set** command is not a configuration command, so this command does not reset the clock. To reset the clock, you need to set a new time for the **clock set** command.

Examples

The following example clears all clock commands:

```
hostname# clear configure clock
```

Related Commands

Command	Description
clock set	Manually sets the time.
clock summer-time	Sets the date range to show daylight saving time.
clock timezone	Sets the time zone.

clear configure cluster

To clear the cluster configuration, and leave the cluster, use the **clear configure cluster** command in global configuration mod.

clear configure cluster

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

If you want to leave a cluster (clustering was enabled on this unit), in practice, you need to clear or replace your entire configuration, not just remove the cluster configuration. If you do not clear your configuration, you will have overlapping interface configurations with existing cluster members.

You cannot make configuration changes while clustering is enabled on a slave unit. First disable clustering by entering **no enable** in cluster group configuration mode.

You must use the console port or ASDM to enable or disable clustering. You cannot use Telnet or SSH.

Examples

The following example removes the cluster configuration:

```
hostname(config)# clear configuration cluster
```

Related Commands

Command	Description
cluster group	Enters cluster configuration mode.
show running-config cluster	Shows the cluster configuration.

clear configure command-alias

To remove all non-default command aliases, use the **clear configure command-alias** command in global configuration mode.

clear configure command-alias

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to remove all non-default command aliases:

```
hostname(config)# clear configure command-alias
```

Related Commands

Command	Description
command-alias	Creates a command alias.
show running-config command-alias	Displays all nondefault command aliases.

clear configure compression

To reset the global compression configuration to the default (all compression techniques enabled), use the **clear configure compression** command in global configuration mode.

clear configure compression

Syntax Description

This command has no arguments or keywords.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•		—

Command History

Release	Modification
7.1(1)	This command was introduced.

Examples

The following example clear the compression configuration:

```
hostname(config)# clear configure compression
```

Related Commands

Command	Description
compression	Enables compression for all SVC, WebVPN, and port forwarding connections.
svc compression	Enables compression of HTTP data over an SVC connection for a specific group or user.

clear configure console

To reset the console connection settings to defaults, use the **clear configure console** command in global configuration mode.

clear configure console

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to reset the console connection settings to defaults:

```
hostname(config)# clear configure console
```

Related Commands

Command	Description
console timeout	Sets the idle timeout for a console connection to the ASA.
show running-config console timeout	Displays the idle timeout for a console connection to the ASA.

clear configure context

To clear all context configurations in the system configuration, use the **clear configure context** command in global configuration mode.

clear configure context [**noconfirm**]

Syntax Description

noconfirm	(Optional) Removes all contexts without prompting you for confirmation. This option is useful for automated scripts.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command lets you remove all contexts, including the admin context. The admin context cannot be removed using the **no context** command, but can be removed using the **clear configure context** command.

Examples

The following example removes all contexts from the system configuration, and does not confirm the deletion:

```
hostname(config)# clear configure context noconfirm
```

Related Commands

Command	Description
admin-context	Sets the admin context.
changeto	Changes between contexts or the system execution space.
context	Creates a security context in the system configuration and enters context configuration mode.

Command	Description
mode	Sets the context mode to single or multiple.
show context	Shows a list of contexts (system execution space) or information about the current context.

clear configure coredump

To remove the coredump filesystem and its contents from your system, enter the **clear configure coredump** command in global configuration mode.

clear configure coredump

Syntax Description

This command has no arguments or keywords.

Defaults

By default, coredumps are not enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

This command removes the coredump file system and its contents from your system. It also clears the coredump log. This command disables coredump and changes the configuration. You must save the configuration after performing this operation. Archive any coredump files that you have collected on your ASA that you would like to analyze, before issuing this command.

This command specifically deletes the following from the configured coredump media (disk0:, disk1:, flash:)

- contents of the coredumpfsys directory
- coredumpfsys directory
- coredumpfsysimage.bin file
- coredump.log file from the coredumpinfo directory

Examples

The following example removes the coredump file system and its contents from the system:

```
hostname(config)# clear configure coredump
```

Related Commands

Command	Description
coredump enable	Enables the coredump feature.
clear coredump	Removes any coredumps currently stored on the coredump file system and clears the coredump log. Does not touch the coredump file system itself and does not change or affect the coredump configuration.
show coredump filesystem	Displays files on the coredump file system, and indicates how full it might be.
show coredump log	Shows the coredump log.

clear configure crypto

To remove the entire crypto configuration, including IPsec, crypto maps, dynamic crypto maps, CA trustpoints, all certificates, certificate map configurations, and ISAKMP, use the **clear configure crypto** command in global configuration mode. To remove specific configurations, use this command with keywords as shown in the syntax. Take caution when using this command.

clear configure crypto [**ca** | **dynamic-map** | **engine** | **ikev1** | **ikev2** | **ipsec-client** | **iskmp** | **map**]

Syntax Description

ca	Removes certification authority policy.
dynamic-map	Removes dynamic crypto map configuration.
engine	Removes crypto engine configuration.
ikev1	Removes the IPsec IKEv1 configuration.
ikev2	Removes the IPsec IKEv2 configuration.
ipsec-client	Removes IPsec configuration.
isakmp	Removes ISAKMP configuration.
map	Removes crypto map configuration.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.4(1)	The **ikev1** and **ikev2** keywords were added.
9.0(1)	Support for multiple context mode was added.

Examples

The following example issued in global configuration mode, removes all of the crypto configuration from the ASA:

```
hostname(config)# clear configure crypto
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto dynamic-map	Clears all or specified crypto dynamic maps from the configuration.
clear configure crypto map	Clears all or specified crypto maps from the configuration.
clear configure isakmp policy	Clears all ISAKMP policy configuration.
show running-config crypto	Displays the entire crypto configuration, including IPsec, crypto maps, dynamic crypto maps, and ISAKMP.

clear configure crypto ca trustpoint

To remove all trustpoints from the configuration, use the **clear configure crypto ca trustpoint** command in global configuration mode.

clear configure crypto ca trustpoint

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example entered in global configuration mode, removes all trustpoints from the configuration:

```
hostname(config)# clear configure crypto ca trustpoint
hostname(config)#
```

Related Commands

Command	Description
crypto ca trustpoint	Enters the trustpoint configuration level for the indicated trustpoint.

clear configure crypto ca trustpool

To reset the trustpool policy to its default values, use the **clear configure crypto ca trustpool** command in global configuration mode.

clear configure crypto ca trustpool

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The trustpool is returned to its default policy values, but the certificate content of the trustpool is not changed.

clear configure crypto dynamic-map

To remove all or specified crypto dynamic maps from the configuration, use the **clear configure crypto dynamic-map** command in global configuration.

clear configure crypto dynamic-map *dynamic-map-name dynamic-seq-num*

Syntax Description

dynamic-map-name	Specifies the name of a specific crypto dynamic map.
dynamic-seq-num	Specifies the sequence number of the crypto dynamic map.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Examples

The following example entered in global configuration mode, removes the crypto dynamic map mymaps with sequence number 3 from the configuration:

```
hostname(config)# clear configure crypto dynamic-map mymaps 3
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto map	Clears the configuration of all or specified crypto maps.
show running-config crypto dynamic-map	Displays all the active configuration for all dynamic crypto maps.
show running-config crypto map	Displays all the active configuration for all crypto maps.

clear configure crypto engine

To switch large modulus operations from hardware to software, use the **clear configure crypto engine** command in global configuration mode.

clear configure crypto engine

Syntax Description

This command has no arguments or keywords.

Defaults

By default, the ASA performs large modulus operations in the software.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.2(3)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

This command is available only with ASA models 5510, 5520, 5540, and 5550. It switches large modulus operations to software and removes the **crypto engine large-mod-accel** command from the running configuration.

This command is equivalent to the **no crypto engine large-mod-accel** command. It applies only if the configuration contains a **crypto engine large-mod-accel** command. To determine whether the configuration contains this command, enter the **show running-config crypto engine** command.

We recommend that you use the **clear configure crypto engine** command during a low-use or maintenance period to minimize a temporary packet loss that can occur during the transition of processing from hardware to software.

Examples

The following example removes the **crypto engine large-mod-accel** command from the running configuration and switches large modulus operations from hardware to sofware:

```
hostname(config)# clear configure crypto engine
```

Related Commands

Command	Description
show running-config crypto engine	Shows if large modulus operations have been switched to hardware.
crypto engine large-mod-accel	Switches large modulus operations from software to hardware.

clear configure crypto ikev1

To remove all of the IKEv1 configuration, use the **clear configure crypto ikev1** command in global configuration mode.

clear configure crypto ikev1 policy *priority*

Syntax Description

priority	Specifies the priority number of the IKEv1 policy to clear.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
8.4(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Examples

The following command, issued in global configuration mode, removes all of the IKEv1 configuration for priority 1 from the ASA:

```
hostname(config)# clear configure crypto ikev1 policy priority 1
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.
crypto isakmp enable	Enables ISAKMP negotiation on the interface on which the IPsec peer communicates with the ASA.
show crypto isakmp stats	Displays runtime statistics.
show crypto isakmp sa	Displays IKE runtime SA database with additional information.
show running-config crypto isakmp	Displays all the active configuration.

clear configure crypto ikev2

To remove all of the IKEv2 configuration, use the **clear configure crypto ikev2** command in global configuration mode.

clear configure crypto ikev2 policy *priority*

Syntax Description

priority	Specifies the IKEv2 priority to clear.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
8.4(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Examples

The following command, issued in global configuration mode, removes all of the IKEv2 policy configuration for priority 1 from the ASA:

```
hostname(config)# clear configure crypto ikev2 policy priority 1
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.
crypto isakmp enable	Enables ISAKMP negotiation on the interface on which the IPsec peer communicates with the ASA.
show crypto isakmp stats	Displays runtime statistics.
show crypto isakmp sa	Displays IKE runtime SA database with additional information.
show running-config crypto isakmp	Displays all the active configuration.

clear configure crypto ipsec

To remove all of the IPsec configuration, use the **clear configure crypto isakmp** command in global configuration mode.

clear configure crypto ipsec ikev1 transform-set *transform*

Syntax Description

ikev1	Specifies you are clearing IKEv1 configuration.
transform-set	Specifies you are clearing a transform set configured for IKEv1.
transform	Specifies the transform to clear.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	The command was introduced.
8.4(1)	The **ikev1** keyword was introduced.
9.0(1)	Support for multiple context mode was added.

Examples

The following command, issued in global configuration mode, removes the IKEv1 transform *secure_VPN* from the ASA:

```
hostname(config)# clear configure crypto ipsec ikev1 transform-set secure_VPN
hostname(config)#
```

Related Commands

Command	Description
crypto isakmp enable	Enables ISAKMP negotiation on the interface on which the IPsec peer communicates with the ASA.
show crypto isakmp stats	Displays runtime statistics.
show crypto isakmp sa	Displays IKE runtime SA database with additional information.
show running-config crypto isakmp	Displays all the active configuration.

clear configure crypto isakmp

To remove all of the ISAKMP configuration, use the **clear configure crypto isakmp** command in global configuration mode.

clear configure crypto isakmp

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	The **clear configure isakmp** command was introduced.
7.2(1)	The **clear configure isakmp** command was deprecated. The **clear configure crypto isakmp** command replaced it.
9.0(1)	Support for multiple context mode was added.

Examples

The following command, issued in global configuration mode, removes all of the ISAKMP configuration from the ASA:

```
hostname(config)# clear configure crypto isakmp
hostname(config)#
```

Related Commands

Command	Description
crypto isakmp enable	Enables ISAKMP negotiation on the interface on which the IPsec peer communicates with the ASA.
show crypto isakmp stats	Displays runtime statistics.
show crypto isakmp sa	Displays IKE runtime SA database with additional information.
show running-config crypto isakmp	Displays all the active configuration.

clear configure crypto map

To remove all or specified crypto maps from the configuration, use the **clear configure crypto map** command in global configuration.

clear configure crypto map *map-name seq-num*

Syntax Description

map-name	Specifies the name of a specific crypto map.
seq-num	Specifies the sequence number of the crypto map.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Examples

The following example entered in global configuration mode, removes the crypto map mymaps with sequence number 3 from the configuration:

```
hostname(config)# clear configure crypto map mymaps 3
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto dynamic-map	Clears the configuration of all or specified crypto dynamic maps.
crypto map interface	Applies a crypto map to an interface.
show running-config crypto map	Displays the active configuration for all crypto maps.
show running-config crypto dynamic-map	Displays the active configuration for all dynamic crypto maps.

clear configure ctl-file

To clear configured CTL file instances, use the **clear configure ctl-file** command in global configuration mode.

clear configure ctl [*ctl_name*]

Syntax Description

ctl_name	(Optional) Specifies the name of the CTL instance.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Examples

The following example shows the use of the **clear configure ctl-file** command to clear configured CTL file instances:

```
hostname# clear configure ctl asa_phone_proxy asa_ctl
```

Related Commands

Command	Description
ctl-file (global)	Specifies the CTL file to create for phone proxy configuration or the CTL file to parse from flash memory.
ctl-file (phone-proxy)	Specifies the CTL file to use for phone proxy configuration.
phone-proxy	Configures the phone proxy instance.

clear configure ctl-provider

To remove all configured Certificate Trust List (CTL) provider instances, use the **clear configure ctl-provider** command in global configuration mode.

clear configure ctl-provider

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Examples

The following example removes all configured Certificate Trust List (CTL) provider instances:

```
hostname# clear configure ctl-provider
```

Related Commands

Command	Description
ctl	Parses the CTL file from the CTL client and installs trustpoints.
ctl-provider	Configures a CTL provider instance in CTL provider mode.
export	Specifies the certificate to be exported to the client.
service	Specifies the port to which the CTL provider listens.

clear configure cts

To clear the configuration for integrating the ASA with Cisco TrustSec, use the **clear configure cts** command in global configuration mode. The command removes the **cts** command statements from the ASA configuration.

clear configure cts

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

There is no undo.

Examples

The following example shows how to clear the configuration to integrate the ASA with Cisco TrustSec:

```
hostname(config)# clear configure cts
```

Related Commands

Command	Description
clear configure all	Clears the entire running configuration on the ASA.
clear cts	Clears data used by the ASA when integrated with Cisco TrustSec.
cts sxp enable	Enables the SXP protocol on the ASA.

clear configure ddns

To clear all DDNS commands, use the **clear configure ddns** command in global configuration mode.

clear configure ddns

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example clears all DDNS commands:

```
hostname(config)# clear configure ddns
```

Related Commands

Command	Description
ddns (DDNS-update-method mode)	Specifies a DDNS update method type for a created DDNS method.
ddns update (interface config mode)	Associates a ASA interface with a DDNS update method or a DDNS update hostname.
ddns update method (global config mode)	Creates a method for dynamically updating DNS resource records.
show ddns update interface	Displays the interfaces associated with each configured DDNS method.
show ddns update method	Displays the type and interval for each configured DDNS method.
show running-config ddns	Displays the type and interval of all configured DDNS methods in the running configuration.

clear configure dhcpd

To clear all of the DHCP server commands, binding, and statistics, use the **clear configure dhcpd** command in global configuration mode.

clear configure dhcpd

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from **clear dhcpd** to **clear configure dhcpd**.

Usage Guidelines

The **clear configure dhcpd** command clears all of the **dhcpd** commands, bindings, and statistical information. To clear only the statistical counters or binding information, use the **clear dhcpd** command.

Examples

The following example shows how to clear all **dhcpd** commands:

```
hostname(config)# clear configure dhcpd
```

Related Commands

Command	Description
clear dhcpd	Clears the DHCP server bindings and statistical counters.
show running-config dhcpd	Displays the current DHCP server configuration.

clear configure dhcprelay

To clear the entire DHCP relay configuration, use the **clear configure dhcprelay** command in global configuration mode.

clear configure dhcprelay [**global | interface** [*ifc*]]

Syntax Description

global	Clears the global DHCP relay agent configuration.
ifc	Clears the DHCP relay configuration on a specified interface.
interface	Clears the DHCP relay agent configuration on all interfaces.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from **clear dhcprelay** to **clear configure dhcprelay**.
9.1(2)	The **global**, **interface**, and *ifc* options were added.

Usage Guidelines

The c**lear configure dhcprelay** command clears the DHCP relay configuration. To clear only the DHCP statistical counters, use the **clear dhcprelay statistics** command.

The **vlan** option for Catalyst 6500 VLANs is available when you clear the DHCP relay configuration on a per-interface basis. You can clear the DHCP relay configuration on a per-interface basis by including the interface name (*ifc* option).

Examples

The following example shows how to clear the DHCP relay configuration:

```
hostname(config)# clear configure dhcprelay
```

The following example shows how to clear the global DHCP relay configuration:

```
hostname(config)# clear configure dhcprelay global
```

The following example shows how to clear the DHCP relay configuration on a per-interface basis:

```
hostname(config)# clear configure dhcprelay interface
```

Related Commands

Command	Description
clear dhcprelay statistics	Clears the DHCP relay agent statistic counters.
debug dhcprelay	Displays debugging information for the DHCP relay agent.
show dhcprelay statistics	Displays DHCP relay agent statistics.
show running-config dhcprelay	Displays the current DHCP relay agent configuration.

clear configure dns

To clear all DNS commands, use the **clear configure dns** command in global configuration mode.

clear configure dns

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example clears all DNS commands:

```
hostname(config)# clear configure dns
```

Related Commands

Command	Description
dns domain-lookup	Enables the ASA to perform a name lookup.
dns name-server	Configures a DNS server address.
dns retries	Specifies the number of times to retry the list of DNS servers when the ASA does not receive a response.
dns timeout	Specifies the amount of time to wait before trying the next DNS server.
show dns-hosts	Shows the DNS cache.

clear configure dynamic-access-policy-config

To clear the DAP configuration, use the **clear configure dynamic-access-policy-config** command in dynamic-access-policy-record configuration mode.

clear config dynamic-access-policy-config *name*

Syntax Description

name	A string that specifies the name of the DAP configuration file.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Dynamic-access-policy-record configuration	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Examples

The following example shows how to set a priority of 15 for the DAP record called Finance.

```
hostname (config) config-dynamic-access-policy-record Finance
hostname(config-dynamic-access-policy-record)# priority 15
hostname(config-dynamic-access-policy-record)#
```

Related Commands

Command	Description
dynamic-access-policy-record	Creates a DAP record.
show running-config dynamic-access-policy-record [*name*]	Displays the running configuration for all DAP records, or for the named DAP record.

clear config dynamic-access-policy-record

To clear a DAP record, use the **clear config dynamic-access-policy-record** command in global configuration mode with the name of the record. To clear all DAP records, use the **no** form of this command.

clear config dynamic-access-policy-record *name*

Syntax Description

name	Specifies the name of the DAP record. The name can be up to 64 characters long and cannot contain spaces.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Examples

The following example shows how to clear a DAP record named Finance.

```
hostname(config)# clear configure dynamic-access-policy-record Finance
hostname(config-dynamic-access-policy-record)#
```

Related Commands

Command	Description
dynamic-access-policy-record [*name*]	Creates a named DAP record.
dynamic-access-policy-config url	Configures the DAP selection configuration file.
show running-config dynamic-access-policy-record [*name*]	Displays the running configuration for all DAP records, or for the named DAP record.

clear configure dynamic-filter

To remove the all dynamic-filter commands, use the **clear configure dynamic-filter** command in global configuration mode.

clear configure dynamic-filter

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
8.2(1)	This command was introduced.

Examples

The following example clears the dynamic-filter configuration:

```
hostname(config)# clear configure dynamic-filter
```

Related Commands

Command	Description
address	Adds an IP address to the blacklist or whitelist.
clear dynamic-filter dns-snoop	Clears Botnet Traffic Filter DNS snooping data.
clear dynamic-filter reports	Clears Botnet Traffic filter report data.
clear dynamic-filter statistics	Clears Botnet Traffic filter statistics.
dns domain-lookup	Enables the ASA to send DNS requests to a DNS server to perform a name lookup for supported commands.
dns server-group	Identifies a DNS server for the ASA.
dynamic-filter ambiguous-is-black	Treats greylisted traffic as blacklisted traffic for action purposes.
dynamic-filter blacklist	Edits the Botnet Traffic Filter blacklist.
dynamic-filter database fetch	Manually retrieves the Botnet Traffic Filter dynamic database.
dynamic-filter database find	Searches the dynamic database for a domain name or IP address.

Command	Description
dynamic-filter database purge	Manually deletes the Botnet Traffic Filter dynamic database.
dynamic-filter drop blacklist	Automatically drops blacklisted traffic.
dynamic-filter enable	Enables the Botnet Traffic Filter for a class of traffic or for all traffic if you do not specify an access list.
dynamic-filter updater-client enable	Enables downloading of the dynamic database.
dynamic-filter use-database	Enables use of the dynamic database.
dynamic-filter whitelist	Edits the Botnet Traffic Filter whitelist.
inspect dns dynamic-filter-snoop	Enables DNS inspection with Botnet Traffic Filter snooping.
name	Adds a name to the blacklist or whitelist.
show asp table dynamic-filter	Shows the Botnet Traffic Filter rules that are installed in the accelerated security path.
show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
show dynamic-filter dns-snoop	Shows the Botnet Traffic Filter DNS snooping summary, or with the **detail** keyword, the actual IP addresses and names.
show dynamic-filter reports	Generates reports of the top 10 botnet sites, ports, and infected hosts.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

clear configure established

To remove all established commands, use the **clear configure established** command in global configuration mode.

clear configure established

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	The **configure** keyword was added.

Usage Guidelines

To remove an established connection created by the **established** command, enter the **clear xlate** command.

Examples

This example shows how to remove established commands:

```
hostname(config)# clear configure established
```

Related Commands

Command	Description
established	Permits return connections on ports that are based on an established connection.
show running-config established	Displays the allowed inbound connections that are based on established connections.
clear xlate	Clears the current translation and connection slot information.

clear configure failover

To remove **failover** commands from the configuration and restore the defaults, use the **clear configure failover** command in global configuration mode.

clear configure failover

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was changed from **clear failover** to **clear configure failover**.

Usage Guidelines

This command clears all **failover** commands from the running configuration and restores the defaults. If you use the **all** keyword with the **show running-config failover** command, you will see the default failover configuration.

The **clear configure failover** command is not available in a security context in multiple context mode; you must enter the command in the system execution space.

Examples

The following example clears all failover commands from the configuration:

```
hostname(config)# clear configure failover
hostname(config)# show running-configuration failover
no failover
```

Related Commands

Command	Description
show running-config failover	Displays the **failover** commands in the running configuration.

clear configure filter

To clear the URL, FTP, and HTTPS filtering configuration, use the **clear configure filter** command in global configuration mode.

clear configure filter

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **clear configure filter** command clears the URL, FTP, and HTTPS filtering configuration.

Examples

The following example clears the URL, FTP, and HTTPS filtering configuration:

```
hostname(config)# clear configure filter
```

Related Commands

Commands	Description
filter ftp	Identifies the FTP traffic to be filtered by a URL filtering server.
filter https	Identifies the HTTPS traffic to be filtered by a Websense server.
filter url	Directs traffic to a URL filtering server.
show running-config filter	Displays the filtering configuration.
url-server	Identifies an N2H2 or Websense server for use with the **filter** command.

clear configure fips

To clear the system or module FIPS configuration information stored in NVRAM, use the **clear configure fips** command in global configuration mode.

clear configure fips

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(4)	This command was introduced.

Examples

```
hostname(config)# clear configure fips
```

Related Commands

Command	Description
crashinfo console disable	Disables the reading, writing and configuration of crash write information to flash.
fips enable	Enables or disables policy checking to enforce FIPS compliance on the system or module.
fips self-test poweron	Executes power-on self-tests.
show crashinfo console	Reads, writes, and configures crash write to flash.
show running-config fips	Displays the FIPS configuration that is running on the ASA.

clear configure firewall

To set the firewall mode to the default routed mode, use the **clear configure firewall** command in global configuration mode.

clear configure firewall

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example sets the firewall mode to the default:

```
hostname(config)# clear configure firewall
```

Related Commands

Command	Description
arp	Adds a static ARP entry.
firewall transparent	Sets the firewall mode to transparent.
show arp statistics	Shows ARP statistics.
show running-config arp	Shows the current configuration of the ARP timeout.

clear configure fixup

To clear the fixup configuration, use the **clear configure fixup** command in global configuration mode.

clear configure fixup

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **clear configure fixup** command removes the fixup configuration.

Examples

The following example clears the fixup configuration:

```
hostname# clear configure fixup
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
policy-map	Associates a class map with specific security actions.

clear configure flow-export

To clear flow-export configurations that are associated with NetFlow data, use the **clear configure flow-export** command in global configuration mode.

clear configure flow-export [destination]

Syntax Description

destination	Clears only the destination-related flow-export configuration.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.1(1)	This command was introduced.

Usage Guidelines

The **destination** keyword clears only the destination-related flow-export configuration; the other flow-export configurations still remain.

Examples

The following example show how to clear all flow-export configurations, including destinations:

```
hostname(config)# clear configure flow-export
```

The following example shows how to clear only the destination-related flow-export configuration:

```
hostname(config)# clear configure flow-export destination
```

Related Commands

Commands	Description
flow-export destination *interface-name ipv4-address | hostname udp-port*	Specifies the IP address or hostname of the NetFlow collector, and the UDP port on which the NetFlow collector is listening.
flow-export template timeout-rate *minutes*	Controls the interval at which the template information is sent to the NetFlow collector.
logging flow-export-syslogs enable	Enables syslog messages after you have entered the **logging flow-export-syslogs disable** command, and the syslog messages that are associated with NetFlow data.
show flow-export counters	Displays all runtime counters in NetFlow.

clear configure fragment

To reset all the IP fragment reassembly configurations to defaults, use the **clear configure fragment** command in global configuration mode.

clear configure fragment [*interface*]

Syntax Description

interface	(Optional) Specifies the ASA interface.

Defaults

If an *interface* is not specified, the command applies to all interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	The **configure** keyword and optional *interface* argument were added. The command was also separated into two commands, **clear fragment** and **clear configure fragment**, to separate clearing of the configuration data from the operational data.

Usage Guidelines

The **clear configure fragment** command resets all the IP fragment reassembly configurations to defaults. In addition, the the **chain**, **size**, and **timeout** keywords are reset to their default values, which are as follows:

- **chain** is 24 packets
- **size** is 200
- **timeout** is 5 seconds

Examples

This example shows how to reset all the IP fragment reassembly configurations to their defaults:

```
hostname(config)# clear configure fragment
```

Related Commands

Command	Description
clear fragment	Clears the operational data of the IP fragment reassembly module.
fragment	Provides additional management of packet fragmentation and improves compatibility with the NFS.

Command	Description
show fragment	Displays the operational data of the IP fragment reassembly module.
show running-config fragment	Displays the IP fragment reassembly configuration.

clear configure ftp

To clear the FTP configuration, use the **clear configure ftp** command in global configuration mode.

clear configure ftp

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **clear configure ftp** command clears the FTP configuration.

Examples

The following example clears the FTP configuration:

```
hostname# clear configure ftp
```

Related Commands

Commands	Description
filter ftp	Identifies the FTP traffic to be filtered by a URL filtering server.
filter https	Identifies the HTTPS traffic to be filtered by a Websense server.
filter url	Directs traffic to a URL filtering server.
show running-config filter	Displays the filtering configuration.
url-server	Identifies an N2H2 or Websense server for use with the **filter** command.

clear configure global

To remove the **global** commands from the configuration, use the **clear configure global** command in global configuration mode.

clear configure global

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	Added keyword **configure**.

Examples

The following example shows how to remove the **global** commands from the configuration:

```
hostname(config)# clear configure global
```

Related Commands

Command	Description
global	Creates entries from a pool of global addresses.
show running-config global	Displays the **global** commands in the configuration.

clear configure group-delimiter

To disable group-name parsing for tunnel group names from the user names that are received when tunnels are being negotiated, use the **clear configure group-delimiter** command in global configuration mode.

clear config group-delimiter

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The delimiter is used to parse tunnel group names from usernames when tunnels are negotiated. If no delimiter is specified, group-name parsing is disabled.

Examples

The following example entered in global configuration mode, removes the group delimiter from the configuration:

```
hostname(config)# clear config group-delimiter
hostname(config)#
```

Related Commands

Command	Description
group-delimiter	Enables group-name parsing and specifies the group delimiter for an IPsec remote access tunnel group.
show running-config group-delimiter	Shows the current configured group delimiter.

clear configure group-policy

To remove the configuration for a particular group policy, use the **clear configure group-policy** command in global configuration mode, and append the name of the group policy. To remove all group-policy commands from the configuration except the default group policy, use this command without arguments.

clear configure group-policy [*name*]

Syntax Description

name	(Optional) Specifies the name of the group policy.

Defaults

Removes all group-policy commands from the configuration, except the default group policy.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Examples

The following example shows how to clear the configuration for the group policy named FirstGroup.

```
hostname(config)# clear configure group-policy FirstGroup
```

Related Commands

Command	Description
group-policy	Creates, edits, or removes a group policy.
group-policy attributes	Enters group-policy attributes configuration mode, which lets you configure AVPs for a specified group policy.
show running-config group-policy	Displays the running configuration for a particular group policy or for all group policies.

clear configure hostname

To reset the hostname to the default, use the **clear configure hostname** command in global configuration mode.

clear configure hostname

Syntax Description

This command has no arguments or keywords.

Defaults

The default value depends on your platform.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example clears the hostname:

```
hostname(config)# clear configure hostname
```

Related Commands

Command	Description
banner	Sets a login, message of the day, or enable banner.
domain-name	Sets the default domain name.
hostname	Sets the hostname for the ASA.

clear configure hpm

To clear the HPM configuration, use the **clear configure hpm** command in global configuration mode.

clear configure hpm

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Examples

The following example clears the HPM configuration, and restores the default:

```
hostname(config)# clear configure hpm
```

Related Commands

Command	Description
hpm topn enable	Enables top hosts reporting in ASDM.
show running-config hpm	Shows the HPM configuration.

clear configure http

To disable the HTTP server and to remove configured hosts that can access the HTTP server, use the **clear configure http** command in global configuration mode.

clear configure http

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to clear the HTTP configuration:

```
hostname(config)# clear configure http
```

Related Commands

Command	Description
http	Specifies hosts that can access the HTTP server by IP address and subnet mask. Specifies the ASA interface through which the host accesses the HTTP server.
http authentication-certificate	Requires authentication via certificate from users who are establishing HTTPS connections to the ASA.
http redirect	Specifies that the ASA redirect HTTP connections to HTTPS.
http server enable	Enables the HTTP server.
show running-config http	Displays the hosts that can access the HTTP server, and whether or not the HTTP server is enabled.

clear configure flow-export through clear configure zonelabs-integrity Commands

clear configure flow-export

To clear flow-export configurations that are associated with NetFlow data, use the **clear configure flow-export** command in global configuration mode.

clear configure flow-export [**destination**]

Syntax Description

destination	Clears only the destination-related flow-export configuration.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.1(1)	This command was introduced.
9.1(2)	An error message was added for a specific use case.

Usage Guidelines

The **destination** keyword clears only the destination-related flow-export configuration; the other flow-export configurations still remain.

In clustering, when you remove the destination flow-export configuration from the master unit, this configuration is also removed from the slave units.

As long as at least one flow-export destination is being referenced in the **flow-export event-type** command, entering the **clear configure flow-export** [**destination**] command fails and none of the flow-export configurations are changed or removed.

The following error message appears in this case:

```
ERROR: "Some destinations may be in use.  Remove references before attempting to clear
flow-export configuration"
```

Examples

The following example show how to clear all flow-export configurations, including destinations:

```
hostname(config)# clear configure flow-export
```

The following example shows how to clear only the destination-related flow-export configuration:

```
hostname(config)# clear configure flow-export destination
```

Related Commands

Commands	Description
flow-export destination	Specifies the IP address or hostname of the NetFlow collector, and the UDP port on which the NetFlow collector is listening.
flow-export template timeout-rate	Controls the interval at which the template information is sent to the NetFlow collector.
logging flow-export-syslogs enable	Enables syslog messages after you have entered the **logging flow-export-syslogs disable** command, and the syslog messages that are associated with NetFlow data.
show flow-export counters	Displays all runtime counters in NetFlow.

clear configure icmp

To clear the configured access rules for ICMP traffic, use the **clear configure icmp** command in global configuration mode.

clear configure icmp

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **clear configure icmp** command clears the configured access rules for ICMP traffic.

Examples

The following example clears the clear configured access rules for ICMP traffic:

```
hostname# clear configure icmp
```

Related Commands

Commands	Description
clear configure icmp	Clears the ICMP configuration.
debug icmp	Enables the display of debug information for ICMP.
show icmp	Displays ICMP configuration.
timeout icmp	Configures the idle timeout for ICMP.

clear configure imap4s

To remove all IMAP4S commands from the configuration and revert to default values, use the **clear configure imap4s** command in global configuration mode.

clear configure imap4s

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to remove the IMAP4S configuration:

```
hostname(config)# clear configure imap4s
hostname(config)#
```

Related Commands

Command	Description
show running-configuration imap4s	Displays the running configuration for IMAP4S.
imap4s	Creates or edits an IMAP4S e-mail proxy configuration.

clear configure interface

To clear the interface configuration, use the **clear configure interface** command in global configuration mode.

clear configure interface [*physical_interface*[**.***subinterface*] | *mapped_name* | *interface_name*]

Syntax Description

interface_name	(Optional) Identifies the interface name set with the **nameif** command.
mapped_name	(Optional) In multiple context mode, identifies the mapped name if it was assigned using the **allocate-interface** command.
physical_interface	(Optional) Identifies the interface ID, such as **gigabitethernet0/1**. See the **interface** command for accepted values.
subinterface	(Optional) Identifies an integer between 1 and 4294967293 designating a logical subinterface.

Defaults

If you do not specify an interface, the ASA clears all interface configuration.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was changed from **clear interface**. This command was also modified to include the new interface numbering scheme.

Usage Guidelines

When you clear the interface configuration for main physical interfaces, the ASA uses the default settings.

You cannot use the interface name in the system execution space, because the **nameif** command is only available within a context. Similarly, if you mapped the interface ID to a mapped name using the **allocate-interface** command, you can only use the mapped name in a context.

Examples

The following example clears the GigabitEthernet0/1 configuration:

```
hostname(config)# clear configure interface gigabitethernet0/1
```

The following example clears the inside interface configuration:

```
hostname(config)# clear configure interface inside
```

The following example clears the int1 interface configuration in a context. “int1” is a mapped name:

```
hostname/contexta(config)# clear configure interface int1
```

The following example clears all interface configuration:

```
hostname(config)# clear configure interface
```

Related Commands

Command	Description
allocate-interface	Assigns interfaces and subinterfaces to a security context.
clear interface	Clears counters for the **show interface** command.
interface	Configures an interface and enters interface configuration mode.
show interface	Displays the runtime status and statistics of interfaces.

clear configure interface bvi

To clear the bridge virtual interface configuration, use the **clear configure interface bvi** command in global configuration mode.

clear configure interface bvi *bridge_group_number*

Syntax Description

bridge_group_number	Specifies the bridge group number as an integer between 1 and 100.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	—	•	•	•	—

Command History

Release	Modification
8.4(1)	We introduced this command.

Examples

The following example clears the interface configuration for bridge group 1:

```
hostname(config)# clear configure interface bvi 1
```

Related Commands

Command	Description
bridge-group	Groups transparent firewall interfaces into a bridge group.
interface	Configures an interface.
interface bvi	Creates a bridge virtual interface.
ip address	Sets the management IP address for a bridge group.
show bridge-group	Shows bridge group information, including member interfaces and IP addresses.
show running-config interface bvi	Shows the bridge group interface configuration.

clear configure ip

To clear all IP addresses set by the **ip address** command, use the **clear configure ip** command in global configuration mode.

clear configure ip

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

In transparent firewall mode, this command clears the management IP address and the management 0/0 IP address, if configured.

If you want to stop all current connections that use the old IP addresses, enter the **clear xlate** command. Otherwise, the connections time out as usual.

Examples

The following example clears all IP addresses:

```
hostname(config)# clear configure ip
```

Related Commands

Command	Description
allocate-interface	Assigns interfaces and subinterfaces to a security context.
clear configure interface	Clears all configuration for an interface.
interface	Configures an interface and enters interface configuration mode.
ip address	Sets the IP address for the interface.
show running-config interface	Displays the interface configuration.

clear configure ip audit

To clear the entire audit policy configuration, use the **clear configure ip audit** command in global configuration mode.

clear configure ip audit [**configuration**]

Syntax Description

configuration	(Optional) You can enter this keyword, but the effect is the same without it.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from **clear ip audit**.

Examples

The following example clears all **ip audit** commands:

```
hostname# clear configure ip audit
```

Related Commands

Command	Description
ip audit attack	Sets the default actions for packets that match an attack signature.
ip audit info	Sets the default actions for packets that match an informational signature.
ip audit interface	Assigns an audit policy to an interface.
ip audit name	Creates a named audit policy that identifies the actions to take when a packet matches an attack signature or an informational signature.
ip audit signature	Disables a signature.

clear configure ip local pool

To remove IP address pools, use the **clear configure ip local pool** command in global configuration mode.

clear ip local pool [*poolname*]

Syntax Description

poolname	(Optional) Specifies the name of the IP address pool.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example removes all IP address pools from the running configuration:

```
hostname(config)# clear config ip local pool
hostname(config)#
```

Related Commands

Command	Description
clear configure ip local pool	Removes all ip local pools.
ip local pool	Configures an IP address pool.

clear configure ipv6 dhcprelay

To clear the IPv6 DHCP relay configuration, use the **clear configure ipv6 dhcprelay** command in global configuration mode.

clear configure ipv6 dhcprelay

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The **clear configure ipv6 dhcprelay** command clears the IPv6 DHCP relay configuration.

Examples

The following example clears the IPv6 DHCP relay configuration:

```
hostname# clear configure ipv6 dhcprelay
```

Related Commands

Commands	Description
clear ipv6 dhcprelay binding	Clears IPv6 DHCP relay binding entries.
debug ipv6 dhcprelay	Enables the display of debugging information for IPv6 DHCP relay.
show ipv6 dhcprelay binding	Shows IPv6 DHCP relay binding entries.

clear configure ipv6 router

To clear OSPFv3 routing processes, use the **clear configure ipv6 router** command in privileged EXEC mode.

clear configure ipv6 router ospf

Syntax Description

ospf	Clears the OSPFv3 routing processes.

Defaults

By default, this command clears all OSPFv3 routing parameters.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use the **clear configure ipv6 router** command to clear OSPFv3 processes.

Examples

The following example clears the OSPFv3 processes:

```
hostname# clear configure ipv6 router
```

Related Commands

Command	Description
clear ipv6 ospf	Deletes all IPv6 settings in the OSPFv3 routing process.
debug ospfv3	Provides debugging information for troubleshooting OSPFv3 routing processes.

clear configure ip verify reverse-path

To clear the **ip verify reverse-path** configuration, use the **clear configure ip verify reverse-path** command in global configuration mode.

clear configure ip verify reverse-path

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from **clear ip verify reverse-path**.

Examples

The following example clears the **ip verify reverse-path** configuration for all interfaces:

```
hostname(config)# clear configure ip verify reverse-path
```

Related Commands

Command	Description
clear ip verify statistics	Clears the unicast RPF statistics.
ip verify reverse-path	Enables the unicast RPF feature to prevent IP spoofing.
show ip verify statistics	Shows the unicast RPF statistics.
show running-config ip verify reverse-path	Shows the **ip verify reverse-path** configuration.

clear configure ipv6

To clear the global IPv6 commands from the running configuration, use the **clear configure ipv6** command in global configuration mode.

clear configure ipv6 [**route** | **access-list**]

Syntax Description

access-list	(Optional) Clears the IPv6 access list commands from the running configuration.
route	(Optional) Clears the commands that statically define routes in the IPv6 routing table from the running configuration.

Defaults

Without keywords, this command clears all IPv6 commands from the running configuration.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command only clears the global IPv6 commands from the running configuration; it does not clear the IPv6 commands entered in interface configuration mode.

Examples

The following example shows how to clear statically defined IPv6 routes from the IPv6 routing table:

```
hostname(config)# clear configure ipv6 route
hostname(config)#
```

Related Commands

Command	Description
ipv6 route	Defines a static route in the IPv6 routing table.
show ipv6 route	Displays the contents of the IPv6 routing table.
show running-config ipv6	Displays the IPv6 commands in the running configuration.

clear configure isakmp

To remove all of the ISAKMP configuration, use the **clear configure isakmp** command in global configuration mode.

clear configure isakmp

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	The **clear configure isakmp** command was introduced.
7.2(1)	This command was deprecated. The **clear configure crypto isakmp** command replaced it.
9.0(1)	Support for multiple context mode was added.

Examples

The following example issued in global configuration mode, removes all of the ISAKMP configuration from the ASA:

```
hostname(config)# clear configure isakmp
hostname(config)#
```

Related Commands

Command	Description
clear configure isakmp policy	Clears all ISAKMP policy configuration.
isakmp enable	Enables ISAKMP negotiation on the interface on which the IPsec peer communicates with the ASA.
show isakmp stats	Displays runtime statistics.
show isakmp sa	Displays IKE runtime SA database with additional information.
show running-config isakmp	Displays the active configuration.

clear configure isakmp policy

To remove all of the ISAKMP policy configuration, use the **clear configure isakmp policy** command in global configuration mode.

clear configure isakmp policy *priority*

Syntax Description

priority	Specifies the priority of the ISAKMP priority to be cleared.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	The **clear configure isakmp policy** command was introduced.
7.2(1)	This command was deprecated. The **clear configure crypto isakmp policy** command replaced it.

Examples

The following example removes the ISAKMP policy with priority 3 from the configuration:

```
hostname(config)# clear configure isakmp policy 3
hostname(config)#
```

Related Commands

Command	Description
isakmp enable	Enables ISAKMP negotiation on the interface on which the IPsec peer communicates with the ASA.
show isakmp stats	Displays runtime statistics.
show isakmp sa	Displays IKE runtime SA database with additional information.
show running-config isakmp	Displays the active configuration.

clear configure ldap attribute-map

To remove all the LDAP attribute maps from the running configuration of the ASA, use the **clear configure ldap attribute-map** command in global configuration mode.

clear configure ldap attribute-map

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Use this command to remove the LDAP attribute maps from the running configuration of the ASA.

Examples

The following example, entered in global configuration mode, removes all LDAP attributes map from the running configuration and then confirms the removal by using the **show running-config ldap attribute-map** command:

```
hostname(config)# clear configuration ldap attribute-map
hostname(config)# show running-config ldap attribute-map
hostname(config)#
```

Related Commands

Command	Description
ldap attribute-map (global config mode)	Creates and names an LDAP attribute map for mapping user-defined attribute names to Cisco LDAP attribute names.
ldap-attribute-map (aaa-server host mode)	Binds an LDAP attribute map to an LDAP server.
map-name	Maps a user-defined LDAP attribute name with a Cisco LDAP attribute name.

Command	Description
map-value	Maps a user-defined attribute value to a Cisco attribute.
show running-config ldap attribute-map	Displays a specific running LDAP attribute map or all running attribute maps.

clear configure logging

To clear logging configuration, use the **clear configure logging** command in global configuration mode.

clear configure logging [**disabled** | **level**]

Syntax Description

disabled	(Optional) Indicates that all disabled syslog messages should be re-enabled. When you use this option, no other logging configuration is cleared.
level	(Optional) Indicates that the severity level assignments for syslog messages should be reset to their default values. When you use this option, no other logging configuration is cleared.

Defaults

With no keywords specified, this command returns all configuration settings to their default values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can use the **show running-config logging** command to view all logging configuration settings. If you use the **clear configure logging** command without either the **disabled** or **level** keyword, all logging configuration settings are cleared and returned to their default values.

Examples

The following example shows how to clear logging configuration settings. The output of the **show logging** command indicates that all logging features have been disabled.

```
hostname(config)# clear configure logging
hostname(config)# show logging
Syslog logging: disabled
    Facility: 20
    Timestamp logging: disabled
    Standby logging: disabled
    Deny Conn when Queue Full: disabled
    Console logging: disabled
    Monitor logging: disabled
    Buffer logging: disabled
    Trap logging: disabled
    History logging: disabled
    Device ID: disabled
```

```
Mail logging: disabled
ASDM logging: disabled
```

Related Commands

Command	Description
show logging	Displays the enabled logging options.
show running-config logging	Displays the logging-related portion of the running configuration.

clear configure logging rate-limit

To reset the logging rate limit, use the **clear configure logging rate-limit** command in global configuration mode.

clear configure logging rate-limit

Syntax DescriptionT

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(4)	This command was introduced.

Examples

The following example shows how to reset the logging rate limit:

```
hostname(config)# clear configure logging rate-limit
```

After the information is cleared, nothing more displays until the hosts reestablish their connections.

Related Commands

Command	Description
logging rate limit	Limits the rate at which syslog messages are generated.
show running config logging rate-limit	Shows the current logging rate limit setting.

clear configure mac-address-table

To clear the **mac-address-table static** and **mac-address-table aging-time** configuration, use the **clear configure mac-address-table** command in global configuration mode.

clear configure mac-address-table

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	—	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example clears the **mac-address-table static** and **mac-address-table aging-time** configuration:

```
hostname# clear configure mac-address-table
```

Related Commands

Command	Description
firewall transparent	Sets the firewall mode to transparent.
mac-address-table aging-time	Sets the timeout for dynamic MAC address entries.
mac-address-table static	Adds static MAC address entries to the MAC address table.
mac-learn	Disables MAC address learning for an interface.
show mac-address-table	Shows the MAC address table, including dynamic and static entries.

clear configure mac-learn

To clear the **mac-learn** configuration, use the **clear configure mac-learn** command in global configuration mode.

clear configure mac-learn

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	—	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example clears the **mac-learn** configuration:

```
hostname# clear configure mac-learn
```

Related Commands

Command	Description
firewall transparent	Sets the firewall mode to transparent.
mac-address-table static	Adds static MAC address entries to the MAC address table.
mac-learn	Disables MAC address learning for an interface.
show mac-address-table	Shows the MAC address table, including dynamic and static entries.

clear configure mac-list

To remove the indicated list of MAC addresses, previously specified in the **mac-list** command, use the **clear configure mac-list** command in global configuration mode:

clear configure mac-list *id*

Syntax Description

id	A MAC address list name.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was modified to conform to CLI standards.

Usage Guidelines

To remove a list of MAC addresses, use the **clear mac-list** command.

Examples

The following example shows how to clear a MAC address list:

```
hostname(config)# clear configure mac-list firstmaclist
```

Related Commands

Command	Description
mac-list	Adds a list of MAC addresses using a first-match search.
show running-config mac-list	Displays the MAC addresses in the MAC address list indicated by the *id* value.

clear configure management-access

To remove the configuration of an internal interface for management access of the ASA, use the **clear configure management-access** command in global configuration mode.

clear configure management-access

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	The keyword **configure** was added.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

The **management-access** command lets you define an internal management interface using the IP address of the firewall interface specified in the *mgmt_if* argument. (The interface names are defined by the **nameif** command and displayed in quotes, " ", in the output of the **show interface** command.) The **clear configure management-access** command removes the configuration of the internal management interface specified with the **management-access** command.

Examples

The following example removes the configuration of an internal interface for management access of the ASA:

```
hostname(config)# clear configure management-access
```

Related Commands

Command	Description
management-access	Configures an internal interface for management access.
show running-config management-access	Displays the name of the internal interface configured for management access.

clear configure media-termination

To clear the configured media-termination instances from a phone proxy, use the **clear configure media-termination** command in privileged EXEC mode.

clear configure media-termination

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Examples

The following example clears the configured media-termination instances from a phone proxy:

```
hostname# clear configure media-termination
```

Related Commands

Command	Description
media-termination address	Configures the media-termination address for a phone proxy instance.

clear configure monitor-interface

To remove all **monitor-interface** commands from the running configuration and restore the default interface health monitoring, use the **clear configure monitor-interface** command in global configuration mode.

clear configure monitor-interface

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

By default, physical interfaces are monitored for failover. Using the **clear monitor-interface** command clears the **no monitor-interface** commands from the running configuration and restores default interface health monitoring. To view the **monitor-interface** commands in the running configuration, use the **show running-config all monitor-interface** command.

Examples

The following example clears the **monitor-interface** commands from the running configuration:

```
hostname(config)# clear configure monitor-interface
hostname(config)#
```

Related Commands

Command	Description
monitor-interface	Enables health monitoring of a designated interface for failover purposes.
show running-config monitor-interface	Displays the **monitor-interface** commands in the running configuration.

clear configure mroute

To remove the **mroute** commands from the running configuration, use the **clear configure mroute** command in global configuration mode.

clear configure mroute

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to remove the **mroute** commands from the configuration:

```
hostname(config)# clear configure mroute
hostname(config)#
```

Related Commands

Command	Description
mroute	Configures a static multicast route.
show mroute	Displays IPv4 multicast routing table.
show running-config mroute	Displays the **mroute** commands in the running configuration.

clear configure mtu

To clear the configured maximum transmission unit values on all interfaces, use the **clear configure mtu** command in global configuration mode.

clear configure mtu

Syntax Description

This command has no arguments or keywords.

Defaults

Using the **clear configure mtu** command sets the maximum transmission unit to the default of 1500 for all Ethernet interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	—	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example clears the current maximum transmission unit values on all interfaces:

```
hostname(config)# clear configure mtu
```

Related Commands

Command	Description
mtu	Specifies the maximum transmission unit for an interface.
show running-config mtu	Displays the current maximum transmission unit block size.

clear configure multicast-routing

To remove the **multicast-routing** command from the running configuration, use the **clear configure multicast-routing** command in global configuration mode.

clear configure multicast-routing

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **clear configure multicast-routing** command removes the multicast routing from the running configuration.

Examples

The following example shows how to remove the **multicast-routing** command from the running configuration:

```
hostname(config)# clear configure multicast-routing
```

Related Commands

Command	Description
multicast-routing	Enables multicast routing on the ASA.

clear configure nac-policy

To remove all NAC policies from the running configuration, except for those that are assigned to group policies, use the **clear configure nac-policy** command in global configuration mode.

clear configure nac-policy

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	—	—	•

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use this command only if you want to remove all NAC policies. Use the **no** form of the **nac-policy** command to remove a single NAC policy from the configuration.

Examples

The following example shows how to remove all NAC policies:

```
hostname(config)# clear config nac-policy
```

Related Commands

Command	Description
nac-policy	Creates and accesses a Cisco NAC policy, and specifies its type.
show nac-policy	Displays NAC policy usage statistics on the ASA.
show running-config nac-policy	Displays the configuration of each NAC policy on the ASA.
show vpn-session_summary.db	Displays the number of IPsec, WebVPN, and NAC sessions.
show vpn-session.db	Displays information about VPN sessions, including NAC results.

clear configure name

To clear the list of names from the configuration, use the **clear configure name** command in global configuration mode.

clear configure name

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	The **configure** keyword was added.

Usage Guidelines

Use this command to clear the list of names in a configuration.

Examples

The following example shows how to clear the list of names in a configuration:

```
hostname(config)# clear configure name
```

Related Commands

Command	Description
name	Associates a name with an IP address.
show running-config name	Displays the list of names associated with IP addresses.

clear configure nat

To remove the NAT configuration, use the **clear configure nat** command in global configuration mode.

clear configure nat

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	Added the keyword **configure**.
8.0(2)	We introduced support for NAT in transparent mode.
8.3(1)	The NAT configuration was migrated to a new set of commands. This command clears the new NAT configuration.

Usage Guidelines

This command clears both network object NAT **nat** commands and twice NAT **nat** commands.

Examples

The following example shows how to remove the NAT configuration:

```
hostname(config)# show running-config nat
nat (any,any) source static any any
!
object network test
 nat (any,any) static 10.2.2.2
hostname(config)# clear configure nat
hostname(config)# show running-config nat
hostname(config)#
```

Related Commands

Command	Description
nat (object network)	Configures network object NAT.

Command	Description
nat (global)	Configures twice NAT.
show running-config nat	Displays the NAT configuration.

clear configure ntp

To clear the NTP configuration, use the **clear configure ntp** command in global configuration mode.

clear configure ntp

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was changed from **clear ntp**.

Examples

The following example clears all **ntp** commands:

```
hostname# clear configure ntp
```

Related Commands

Command	Description
ntp authenticate	Enables NTP authentication.
ntp authentication-key	Sets the NTP authentication key.
ntp server	Identifies an NTP server to set the time on the ASA.
ntp trusted-key	Specifies the NTP trusted key.
show running-config ntp	Shows the NTP configuration.

clear configure object

To clear all unused network objects and service objects from the configuration, including any NAT objects within these objects, use the **clear configure object** command in global configuration mode.

clear configure object

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Examples

The following example shows how to remove all network objects and service objects from the configuration:

```
hostname(config)# clear configure object
```

Related Commands

Command	Description
object-network	Defines a named network object that is reflected in all configurations in which the object is used.
object-service	Defines a service object that is reflected in all configurations in which the object is used.
show running-config object	Displays the objects in the configuration.

clear configure object-group

To remove all the **object group** commands from the configuration, use the **clear configure object-group** command in global configuration mode.

clear configure object-group [**protocol** | **service** | **icmp-type** | **network** | **security-group**]

Syntax Description

icmp-type	(Optional) Clears all ICMP groups.
network	(Optional) Clears all network groups.
protocol	(Optional) Clears all protocol groups.
security-group	(Optional) Clears all security groups.
service	(Optional) Clears all service groups.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	The **security-group** keyword was added.

Examples

The following example shows how to remove all the **object-group** commands from the configuration:

```
hostname(config)# clear configure object-group
```

Related Commands

Command	Description
group-object	Adds network object groups.
network-object	Adds a network object to a network object group.
object-group	Defines object groups to optimize your configuration.
port-object	Adds a port object to a service object group.
show running-config object-group	Displays the current object groups.

clear configure object-group-search

To clear the object-group-search configuration, use the **clear config object-group-search** command in global configuration mode.

clear config object-group-search

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Examples

The following example shows how to clear the object-group-search configuration:

```
hostname# clear config object-group-search
```

Related Commands

Command	Description
show object-group	Shows the hit count if the object group is of the network object-group type.
show running-config object-group	Displays the current object groups.
show running-config object-group-search	Shows the object-group-search configuration in the running configuration.

clear configure pager

To remove the number of lines set to display in a Telnet session before the "---More---" prompt appears from the running configuration, use the **clear configure pager** command in global configuration mode.

clear configure pager

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
4.0(1)	This command was introduced.

Examples

The following example shows how to remove the number of lines set to display in a Telnet session before the "---More---" prompt appears from the running configuration:

```
hostname(config)# clear configure pager
hostname(config)#
```

Related Commands

Command	Description
show pager	Displays the default number of lines set to display in a Telnet session before the "---More---" prompt appears.
show running-config pager	Displays the number of lines set to display in a Telnet session before the "---More---" prompt appears in the running configuration.
terminal pager	Sets the number of lines to display in a Telnet session before the "---More---" prompt appears. This command is not saved to the running configuration.

clear configure passwd

To clear the login password configuration and reset the remote password, use the **clear configure passwd** command in global configuration mode.

clear configure {**passwd** | **password**}

Syntax Description

passwd | **password**	You can enter either command; they are aliased to each other.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was changed from **clear passwd**.
9.1(2)	Resets the remote password and removes the default password “cisco.”

Examples

The following example resets the remote password and removes the default password “cisco”:

```
hostname(config)# clear configure passwd
```

Related Commands

Command	Description
enable	Enters privileged EXEC mode.
enable password	Sets the enable password.
passwd	Sets the login password.
show curpriv	Shows the currently logged in username and the user privilege level.
show running-config passwd	Shows the login password in encrypted form.

clear configure password-policy

To reset password policy for the current context to the default value, use the **clear configure password-policy** command in global configuration mode.

clear configure password-policy

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
9.1(2)	This command was introduced.

Examples

The following example clears the password policy and restores it to the default value:

```
hostname(config)# clear configure password-policy
```

Related Commands

Command	Description
show run password-policy	Shows the password policy for the current context.
password-policy authenticate-enable	Determines whether users are allowed to modify their own user account without authenticating.

clear configure phone-proxy

To clear the Phone Proxy configuration, use the **clear configure phone-proxy** command in global configuration mode.

clear configure phone-proxy [*phone_proxy_name*]

Syntax Description

phone_proxy_name	Specifies the name of the Phone Proxy instance.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Examples

The following example clears the Phone Proxy configuration:

```
hostname# clear configure phone-proxy asa_phone_proxy
```

Related Commands

Command	Description
phone-proxy	Configures the Phone Proxy instance.

clear configure pim

To clear all of the global **pim** commands from the running configuration, use the **clear configure pim** command in global configuration mode.

clear configure pim

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **clear configure pim** command clears all of the **pim** commands from the running configuration. To clear PIM traffic counters and topology information, use the **clear pim counters** and the **clear pim topology** commands.

The **clear configure pim** command only clears the **pim** commands entered in global configuration mode; it does not clear the interface-specific **pim** commands.

Examples

The following example shows how to clear all **pim** commands from the running configuration:

```
hostname(config)# clear configure pim
```

Related Commands

Command	Description
clear pim topology	Clears the PIM topology table.
clear pim counters	Clears the PIM traffic counters.
show running-config pim	Displays the **pim** commands in the running configuration.

clear configure policy-map

To remove the all **policy-map** commands, use the **clear configure policy-map** command in global configuration mode.

clear configure policy-map [**type inspect** [*protocol*]}

Syntax Description

protocol	(Optional) Specifies the type of inspection policy map that you want to clear. Available types include: • **dcerpc** • **dns** • **esmtp** • **ftp** • **gtp** • **h323** • **http** • **im** • **mgcp** • **netbios** • **p2p** • **radius-accounting** • **sip** • **skinny** • **snmp**
type inspect	(Optional) Clears inspection policy maps.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To clear the policy map for a specific policy map name, use the **no** form of the **policy-map** command.

Examples

The following example shows the **clear configure policy-map** command:

```
hostname(config)# clear configure policy-map
```

Related Commands

Command	Description
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
show running-config policy-map	Displays the entire policy configuration.

clear configure pop3s

To remove all POP3S commands from the configuration, reverting to default values, use the **clear configure pop3s** command in global configuration mode.

clear configure pop3s

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to remove the POP3S configuration:

```
hostname(config)# clear configure pop3s
hostname(config)#
```

Related Commands

Command	Description
show running-configuration pop3s	Displays the running configuration for POP3S.
pop3s	Creates or edits a POP3S e-mail proxy configuration.

clear configure prefix-list

To remove the **prefix-list** commands from the running configuration, use the **clear configure prefix-list** command in global configuration mode.

clear configure prefix-list [*prefix_list_name*]

Syntax Description

prefix_list_name	(Optional) The name of a prefix list. When a prefix list name is specified, only the commands for that prefix list are removed from the configuration.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from **clear prefix-list** to **clear configure prefix-list**.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The **clear configure prefix-list** command removes the **prefix-list** commands and the **prefix-list description** commands from the running configuration. If a prefix list name is specified, then the **prefix-list** command and **prefix-list description** command, if present, for that prefix list only are removed from the running configuration.

This command does not remove the **no prefix-list sequence** command from the running configuration.

Examples

The following example removes all **prefix-list** commands from the running configuration for a prefix list named MyPrefixList:

```
hostname# clear configure prefix-list MyPrefixList
```

Related Commands

Command	Description
show running-config prefix-list	Displays the **prefix-list** commands in the running configuration.

clear configure priority-queue

To remove the priority queue specification from the configuration, use the **clear configure priority-queue** command in global configuration mode.

clear configure priority queue *interface-name*

Syntax Description

interface-name	Specifies the name of the interface for which you want to show the priority queue details

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

This example removes the priority-queue configuration on the interface named test:

```
hostname(config)# clear configure priority-queue test
```

Related Commands

Command	Description
priority-queue	Configures priority queueing on an interface.
show running-config priority-queue	Displays the current priority-queue configuration for the named interface.

clear configure privilege

To remove the configured privilege levels for commands, use the **clear configure privilege** command in global configuration mode.

clear configure privilege

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was modified to conform to CLI guidelines.

Usage Guidelines

There is no undo.

Examples

This example shows how to reset the configured privilege levels for the commands:

```
hostname(config)# clear configure privilege
```

Related Commands

Command	Description
privilege	Configures the command privilege levels.
show curpriv	Displays current privilege level
show running-config privilege	Displays privilege levels for commands.

clear configure regex

To remove all regular expressions, use the **clear configure regex** command in global configuration mode.

clear configure regex

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To clear the regular expression for a specific regular expression name, use the **no** form of the **regex** command.

Examples

The following example shows how to clear all configured regular expressions:

```
hostname(config)# clear configure regex
```

Related Commands

Command	Description
class-map type regex	Creates a regular expression class map.
regex	Creates a regular expression.
show running-config regex	Shows all regular expressions.
test regex	Tests a regular expression.

clear configure route

To remove the **route** commands from the configuration that do not contain the **connect** keyword, use the **clear configure route** command in global configuration mode.

clear configure route [*interface_name ip_address* [*netmask gateway_ip*]]

Syntax Description

gateway_ip	(Optional) Specifies the IP address of the gateway router (the next hop address for this route).
interface_name	(Optional) Internal or external network interface name.
ip_address	(Optional) Internal or external network IP address.
netmask	(Optional) Specifies a network mask to apply to the *ip_address*.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	Added keyword **configure**.

Usage Guidelines

Use **0.0.0.0** to specify a default route. You can abbreviate the 0.0.0.0 IP address as **0** and the 0.0.0.0 *netmask* as **0.**

Examples

The following example shows how to remove the **route** commands from the configuration that do not contain the **connect** keyword:

```
hostname(config)# clear configure route
```

Related Commands

Command	Description
route	Specifies a static or default route for the an interface.
show route	Displays route information.
show running-config route	Displays configured routes.

clear configure route-map

To remove all of the route maps, use the **clear configure route-map** command in global configuration mode.

clear configure route-map

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the **clear configure route-map** command in global configuration mode to remove all the **route-map** commands in the configuration. The **route-map** command is used to configure conditions of redistributing the routes from one routing protocol into another routing protocol.

To remove the individual **route-map** commands, use the **no route-map** command.

Examples

The following example shows how to remove the conditions of redistributing routes from one routing protocol into another routing protocol:

```
hostname(config)# clear configure route-map
```

Related Commands

Command	Description
route-map	Defines the conditions for redistributing routes from one routing protocol into another.
show running-config route-map	Displays information about the route map configuration.

clear configure router

To clear the router configuration commands from the running configuration, use the **clear configure router** command in global configuration mode.

clear configure router [**ospf** [*id*] | **rip** | **eigrp** [*as-number*]]

Syntax Description

as-number	(Optional) Clears the configuration commands for the specified EIGRP autonomous system number, also known as the process ID. If not specified, the configuration commands for all EIGRP routing processes are cleared. The range of values is 1 through 65535. Because only one EIGRP routing process is supported on the ASA, including the optional *as-number* argument has the same effect as omitting it.
eigrp	(Optional) Specifies that only EIGRP router configuration commands are removed from the configuration. EIGRP interface configuration mode commands are not removed.
id	(Optional) Clears the configuration commands for the specified OSPF process ID. If not specified, the configuration commands for all OSPF processes are removed.
ospf	(Optional) Specifies that only OSPF configuration commands are removed from the configuration.
rip	Specifies that only RIP configuration commands are removed from the configuration.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from the **clear router** command to the **clear configure router** command.
7.2(1)	The **rip** keyword was added to the command.
8.0(2)	The **eigrp** keyword was added to the command.
9.0(1)	Multiple context mode is supported.

Examples

The following example clears all OSPF commands associated with OSPF process 1 from the running configuration:

```
hostname(config)# clear configure router ospf 1
```

The following example clears all global configuration mode commands associated with RIP routing process from the running configuration. It does not clear RIP commands entered in interface configuration mode.

```
hostname(config)# clear configure router rip
```

Related Commands

Command	Description
show running-config router	Displays the commands in the global router configuration.
router eigrp	Enables an EIGRP routing process and enters router configuration mode for that process.
router ospf	Enables an OSPF routing process and enters router configuration mode for that process.
router rip	Enables a RIP routing process and enters router configuration mode for that process.

clear configure same-security-traffic

To clear the same-security-traffic configuration, use the **clear configure same-security-traffic** command in global configuration mode.

clear configure same-security-traffic

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example clears the configuration when the **same-security-traffic** command is issued:

```
hostname(config)# clear configure same-security-traffic
```

Related Commands

Command	Description
same-security-traffic	Permits communication between interfaces with equal security levels.
show running-config same-security-traffic	Displays the configuration when the **same-security-traffic** command is issued.

clear configure service-policy

To clear the service policy configuration, use the **clear configure service-policy** command in global configuration mode.

clear configure service-policy

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is an example of the **clear configure service-policy** command:

```
hostname(config)# clear configure service-policy
```

Related Commands

Command	Description
show service-policy	Displays the service policy.
show running-config service-policy	Displays the service policies configured in the running configuration.
service-policy	Configures the service policy.
clear service-policy	Clears service policy statistics.

clear configure sla monitor

To remove the **sla monitor** commands from the running configuration, use the **clear configure sla monitor** command in global configuration mode.

clear configure sla monitor [*sla-id*]

Syntax Description

sla-id	(Optional) The ID of the SLA operation. Valid values are from 1 to 2147483647.

Defaults

If the *sla-id* argument is not specified, all SLA operation configurations are cleared.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command clears the **sla monitor** command, associated SLA monitor configuration mode commands, and the associated **sla monitor** schedule command, if present. It does not remove the **track rtr** commands from the configuration.

To view the **sla monitor** commands in the running configuration, use the **show running-config sla monitor** command.

Examples

The following example clears all **sla monitor** commands from the configuration:

```
hostname(config)# clear configure sla monitor
```

The following example clears the **sla monitor** commands associated with the SLA operation ID 5:

```
hostname(config)# clear configure sla monitor 5
```

Related Commands

Command	Description
show running-config sla monitor	Displays the **sla monitor** commands in the running configuration.

clear configure smtps

To remove all SMTPS commands from the configuration and revert to default values, use the **clear configure smtps** command in global configuration mode.

clear configure smtps

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to remove the SMTPS configuration:

```
hostname(config)# clear configure smtps
```

Related Commands

Command	Description
show running-configuration smtps	Displays the running configuration for SMTPS.
smtps	Creates or edits an SMTPS e-mail proxy configuration.

clear configure smtp-server

To clear all of the SMTP server commands and statistics, use the **clear configure smtp-server** command in global configuration mode.

clear configure smtp-server

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.1(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

The **clear configure smtp-server** command clears all of the **smtp** commands and statistical information.

Examples

The following example shows how to clear all **smtp-server** commands:

```
hostname(config)# clear configure smtp-server
```

Related Commands

Command	Description
show running-config smtp-server	Displays the current SMTP server configuration.

clear configure snmp-map

To clear the SNMP map configuration, use the **clear configure snmp-map** command in global configuration mode.

clear configure snmp-map

Syntax DescriptionT

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **clear configure snmp-map** command removes the SNMP map configuration.

Examples

The following example clears the SNMP map configuration:

```
hostname# clear configure snmp-map
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
deny version	Disallows traffic using a specific version of SNMP.
inspect snmp	Enable SNMP application inspection.
snmp-map	Defines an SNMP map and enables SNMP map configuration mode.

clear configure snmp-server

To disable the SNMP server and remove all SNMP configurations, use the **clear configure snmp-server** command in global configuration mode.

clear configure snmp-server [**group** | **host** | **user**]

Syntax Description

group	Removes all SNMP groups.
host	Removes all SNMP hosts.
user	Removes all SNMP users.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to disable the SNMP server:

```
hostname# clear configure snmp-server
```

Related Commands

Command	Description
snmp-server	Provides the ASA event information through SNMP.
show snmp-server statistics	Displays information about the SNMP server configuration.

clear configure ssh

To clear all SSH commands from the running configuration, use the **clear configure ssh** command in global configuration mode.

clear configure ssh

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from the **clear ssh** command to the **clear configure ssh** command.

Usage Guidelines

This command clears all SSH commands from the configuration. To clear specific commands, use the **no** form of those commands.

Examples

The following example clears all SSH commands from the configuration:

```
hostname(config)# clear configure ssh
```

Related Commands

Command	Description
show running-config ssh	Displays the current SSH commands in the running configuration.
ssh	Allows SSH connectivity to the ASA from the specified client or network.
ssh scopy enable	Enables a secure copy server on the ASA.
ssh timeout	Sets the timeout value for idle SSH sessions.
ssh version	Restricts the ASA to using either SSH Version 1 or SSH Version 2.

clear configure ssl

To remove all SSL commands from the configuration and revert to default values, use the **clear configure ssl** command in global configuration mode.

clear configure ssl

Syntax Description

This command has no arguments or keywords.

Defaults

By default:

- Both the SSL client and SSL server versions are **any**.
- SSL encryption is 3DES-SHA1, DES-SHA1, RC4-MD5, in that order.
- There is no trustpoint association; the ASA uses the default RSA key-pair certificate.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to use the **clear configure ssl** command:

```
hostname(config)# clear configure ssl
```

Related Commands

Command	Description
show running-config ssl	Displays the current set of configured **ssl** commands.
ssl client-version	Specifies the SSL/TLS protocol version that the ASA uses when acting as a client.
ssl server-version	Specifies the SSL/TLS protocol version that the ASA uses when acting as a server.
ssl trust-point	Specifies the certificate trustpoint that represents the SSL certificate for an interface.

clear configure static

To remove all the **static** commands from the configuration, use the **clear configure static** command in global configuration mode.

clear configure static

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	The keyword **configure** was added.

Examples

This example shows how to remove all the **static** commands from the configuration:

```
hostname(config)# clear configure static
```

Related Commands

Command	Description
show running-config static	Displays all **static** commands in the configuration.
static	Configures a persistent one-to-one address translation rule by mapping a local IP address to a global IP address.

clear configure sunrpc-server

To clear the remote processor call services from the ASA, use the **clear configure sunrpc-server** command in global configuration mode.

clear configure sunrpc-server [**active**]

Syntax Description

active	(Optional) Identifies the SunRPC services that are currently active on the ASA.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **sunrpc-server** command displays the configured **router ospf** commands.

Note If the highest-level IP address on the ASA is a private address, this address is sent in hello packets and database definitions. To prevent this action, set the **router-id** *ip_address* argument to a global address.

Examples

The following example shows how to clear the SunRPC services from the ASA:

```
hostname(config)# clear configure sunrpc-server active
```

Related Commands

Command	Description
sunrpc-server	Creates the SunRPC services table.
show running-config sunrpc-server	Displays the information about the SunRPC configuration.

clear configure sysopt

To clear the configuration for all **sysopt** commands, use the **clear configure sysopt** command in global configuration mode.

clear configure sysopt

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from **clear sysopt**.
9.0(1)	Support for multiple context mode was added.

Examples

The following example clears all **sysopt** command configuration:

```
hostname(config)# clear configure sysopt
```

Related Commands

Command	Description
show running-config sysopt	Shows the **sysopt** command configuration.
sysopt connection permit-ipsec	Permits any packets that come from an IPsec tunnel without checking any ACLs for interfaces.
sysopt connection tcpmss	Overrides the maximum TCP segment size or ensures that the maximum is not less than a specified size.
sysopt connection timewait	Forces each TCP connection to linger in a shortened TIME_WAIT state after the final normal TCP close-down sequence.
sysopt nodnsalias	Disables alteration of the DNS A record address when you use the **alias** command.

clear configure tcp-map

To clear the TCP map configuration, use the **clear configure tcp-map** command in global configuration mode.

clear configure tcp-map

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to clear the TCP map configuration:

```
hostname(config)# clear configure tcp-map
```

Related Commands

Command	Description
tcp-map	Creates a TCP map and accesses tcp-map configuration mode.
show running-config tcp-map	Displays the information about the TCP map configuration.

clear configure telnet

To remove the Telnet connection and idle timeout from the configuration, use the **clear configure telnet** command in global configuration mode.

clear configure telnet

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	The keyword **configure** was added.

Examples

This example shows how to remove the Telnet connection and the idle timeout from the ASA configuration:

```
hostname(config)# clear configure telnet
```

Related Commands

Command	Description
show running-config telnet	Displays the current list of IP addresses that are authorized to use Telnet connections to the ASA.
telnet	Adds Telnet access to the console and sets the idle timeout.

clear configure terminal

To clear the terminal display width setting, use the **clear configure terminal** command in global configuration mode.

clear configure terminal

Syntax Description

This command has no arguments or keywords.

Defaults

The default display width is 80 columns.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	The **configure** keyword was added.

Examples

The following example clears the display width:

```
hostname# clear configure terminal
```

Related Commands

Command	Description
terminal	Sets the terminal line parameters.
terminal width	Sets the terminal display width.
show running-config terminal	Displays the current terminal settings.

clear configure threat-detection

To clear the threat detection configuration, use the **clear configure threat-detection** command in global configuration mode.

clear configure threat-detection

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

This command clears all **threat-detection** configuration commands.

Examples

The following example clears all threat detection commands:

```
hostname# clear configure threat-detection
```

Related Commands

Command	Description
clear threat-detection rate	Clears basic threat detection statistics.
clear threat-detection shun	Releases currently shunned hosts.
show running-config threat-detection	Shows the threat detection configuration.
threat-detection basic-threat	Enables basic threat detection.
threat-detection scanning-threat	Enables scanning threat detection.

clear configure timeout

To restore the default idle time durations in the configuration, use the **clear configure timeout** command in global configuration mode.

clear configure timeout

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

This example shows how to remove the maximum idle time durations from the configuration:

```
hostname(config)# clear configure timeout
```

Related Commands

Command	Description
show running-config timeout	Displays the timeout value of the designated protocol.
timeout	Sets the maximum idle time duration.

clear configure time-range

To clear all configured time ranges, use the **clear configure time-range** command in global configuration mode.

clear configure time-range

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example clears all configured time ranges:

```
hostname(config)# clear configure time-range
```

Related Commands

Command	Description
time-range	Enters time-range configuration mode and defines a time range that you can attach to traffic rules, or an action.

clear configure tls-proxy

To remove all configured TLS proxy instances, use the **clear configure tls-proxy** command in global configuration mode.

clear configure tls-proxy

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Examples

The following following example removes all configured TLS proxy instances using the **clear configure tls-proxy** command:

```
hostname# clear configure tls-proxy
```

Related Commands

Command	Description
client	Defines a cipher suite and sets the local dynamic certificate issuer or keypair.
ctl-provider	Defines a CTL provider instance and enters provider configuration mode.
show running-config tls-proxy	Shows running configuration of all or specified TLS proxies.
tls-proxy	Defines a TLS proxy instance and sets the maximum sessions.

clear configure tunnel-group

To remove all or specified tunnel groups from the configuration, use the **clear config tunnel-group** command in global configuration.

clear config tunnel-group [*name*]

Syntax Description

name	(Optional) Specifies the name of a tunnel group.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Examples

The following example entered in global configuration mode, removes the toengineering tunnel group from the configuration:

```
hostname(config)# clear config tunnel-group toengineering
hostname(config)#
```

Related Commands

Command	Description
show running-config tunnel-group	Displays information about all or selected tunnel-groups.
tunnel-group	Enters tunnel-group configuration mode for the specified type.

clear configure tunnel-group-map

To clear the policy and rules by which the tunnel group name is derived from the content of the certificate, use the **clear configure tunnel-group-map** command in global configuration mode.

clear configure tunnel-group-map

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

The tunnel-group-map commands configure the policy and rules by which certificate-based IKE sessions are mapped to tunnel groups. To associate the certificate map entries created using the **crypto ca certificate map** command with tunnel groups, use the **tunnel-group-map** command in global configuration mode. You can invoke this command multiple times as long as each invocation is unique and you do not reference a map index more than once.

The **crypto ca certificate map** command maintains a prioritized list of certificate mapping rules. There can be only one map. But this map can have up to 65535 rules. See the documentation on the **crypto ca certificate map** command for more information.

The processing that derives the tunnel group name from the certificate ignores entries in the certificate map that are not associated with a tunnel group (any map rule not identified by this command).

Examples

The following example entered in global configuration mode, specifies a default tunnel group to use when the name cannot be derived by other configured methods:

```
hostname(config)# clear configure tunnel-group-map
```

Related Commands

Command	Description
crypto ca certificate map	Enters crypto ca certificate map configuration mode.
subject-name (crypto ca certificate map)	Identifies the DN from the CA certificate that is to be compared to the rule entry string.
tunnel-group-map default-group	Designates an existing tunnel group name as the default tunnel group.
tunnel-group-map enable	Configures the policy and rules by which certificate-based IKE sessions are mapped to tunnel groups.

clear configure uc-ime

To clear the running configuration for the Cisco Intercompany Media Engine proxy on the ASA, use the **clear configure uc-ime** command in global configuration mode.

clear configure uc-ime [*name*]

Syntax Description

name	(Optional) Specifies the instance name of the Cisco Intercompany Media Engine proxy configured on the ASA. The *name* argument is limited to 64 characters. Only one Cisco Intercompany Media Engine proxy can be configured on the ASA.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
8.3(1)	The command was introduced.

Usage Guidelines

This command has no usage guidelines.

Examples

The following example clears the running configuration for the Cisco Intercompany Media Engine proxy:

```
hostname(config)# clear configure local-ent-ime
```

Related Commands

Command	Description
clear uc-ime	Clears the statistical counters for the Cisco Intercompany Media Engine proxy.
show running-config uc-ime	Shows the running configuration of the Cisco Intercompany Media Engine proxy.

Command	Description
show uc-ime	Displays statistical or detailed information about fallback notifications, mapping service sessions, and signaling sessions.
uc-ime	Creates the Cisco Intercompany Media Engine proxy instance on the ASA.

clear configure url-block

To clear clears URL pending block buffer and long URL support configuration, use the **clear configure url-block** command in global configuration mode.

clear configure url-block

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **clear configure url-block** command clears URL pending block buffer and long URL support configuration.

Examples

The following example clears the URL pending block buffer and long URL support configuration:

```
hostname# clear configure url-block
```

Related Commands

Commands	Description
clear url-block block statistics	Clears the block buffer usage counters.
show url-block	Displays information about the URL cache, which is used for buffering URLs while waiting for responses from an N2H2 or Websense filtering server.
url-block	Manages the URL buffers used for web server responses.
url-cache	Enables URL caching while pending responses from an N2H2 or Websense server and sets the size of the cache.
url-server	Identifies an N2H2 or Websense server for use with the **filter** command.

clear configure url-cache

To clear the URL cache, use the **clear configure url-cache** command in global configuration mode.

clear configure url-cache

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **clear configure url-cache** command clears the URL cache.

Examples

The following example clears the URL cache:

```
hostname# clear configure url-cache
```

Related Commands

Commands	Description
clear url-cache statistics	Removes **url-cache** command statements from the configuration.
filter url	Directs traffic to a URL filtering server.
show url-cache statistics	Displays information about the URL cache, which is used for buffering URLs while waiting for responses from an N2H2 or Websense filtering server.
url-cache	Enables URL caching while pending responses from an N2H2 or Websense server and sets the size of the cache.
url-server	Identifies an N2H2 or Websense server for use with the **scsc** command.

clear configure url-list

To remove a configured set of URLs that WebVPN users can access , use the **clear configure url-list** command in global configuration mode.

clear configure url-list [*listname***]**

Syntax Description

listname	Groups the set of URLs that WebVPN users can access. The maximum is 64 characters.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To remove all configured URLs, use this command without the *listname* argument.

To remove only the URLs for a specific list, use this command with that *listname* argument.

Examples

The following example shows how to remove the URL list called Marketing URLs.

```
hostname(config)# clear configure url-list Marketing URLs
```

Related Commands

Command	Description
show running-configuration url-list	Displays the current set of configured **url-list** commands.
url-list	Configures the set of URLs that WebVPN users can access.
url-list	Enables WebVPN URL access for a specific group policy or user.

clear configure url-server

To clear the URL filtering server configuration, use the **clear configure url-server** command in global configuration mode.

clear configure url-server

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **clear configure url-server** command clears the URL filtering server configuration.

Examples

The following example URL filtering server configuration:

```
hostname# clear configure url-server
```

Related Commands

Commands	Description
clear url-server	Clears the URL filtering server statistics.
show url-server	Displays information about the URL cache, which is used for buffering URLs while waiting for responses from an N2H2 or Websense filtering server.
url-cache	Enables URL caching while pending responses from an N2H2 or Websense server and sets the size of the cache.
url-block	Manages the URL buffers used for web server responses while waiting for a filtering decision from the filtering server.
url-server	Identifies an N2H2 or Websense server for use with the **filter** command.

clear configure user-identity

To clear the configuration for the Identity Firewall, use the **clear configure user-identity** command in global configuration mode.

clear configure user-identity [**ad-agent** | **logout-probe** | **action** | **domain**]

Syntax Description

action	Removes the configuration for the following Identity Firewall actions configured by the following commands: • **user-identity action ad-agent-down** • **user-identity action domain-controller-down** • **user-identity action mac-address-mismatch** • **user-identity action netbios-response-fail**
ad-agent	Removes all configuration for the Active Directory Agent configured for the Identity Firewall.
domain	Removes all domains configured for the Identity Firewall. Specifying this keyword only removes the domains that are not referenced by a domain object (for example, in the **object-group** or **access-list** commands).
logout-probe	Removes all configuration for the logout probe configured for the Identity Firewall. When NetBIOS probing is enabled for the Identity Firewall, the ASA probes the user client IP address to determine whether the client is still active. By default, NetBIOS probing is disabled.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
8.4(2)	This command was introduced.

Examples

The following example clears the Active Directory Agent configured for the Identity Firewall:

```
hostname# clear configure user-identity ad-agent
```

Related Commands

Commands	Description
user-identity enable	Creates the Cisco Identify Firewall instance.
user-identity logout-probe	Enables NetBIOS probing for the Cisco Identify Firewall instance.

clear configure username

To clear the username database, use the **clear configure username** command in global configuration mode.

clear configure username [*name*]

Syntax Description

name	(Optional) Provides the name of the user.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.1(2)	Password policy authentication changes were added.

Usage Guidelines

To clear the configuration for a particular user, use this command and append the username.

The internal user authentication database consists of the users entered with the **username** command. The **login** command uses this database for authentication.

When password policy authentication is enabled, this command does not allow users to delete their password. For example:

- Entering the **clear config username** *your_own _username* command is not allowed.
- Entering the **clear config username** command is allowed, but the user account is skipped and not deleted.

Examples

The following example shows how to clear the configuration for the user named anyuser:

```
hostname(config)# clear configure username anyuser
```

Related Commands

Command	Description
show running-config username	Displays the running configuration for a particular user or for all users.
username	Adds a user to the ASA database.
username attributes	Lets you configure AVPs for specific users.

clear configure virtual

To remove the authentication virtual server from the configuration, use the **clear configure virtual** command in global configuration mode.

clear configure virtual

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was modified to conform to CLI guidelines.

Usage Guidelines

There is no undo.

Examples

The following example shows the **clear configure virtual** command:

```
hostname(config)# clear configure virtual
```

Related Commands

Command	Description
show running-config virtual	Displays the IP address for the authentication virtual server.
virtual http	Allows separate authentication with the ASA and with the HTTP server.
virtual telnet	Authenticates users with the virtual Telnet server for traffic types for which the ASA does not supply an authentication prompt.

clear configure vpdn group

To remove all **vpdn group** commands from the configuration, use the **clear configure vpdn group** command in global configuration mode.

clear configure vpdn group

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

Entering the **clear configure vpdn group** command has no affect on active PPPoE connections.

Examples

The following example shows how to clear the VPDN group configuration:

```
hostname(config)# clear configure vpdn group
```

Related Commands

Command	Description
clear configure vpdn username	Removes all **vpdn username** commands from the configuration.
show running-config vpdn username	Shows the current configuration for VPDN usernames.

clear configure vpdn username

To remove all **vpdn username** commands from the configuration, use the **clear configure vpdn username** command in global configuration mode.

clear configure vpdn username

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Entering the **clear configure vpdn username** command has no affect on active PPPoE connections.

Examples

The following example shows how to clear the VPDN username configuration:

```
hostname(config)# clear configure vpdn username
```

Related Commands

Command	Description
clear configure vpdn group	Removes all **vpdn group** commands from the configuration.
show running-config vpdn username	Shows the current configuration for VPDN usernames.

clear configure vpn-load-balancing

To remove the previously specified VPN load-balancing configuration, thus disabling VPN load-balancing, use the **clear configure vpn load-balancing** command in global configuration mode.

clear configure vpn load-balancing

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

The **clear configure vpn load-balancing** command also clears the following related commands: **cluster encryption**, **cluster ip address**, **cluster key**, **cluster port**, **nat**, **participate**, and **priority**.

Examples

The following example removes VPN load-balancing configuration statements from the configuration:

```
hostname(config)# clear configure vpn load-balancing
```

Related Commands

show running-config load-balancing	Displays the current VPN load-balancing configuration.
vpn load-balancing	Enters vpn load-balancing configuration mode.

clear configure wccp

To remove all WCCP configuration, use the **clear configure wccp** command in global configuration mode.

clear configure wccp

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to clear the WCCP configuration:

```
hostname(config)# clear configure wccp
```

Related Commands

Command	Description
show wccp	Displays the WCCP configuration.
wccp redirect	Enables support of WCCP redirection.

clear configure xlate

To clear the **xlate per-session** rules, use the **clear configure xlate** command in global configuration mode.

clear configure xlate

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

This command clears manually-created rules, and keeps the default configuration.

Examples

The following example shows the running configuration plus default rules, and then clears the manually-created rules:

```
hostname(config)# show running-config all xlate
xlate per-session deny tcp any4 any4
xlate per-session deny tcp any4 any6
xlate per-session deny tcp any6 any4
xlate per-session deny tcp any6 any6
xlate per-session deny udp any4 any4 eq domain
xlate per-session deny udp any4 any6 eq domain
xlate per-session deny udp any6 any4 eq domain
xlate per-session deny udp any6 any6 eq domain
xlate per-session permit tcp any4 any4
xlate per-session permit tcp any4 any6
xlate per-session permit tcp any6 any4
xlate per-session permit tcp any6 any6
xlate per-session permit udp any4 any4 eq domain
xlate per-session permit udp any4 any6 eq domain
xlate per-session permit udp any6 any4 eq domain
xlate per-session permit udp any6 any6 eq domain
hostname(config)# clear configure xlate
hostname(config)# show running-config xlate
hostname(config)# show running-config all xlate
```

```
xlate per-session permit tcp any4 any4
xlate per-session permit tcp any4 any6
xlate per-session permit tcp any6 any4
xlate per-session permit tcp any6 any6
xlate per-session permit udp any4 any4 eq domain
xlate per-session permit udp any4 any6 eq domain
xlate per-session permit udp any6 any4 eq domain
xlate per-session permit udp any6 any6 eq domain
hostname(config)#
```

Related Commands

Command	Description
nat (global)	Adds a twice NAT rule.
nat (object)	Adds an object NAT rule.
show running-config xlate	Shows the **xlate per-session** rules.
xlate per-session	Adds a per-session PAT rule.

clear configure zonelabs-integrity

To remove all Zone Labs Integrity servers from the running configuration, use the **clear configure zonelabs-integrity** command in global configuration mode.

clear configure zonelabs-integrity

Syntax Description

This command has no arguments or keywords.

Defaults

Removes all Zone Labs Integrity servers.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2.(1)	This command was introduced.

Usage Guidelines

The **clear configure zonelabs-integrity** command removes all Zone Labs Integrity servers from the running configuration, including active and standby Integrity servers.

Examples

The following example shows the removal of two configured Zone Labs Integrity servers:

```
hostname(config)# show running-config zonelabs-integrity
zonelabs-integrity server-address 10.0.9.1 10.0.9.2
hostname(config)# clear configure zonelabs-integrity
hostname(config)# show running-config zonelabs-integrity
hostname(config)#
```

Related Commands

Command	Description
show running-config [all] zonelabs-integrity	Displays the configured Zone Labs Integrity servers.

CHAPTER 8

clear conn through clear isakmp sa Commands

clear conn

To clear a specific connection or multiple connections, use the **clear conn** command in privileged EXEC mode.

clear conn [**all**] [**protocol** {**tcp** | **udp**}] [**address** *src_ip*[**-***src_ip*] [**netmask** *mask*]] [**port** *src_port*[**-***src_port*]] [**address** *dest_ip*[**-***dest_ip*] [**netmask** *mask*]] [**port** *dest_port*[**-***dest_port*] [**user** [*domain_nickname*\]*user_name* | **user-group** [*domain_nickname*\\]*user_group_name*]]

Syntax Description

address	(Optional) Clears connections with the specified source or destination IP address.
all	(Optional) Clears all connections, including to-the-box connections. Without the **all** keyword, only through-the-box connections are cleared.
dest_ip	(Optional) Specifies the destination IP address (IPv4 or IPv6). To specify a range, separate the IP addresses with a dash (-). For example: `10.1.1.1-10.1.1.5`
dest_port	(Optional) Specifies the destination port number. To specify a range, separate the port numbers with a dash (-). For example: `1000-2000`
netmask *mask*	(Optional) Specifies a subnet mask for use with the given IP address.
port	(Optional) Clears connections with the specified source or destination port.
protocol {tcp | udp}	(Optional) Clears connections with the protocol **tcp** or **udp**.
src_ip	(Optional) Specifies the source IP address (IPv4 or IPv6). To specify a range, separate the IP addresses with a dash (-). For example: `10.1.1.1-10.1.1.5`
src_port	(Optional) Specifies the source port number. To specify a range, separate the port numbers with a dash (-). For example: `1000-2000`
user [*domain_nickname*\]*user_name*	(Optional) Clears connections that belong to the specified user. When you do not include the *domain_nickname* argument, the ASA clears connections for the user in the default domain.
user-group [*domain_nickname*\\]*user_group_name*	(Optional) Clears connections that belong to the specified user group. When you do not include the *domain_nickname* argument, the ASA clears connections for the user group in the default domain.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(8)/7.2(4)/8.0(4)	This command was introduced.
8.4(2)	Added the **user** and **user-group** keywords to support the Identity Firewall.

Usage Guidelines

This command supports IPv4 and IPv6 addresses.

When you make security policy changes to the configuration, all *new* connections use the new security policy. Existing connections continue to use the policy that was configured at the time of the connection establishment. To ensure that all connections use the new policy, you need to disconnect the current connections so they can reconnect using the new policy using the **clear conn** command. You can alternatively use the **clear local-host** command to clear connections per host, or the **clear xlate** command for connections that use dynamic NAT.

When the ASA creates a pinhole to allow secondary connections, this is shown as an incomplete connection in the **show conn** command output. To clear this incomplete connection, use the **clear conn** command.

Examples

The following example shows how to remove all connections and then clear the management connection between 10.10.10.108:4168 and 10.0.8.112:22:

```
hostname# show conn all
TCP mgmt 10.10.10.108:4168 NP Identity Ifc 10.0.8.112:22, idle 0:00:00, bytes 3084, flags
UOB

hostname# clear conn address 10.10.10.108 port 4168 address 10.0.8.112 port 22
```

Related Commandss

Commands	Description
clear local-host	Clears all connections by a specific local host or all local hosts.
clear xlate	Clears a dynamic NAT session, and any connections using NAT.
show conn	Shows connection information.
show local-host	Displays the network states of local hosts.
show xlate	Shows NAT sessions.

clear console-output

To remove the currently captured console output, use the **clear console-output** command in privileged EXEC mode.

clear console-output

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to remove the currently captured console output:

```
hostname# clear console-output
```

Related Commands

Command	Description
console timeout	Sets the idle timeout for a console connection to the ASA.
show console-output	Displays the captured console output.
show running-config console timeout	Displays the idle timeout for a console connection to the ASA.

clear coredump

To clear the coredump log, use the **clear coredump** command in global configuration mode.

clear coredump

Syntax Description

This command has no arguments or keywords.

Defaults

By default, coredumps are not enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

This command removes the coredump file system contents and the coredump log. The coredump file system remains intact. The current coredump configuration remains unchanged.

Examples

The following example removes the coredump file system contents and the coredump log:

```
hostname(config)# clear coredump
Proceed with removing the contents of the coredump filesystem on 'disk0:' [confirm]
```

Related Commands

Command	Description
coredump enable	Enables the coredump feature.
clear configure coredump	Removes the coredump file system and its contents from your system.
show coredump filesystem	Displays files on the coredump filesystem.
show coredump log	Shows the coredump log.

clear counters

To clear the protocol stack counters, use the **clear counters** command in global configuration mode.

clear counters [all | context *context-name* **| summary | top** *N* **] [detail] [protocol** *protocol_name* [:*counter_name*]] [**threshold** *N*]

Syntax Description

all	(Optional) Clears all filter details.
context *context-name*	(Optional) Specifies the context name.
:*counter_name*	(Optional) Specifies a counter by name.
detail	(Optional) Clears detailed counters information.
protocol *protocol_name*	(Optional) Clears the counters for the specified protocol.
summary	(Optional) Clears the counter summary.
threshold *N*	(Optional) Clears the counters at or above the specified threshold. The range is 1 through 4294967295.
top *N*	(Optional) Clears the counters at or above the specified threshold. The range is 1 through 4294967295.

Defaults

The **clear counters summary detail** command is the default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to clear the protocol stack counters:

```
hostname(config)# clear counters
```

Related Commands

Command	Description
show counters	Displays the protocol stack counters.

clear crashinfo

To delete the contents of the crash file in flash memory, use the **clear crashinfo** command in privileged EXEC mode.

clear crashinfo

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to delete the crash file:

```
hostname# clear crashinfo
```

Related Commands

crashinfo force	Forces a crash of the ASA.
crashinfo save disable	Disables crash information from writing to flash memory.
crashinfo test	Tests the ability of the ASA to save crash information to a file in flash memory.
show crashinfo	Displays the contents of the crash file stored in flash memory.

clear crypto accelerator statistics

To clear the the global and accelerator-specific statistics from the crypto accelerator MIB, use the **clear crypto accelerator statistics** command in privileged EXEC mode.

clear crypto accelerator statistics

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the mode in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Examples

The following example entered in global configuration mode, displays crypto accelerator statistics:

```
hostname(config)# clear crypto accelerator statistics
hostname(config)#
```

Related Commands

Command	Description
clear crypto protocol statistics	Clears the protocol-specific statistics in the crypto accelerator MIB.
show crypto accelerator statistics	Displays the global and accelerator-specific statistics in the crypto accelerator MIB.
show crypto protocol statistics	Displays the protocol-specific statistics from the crypto accelerator MIB.

clear crypto ca crls

To empty the CRL cache of all CRLs associated with a specified trustpoint, all CRLs associated with the trustpool from the cache, or the CRL cache of all CRLs, use the **clear crypto ca crls** command in privileged EXEC mode.

clear crypto ca crls [**trustpool** | trustpoint *trustpointname*]

Syntax Description

trustpointname	The name of a trustpoint. If you do not specify a name, this command clears all CRLs cached on the system. If you give the trustpoint keyword without a trustpointname, the command fails.
trustpool	Indicates that the action should be applied only to the CRLs that are associated with certificates in the trustpool.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	

Command History

Release	Modification
9.0(1)	This command was introduced.

Examples

The following independent examples issued in privileged EXEC configuration mode clear all of the trustpool CRLs, clears all of the CRLs associated with trustpoint123, and removes all of the cached CRLs from the ASA:

```
hostname# clear crypto ca crl trustpool
hostname# clear crypto ca crl trustpoint trustpoint123
hostname# clear crypto ca crl
```

Related Commands

Command	Description
crypto ca crl request	Downloads the CRL based on the CRL configuration of the trustpoint.
show crypto ca crl	Displays all cached CRLs or CRLs cached for a specified trustpoint.

clear crypto ca trustpool

To remove all certificates from the trustpool, use the **clear crypto ca trustpool** command in global configuration mode.

clear crypto ca trustpool [**noconfirm**]

Syntax Description

noconfirm	Suppresses user confirmation prompts, and the command will be processes as requested.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•		—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The user is asked to confirm this action before carrying it out.

Examples

```
hostname# clear crypto ca trustpool
You are about to clear the trusted certificate pool. Do you want to continue? (y/n)
hostname#
```

Related Commands

Command	Description
crypto ca trustpool export	Exports the certificates that constitute the PKI trustpool.
crypto ca trustpool import	Imports the certificates that constitute the PKI trustpool.
crypto ca trustpool remove	Removes a single specified certificate from the trustpool.

clear crypto ikev1

To remove the IPsec IKEv1 SAs or statistics, use the **clear crypto ikev1** command in privileged EXEC mode. To clear all IKEv1 SAs, use this command without arguments.

clear crypto ikev1 {**sa** *IP_address_hostname* | **stats**}

Syntax Description

sa	Clears the SA.
IP_address_hostname	An IP address or hostname.
stats	Clears the IKEv1 statistics.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
8.4(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

To clear all IPsec IKEv1 SAs, use this command without arguments.

Examples

The following example, issued in global configuration mode, removes all of the IPsec IKEv1 statistics from the ASA:

```
hostname# clear crypto ikev1 stats
hostname#
```

The following example, entered in global configuration mode, deletes SAs with a peer IP address of 10.86.1.1:

```
hostname# clear crypto ikev1 peer 10.86.1.1
hostname#
```

Related Commands

Command	Description
clear configure crypto map	Clears all or specified crypto maps from the configuration.
clear configure isakmp	Clears all ISAKMP policy configuration.
show ipsec sa	Displays information about IPSec SAs, including counters, entry, map name, peer IP address and hostname.
show running-config crypto	Displays the entire crypto configuration, including IPsec, crypto maps, dynamic crypto maps, and ISAKMP.

clear crypto ikev2

To remove the IPsec IKEv2 SAs or statistics, use the **clear crypto ikev2** command in privileged EXEC mode. To clear all IKEv2 SAs, use this command without arguments.

clear crypto ikev2 {**sa** *IP_address_hostname* | **stats**}

Syntax Description

sa	Clears the SA.
IP_address_hostname	An IP address or hostname.
stats	Clears the IKEv2 statistics.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
8.4(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

To clear all IPsec IKEv2 SAs, use this command without arguments.

Examples

The following example, issued in global configuration mode, removes all of the IPsec IKEv2 statistics from the ASA:

```
hostname# clear crypto ikev2 stats
hostname#
```

The following example, entered in global configuration mode, deletes SAs with a peer IP address of 10.86.1.1:

```
hostname# clear crypto ikev2 peer 10.86.1.1
hostname#
```

Related Commands

Command	Description
clear configure crypto map	Clears all or specified crypto maps from the configuration.
clear configure isakmp	Clears all ISAKMP policy configuration.
show ipsec sa	Displays information about IPsec SAs, including counters, entry, map name, peer IP address and hostname.
show running-config crypto	Displays the entire crypto configuration, including IPsec, crypto maps, dynamic crypto maps, and ISAKMP.

clear crypto ipsec sa

To remove the IPsec SA counters, entries, crypto maps or peer connections, use the **clear crypto ipsec sa** command in privileged EXEC mode. To clear all IPsec SAs, use this command without arguments.

clear [crypto] ipsec sa [counters | entry {*hostname* | *ip_address*} **{esp | ah}** *spi* **| map** *map name* **|**
peer {*hostname* | *ip_address*}**]**

Syntax Description

ah	Authentication header.
counters	Clears all IPsec per SA statistics.
entry	Deletes the tunnel that matches the specified IP address/hostname, protocol, and SPI value.
esp	Encryption security protocol.
hostname	Identifies a hostname assigned to an IP address.
ip_address	Identifies an IP address.
map	Deletes all tunnels associated with the specified crypto map as identified by map name.
map name	An alphanumeric string that identifies a crypto map. The maximum is 64 characters.
peer	Deletes all IPsec SAs to a peer as identified by the specified hostname or IP address.
spi	Identifies the Security Parameters Index (a hexidecimal number). This must be the inbound SPI. We do not support this command for the outbound SPI.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

To clear all IPsec SAs, use this command without arguments.

Examples

The following example, issued in global configuration mode, removes all of the IPsec SAs from the ASA:

```
hostname# clear crypto ipsec sa
hostname#
```

The following example, entered in global configuration mode, deletes SAs with a peer IP address of 10.86.1.1:

```
hostname# clear crypto ipsec peer 10.86.1.1
hostname#
```

Related Commands

Command	Description
clear configure crypto map	Clears all or specified crypto maps from the configuration.
clear configure isakmp	Clears all ISAKMP policy configuration.
show ipsec sa	Displays information about IPsec SAs, including counters, entry, map name, peer IP address and hostname.
show running-config crypto	Displays the entire crypto configuration, including IPsec, crypto maps, dynamic crypto maps, and ISAKMP.

clear crypto protocol statistics

To clear the protocol-specific statistics in the crypto accelerator MIB, use the **clear crypto protocol statistics** command in privileged EXEC mode.

clear crypto protocol statistics *protocol*

Syntax Description

protocol	Specifies the name of the protocol for which you want to clear statistics. Protocol choices are as follows: • **all**—All protocols currently supported. • **ikev1**—Internet Key Exchange (IKE) version 1. • **ikev2**—Internet Key Exchange (IKE) version 2. • **ipsec-client**—IP Security (IPsec) Phase-2 protocols. • **other**—Reserved for new protocols. • **srtp**—Secure RTP (SRTP) protocol • **ssh**—Secure Shell (SSH) protocol • **ssl-client—**Secure Socket Layer (SSL) protocol.

Defaults

No default behavior or values.

Command Modes

The following table shows the mode in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.4(1)	The **ikev1** and **ikev2** keywords were added.
9.0(1)	Support for multiple context mode was added.

Examples

The following example, entered in global configuration mode, clears all crypto accelerator statistics:

```
hostname# clear crypto protocol statistics all
hostname#
```

Related Commands

Command	Description
clear crypto accelerator statistics	Clears the global and accelerator-specific statistics in the crypto accelerator MIB.
show crypto accelerator statistics	Displays the global and accelerator-specific statistics from the crypto accelerator MIB.
show crypto protocol statistics	Displays the protocol-specific statistics in the crypto accelerator MIB.

clear cts

To clear data used by the ASA when integrated with Cisco TrustSec, use the **clear cts** command in global configuration mode:

clear cts {**environment-data** | **pac**}

Syntax Description

environment-data	Clears all CTS environment data.
pac	Clears the stored CTS PAC.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Using the **environment-data** keyword with the **clear cts** command clears the Cisco TrustSec environment data downloaded from the Cisco ISE. You can trigger the next environment data refresh manually or the ASA will refresh the data when the refresh timer expires. Running the **clear cts environment-data** does not remove the Cisco TrustSec PAC from the ASA. Because running the **clear cts nvironment-data** command impacts traffic policy, you are prompted to confirm the action.

Using the **pac** keyword with the **clear cts** command clears the PAC information stored in NVRAM on the ASA. Without a PAC, the ASA cannot download Cisco TrustSec environment data. However, environment data that is already on the ASA remains in use. Because running the **clear cts pac** command renders the ASA unable to retrieve environment data updates, you are prompted to confirm the action.

Restrictions

- HA: This command is not supported on the standby device in an HA configuration. Running the **clear cts** [**environment-data** | **pac**] on the standby device displays the following error message:

  This command is only permitted on the primary device.

- Clustering: This command is only supported on the master device. Running the **clear cts** [**environment-data** | **pac**] on the slave device displays the following error message:

  This command is only permitted on the master device.

Examples

The following examples show how to clear data from the ASA used for the ASA integration with Cisco TrustSec:

```
hostname# clear cts pac
Are you sure you want to delete the cts PAC? (y/n)

hostname# clear cts environment-data
Are you sure you want to delete the cts environment data? (y/n)
```

Related Commands

Command	Description
clear configure all	Clears the entire running configuration on the ASA.
clear configure cts	Clears the configuration for integrating the ASA with Cisco TrustSec.
cts sxp enable	Enables the SXP protocol on the ASA.

clear dhcpd

To clear the DHCP server bindings and statistics, use the **clear dhcp** command in privileged EXEC mode.

clear dhcpd {**binding** [*ip_address*] | **statistics**}

Syntax Description

binding	Clears all the client address bindings.
ip_address	(Optional) Clears the binding for the specified IP address.
statistics	Clears statistical information counters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If you include the optional IP address in the **clear dhcpd binding** command, only the binding for that IP address is cleared.

To clear all of the DHCP server commands, use the **clear configure dhcpd** command.

Examples

The following example shows how to clear the **dhcpd** statistics:

```
hostname# clear dhcpd statistics
```

Related Commands

Command	Description
clear configure dhcpd	Removes all DHCP server settings.
show dhcpd	Displays DHCP binding, statistic, or state information.

clear dhcprelay statistics

To clear the DHCP relay statistic counters, use the **clear dhcprelay statistics** command in privileged EXEC mode.

clear dhcprelay statistics

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **clear dhcprelay statistics** command only clears the DHCP relay statistic counters. To clear the entire DHCP relay configuration, use the **clear configure dhcprelay** command.

Examples

The following example shows how to clear the DHCP relay statistics:

```
hostname# clear dhcprelay statistics
hostname#
```

Related Commands

Command	Description
clear configure dhcprelay	Removes all DHCP relay agent settings.
debug dhcprelay	Displays debugging information for the DHCP relay agent.
show dhcprelay statistics	Displays DHCP relay agent statistic information.
show running-config dhcprelay	Displays the current DHCP relay agent configuration.

clear dns

To clear all IP addresses associated with the specified fully qualified domain name (FQDN) host, use the **clear dns** command in privileged EXEC mode.

clear dns [**host** *fqdn_name*]

Syntax Description

fqdn_name	(Optional) Specifies the fully qualified domain name of the selected host.
host	(Optional) Indicates the IP address of the specified host.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(2)	This command was introduced.

Examples

The following example clears the IP address associated with the specified FQDN host:

```
hostname# clear dns 10.1.1.2 www.example.com
```

Note The setting of the **dns expire-entry** keyword is ignored for this command. New DNS queries are sent for each activated FQDN host.

Related Commands

Command	Description
dns domain-lookup	Enables the ASA to perform a name lookup.
dns name-server	Configures a DNS server address.
dns retries	Specifies the number of times to retry the list of DNS servers when the ASA does not receive a response.
dns timeout	Specifies the amount of time to wait before trying the next DNS server.
show dns-hosts	Shows the DNS cache.

clear dns-hosts cache

To clear the DNS cache, use the **clear dns-hosts cache** command in privileged EXEC mode.

clear dns-hosts cache

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command does not clear static entries that you added with the **name** command.

Examples

The following example clears the DNS cache:

```
hostname# clear dns-hosts cache
```

Related Commands

Command	Description
dns domain-lookup	Enables the ASA to perform a name lookup.
dns name-server	Configures a DNS server address.
dns retries	Specifies the number of times to retry the list of DNS servers when the ASA does not receive a response.
dns timeout	Specifies the amount of time to wait before trying the next DNS server.
show dns-hosts	Shows the DNS cache.

clear dynamic-filter dns-snoop

To clear Botnet Traffic Filter DNS snooping data, use the **clear dynamic-filter dns-snoop** command in in privileged EXEC mode.

clear dynamic-filter dns-snoop

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Examples

The following example clears all Botnet Traffic Filter DNS snooping data:

```
hostname# clear dynamic-filter dns-snoop
```

Related Commands

Command	Description
address	Adds an IP address to the blacklist or whitelist.
clear configure dynamic-filter	Clears the running Botnet Traffic Filter configuration.
clear dynamic-filter reports	Clears Botnet Traffic filter report data.
clear dynamic-filter statistics	Clears Botnet Traffic filter statistics.
dns domain-lookup	Enables the ASA to send DNS requests to a DNS server to perform a name lookup for supported commands.
dns server-group	Identifies a DNS server for the ASA.
dynamic-filter ambiguous-is-black	Treats greylisted traffic as blacklisted traffic for action purposes.
dynamic-filter blacklist	Edits the Botnet Traffic Filter blacklist.
dynamic-filter database fetch	Manually retrieves the Botnet Traffic Filter dynamic database.
dynamic-filter database find	Searches the dynamic database for a domain name or IP address.

Command	Description
dynamic-filter database purge	Manually deletes the Botnet Traffic Filter dynamic database.
dynamic-filter drop blacklist	Automatically drops blacklisted traffic.
dynamic-filter enable	Enables the Botnet Traffic Filter for a class of traffic or for all traffic if you do not specify an access list.
dynamic-filter updater-client enable	Enables downloading of the dynamic database.
dynamic-filter use-database	Enables use of the dynamic database.
dynamic-filter whitelist	Edits the Botnet Traffic Filter whitelist.
inspect dns dynamic-filter-snoop	Enables DNS inspection with Botnet Traffic Filter snooping.
name	Adds a name to the blacklist or whitelist.
show asp table dynamic-filter	Shows the Botnet Traffic Filter rules that are installed in the accelerated security path.
show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
show dynamic-filter dns-snoop	Shows the Botnet Traffic Filter DNS snooping summary, or with the **detail** keyword, the actual IP addresses and names.
show dynamic-filter reports	Generates reports of the top 10 botnet sites, ports, and infected hosts.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

clear dynamic-filter reports

To clear report data for the Botnet Traffic Filter, use the **clear dynamic-filter reports** command in privileged EXEC mode.

clear dynamic-filter reports {**top** [**malware-sites** | **malware-ports** | **infected-hosts**] | **infected-hosts**}

Syntax Description

malware-ports	(Optional) Clears report data for the top 10 malware ports.
malware-sites	(Optional) Clears report data for the top 10 malware sites.
infected-hosts (**top**)	(Optional) Clears report data for the top 10 infected hosts.
top	Clears report data for the top 10 malware sites, ports, and infected hosts.
infected-hosts	Clears report data for infected hosts.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
8.2(1)	This command was introduced.
8.2(2)	The **botnet-sites** and **botnet-ports** keywords were changed to **malware-sites** and **malware-ports**. The **top** keyword was added to differentiate clearing the top 10 reports and the new infected-hosts reports. The **infected-hosts** keyword was added (without **top**).

Examples

The following example clears all Botnet Traffic Filter top 10 report data:

```
hostname# clear dynamic-filter reports top
```

The following example clears only the top 10 malware sites report data:

```
hostname# clear dynamic-filter reports top malware-sites
```

The following example clears all infected hosts report data:

```
hostname# clear dynamic-filter reports infected-hosts
```

Related Commands

Command	Description
address	Adds an IP address to the blacklist or whitelist.
clear configure dynamic-filter	Clears the running Botnet Traffic Filter configuration.
clear dynamic-filter dns-snoop	Clears Botnet Traffic Filter DNS snooping data.
clear dynamic-filter statistics	Clears Botnet Traffic filter statistics.
dns domain-lookup	Enables the ASA to send DNS requests to a DNS server to perform a name lookup for supported commands.
dns server-group	Identifies a DNS server for the ASA.
dynamic-filter ambiguous-is-black	Treats greylisted traffic as blacklisted traffic for action purposes.
dynamic-filter blacklist	Edits the Botnet Traffic Filter blacklist.
dynamic-filter database fetch	Manually retrieves the Botnet Traffic Filter dynamic database.
dynamic-filter database find	Searches the dynamic database for a domain name or IP address.
dynamic-filter database purge	Manually deletes the Botnet Traffic Filter dynamic database.
dynamic-filter drop blacklist	Automatically drops blacklisted traffic.
dynamic-filter enable	Enables the Botnet Traffic Filter for a class of traffic or for all traffic if you do not specify an access list.
dynamic-filter updater-client enable	Enables downloading of the dynamic database.
dynamic-filter use-database	Enables use of the dynamic database.
dynamic-filter whitelist	Edits the Botnet Traffic Filter whitelist.
inspect dns dynamic-filter-snoop	Enables DNS inspection with Botnet Traffic Filter snooping.
name	Adds a name to the blacklist or whitelist.
show asp table dynamic-filter	Shows the Botnet Traffic Filter rules that are installed in the accelerated security path.
show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
show dynamic-filter dns-snoop	Shows the Botnet Traffic Filter DNS snooping summary, or with the **detail** keyword, the actual IP addresses and names.
show dynamic-filter reports infected-hosts	Generates reports of infected hosts.
show dynamic-filter reports top	Generates reports of the top 10 malware sites, ports, and infected hosts.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

clear dynamic-filter statistics

To clear Botnet Traffic Filter statistics, use the **clear dynamic-filter statistics** command in in privileged EXEC mode.

clear dynamic-filter statistics [**interface** *name*]

Syntax Description

interface *name*	(Optional) Clears statistics for a particular interface.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Examples

The following example clears all Botnet Traffic Filter DNS statistics:

```
hostname# clear dynamic-filter statistics
```

Related Commands

Command	Description
dynamic-filter ambiguous-is-black	Treats greylisted traffic as blacklisted traffic for action purposes.
dynamic-filter drop blacklist	Automatically drops blacklisted traffic.
address	Adds an IP address to the blacklist or whitelist.
clear configure dynamic-filter	Clears the running Botnet Traffic Filter configuration.
clear dynamic-filter dns-snoop	Clears Botnet Traffic Filter DNS snooping data.
clear dynamic-filter reports	Clears Botnet Traffic filter report data.
dns domain-lookup	Enables the ASA to send DNS requests to a DNS server to perform a name lookup for supported commands.
dns server-group	Identifies a DNS server for the ASA.
dynamic-filter blacklist	Edits the Botnet Traffic Filter blacklist.
dynamic-filter database fetch	Manually retrieves the Botnet Traffic Filter dynamic database.

Command	Description
dynamic-filter database find	Searches the dynamic database for a domain name or IP address.
dynamic-filter database purge	Manually deletes the Botnet Traffic Filter dynamic database.
dynamic-filter enable	Enables the Botnet Traffic Filter for a class of traffic or for all traffic if you do not specify an access list.
dynamic-filter updater-client enable	Enables downloading of the dynamic database.
dynamic-filter use-database	Enables use of the dynamic database.
dynamic-filter whitelist	Edits the Botnet Traffic Filter whitelist.
inspect dns dynamic-filter-snoop	Enables DNS inspection with Botnet Traffic Filter snooping.
name	Adds a name to the blacklist or whitelist.
show asp table dynamic-filter	Shows the Botnet Traffic Filter rules that are installed in the accelerated security path.
show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
show dynamic-filter dns-snoop	Shows the Botnet Traffic Filter DNS snooping summary, or with the **detail** keyword, the actual IP addresses and names.
show dynamic-filter reports infected-hosts	Generates reports of infected hosts.
show dynamic-filter reports top	Generates reports of the top 10 malware sites, ports, and infected hosts.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

clear eigrp events

To clear the EIGRP event log, use the **clear eigrp events** command in privileged EXEC mode.

clear eigrp [*as-number*] **events**

Syntax Description

as-number	(Optional) Specifies the autonomous system number of the EIGRP process for which you are clearing the event log. Because the ASA only supports one EIGRP routing process, you do not need to specify the autonomous system number (process ID).

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

You can use the **show eigrp events** command to view the EIGRP event log.

Examples

The following example clears the EIGRP event log:

```
hostname# clear eigrp events
```

Related Commands

Command	Description
show eigrp events	Displays the EIGRP event log.

clear eigrp neighbors

To delete entries from the EIGRP neighbor table, use the **clear eigrp neighbors** command in privileged EXEC mode.

clear eigrp [*as-number*] **neighbors** [*ip-addr* | *if-name*] [**soft**]

Syntax Description

as-number	(Optional) Specifies the autonomous system number of the EIGRP process for which you are deleting neighbor entries. Because the ASA only supports one EIGRP routing process, you do not need to specify the autonomous system number (AS), which is the process ID.
if-name	(Optional) The name of an interface as specified by the **nameif** command. Specifying an interface name removes all neighbor table entries that were learned through this interface.
ip-addr	(Optional) The IP address of the neighbor you want to remove from the neighbor table.
soft	Causes the ASA to resynchronize with the neighbor without resetting the adjacency.

Defaults

If you do not specify a neighbor IP address or an interface name, all dynamic entries are removed from the neighbor table.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The **clear eigrp neighbors** command does not remove neighbors defined using the **neighbor** command from the neighbor table. Only dynamically discovered neighbors are removed.

You can use the **show eigrp neighbors** command to view the EIGRP neighbor table.

Examples

The following example removes all entries from the EIGRP neighbor table:

```
hostname# clear eigrp neighbors
```

The following example removes all entries learned through the interface named “outside” from the EIGRP neighbor table:

```
hostname# clear eigrp neighbors outside
```

Related Commands

Command	Description
debug eigrp neighbors	Displays debugging information for EIGRP neighbors.
debug ip eigrp	Displays debugging information for EIGRP protocol packets.
show eigrp neighbors	Displays the EIGRP neighbor table.

clear eigrp topology

To delete entries from the EIGRP topology table, use the **clear eigrp topology** command in privileged EXEC mode.

clear eigrp [*as-number*] **topology** *ip-addr* [*mask*]

Syntax Description

as-number	(Optional) Specifies the autonomous system number of the EIGRP process. Because the ASA only supports one EIGRP routing process, you do not need to specify the autonomous system number (AS), which is the process ID.
ip-addr	The IP address to clear from the topology table.
mask	(Optional) The network mask to apply to the *ip-addr* argument.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

This command clears existing EIGRP entries from the EIGRP topology table. You can use the **show eigrp topology** command to view the topology table entries.

Examples

The following example removes entries in the 192.168.1.0 network from EIGRP topology table:

```
hostname# clear eigrp topology 192.168.1.0 255.255.255.0
```

Related Commands

Command	Description
show eigrp topology	Displays the EIGRP topology table.

clear failover statistics

To clear the failover statistic counters, use the **clear failover statistics** command in privileged EXEC mode.

clear failover statistics

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command clears the statistics displayed with the **show failover statistics** command and the counters in the Stateful Failover Logical Update Statistics section of the **show failover** command output. To remove the failover configuration, use the **clear configure failover** command.

Examples

The following example shows how to clear the failover statistic counters:

```
hostname# clear failover statistics
hostname#
```

Related Commands

Command	Description
debug fover	Displays failover debugging information.
show failover	Displays information about the failover configuration and operational statistics.

clear flow-export counters

To reset runtime counters that are associated with NetFlow data to zero, use the **clear flow-export counters** command in privileged EXEC mode.

clear flow-export counters

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.1(1)	This command was introduced.

Usage Guidelines

The runtime counters include statistical data as well as error data.

Examples

The following example shows how to reset runtime counters that are associated with NetFlow data:

```
hostname# clear flow-export counters
```

Related Commands

Commands	Description
flow-export destination *interface-name ipv4-address* | *hostname udp-port*	Specifies the IP address or hostname of the NetFlow collector, and the UDP port on which the NetFlow collector is listening.
flow-export template timeout-rate *minutes*	Controls the interval at which the template information is sent to the NetFlow collector.
logging flow-export-syslogs enable	Enables syslog messages after you have entered the **logging flow-export-syslogs disable** command, and the syslog messages that are associated with NetFlow data.
show flow-export counters	Displays all runtime counters in NetFlow.

clear fragment

To clear the operational data of the IP fragment reassembly module, enter the **clear fragment** command in privileged EXEC mode.

clear fragment {**queue** | **statistics**} [*interface*]

Syntax Description

interface	(Optional) Specifies the ASA interface.
queue	Clears the IP fragment reassembly queue.
statistics	Clears the IP fragment reassembly statistics.

Defaults

If an *interface* is not specified, the command applies to all interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	The command was separated into two commands, **clear fragment** and **clear configure fragment**, to separate clearing of the configuration data from the operational data.

Usage Guidelines

This command clears either the currently queued fragments that are waiting for reassembly (if the **queue** keyword is entered) or clears all IP fragment reassembly statistics (if the **statistics** keyword is entered). The statistics are the counters, which tell how many fragments chains were successfully reassembled, how many chains failed to be reassembled, and how many times the maximum size was crossed resulting in overflow of the buffer.

Examples

The following example shows how to clear the operational data of the IP fragment reassembly module:

```
hostname# clear fragment queue
```

Related Commands

Command	Description
clear configure fragment	Clears the IP fragment reassembly configuration and resets the defaults.
fragment	Provides additional management of packet fragmentation and improves compatibility with the NFS.

Command	Description
show fragment	Displays the operational data of the IP fragment reassembly module.
show running-config fragment	Displays the IP fragment reassembly configuration.

clear gc

To remove the garbage collection (GC) process statistics, use the **clear gc** command in privileged EXEC mode.

clear gc

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to remove the GC process statistics:

```
hostname# clear gc
```

Related Commands

Command	Description
show gc	Displays the GC process statistics.

clear igmp counters

To clear all IGMP counters, use the **clear igmp counters** command in privileged EXEC mode.

clear igmp counters [*if_name*]

Syntax Description

if_name	The interface name, as specified by the **nameif** command. Including an interface name with this command causes only the counters for the specified interface to be cleared.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example clears the IGMP statistical counters:

```
hostname# clear igmp counters
```

Related Commands

Command	Description
clear igmp group	Clears discovered groups from the IGMP group cache.
clear igmp traffic	Clears the IGMP traffic counters.

clear igmp group

To clear discovered groups from the IGMP group cache, use the **clear igmp** command in privileged EXEC mode.

clear igmp group [*group* | **interface** *name*]

Syntax Description

group	IGMP group address. Specifying a particular group removes the specified group from the cache.
interface *name*	Interface name, as specified by the **namif** command. When specified, all groups associated with the interface are removed.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If you do not specify a group or an interface, all groups are cleared from all interfaces. If you specify a group, only the entries for that group are cleared. If you specify an interface, then all groups on that interface are cleared. If you specify both a group and an interface, only the specified groups on the specified interface are cleared.

This command does not clear statically configured groups.

Examples

The following example shows how to clear all discovered IGMP groups from the IGMP group cache:

```
hostname# clear igmp group
```

Related Commands

Command	Description
clear igmp counters	Clears all IGMP counters.
clear igmp traffic	Clears the IGMP traffic counters.

clear igmp traffic

To clear the IGMP traffic counters, use the **clear igmp traffic** command in privileged EXEC mode.

clear igmp traffic

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example clears the IGMP statistical traffic counters:

```
hostname# clear igmp traffic
```

Related Commands

Command	Description
clear igmp group	Clears discovered groups from the IGMP group cache.
clear igmp counters	Clears all IGMP counters.

clear interface

To clear interface statistics, use the **clear interface** command in privileged EXEC mode.

clear interface [*physical_interface*[**.***subinterface*] | *mapped_name* | *interface_name*]

Syntax Description

interface_name	(Optional) Identifies the interface name set with the **nameif** command.
mapped_name	(Optional) In multiple context mode, identifies the mapped name if it was assigned using the **allocate-interface** command.
physical_interface	(Optional) Identifies the interface ID, such as **gigabitethernet0/1**. See the **interface** command for accepted values.
subinterface	(Optional) Identifies an integer between 1 and 4294967293 designating a logical subinterface.

Defaults

By default, this command clears all interface statistics.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If an interface is shared among contexts, and you enter this command within a context, the ASA clears only statistics for the current context. If you enter this command in the system execution space, the ASA clears the combined statistics.

You cannot use the interface name in the system execution space, because the **nameif** command is only available within a context. Similarly, if you mapped the interface ID to a mapped name using the **allocate-interface** command, you can only use the mapped name in a context.

Examples

The following example clears all interface statistics:

```
hostname# clear interface
```

Related Commands

Command	Description
clear configure interface	Clears the interface configuration.
interface	Configures an interface and enters interface configuration mode.
show interface	Displays the runtime status and statistics of interfaces.
show running-config interface	Displays the interface configuration.

clear ip audit count

To clear the count of signature matches for an audit policy, use the **clear ip audit count** command in privileged EXEC mode.

clear ip audit count [**global** | **interface** *interface_name*]

Syntax Description

global	(Default) Clears the number of matches for all interfaces.
interface *interface_name*	(Optional) Clears the number of matches for the specified interface.

Defaults

If you do not specify a keyword, this command clears the matches for all interfaces (**global**).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example clears the count for all interfaces:

```
hostname# clear ip audit count
```

Related Commands

Command	Description
ip audit interface	Assigns an audit policy to an interface.
ip audit name	Creates a named audit policy that identifies the actions to take when a packet matches an attack signature or an informational signature.
show ip audit count	Shows the count of signature matches for an audit policy.
show running-config ip audit attack	Shows the configuration for the **ip audit attack** command.

clear ip verify statistics

To clear the unicast RPF statistics, use the **clear ip verify statistics** command in privileged EXEC mode.

clear ip verify statistics [**interface** *interface_name*]

Syntax Description

interface *interface_name*	Sets the interface on which you want to clear unicast RPF statistics.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

See the **ip verify reverse-path** command to enable unicast RPF.

Examples

The following example clears the unicast RPF statistics:

```
hostname# clear ip verify statistics
```

Related Commands

Command	Description
clear configure ip verify reverse-path	Clears the **ip verify reverse-path** configuration.
ip verify reverse-path	Enables the unicast RPF feature to prevent IP spoofing.
show ip verify statistics	Shows the unicast RPF statistics.
show running-config ip verify reverse-path	Shows the **ip verify reverse-path** configuration.

clear ipsec sa

To clear IPsec SAs entirely or based on specified parameters, use the **clear ipsec sa** command in privileged EXEC mode.

clear ipsec sa [**counters** | **entry** *peer-addr protocol spi* | **peer** *peer-addr* | **map** *map-name*]

Syntax Description

counters	(Optional) Clears all counters.
entry	(Optional) Clears IPsec SAs for a specified IPsec peer, protocol and SPI.
inactive	(Optional) Clears IPsec SAs that are unable to pass traffic.
map *map-name*	(Optional) Clears IPsec SAs for the specified crypto map.
peer	(Optional) Clears IPsec SAs for a specified peer.
peer-addr	Specifies the IP address of an IPsec peer.
protocol	Specifies an IPsec protocol: **esp** or **ah**.
spi	Specifies an IPsec SPI.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

You can also use an alternate form of this command to perform the same function: **clear crypto ipsec sa**.

Examples

The following example, entered in global configuration mode, clears all IPsec SA counters:

```
hostname# clear ipsec sa counters
hostname#
```

Related Commands

Command	Description
show ipsec sa	Displays IPsec SAs based on specified parameters.
show ipsec stats	Displays global IPsec statistics from the IPsec flow MIB.

clear ipv6 access-list counters

To clear the IPv6 access list statistical counters, use the **clear ipv6 access-list counters** command in privileged EXEC mode.

clear ipv6 access-list *id* **counters**

Syntax Description

id	The IPv6 access list identifier.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to clear the statistical data for the IPv6 access list 2:

```
hostname# clear ipv6 access-list 2 counters
hostname#
```

Related Commands

Command	Description
clear configure ipv6	Clears the **ipv6 access-list** commands from the current configuration.
ipv6 access-list	Configures an IPv6 access list.
show ipv6 access-list	Displays the **ipv6 access-list** commands in the current configuration.

clear ipv6 dhcprelay binding

To clear the IPv6 DHCP relay binding entries, use the **clear ipv6 dhcprelay binding** command in privileged EXEC mode.

clear ipv6 dhcprelay binding [**ip**]

Syntax Description

ip	(Optional) Specifies the IPv6 address for the DHCP relay binding. If the IP address is specified, only the relay binding entries associated with that IP address are cleared.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Examples

The following example shows how to clear the statistical data for the IPv6 DHCP relay binding:

```
hostname# clear ipv6 dhcprelay binding
hostname#
```

Related Commands

Command	Description
show ipv6 dhcprelay binding	Shows the relay binding entries created by the relay agent.
show ipv6 dhcprelay statistics	Shows the IPv6 DHCP relay agent information.

clear ipv6 dhcprelay statistics

To clear the IPv6 DHCP relay agent statistics, use the **clear ipv6 dhcprelay statistics** command in privileged EXEC mode.

clear ipv6 dhcprelay statistics

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Examples

The following example shows how to clear the statistical data for the IPv6 DHCP relay agent:

```
hostname# clear ipv6 dhcprelay statistics
hostname#
```

Related Commands

Command	Description
show ipv6 dhcprelay binding	Shows the relay binding entries created by the relay agent.
show ipv6 dhcprelay statistics	Shows the DHCP relay agent information for IPv6.

clear ipv6 mld traffic

To clear the IPv6 Multicast Listener Discovery (MLD) traffic counters, use the **clear ipv6 mld traffic** command in privileged EXEC mode.

clear ipv6 mld traffic

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.2(4)	This command was introduced.

Usage Guidelines

The **clear ipv6 mld traffic** command allows you to reset all the MLD traffic counters.

Examples

The following example shows how to clear the traffic counters for IPv6 MLD:

```
hostname# clear ipv6 mld traffic
hostname#
```

Related Commands

Command	Description
debug ipv6 mld	Displays all debugging messages for MLD.
show debug ipv6 mld	Displays the MLD commands for IPv6 in the current configuration.

clear ipv6 neighbors

To clear the IPv6 neighbor discovery cache, use the **clear ipv6 neighbors** command in privileged EXEC mode.

clear ipv6 neighbors

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command deletes all discovered IPv6 neighbor from the cache; it does not remove static entries.

Examples

The following example deletes all entries, except static entries, in the IPv6 neighbor discovery cache:

```
hostname# clear ipv6 neighbors
hostname#
```

Related Commands

Command	Description
ipv6 neighbor	Configures a static entry in the IPv6 neighbor discovery cache.
show ipv6 neighbor	Displays IPv6 neighbor cache information.

clear ipv6 ospf

To clear OSPFv3 routing parameters, use the **clear ipv6 ospf** command in privileged EXEC mode.

clear ipv6 [*process_id*] [**counters**] [**events**] [**force-spf**] [**process**] [**redistribution**] [**traffic**]

Syntax Description

counters	Resets the OSPF process counters.
events	Clears the OSPF event log.
force-ospf	Clears the SPF for OSPF processes.
process	Resets the OSPFv3 process.
process_id	Clears the process ID number. Valid values range from 1 to 65535.
redistribution	Clears OSPFv3 route redistribution.
traffic	Clears traffic-related statistics.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

This command removes all OSPFv3 routing parameters.

Examples

The following example shows how to clear all OSPFv3 route redistribution:

```
hostname# clear ipv6 ospf redistribution
hostname#
```

Related Commands

Command	Description
show running-config ipv6 router	Shows the running configuration of OSPFv3 processes.
clear configure ipv6 router	Clears OSPFv3 routing processes.

clear ipv6 traffic

To reset the IPv6 traffic counters, use the **clear ipv6 traffic** command in privileged EXEC mode.

clear ipv6 traffic

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Using this command resets the counters in the output from the **show ipv6 traffic** command.

Examples

The following example resets the IPv6 traffic counters. The output from the **ipv6 traffic** command shows that the counters have been reset:

```
hostname# clear ipv6 traffic
hostname# show ipv6 traffic
IPv6 statistics:
  Rcvd:  1 total, 1 local destination
         0 source-routed, 0 truncated
         0 format errors, 0 hop count exceeded
         0 bad header, 0 unknown option, 0 bad source
         0 unknown protocol, 0 not a router
         0 fragments, 0 total reassembled
         0 reassembly timeouts, 0 reassembly failures
  Sent:  1 generated, 0 forwarded
         0 fragmented into 0 fragments, 0 failed
         0 encapsulation failed, 0 no route, 0 too big
  Mcast: 0 received, 0 sent

ICMP statistics:
  Rcvd: 1 input, 0 checksum errors, 0 too short
        0 unknown info type, 0 unknown error type
        unreach: 0 routing, 0 admin, 0 neighbor, 0 address, 0 port
        parameter: 0 error, 0 header, 0 option
        0 hopcount expired, 0 reassembly timeout,0 too big
```

```
        0 echo request, 0 echo reply
        0 group query, 0 group report, 0 group reduce
        0 router solicit, 0 router advert, 0 redirects
        0 neighbor solicit, 1 neighbor advert
  Sent: 1 output
        unreach: 0 routing, 0 admin, 0 neighbor, 0 address, 0 port
        parameter: 0 error, 0 header, 0 option
        0 hopcount expired, 0 reassembly timeout,0 too big
        0 echo request, 0 echo reply
        0 group query, 0 group report, 0 group reduce
        0 router solicit, 0 router advert, 0 redirects
        0 neighbor solicit, 1 neighbor advert

UDP statistics:
  Rcvd: 0 input, 0 checksum errors, 0 length errors
        0 no port, 0 dropped
  Sent: 0 output

TCP statistics:
  Rcvd: 0 input, 0 checksum errors
  Sent: 0 output, 0 retransmitted
```

Related Commands

Command	Description
show ipv6 traffic	Displays IPv6 traffic statistics.

clear isakmp sa

To remove all of the IKE runtime SA database, use the **clear isakmp sa** command in global configuration or privileged EXEC mode.

clear isakmp sa

Syntax Description

This command has no keywords or arguments.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	The **clear isakmp sa** command was changed to **clear crypto isakmp sa**.
9.0(1)	Support for multiple context mode was added.

Examples

The following example removes the IKE runtime SA database from the configuration:

```
hostname# clear isakmp sa
hostname#
```

Related Commands

Command	Description
clear isakmp	Clears the IKE runtime SA database.
isakmp enable	Enables ISAKMP negotiation on the interface on which the IPsec peer communicates with the ASA.
show isakmp stats	Displays runtime statistics.
show isakmp sa	Displays IKE runtime SA database with additional information.
show running-config isakmp	Displays all the active ISAKMP configuration.

CHAPTER 9

clear local-host through clear xlate Commands

clear local-host

To reinitalize per-client run-time states such as connection limits and embryonic limits, use the **clear local-host** command in privileged EXEC mode. t

clear local-host [*ip_address*] [**all**]

Syntax Description

all	(Optional) Clears all connections, including to-the-box traffic. Without the **all** keyword, only through-the-box traffic is cleared.
ip_address	(Optional) Specifies the local host IP address.

Defaults

Clears all through-the-box run-time states.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

When you make security policy changes to the configuration, all *new* connections use the new security policy. Existing connections continue to use the policy that was configured at the time of the connection establishment. To ensure that all connections use the new policy, you need to disconnect the current connections so they can reconnect using the new policy using the **clear local-host** command. You can alternatively use the **clear conn** command for more granular connection clearing, or the **clear xlate** command for connections that use dynamic NAT.

The **clear local-host** command releases the hosts from the host license limit. You can see the number of hosts that are counted toward the license limit by entering the **show local-host** command.

Examples

The following example clears the run-time state and assocaited connections for the host 10.1.1.15:

```
hostname# clear local-host 10.1.1.15
```

Related Commands

Command	Description
clear conn	Terminates connections in any state.
clear xlate	Clears a dynamic NAT session, and any connections using NAT.
show local-host	Displays the network states of local hosts.

clear logging asdm

To clear the ASDM logging buffer, use the **clear logging asdm** command in privileged EXEC mode.

clear logging asdm

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was changed from the **clear pdm logging** command to the **clear asdm log** command.

Usage Guidelines

ASDM system log messages are stored in a separate buffer from the ASA system log messages. Clearing the ASDM logging buffer only clears the ASDM system log messages; it does not clear the ASA system log messages. To view the ASDM system log messages, use the **show asdm log** command.

Examples

The following example clears the ASDM logging buffer:

```
hostname(config)# clear logging asdm
hostname(config)#
```

Related Commands

Command	Description
show asdm log_sessions	Displays the contents of the ASDM logging buffer.

clear logging buffer

To clear the log buffer, use the **clear logging buffer** command in privileged EXEC mode.

clear logging buffer

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

This example shows how to clear the contents of the log buffer:

```
hostname# clear logging buffer
```

Related Commands

Command	Description
logging buffered	Configures the log buffer.
show logging	Displays logging information.

clear logging queue bufferwrap

To clear the saved log buffers (ASDM, internal, FTP, and flash), use the **clear logging queue bufferwrap** command in privileged EXEC mode.

clear logging queue bufferwrap

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Examples

The following example shows how to clear the contents of the saved log buffers:

```
hostname# clear logging queue bufferwrap
```

Related Commands

Command	Description
logging buffered	Configures the log buffer.
show logging	Displays logging information.

clear mac-address-table

To clear dynamic MAC address table entries, use the **clear mac-address-table** command in privileged EXEC mode.

clear mac-address-table [*interface_name*]

Syntax Description

interface_name	(Optional) Clears the MAC address table entries for the selected interface.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	—	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example clears the dynamic MAC address table entries:

```
hostname# clear mac-address-table
```

Related Commands

Command	Description
arp	Adds a static ARP entry.
firewall transparent	Sets the firewall mode to transparent.
mac-address-table aging-time	Sets the timeout for dynamic MAC address entries.
mac-learn	Disables MAC address learning.
show mac-address-table	Shows MAC address table entries.

clear memory delayed-free-poisoner

To clear the delayed free-memory poisoner tool queue and statistics, use the **clear memory delayed-free-poisoner** command in privileged EXEC mode.

clear memory delayed-free-poisoner

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **clear memory delayed-free-poisoner** command returns all memory held in the delayed free-memory poisoner tool queue to the system without validation and clears the related statistical counters.

Examples

The following example clears the delayed free-memory poisoner tool queue and statistics:

```
hostname# clear memory delayed-free-poisoner
```

Related Commands

Command	Description
memory delayed-free-poisoner enable	Enables the delayed free-memory poisoner tool.
memory delayed-free-poisoner validate	Forces validation of the delayed free-memory poisoner tool queue.
show memory delayed-free-poisoner	Displays a summary of the delayed free-memory poisoner tool queue usage.

clear memory profile

To clear the memory buffers held by the memory profiling function, use the **clear memory profile** command in privileged EXEC mode.

clear memory profile [peak]

Syntax Description

peak	(Optional) Clears the contents of the peak memory buffer.

Defaults

Clears the current "in use" profile buffer by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	—	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **clear memory profile** command releases the memory buffers held by the profiling function, and therefore requires that profiling stop before it is cleared.

Examples

The following example clears the memory buffers held by the profiling function:

```
hostname# clear memory profile
```

Related Commands

Command	Description
memory profile enable	Enables the monitoring of memory usage (memory profiling).
memory profile text	Configures a text range of memory to profile.
show memory profile	Displays information about the memory usage (profiling) of the ASA.

clear mfib counters

To clear MFIB router packet counters, use the **clear mfib counters** command in privileged EXEC mode.

clear mfib counters [*group* [*source*]]

Syntax Description

group	(Optional) IP address of the multicast group.
source	(Optional) IP address of the multicast route source. This is a unicast IP address in four-part dotted-decimal notation.

Defaults

When this command is used with no arguments, route counters for all routes are cleared.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example clears all MFIB router packet counters:

```
hostname# clear mfib counters
```

Related Commands

Command	Description
show mfib count	Displays MFIB route and packet count data.

clear module

To clear information about the SSM on the ASAs, information about the SSC on the ASA 5505, information about the SSP installed on the ASA 5585-X, information about the IPS SSP installed on the ASA 5585-X, information about the ASA Services Module, and system information, use the **clear module** command in privileged EXEC mode.

clear module [*mod_id* | *slot*] [**all** | [**details** | **recover** | **log** [**console**]]]

Syntax Description

all	(Default) Clears all SSM information.
console	(Optional) Clears console log information for the module.
details	(Optional) Clears additional information, including remote management configuration for SSMs (for example, ASA-SSM-*x*0).
log	(Optional) Clears log information for the module.
mod_id	Clears the module name used for software modules, such as IPS.
recover	(Optional) For SSMs, clears the settings for the **hw-module module recover** command. **Note** The **recover** keyword is valid only when you have created a recovery configuration for the SSM by using the **configure** keyword with the **hw-module module recover** command. (Optional) For an IPS module installed on the ASA 5512-X, 5515-X, 5525-X, 5545-X, or 5555-X, clears the settings for the **sw-module module** *mod_id* **recover configure image** *image_location* command.
slot	Clears the module slot number, which can be 0 or 1.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.
8.2(1)	Supports the SSC.
8.2(5)	Supports the ASA 5585-X and the IPS SSP on the ASA 5585-X.
8.4(2)	Supports a dual SSP installation.

Release	Modification
8.5(1)	Supports the ASASM.
8.6(1)	Supports the ASA 5512-X, 5515-X, 5525-X, 5545-X, and 5555-X.

Usage Guidelines

This command clears information about the SSC, SSM, ASASM, IPS SSP, and device and built-in interfaces.

Examples

The following example clears the recovery settings for an SSM:

```
hostname# clear module 1 recover
```

Related Commands

Command	Description
hw-module module recover	Recovers an SSM by loading a recovery image from a TFTP server.
hw-module module reset	Shuts down an SSM and performs a hardware reset.
hw-module module reload	Reloads the SSM software.
hw-module module shutdown	Shuts down the SSM software in preparation for being powered off without losing configuration data.
show module	Shows SSM information.

clear nac-policy

To reset NAC policy usage statistics, use the **clear nac-policy** command in global configuration mode.

clear nac-policy [*nac-policy-name*]

Syntax Description

nac-policy-name	(Optional) Name of the NAC policy for which to reset usage statistics.

Defaults

If you do not specify a name, the CLI resets the usage statistics for all NAC policies.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	—	—	•

Command History

Release	Modification
8.0(2)	This command was introduced.

Examples

The following example resets the usage statistics for the NAC policy named framework1:

```
hostname(config)# clear nac-policy framework1
```

The following example resets all NAC policy usage statistics:

```
hostname(config)# clear nac-policy
```

Related Commands

Command	Description
show nac-policy	Displays NAC policy usage statistics on the ASA.
show vpn-session_summary.db	Displays the number of IPsec, WebVPN, and NAC sessions.
show vpn-session.db	Displays information about VPN sessions, including NAC results.

clear nat counters

To clear NAT policy counters, use the **clear nat counters** command in global configuration mode.

clear nat counters [*src_ifc* [*src_ip* [*src_mask*]] [*dst_ifc* [*dst_ip* [*dst_mask*]]]]

Syntax Description

dst_ifc	(Optional) Specifies destination interface to filter.
dst_ip	(Optional) Specifies destination IP address to filter.
dst_mask	(Optional) Specifies mask for destination IP address.
src_ifc	(Optional) Specifies source interface to filter.
src_ip	(Optional) Specifies source IP address to filter.
src_mask	(Optional) Specifies mask for source IP address.

Defaults

This command has no default settings.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0 (4)	This command was introduced.

Examples

This example shows how to clear the NAT policy counters:

```
hostname(config)# clear nat counters
```

Related Commands

Command	Description
nat	Identifies addresses on one interface that are translated to mapped addresses on another interface.
nat-control	Enables or disables NAT configuration requirements.
show nat counters	Displays the protocol stack counters.

clear object-group

To clear the hit counts of objects in a network object group, use the **show object-group** command in privileged EXEC mode.

clear object-group *obj-name* **counters**

Syntax Description

counters	Identifies the counters in the network object group.
obj-name	Identifies the existing network object group.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

Use this command to clear hit counts of objects in a network object group only.

Examples

The following example shows how to clear the network object hit count for the network object group named “Anet”:

```
hostname# clear object-group Anet counters
```

Related Commands

Command	Description
show object-group	Shows object group information and shows hit counts if the specified object group is of the network object-group type.

clear ospf

To clear OSPF process information, use the **clear ospf** command in privileged EXEC mode.

clear ospf [*pid*] {**process** | **counters**}

Syntax Description

counters	Clears the OSPF counters.
pid	(Optional) Internally used identification parameter for an OSPF routing process; valid values are from 1 to 65535.
process	Restarts the OSPF routing process.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

This command does not remove any part of the configuration. Use the **no** form of the configuration commands to clear specific commands from the configuration or use the **clear configure router ospf** command to remove all global OSPF commands from the configuration.

Note The **clear configure router ospf** command does not clear OSPF commands entered in interface configuration mode.

Examples

The following example shows how to clear the OSPF neighbor counters:

```
hostname# clear ospf counters
```

Related Commands

Command	Description
clear configure router	Clears all global router commands from the running configuration.

clear pclu

To clear PC logical update statistics, use the **clear pclu** command in privileged EXEC mode.

clear pclu

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example clears PC information:

```
hostname# clear pclu
```

clear phone-proxy secure-phones

To clear the secure phone entries in the phone proxy database, use the **clear phone-proxy secure-phones** command in privileged EXEC mode.

clear phone-proxy secure-phones [*mac_address* | **noconfirm]**

Syntax Description

mac_address	Removes the IP phone from the phone proxy database with the specified MAC address.
noconfirm	Removes all the secure phone entries in the phone proxy database without prompting for confirmation. If you do not specify the **noconfirm** keyword, you are prompted to confirm whether to remove all the secure phone entries.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

Because secure phones always request a CTL file upon bootup, the phone proxy creates a database that marks the phone as secure. The entries in the secure phone database are removed after a specified configured timeout (via the **timeout secure-phones** command). Alternatively, you can use the **clear phone-proxy secure-phones** command to clear the phone proxy database without waiting for the configured timeout.

Examples

The following example clears secure entries in the phone proxy database:

```
hostname# clear phone-proxy secure-phones 001c.587a.4000
```

Related Commands

Command	Description
timeout secure-phones	Configures the idle timeout after which the secure phone entry is removed from the phone proxy database.

clear pim counters

To clear the PIM traffic counters, use the **clear pim counters** command in privileged EXEC mode.

clear pim counters

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command only clears the traffic counters. To clear the PIM topology table, use the **clear pim topology** command.

Examples

The following example clears the PIM traffic counters:

```
hostname# clear pim counters
```

Related Commands

Command	Description
clear pim reset	Forces MRIB synchronization through reset.
clear pim topology	Clears the PIM topology table.
show pim traffic	Displays the PIM traffic counters.

clear pim reset

To force MRIB synchronization through reset, use the **clear pim reset** command in privileged EXEC mode.

clear pim reset

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

All information from the topology table is cleared, and the MRIB connection is reset. This command can be used to synchronize states between the PIM topology table and the MRIB database.

Examples

The following example clears the topology table and resets the MRIB connection:

```
hostname# clear pim reset
```

Related Commands

Command	Description
clear pim counters	Clears PIM counters and statistics.
clear pim topology	Clears the PIM topology table.
clear pim counters	Clears PIM traffic counters.

clear pim topology

To clear the PIM topology table, use the **clear pim topology** command in privileged EXEC mode.

clear pim topology [*group*]

Syntax Description

group	(Optional) Specifies the multicast group address or name to be deleted from the topology table.

Defaults

Without the optional *group* argument, all entries are cleared from the topology table.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command clears existing PIM routes from the PIM topology table. Information obtained from the MRIB table, such as IGMP local membership, is retained. If a multicast group is specified, only those group entries are cleared.

Examples

The following example clears the PIM topology table:

```
hostname# clear pim topology
```

Related Commands

Command	Description
clear pim counters	Clears PIM counters and statistics.
clear pim reset	Forces MRIB synchronization through reset.
clear pim counters	Clears PIM traffic counters.

clear priority-queue statistics

To clear the priority-queue statistics counters for an interface or for all configured interfaces, use the **clear priority-queue statistics** command in either global configuration or privileged EXEC mode.

clear priority-queue statistics [*interface-name*]

Syntax Description

interface-name	(Optional) Specifies the name of the interface for which you want to show the best-effort and low-latency queue details.

Defaults

If you omit the interface name, this command clears the priority-queue statistics for all configured interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows the use of the **clear priority-queue statistics** command in privileged EXEC mode to remove the priority queue statistics for the interface named “test”:

```
hostname# clear priority-queue statistics test
hostname#
```

Related Commands

Command	Description
clear configure priority queue	Removes the priority-queue configuration from the named interface.
priority-queue	Configures priority queueing on an interface.
show priority-queue statistics	Shows the priority queue statistics for a specified interface or for all interfaces.
show running-config priority-queue	Shows the current priority-queue configuration on the named interface.

clear process

To clear statistics for specified processes running on the ASA, use the **clear process** command in privileged EXEC mode.

clear process [**cpu-hog** | **internals**]

Syntax Description

cpu-hog	Clears CPU hogging statistics.
internals	Clears process internal statistics.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to clear CPU hogging statistics:

```
hostname# clear process cpu-hog
hostname#
```

Related Commands

Command	Description
show processes	Displays a list of the processes that are running on the ASA.

clear resource usage

To clear resource usage statistics, use the **clear resource usage** command in privileged EXEC mode.

clear resource usage [**context** *context_name* | **all** | **summary** | **system**] [**resource** {[**rate**] *resource_name* | **all**}]

Syntax Description

context *context_name*	(Multiple mode only) Specifies the context name for which you want to clear statistics. Specify **all** (the default) for all contexts.
resource [**rate**] *resource_name*	Clears the usage of a specific resource. Specify **all** (the default) for all resources. Specify **rate** to clear the rate of usage of a resource. Resources that are measured by rate include **conns**, **inspects**, and **syslogs**. You must specify the **rate** keyword with these resource types. The conns resource is also measured as concurrent connections; only use the **rate** keyword to view the connections per second. Resources include the following types: • **asdm**—ASDM management sessions. • **conns**—TCP or UDP connections between any two hosts, including connections between one host and multiple other hosts. • **inspects**—Application inspections. • **hosts**—Hosts that can connect through the ASA. • **mac-addresses**—For transparent firewall mode, the number of MAC addresses allowed in the MAC address table. • **ssh**—SSH sessions. • **syslogs**—Syslog messages. • **telnet**—Telnet sessions. • (Multiple mode only) **VPN Other**—Site-to-site VPN sessions. • (Multiple mode only) **VPN Burst Other**—Site-to-site VPN burst sessions. • **xlates**—NAT translations.
summary	(Multiple mode only) Clears the combined context statistics.
system	(Multiple mode only) Clears the system-wide (global) usage statistics.

Defaults

For multiple context mode, the default context is **all**, which clears resource usage for every context. For single mode, the context name is ignored and all resource statistics are cleared.

The default resource name is **all**, which clears all resource types.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example clears all resource usage statistics for all contexts, but not the system-wide usage statistics:

```
hostname# clear resource usage
```

The following example clears the system-wide usage statistics:

```
hostname# clear resource usage system
```

Related Commands

Command	Description
context	Adds a security context.
show resource types	Shows a list of resource types.
show resource usage	Shows the resource usage of the ASA.

clear route

To remove dynamically learned routes from the configuration, use the **clear route** command in privileged EXEC mode.

clear route [*interface_name*]

Syntax Description

interface_name	(Optional) Internal or external network interface name.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to remove dynamically learned routes:

```
hostname# clear route
```

Related Commands

Command	Description
route	Specifies a static or default route for the an interface.
show route	Displays route information.
show running-config route	Displays configured routes.

clear service-policy

To clear operational data or statistics (if any) for enabled policies, use the **clear service-policy** command in privileged EXEC mode.

clear service-policy [**global** | **interface** *intf*] [**user-statistics**]

Syntax Description

global	(Optional) Clears the statistics of the global service policy.
interface *intf*	(Optional) Clears the service policy statistics of a specific interface.
user-statistics	(Optional) Clears the global counters for user statistics but does not clear the per-user statistics. Per-user or per-user-group statistics can still be seen using **show user-identity statistics** command. When the **accounting** keyword for the **user-statistics** command is specified, all global counters for sent packets, received packets, and sent dropped packets are cleared. When the **scanning** keyword **user-statistics** command is specified, the global counter for sent dropped packets is cleared. For the ASA to collect these user statistics, you must configure a policy map to collect user statistics. See the **user-statistics** command in this guide.

Defaults

By default, this command clears all the statistics for all enabled service policies.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To clear service policy startistics for inspection engines, see the **clear service-policy inspect** commands.

Examples

The following example shows the syntax of the **clear service-policy** command:

```
hostname# clear service-policy outside_security_map interface outside
```

Related Commands

Command	Description
clear service-policy inspect gtp	Clears service policy statistics for the GTP inspection engine.
clear service-policy inspect radius-accounting	Clears service policy statistics for the RADIUS accounting inspection engine.
show service-policy	Displays the service policy.
show running-config service-policy	Displays the service policies configured in the running configuration.
clear configure service-policy	Clears service policy configurations.
service-policy	Configures service policies.

clear service-policy inspect gtp

To clear global GTP statistics, use the **clear service-policy inspect gtp** command in privileged EXEC mode.

clear service-policy inspect gtp {**pdp-context** [**all** | **apn** *ap_name* | **imsi** *IMSI_value* | **ms-addr** *IP_address* | **tid** *tunnel_ID* | **version** *version_num*] | **requests** | **statistics** [**gsn** *IP_address*] }

Syntax Description.

all	Clears all GTP PDP contexts.
apn	(Optional) Clears the PDP contexts based on the APN specified.
ap_name	Identifies the specific access point name.
gsn	(Optional) Identifies the GPRS support node, which is the interface between the GPRS wireless data network and other networks.
gtp	(Optional) Clears the service policy for GTP.
imsi	(Optional) Clears the PDP contexts based on the IMSI specified.
IMSI_value	Hexadecimal value that identifies the specific IMSI.
interface	(Optional) Identifies a specific interface.
int	Identifies the interface for which information will be cleared.
IP_address	IP address for which statistics will be cleared.
ms-addr	(Optional) Clears PDP contexts based on the MS Address specified.
pdp-context	(Optional) Identifies the Packet Data Protocol context.
requests	(Optional) Clears GTP requests.
statistics	(Optional) Clears GTP statistics for the **inspect gtp** command.
tid	(Optional) Clears the PDP contexts based on the TID specified.
tunnel_ID	Hexadecimal value that identifies the specific tunnel.
version	(Optional) Clears the PDP contexts based on the GTP version.
version_num	Specifies the version of the PDP context. The valid range is 0 to 255.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The Packet Data Protocol context is identified by the tunnel ID, which is a combination of IMSI and NSAPI. A GTP tunnel is defined by two associated PDP contexts in different GSN nodes and is identified with a tunnel ID. A GTP tunnel is necessary to forward packets between an external packet data network and a mobile station (MS) user.

Examples

The following example clears GTP statistics:

```
hostname# clear service-policy inspect gtp statistics
```

Related Commands

Commands	Description
debug gtp	Displays detailed information about GTP inspection.
gtp-map	Defines a GTP map and enables GTP map configuration mode.
inspect gtp	Applies a GTP map to use for application inspection.
show service-policy inspect gtp	Displays the GTP configuration.
show running-config gtp-map	Shows the GTP maps that have been configured.

clear service-policy inspect radius-accounting

To clear RADIUS accounting users, use the **clear service-policy inspect radius-accounting** command in privileged EXEC mode.

clear service-policy inspect radius-accounting users {**all** | *ip_address* | *policy_map*}

Syntax Description.

all	Clears all users.
ip_address	Clears a user with this IP address.
policy_map	Clears users associated with this policy map.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example clears all RADIUS accounting users:

```
hostname# clear service-policy inspect radius-accounting users all
```

clear shared license

To reset shared license statistics, shared license client statistics, and shared license backup server statistics to zero, use the **clear shared license** command in privileged EXEC mode.

clear shared license [**all** | **backup** | **client** [*hostname*]]

Syntax Description

all	(Optional) Clears all statistics. This is the default setting.
backup	(Optional) Clears statistics for the backup server.
client	(Optional) Clears statistics for all participants.
hostname	(Optional) Clears statistics for a particular participant.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•		—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

The shared license counters include statistical data as well as error data.

Examples

The following example shows how to reset all shared license counters:

```
hostname# clear shared license all
```

Related Commands

Command	Description
activation-key	Enters a license activation key.
clear configure license-server	Clears the shared licensing server configuration.
license-server address	Identifies the shared licensing server IP address and shared secret for a participant.
license-server backup address	Identifies the shared licensing backup server for a participant.
license-server backup backup-id	Identifies the backup server IP address and serial number for the main shared licensing server.

Command	Description
license-server backup enable	Enables a unit to be the shared licensing backup server.
license-server enable	Enables a unit to be the shared licensing server.
license-server port	Sets the port on which the server listens for SSL connections from participants.
license-server refresh-interval	Sets the refresh interval provided to participants to set how often they should communicate with the server.
license-server secret	Sets the shared secret on the shared licensing server.
show activation-key	Shows the current licenses installed.
show running-config license-server	Shows the shared licensing server configuration.
show shared license	Shows shared license statistics.
show vpn-sessiondb	Shows license information about VPN sessions.

clear shun

To disable all the shuns that are currently enabled and clear the shun statistics, use the **clear shun** command in privileged EXEC mode.

clear shun [*statistics*]

Syntax Description

statistics	(Optional) Clears the interface counters only.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to disable all the shuns that are currently enabled and clear the shun statistics:

```
hostname(config)# clear shun
```

Related Commands

Command	Description
shun	Enables a dynamic response to an attacking host by preventing new connections and disallowing packets from any existing connection.
show shun	Displays the shun information.

clear snmp-server statistics

To clear SNMP server statistics (SNMP packet input and output counters), use the **clear snmp-server statistics** command in privileged EXEC mode.

clear snmp-server statistics

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to clear SNMP server statistics:

```
hostname# clear snmp-server statistics
```

Related Commands

Command	Description
clear configure snmp-server	Clears the SNMP server configuration.
show snmp-server statistics	Displays SNMP server configuration information.

clear ssl

To clear SSL information for debugging purposes, use the **clear ssl** command in privileged EXEC mode.

clear ssl {cache [**all**] | errors | mib | objects}

Syntax Description

all	Clears all sessions and statistics in SSL session cache.
cache	Clears expired sessions in SSL session cache.
errors	Clears ssl errors.
mib	Clears SSL MIB statistics.
objects	Clears SSL object statistics.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
8.4(1)	This command was introduced.

Usage Guidelines

DTLS cache is never cleared because it would impact AnyConnect functionality.

Examples

The following example shows clearing ssl cache and clearing all sessions and statistics in SSL session cache.

```
hostname# clear ssl cache
SSL session cache cleared: 2
No SSL VPNLB session cache
No SSLDEV session cache
DLTS caches are not cleared

hostname# clear ssl cache all
Clearing all sessions and statistics
SSL session cache cleared: 5
No SSL VPNLB session cache
No SSLDEV session cache
DLTS caches are not cleared
```

clear startup-config errors

To clear configuration error messages from memory, use the **clear startup-config errors** command in privileged EXEC mode.

clear startup-config errors

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To view configuration errors generated when the ASA loaded the startup configuration, use the **show startup-config errors** command.

Examples

The following example clears all configuration errors from memory:

```
hostname# clear startup-config errors
```

Related Commands

Command	Description
show startup-config errors	Shows configuration errors generated when the ASA loaded the startup configuration.

clear sunrpc-server active

To clear the pinholes opened by Sun RPC application inspection, use the **clear sunrpc-server active** command in privileged EXEC mode.

clear sunrpc-server active

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the **clear sunrpc-server active** command to clear the pinholes opened by Sun RPC application inspection that allow service traffic, such as NFS or NIS, to pass through the ASA.

Examples

The following example shows how to clear the SunRPC services table:

```
hostname# clear sunrpc-server
```

Related Commands

Command	Description
clear configure sunrpc-server	Clears the Sun remote processor call services from the ASA.
inspect sunrpc	Enables or disables Sun RPC application inspection and configures the port used.
show running-config sunrpc-server	Displays information about the SunRPC services configuration.
show sunrpc-server active	Displays information about active Sun RPC services.

clear threat-detection rate

To clear statistics when you enable basic threat detection using the **threat-detection basic-threat** command, use the **clear threat detection rate** command in privileged EXEC mode.

clear threat-detection rate

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Examples

The following example clears the rate statistics:

```
hostname# clear threat-detection rate
```

Related Commands

Command	Description
show running-config all threat-detection	Shows the threat detection configuration, including the default rate settings if you did not configure them individually.
show threat-detection rate	Shows basic threat detection statistics.
threat-detection basic-threat	Enables basic threat detection.
threat-detection rate	Sets the threat detection rate limits per event type.
threat-detection scanning-threat	Enables scanning threat detection.

clear threat-detection scanning-threat

To clear the attackers and targets after you enable scanning threat detection with the **threat-detection scanning-threat** command, use the **clear threat-detection scanning-threat** command in privileged EXEC mode.

clear threat-detection scanning-threat [attacker [*ip_address* [*mask*]] |
target [*ip_address* [*mask*]]

Syntax Description

attacker	(Optional) Clears only attackers.
ip_address	(Optional) Clears a specific IP address.
mask	(Optional) Sets the subnet mask.
target	(Optional) Clears only targets.

Defaults

If you do not specify an IP address, all hosts are released.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

To view current attackers and targets, use the **show threat-detection scanning-threat** command.

Examples

The following example shows targets and attackers with the **show threat-detection scanning-threat** command, and then clears all targets:

```
hostname# show threat-detection scanning-threat
Latest Target Host & Subnet List:
    192.168.1.0
    192.168.1.249
   Latest Attacker Host & Subnet List:
    192.168.10.234
    192.168.10.0
    192.168.10.2
    192.168.10.3
    192.168.10.4
    192.168.10.5
    192.168.10.6
```

```
    192.168.10.7
    192.168.10.8
    192.168.10.9
hostname# clear threat-detection scanning-threat target
```

Related Commands

Command	Description
show threat-detection shun	Shows currently shunned hosts.
show threat-detection statistics host	Shows the host statistics.
show threat-detection statistics protocol	Shows the protocol statistics.
show threat-detection statistics top	Shows the top 10 statistics.
threat-detection scanning-threat	Enables scanning threat detection.

clear threat-detection shun

To release the currently shunned hosts after you enable scanning threat detection with the **threat-detection scanning-threat** command and automatically shunning attacking hosts, use the **clear threat-detection shun** command in privileged EXEC mode.

clear threat-detection shun [*ip_address* [*mask*]]

Syntax Description

ip_address	(Optional) Releases a specific IP address from being shunned.
mask	(Optional) Sets the subnet mask for the shunned host IP address.

Defaults

If you do not specify an IP address, all hosts are released.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

To view currently shunned hosts, use the **show threat-detection shun** command.

Examples

The following example views currently shunned hosts with the **show threat-detection shun** command, and then releases host 10.1.1.6 from being shunned:

```
hostname# show threat-detection shun
Shunned Host List:
10.1.1.6
198.1.6.7
hostname# clear threat-detection shun 10.1.1.6 255.255.255.255
```

Related Commands

Command	Description
show threat-detection shun	Shows currently shunned hosts.
show threat-detection statistics host	Shows the host statistics.
show threat-detection statistics protocol	Shows the protocol statistics.

Command	Description
show threat-detection statistics top	Shows the top 10 statistics.
threat-detection scanning-threat	Enables scanning threat detection.

clear threat-detection statistics

To clear the statistics after you enable TCP Intercept statistics with the **threat-detection statistics tcp-intercept** command, use the **clear threat-detection scanning-threat** command in privileged EXEC mode.

clear threat-detection statistics [tcp-intercept]

Syntax Description

tcp-intercept	(Optional) Clears TCP Intercept statistics.

Defaults

Clears TCP Intercept statistics.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
8.0(4)	This command was introduced.

Usage Guidelines

To view TCP Intercept statistics, enter the **show threat-detection statistics top** command.

Examples

The following example shows TCP Intercept statistics with the **show threat-detection statistics top tcp-intercept** command, and then clears all statistics:

```
hostname# show threat-detection statistics top tcp-intercept

Top 10 Protected Servers under Attack (sorted by average rate)
Monitoring Window Size: 30 mins    Sampling Interval: 30 secs
<Rank> <Server IP:Port> <Interface> <Ave Rate> <Cur Rate> <Total> <Source IP (Last Attack
Time)>
------------------------------------------------------------------------------
1    192.168.1.2:5000 inside 1249 9503 2249245 <various> Last: 10.0.0.3 (0 secs ago)
2    192.168.1.3:5000 inside 10 10 6080 10.0.0.200 (0 secs ago)
3    192.168.1.4:5000 inside 2 6 560 10.0.0.200 (59 secs ago)
4    192.168.1.5:5000 inside 1 5 560 10.0.0.200 (59 secs ago)

10   192.168.1.11:5000 inside 0 0 550 10.0.0.200 (5 mins ago)
```

```
hostname# clear threat-detection statistics
```

Related Commands

Command	Description
show threat-detection statistics top	Shows the top 10 statistics.
threat-detection statistics	Enables threat detection statistics.

clear traffic

To reset the counters for transmit and receive activity, use the **clear traffic** command in privileged EXEC mode.

clear traffic

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **clear traffic** command resets the counters for transmit and receive activity that is displayed with the **show traffic** command. The counters indicate the number of packets and bytes moving through each interface since the last clear traffic command was entered or since the ASA came online. And the number of seconds indicate the duration the ASA has been online since the last reboot.

Examples

The following example shows the **clear traffic** command:

```
hostname# clear traffic
```

Related Commands

Command	Description
show traffic	Displays the counters for transmit and receive activity.

clear uauth

To delete all the cached authentication and authorization information for a user or for all users, use the **clear uauth** command in privileged EXEC mode.

clear uauth [*username*]

Syntax Description

username	(Optional) Specifies the user authentication information to remove by username.

Defaults

Omitting the *username* argument deletes the authentication and authorization information for all users.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **clear uauth** command deletes the AAA authorization and authentication caches for one user or for all users, which forces the user or users to reauthenticate the next time that they create a connection.

This command is used with the **timeout** command.

Each user host IP address has an authorization cache attached to it. If the user attempts to access a service that has been cached from the correct host, the ASA considers it preauthorized and immediately proxies the connection. Once you are authorized to access a website, for example, the authorization server is not contacted for each image as it is loaded (assuming the images come from the same IP address). This process significantly increases performance and reduces the load on the authorization server.

The cache allows up to 16 address and service pairs for each user host.

Note When you enable Xauth, an entry is added to the uauth table (as shown by the **show uauth** command) for the IP address that is assigned to the client. However, when using Xauth with the Easy VPN Remote feature in Network Extension Mode, the IPsec tunnel is created from network to network, so that the users behind the firewall cannot be associated with a single IP address. For this reason, a uauth entry cannot be created upon completion of Xauth. If AAA authorization or accounting services are required, you can enable the AAA authentication proxy to authenticate users behind the firewall. For more information on AAA authentication proxies, see the AAA commands.

Use the **timeout uauth** command to specify how long the cache should be kept after the user connections become idle. Use the **clear uauth** command to delete all the authorization caches for all the users, which will cause them to have to reauthenticate the next time that they create a connection.

Examples

The following example shows how to cause the user to reauthenticate:

```
hostname(config)# clear uauth user
```

Related Commands

Command	Description
aaa authentication	Enables, disables, or views LOCAL, TACACS+ or RADIUS user authentication (on a server designated by the **aaa-server** command).
aaa authorization	Enablse, disables, or views TACACS+ or RADIUS user authorization (on a server designated by the **aaa-server** command).
show uauth	Displays current user authentication and authorization information.
timeout	Sets the maximum idle time duration.

clear uc-ime

To clear the counters used to display statistics about the Cisco Intercompany Media Engine proxy, use the **clear uc-ime** command in privileged EXEC mode.

clear uc-ime [[**mapping-service-sessions** | **signaling-sessions** | **fallback-notification**] **statistics**]

Syntax Description

fallback-notification	(Optional) Clears the counters for fallback notification statistics.
mapping-service-sessions	(Optional) Clears the counters for mapping-service-session statistics.
signaling-sessions	(Optional) Clears the counters for signaling-session statistics.
statistics	(Optional) The keyword to configure which counters to clear for the Cisco Intercompany Media Engine proxy.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Examples

The following example clears the counters which are used to display signaling-sessions statistics:

```
hostname# clear configure signaling-sessions statistics
```

Related Commands

Command	Description
clear configure uc-ime	Clears the running configuration for the Cisco Intercompany Media Engine proxy on the ASA.
show running-config uc-ime	Shows the running configuration of the Cisco Intercompany Media Engine proxy.
show uc-ime	Displays statistical or detailed information about fallback notifications, mapping-service sessions, and signaling sessions.
uc-imc	Creates the Cisco Intercompany Media Engine proxy instance on the ASA.

clear url-block block statistics

To clear the block buffer usage counters, use the **clear url-block block statistics** command in privileged EXEC mode.

clear url-block block statistics

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introducded.

Usage Guidelines

The **clear url-block block statistics** command clears the block buffer usage counters, except for the Current number of packets held (global) counter.

Examples

The following example clears the URL block statistics and displays the status of the counters after they have been cleared:

```
hostname# clear url-block block statistics
hostname# show url-block block statistics

URL Pending Packet Buffer Stats with max block  0
-----------------------------------------------------
Cumulative number of packets held: | 0
Maximum number of packets held (per URL): | 0
Current number of packets held (global): | 38
Packets dropped due to
| exceeding url-block buffer limit: | 0
| HTTP server retransmission: | 0
Number of packets released back to client: | 0
```

Related Commands

Commands	Description
filter url	Directs traffic to a URL filtering server.
show url-block	Displays information about the URL cache, which is used for buffering URLs while waiting for responses from an N2H2 or Websense filtering server.
url-block	Manages the URL buffers used for web server responses.
url-cache	Enables URL caching while pending responses from an N2H2 or Websense server and sets the size of the cache.
url-server	Identifies an N2H2 or Websense server for use with the **filter** command.

clear url-cache statistics

To remove **url-cache** command statements from the configuration, use the **clear url-cache** command in privileged EXEC mode.

clear url-cache statistics

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **clear url-cache** command removes URL cache statistics from the configuration.

Using the URL cache does not update the Websense accounting logs for Websense protocol Version 1. If you are using Websense protocol Version 1, let Websense run to accumulate logs so you can view the Websense accounting information. After you get a usage profile that meets your security needs, enter the **url-cache** command to increase throughput. Accounting logs are updated for Websense protocol Version 4 and for N2H2 URL filtering while using the **url-cache** command.

Examples

The following example clears the URL cache statistics:

```
hostname# clear url-cache statistics
```

Related Commands

Commands	Description
filter url	Directs traffic to a URL filtering server.
show url-cache statistics	Displays information about the URL cache, which is used for buffering URLs while waiting for responses from an N2H2 or Websense filtering server.
url-block	Manages the URL buffers used for web server responses while waiting for a filtering decision from the filtering server.

url-cache	Enables URL caching while pending responses from an N2H2 or Websense server and sets the size of the cache.
url-server	Identifies an N2H2 or Websense server for use with the **filter** command.

clear url-server

To clear URL filtering server statistics, use the **clear url-server** command in privileged EXEC mode.

clear url-server statistics

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **clear url-server** command removes URL filtering server statistics from the configuration.

Examples

The following example clears the URL server statistics:

```
hostname# clear url-server statistics
```

Related Commands

Commands	Description
filter url	Directs traffic to a URL filtering server.
show url-server	Displays information about the URL cache, which is used for buffering URLs while waiting for responses from an N2H2 or Websense filtering server.
url-block	Manages the URL buffers used for web server responses while waiting for a filtering decision from the filtering server.
url-cache	Enables URL caching while pending responses from an N2H2 or Websense server and sets the size of the cache.
url-server	Identifies an N2H2 or Websense server for use with the **filter** command.

clear user-identity active-user-database

To set the status of specified users to logged out for the Identity Firewall, use the **clear user-identity active-user-database** command in privileged EXEC mode.

clear user-identity active-user-database [**user** [*domain_nickname*\]*use_rname*] | **user-group** [*domain_nickname*\\]*user_group_name*]

Syntax Description

*domain_nickname**user_group_name*	Specifies a user group for which to clear statistics. The *group_name* can contain any character including [a-z], [A-Z], [0-9], [!@#$%^&()-_{}.]. If *domain_NetBIOS_name**group_name* contains a space, you must enclose the domain name and user name in quotation marks.
*domain_nickname**use_rname*	Specifies a user for which to clear statistics. The *user_name* can contain any character including [a-z], [A-Z], [0-9], [!@#$%^&()-_{}.]. If *domain_NetBIOS_name**user_name* contains a space, you must enclose the domain name and user name in quotation marks.
user	Specifies to clear statistics for users.
user-group	Specifies to clear statistics for user groups.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.4(2)	This command was introduced.

Usage Guidelines

This command sets the status of the specified user, all users belong to the specified user group, or all users to logged out.

When you specify the **user-group** keyword, the status of all users belong to the specified user group are set to logged out. When you do not specify the *domain_nickname* argument with the **user-group** keyword, users in the groups with *user_group_name* in default domain are given the logged out status.

When you specify the **user** keyword, the status of the specified user is set to logged out. When you do not specify the *domain_nickname* argument with the **user** keyword, the user with *user_name* in default domain receives a logged out status.

When you do not specify either the **user** or **user-group** keywords, all users have their status set to logged out.

Examples

The following example sets the status of all users in user group users1 in the SAMPLE domain to logged out:

```
hostname# clear user-identity active-user-database user-group SAMPLE\users1
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.
show user-identity user active	Displays the active users for the Identify Firewall.

clear user-identity ad-agent statistics

To clear the AD Agent statistics for the Identity Firewall, use the **clear user-identity ad-agent statistics** command in privileged EXEC mode.

clear user-identity ad-agent statistics

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.4(2)	This command was introduced.

Usage Guidelines

The ASA maintains the following information about the primary and secondary AD Agents:

- Status of the AD Agents
- Status of the domains
- Statistics for the AD Agents

Use the **clear user-identity ad-agent statistics** command to clear the statistics data of AD Agents.

Examples

The following example clears the AD Agent statistics for the Identity Firewall:

```
hostname# clear user-identity ad-agent statistics
hostname# show user-identity ad-agent statistics

    Primary AD Agent                Total  Last Activity
    -------------------------  ----------  ------------------------
    Input packets:                      0  N/A
    Output packets:                     0  N/A
    Send updates:                       0  N/A
    Recv updates:                       0  N/A
    Keepalive failed:                   0  N/A
    Send update failed:                 0  N/A
    Query failed:                       0  N/A

    Secondary AD Agent              Total  Last Activity
```

```
-------------------------  ----------  ------------------------
Input packets:                      0  N/A
Output packets:                     0  N/A
Send updates:                       0  N/A
Recv updates:                       0  N/A
Keepalive failed:                   0  N/A
Send update failed:                 0  N/A
Query failed:                       0  N/A
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.
show user-identity ad-agent [**statistics**]	Displays statistical information about the AD Agent for the Identity Firewall.

clear user-identity statistics

To clear the counters used to display statistics about the Identity Firewall, use the **clear user-identity statistics** command in privileged EXEC mode.

clear user-identity statistics [**user** [*domain_nickname*\\]*use_rname*] | **user-group** [*domain_nickname*\\]*user_group_name*]

Syntax Description

*domain_nickname**user_group_name*	Specifies a user group for which to clear statistics. The *group_name* can contain any character including [a-z], [A-Z], [0-9], [!@#$%^&()-_{}.]. If *domain_NetBIOS_name**group_name* contains a space, you must enclose the domain name and user name in quotation marks.
*domain_nickname**use_rname*	Specifies a user for which to clear statistics. The *user_name* can contain any character including [a-z], [A-Z], [0-9], [!@#$%^&()-_{}.]. If *domain_NetBIOS_name**user_name* contains a space, you must enclose the domain name and user name in quotation marks.
user	Specifies to clear statistics for users.
user-group	Specifies to clear statistics for user groups.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.4(2)	This command was introduced.

Usage Guidelines

When *domain_nickname* is not specified before *user_group_name*, the ASA removes the Identity Firewall statistics for the group with *user_group_name* in the default domain.

When *domain_nickname* is not specified before *user_name*, the ASA removes the Identity Firewall statistics for the user with *user_name* in the default domain.

Examples

The following example clears the counters which are used to display statistics for a user group:

```
hostname# clear user-identity statistics user-group SAMPLE\users1
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.
show user-identity statistics	Displays statistics for a user or user group for the Identify Firewall.

clear user-identity user-not-found

To clear the ASA local user-not-found database for the Identity Firewall, use the **clear user-identity user-not-found** command in privileged EXEC mode.

clear user-identity user-not-found

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.4(2)	This command was introduced.

Usage Guidelines

The ASA maintains a local user-not-found database of the IP addresses not found in Microsoft Active Directory. The ASA keeps only the last 1024 packets (contiguous packets from the same source IP address are treated as one packet) of the user-not-found list and not the entire list in the database.

User the **clear user-identity user-not-found** command to clear the local database on the ASA.

Tip Use the **show user-identity user-not-found** command to display the IP addresses of the users who are not found in Microsoft Active Directory.

Examples

The following example clears the local user-not-found database for the Identity Firewall:

```
hostname# show user-identity user-not-found
172.13.1.2
171.1.45.5
169.1.1.2
172.13.12
hostname# clear user-identity user-not-found
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.
show user-identity user-not-found	Displays the IP addresses of the Active Directory users not found in the ASA user-not-found database.

clear user-identity user no-policy-activated

To clear the local records on the ASA of users who are not activated for the Identity Firewall, use the **clear user-identity user no-policy-activated** command in privileged EXEC mode.

clear user-identity user no-policy-activated

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.4(2)	This command was introduced.

Usage Guidelines

Use the **clear user-identity user no-policy-activated** to clear the local records of users not activated by any security policy, meaning the user is not part of an activated user group or not referenced in an access list or service policy configuration.

The **clear user-identity user no-policy-activated** command also clears the IP addresses of users who are active but not activated.

When you create a user group for the Identity Firewall, it must be activated, meaning the group is an import user group (defined as a user group in an access list or service policy configuration) or a local user group (defined in an object-group user).

Examples

The following example clears the local records on the ASA for users who are not activated:

```
hostname# clear user-identity user no-policy-activated
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.
show user-identity group	Displays the list of activated user groups for the Identity Firewall.

clear vpn-sessiondb statistics

To clear information about VPN sessions, including all statistics or specific sessions or protocols, use the **clear vpn-sessiondb statistics** command in privileged EXEC mode.

clear vpn-sessiondb {**all** | **anyconnect** | **email-proxy** | **global** | **index** *index_number* | **ipaddress** *IPaddr* | **l2l** | **name** *username* | **protocol** *protocol* | **ra-ikev1-ipsec** | **tunnel-group** *name* | **vpn-lb** | **webvpn**}

Syntax Descriptions

all	Clears statistics for all sessions.
anyconnect	Clears statistics for AnyConnect VPN client sessions.
email-proxy	Clears statistics for e-mail proxy sessions.
global	Clears statistics for global session data.
index *indexnumber*	Clears statistics of a single session by index number. The output of the **show vpn-sessiondb detail** command displays index numbers for each session.
ipaddress *IPaddr*	Clears statistics for sessions of the IP address that you specify.
l2l	Clears stastistics for VPN LAN-to-LAN sessions.
protocol *protocol*	Clears statistics for the following protocols: • ikev1—Sessions using the IKEv1 protocol. • ikev2—Sessions using theIKEv2 protocol. • ipsec—IPsec sessions using either IKEv1 or IKEv2. • ipseclan2lan—IPsec LAN-to-LAN sessions. • ipseclan2lanovernatt—IPsec LAN-to-LAN over NAT-T sessions. • ipsecovernatt—IPsec over NAT-T sessions. • ipsecovertcp—IPsec over TCP sessions. • ipsecoverudp—IPsec over UDP sessions. • l2tpOverIpSec—L2TP over IPsec sessions. • l2tpOverIpsecOverNatT—L2TP over IPsec over NAT-T sessions. • ospfv3—OSPFv3 over IPsec sessions. • webvpn—Clientless SSL VPN sessions. • imap4s—IMAP4 sessions. • pop3s—POP3 sessions. • smtps—SMTP sessions. • anyconnectParent—AnyConnect client sessions, regardless of the protocol used for the session (terminates AnyConnect IPsec IKEv2 and SSL sessions). • ssltunnel—SSL VPN sessions, including AnyConnect sessions using SSL and clientless SSL VPN sessions. • dtlstunnel—AnyConnect client sessions with DTLS enabled.
ra-ikev1-ipsec	Clears statistics for IPsec IKEv1 sessions.

tunnel-group *groupname*	Clears statistics for sessions for the tunnel group (connection profile) that you specify.
vpn-lb	Clears statistics for VPN load balancing management sessions.
webvpn	Clears statistics for clientless SSL VPN sessions.

Defaults

There is no default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•		—

Command History

Release	Modification
8.4(1)	This command was introduced.

clear wccp

To reset WCCP information, use the **clear wccp** command in privileged EXEC mode.

clear wccp [**web-cache** | *service_number*]

Syntax Description

web-cache	Specifies the web-cache service.
service-number	A dynamic service identifier, which means the service definition is dictated by the cache. The dynamic service number can be from 0 to 255. There is a maximum allowable number of 256 that includes the web-cache service specified with the **web-cache** keyword.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to reset the WCCP information for the web-cache service:

```
hostname# clear wccp web-cache
```

Related Commands

Command	Description
show wccp	Displays the WCCP configuration.
wccp redirect	Enables support of WCCP redirection.

clear webvpn sso-server statistics

To reset the statistics from the WebVPN Single Sign-On (SSO) server, use the **clear webvpn sso-server statistics** command in privileged EXEC mode.

clear webvpn sso-server statistics *servername*

Syntax Description

servername	Specifies the name of the SSO server to be reset.

Defaults

No default behavior or values.

Command Modes

The following table shows the mode in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•		—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

This command does not reset the "pending requests" statistic.

Examples

The following example displays crypto accelerator statistics:

```
hostname # clear webvpn sso-server statistics
hostname #
```

Related Commands

Command	Description
clear crypto accelerator statistics	Clears the global and accelerator-specific statistics in the crypto accelerator MIB.
clear crypto protocol statistics	Clears the protocol-specific statistics in the crypto accelerator MIB.
show crypto accelerator statistics	Displays the global and accelerator-specific statistics in the crypto accelerator MIB.
show crypto protocol statistics	Displays the protocol-specific statistics from the crypto accelerator MIB.

clear xlate

To clear current dynamic translation and connection information, use the **clear xlate** command in privileged EXEC mode.

clear xlate [**global** *ip1*[**-***ip2*] [**netmask** *mask*]] [**local** *ip1*[**-***ip2*] [**netmask** *mask*]] [**gport** *port1*[**-***port2*]] [**lport** *port1*[**-***port2*]] [**interface** *if_name*] [**state** *state*]

Syntax Description

global *ip1*[**-***ip2*]	(Optional) Clears the active translations by global IP address or range of addresses.
gport *port1*[*-port2*]	(Optional) Clears the active translations by the global port or range of ports.
interface *if_name*	(Optional) Displays the active translations by interface.
local *ip1*[**-***ip2*]	(Optional) Clears the active translations by local IP address or range of addresses.
lport *port1*[*-port2*]	(Optional) Clears the active translations by local port or range of ports.
netmask *mask*	(Optional) Specifies the network mask to qualify the global or local IP addresses.
state *state*	(Optional) Clears the active translations by state. You can enter one or more of the following states: • **static**—Specifies **static** translations. • **portmap**—Specifies PAT global translations. • **norandomseq**—Specifies a **nat** or **static** translation with the **norondomseq** setting. • **identity**—Specifies **nat 0** identity address translations. When specifying more than one state, separate the states with a space.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **clear xlate** command clears the contents of the translation slots ("xlate" refers to the translation slot). Translation slots can persist after key changes have been made. Always use the **clear xlate** command after adding, changing, or removing the **global** or **nat** commands in your configuration.

An xlate describes a NAT or PAT session. These sessions can be viewed with the **show xlate** command with the **detail** option. There are two types of xlates: static and dynamic.

A static xlate is a persistent xlate that is created using the **static** command. The **clear xlate** command does not clear for a host in a static entry. Static xlates can only be removed by removing the **static** command from the configuration; the **clear xlate** command does not remove the static translation rule. If you remove a static command from the configuration, preexisting connections that use the static rule can still forward traffic. Use the **clear local-host** or **clear conn** command to deactivate these connections.

A dynamic xlate is an xlate that is created on demand with traffic processing (through the **nat** or **global** command). The **clear xlate** command removes dynamic xlates and their associated connections. You can also use the **clear local-host** or **clear conn** command to clear the xlate and associated connections. If you remove a **nat** or a **global** command from the configuration, the dynamic xlate and associated connections may remain active. Use the **clear xlate** command to remove these connections.

Examples

The following example shows how to clear the current translation and connection slot information:

```
hostname# clear xlate global
```

Related Commands

Command	Description
clear local-host	Clears local host network information.
clear uauth	Clears cached user authentication and authorization information.
show conn	Displays all active connections.
show local-host	Displays the local host network information.
show xlate	Displays the current translation information.

CHAPTER 10

client-access-rule through crl configure Commands

client-access-rule

To configure rules that limit the remote access client types and versions that can connect via IPsec through the ASA, use the **client-access-rule** command in group-policy configuration mode. To delete a rule, use the **no** form of this command.

client-access-rule *priority* {**permit** | **deny**} **type** *type* **version** *version* | **none**

no client-access-rule *priority* [{**permit** | **deny**} **type** *type* **version** *version*]

Syntax Description

deny	Denies connections for devices of a particular type and/or version.
none	Allows no client access rules. Sets **client-access-rule** to a null value, thereby allowing no restriction. Prevents inheriting a value from a default or specified group policy.
permit	Permits connections for devices of a particular type and/or version.
priority	Determines the priority of the rule. The rule with the lowest integer has the highest priority. Therefore, the rule with the lowest integer that matches a client type and/or version is the rule that applies. If a lower priority rule contradicts, the ASA ignores it.
type *type*	Identifies device types via free-form strings, for example VPN 3002. A string must match exactly its appearance in the **show vpn-sessiondb remote** command output, except that you can use the * character as a wildcard.
version *version*	Identifies the device version via free-form strings, for example 7.0. A string must match exactly its appearance in the **show vpn-sessiondb remote** command output, except that you can use the * character as a wildcard.

Defaults

By default, there are no access rules.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To delete all rules, use the **no client-access-rule command** with only the *priority* argument. This deletes all configured rules, including a null rule created by issuing the **client-access-rule none** command.

When there are no client access rules, users inherit any rules that exist in the default group policy. To prevent users from inheriting client access rules, use the **client-access-rule none** command. The result of doing so is that all client types and versions can connect.

Construct rules according to these caveats:

- If you do not define any rules, the ASA permits all connection types.
- When a client matches none of the rules, the ASA denies the connection. This means that if you define a deny rule, you must also define at least one permit rule, or the ASA denies all connections.
- For both software and hardware clients, type and version must match exactly their appearance in the **show vpn-sessiondb remote** command output.
- The * character is a wildcard, which you can use multiple times in each rule. For example, **client-access-rule 3 deny type * version 3.*** creates a priority 3 client access rule that denies all client types running release versions 3.x software.
- You can construct a maximum of 25 rules per group policy.
- There is a limit of 255 characters for an entire set of rules.
- You can use n/a for clients that do not send client type and/or version.

Examples

The following example shows how to create client access rules for the group policy named FirstGroup. These rules permit VPN Clients running software version 4.1, while denying all VPN 3002 hardware clients:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# client-access-rule 1 d t VPN3002 v *
hostname(config-group-policy)# client-access-rule 2 p * v 4.1
```

client-bypass-proxy

To configure how the ASA manages IPv4 traffic when it is expecting only IPv6 traffic or how it manages IPv6 traffic when it is expecting only IPv4 traffic, use the **client-bypass-proxy** command in group-policy configuration mode. To clear the client bypass protocol setting, use the **no** form of this command.

client-bypass-protocol {**enable** | **disable**}

no client-bypass-protocol {**enable** | **disable**}

Syntax Description

enable	If Client Bypass Protocol is enabled, the the IP traffic for which the ASA did not assign an IP address type is sent from the client in the clear.
disable	If Client Bypass Protocol is disabled, the IPv6 traffic for wich the ASA did not assing an IP address type is is dropped.

Defaults

Client Bypass Protocol is disabled by default in the DfltGrpPolicy.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The Client Protocol Bypass feature allows you to configure how the ASA manages IPv4 traffic when it is expecting only IPv6 traffic or how it manages IPv6 traffic when it is expecting only IPv4 traffic.

When the AnyConnect client makes a VPN connection to the ASA, the ASA could assign it an IPv4, IPv6, or both an IPv4 and IPv6 address. If the ASA assigns the AnyConnect connection only an IPv4 address or only an IPv6 address, you can now configure the Client Bypass Protocol to drop network traffic for which the ASA did not assign an IP address, or allow that traffic to bypass the ASA and be sent from the client unencrypted or “in the clear.”

For example, assume that the ASA assigns only an IPv4 address to an AnyConnect connection and the endpoint is dual stacked. When the endpoint attempts to reach an IPv6 address, if Client Bypass Protocol is disabled, the IPv6 traffic is dropped; however, if Client Bypass Protocol is enabled, the IPv6 traffic is sent from the client in the clear.

Examples

The following example enables client bypass protocol:

```
hostname(config-group-policy)# client-bypass-protocol enable
hostname(config-group-policy)#
```

The following example disables client bypass protocol:

```
hostname(config-group-policy)# client-bypass-protocol disable
hostname(config-group-policy)#
```

The following example clears the client bypass protocol setting:

```
hostname(config-group-policy)# no client-bypass-protocol enable
hostname(config-group-policy)#
```

client (ctl-provider)

To specify clients allowed to connect to the Certificate Trust List provider, or to specify a username and password for client authentication, use the **client** command in ctl provider configuration mode. To remove the configuration, use the **no** form of this command.

client [[**interface** *if_name*] *ipv4_addr*] | [**username** *user_name* **password** *password* [**encrypted**]]

no client [[**interface** *if_name*] *ipv4_addr*] | [**username** *user_name* **password** *password* [**encrypted**]]

Syntax Description

encrypted	Specifies encryption for the password.
interface *if_name*	Specifies the interface allowed to connect.
ipv4_addr	Specifies the IP address of the client.
password *password*	Specifies the password for client authentication.
username *user_name*	Specifies the username for client authentication.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ctl provider configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use the **client** command in ctl provider configuration mode to specify the clients allowed to connect to the CTL provider, and to set the username and password for client authentication. More than one command may be issued to define multiple clients. The username and password must match the CCM Administrator's username and password for the CallManager cluster.

Examples

The following example shows how to create a CTL provider instance:

```
hostname(config)# ctl-provider my_ctl
hostname(config-ctl-provider)# client interface inside 172.23.45.1
hostname(config-ctl-provider)# client username CCMAdministrator password XXXXXX encrypted
hostname(config-ctl-provider)# export certificate ccm_proxy
hostname(config-ctl-provider)# ctl install
```

Related Commands

Commands	Description
ctl	Parses the CTL file from the CTL client and installs trustpoints.
ctl-provider	Configures a CTL provider instance in ctl provider configuration mode.
export	Specifies the certificate to be exported to the client
service	Specifies the port to which the CTL provider listens.
tls-proxy	Defines a TLS proxy instance and sets the maximum sessions.

client (tls-proxy)

To configure trustpoints, keypairs, and cipher suites, use the **client** command in tls proxy configuration mode. To remove the configuration, use the **no** form of this command.

client [**cipher-suite** *cipher_suite*] | [**ldc** [**issuer** *ca_tp_name* | **key-pair** *key_label*]]

no client [**cipher-suite** *cipher_suite*] | [**ldc** [**issuer** *ca_tp_name* | **key-pair** *key_label*]

Syntax Description

cipher-suite *cipher_suite*	Specifies the cipher suite. Options include des-sha1, 3des-sha1, aes128-sha1, aes256-sha1, or null-sha1.
issuer *ca_tp_name*	Specifies the local CA trustpoint to issue client dynamic certificates.
keypair *key_label*	Specifies the RSA keypair to be used by client dynamic certificates.
ldc	Specifies the local dynamic certificate issuer or keypair.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tls proxy configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use the **client** command in tls proxy configuration mode to control the TLS handshake parameters for the ASA as the TLS client role in TLS proxy. This includes cipher suite configuration, or to set the local dynamic certificate issuer or keypair. The local CA that issues client dynamic certificates is defined by the **crypto ca trustpoint** command, and the trustpoint must have the **proxy-ldc-issuer** command configured, or the default local CA server (LOCAL-CA-SERVER).

The keypair value must have been generated with the **crypto key generate** command.

For client proxy (the proxy acts as a TLS client to the server), the user-defined cipher suite replaces the default cipher suite, or the one defined by the **ssl encryption** command. You can use this command to achieve different ciphers between the two TLS sessions. You should use AES ciphers with the CallManager server.

Examples

The following example shows how to create a TLS proxy instance:

```
hostname(config)# tls-proxy my_proxy
```

```
hostname(config-tlsp)# server trust-point ccm_proxy
hostname(config-tlsp)# client ldc issuer ldc_server
hostname(config-tlsp)# client ldc keypair phone_common
```

Related Commands

Commands	Description
ctl-provider	Defines a CTL provider instance and enters ctl provider configuration mode.
server trust-point	Specifies the proxy trustpoint certificate to be presented during the TLS handshake.
show tls-proxy	Shows the TLS proxies.
tls-proxy	Defines a TLS proxy instance and sets the maximum number of sessions.

client-firewall

To set personal firewall policies that the ASA pushes to the VPN client during IKE tunnel negotiation, use the **client-firewall** command in group-policy configuration mode. To delete a firewall policy, use the **no** form of this command.

client-firewall none

no client-firewall {**opt** | **req**} **custom vendor-id** *num* **product-id** *num* **policy** {**AYT** | **CPP acl-in** *acl* **acl-out** *acl*} [**description** *string*]

client-firewall {**opt** | **req**} **zonelabs-integrity**

Note When the firewall type is **zonelabs-integrity**, do not include arguments. The Zone Labs Integrity Server determines the policies.

client-firewall {**opt** | **req**} **zonelabs-zonealarm policy** {**AYT** | **CPP acl-in** *acl* **acl-out** *acl*}

client-firewall {**opt** | **req**} **zonelabs-zonealarmorpro policy** {**AYT** | **CPP acl-in** *acl* **acl-out** *acl*}

client-firewall {**opt** | **req**} **zonelabs-zonealarmpro policy** {**AYT** | **CPP acl-in** *acl* **acl-out** *acl*}

client-firewall {**opt** | **req**} **cisco-integrated acl-in** *acl* **acl-out** *acl*}

client-firewall {**opt** | **req**} **sygate-personal**

client-firewall {**opt** | **req**} **sygate-personal-pro**

client-firewall {**opt** | **req**} **sygate-personal-agent**

client-firewall {**opt** | **req**} **networkice-blackice**

client-firewall {**opt** | **req**} **cisco-security-agent**

Syntax Description

acl-in *acl*	Provides the policy the client uses for inbound traffic.
acl-out *acl*	Provides the policy the client uses for outbound traffic.
AYT	Specifies that the client PC firewall application controls the firewall policy. The ASA checks to make sure the firewall is running. It asks, “Are You There?” If there is no response, the ASA tears down the tunnel.
cisco-integrated	Specifies the Cisco Integrated firewall type.
cisco-security-agent	Specifies the Cisco Intrusion Prevention Security Agent firewall type.
CPP	Specifies Policy Pushed as source of the VPN Client firewall policy.
custom	Specifies the Custom firewall type.
description *string*	Describes the firewall.
networkice-blackice	Specifies the Network ICE Black ICE firewall type.

none	Indicates that there is no client firewall policy. Sets a firewall policy with a null value, thereby disallowing one. Prevents inheriting a firewall policy from a default or specified group policy.
opt	Indicates an optional firewall type.
product-id	Identifies the firewall product.
req	Indicates a required firewall type.
sygate-personal	Specifies the Sygate Personal firewall type.
sygate-personal-pro	Specifies the Sygate Personal Pro firewall type.
sygate-security-agent	Specifies the Sygate Security Agent firewall type.
vendor-id	Identifies the firewall vendor.
zonelabs-integrity	Specifies the Zone Labs Integrity Server firewall type.
zonelabs-zonealarm	Specifies the Zone Labs Zone Alarm firewall type.
zonelabs-zonealarmorpro policy	Specifies the Zone Labs Zone Alarm or Pro firewall type.
zonelabs-zonealarmpro policy	Specifies the Zone Labs Zone Alarm Pro firewall type.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	The **zonelabs-integrity** firewall type was added.

Usage Guidelines

Only one instance of this command can be configured.

To delete all firewall policies, use the **no client-firewall** command without arguments. This command deletes all configured firewall policies, including a null policy created by issuing the **client-firewall none** command.

When there are no firewall policies, users inherit any that exist in the default or other group policy. To prevent users from inheriting such firewall policies, use the **client-firewall none** command.

Examples

The following example shows how to set a client firewall policy that requires Cisco Intrusion Prevention Security Agent for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# client-firewall req cisco-security-agent
```

client trust-point

To specify the proxy trustpoint certificate to be presented during the TLS handshake when configuring the TLS Proxy for Cisco Unified Presence Server (CUPS), use the **client trust-point** command in tls-proxy configuration mode. To remove the proxy trustpoint certificate, use the **no** form of this command.

client trust-point *proxy_trustpoint*

no client trust-point [*proxy_trustpoint*]

Syntax Description

proxy_trustpoint	Specifies the trustpoint defined by the **crypto ca trustpoint** command.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tls proxy configuration	•	•	•	•	—

Command History

Release	Modification
8.0(4)	This command was introduced.

Usage Guidelines

The **client trust-point** command specifies the trustpoint and associated certificate that the ASA uses in the TLS handshake when the ASA assumes the role of the TLS client. The certificate must be owned by the ASA (identity certificate).

The certificate can be self-signed, enrolled with a certificate authority, or from an imported credential. The **client trust-point** command has precedence over the global **ssl trust-point** command.

Examples

The following example shows the use of the **client trust-point** command to specify the use of trustpoint "ent_y_proxy" in the TLS handshake with the TLS server. The handshake is likely to originate from entity Y to entity X, where the TLS server resides. The ASA functions as the TLS proxy for entity Y.

```
hostname(config-tlsp)# client trust-point ent_y_proxy
```

Usage Guidelines

When there are multiple trustpoints associated with the same CA certificate, only one of the trustpoints can be configured for a specific client type. However, one of the trustpoints can be configured for one client type and the other trustpoint with another client type.

If there is a trustpoint associated with the same CA certificate that is already configured with a client type, the new trustpoint is not allowed to be configured with the same client-type setting. The **no** form of the command clears the setting so that a trustpoint cannot be used for any client validation.

Remote access VPNs can use Secure Sockets Layer (SSL) VPN, IP Security (IPsec), or both, depending on deployment requirements, to permit access to any network application or resource.

Examples

The following example enters crypto ca trustpoint configuration mode for the trustpoint, central, and designates it as an SSL trustpoint:

```
hostname(config)# crypto ca trustpoint central
hostname(config-ca-trustpoint)# client-types ssl
hostname(config-ca-trustpoint)#
```

The following example enters crypto ca trustpoint configuration mode for the trustpoint, checkin1, and designated it as an IPsec trustpoint:

```
hostname(config)# crypto ca trustpoint checkin1
hostname(config-ca-trustpoint)# client-types ipsec
hostname(config-ca-trustpoint)#
```

Related Commands

Command	Description
crypto ca trustpoint	Enters trustpoint configuration mode.
id-usage	Specifies how the enrolled identity of a trustpoint can be used.
ssl trust-point	Specifies the certificate trustpoint that represents the SSL certificate for an interface.

client-update

To issue a client-update for all active remote VPN software and hardware clients and ASAs configured as Auto Update clients, on all tunnel-groups or for a particular tunnel group, use the **client-update** command in privileged EXEC mode.

To configure and change client-update parameters at the global level, including VPN software and hardware clients and ASAs configured as Auto Update clients, use the **client-update** command in global configuration mode.

To configure and change client-update tunnel-group IPsec-attributes parameters for VPN software and hardware clients, use the **client-update** command in tunnel-group ipsec-attributes configuration mode.

To disable a client update, use the **no** form of this command.

Global configuration mode command:

client-update {**enable** | **component** {**asdm** | **image**} | **device-id** *dev_string* | **family** *family_name* | **type** *type*} **url** *url-string* **rev-nums** *rev-nums*}

no client-update {**enable** | **component** {**asdm** | **image**} | **device-id** *dev_string* | **family** *family_name* | **type** *type*} **url** *url-string* **rev-nums** *rev-nums*}

Tunnel-group ipsec-attributes configuration mode command:

client-update type *type* **url** *url-string* **rev-nums** *rev-nums*

no client-update type *type* **url** *url-string* **rev-nums** *rev-nums*

Privileged EXEC mode command:

client-update {**all** | *tunnel-group*}

no client-update *tunnel-group*

Syntax Description

all	(Available only in privileged EXEC mode.) Applies the action to all active remote clients in all tunnel groups. You cannot use the keyword **all** with the **no** form of the command.
component {**asdm** | **image**}	The software component for ASAs configured as Auto Update clients.
device-id *dev_string*	If the Auto Update client is configured to identify itself with a unique string, specify the same string that the client uses. The maximum length is 63 characters.
enable	(Available only in global configuration mode). Enables remote client software updates.
family *family_name*	If the Auto Update client is configured to identify itself by device family, specify the same device family that the client uses. It can be asa, pix, or a text string with a maximum length of 7 characters.
rev-nums *rev-nums*	(Not available in privileged EXEC mode.) Specifies the software or firmware images for this client. For Windows, WIN9X, WinNT, and VPN3002 clients, enter up to 4, in any order, separated by commas. For ASAs, only one is allowed. The maximum length of the string is 127 characters.

tunnel-group	(Available only in privileged EXEC mode.) Specifies the name of a valid tunnel-group for remote client update.
type *type*	(Not available in privileged EXEC mode.) Specifies the operating systems of remote PCs or the type of ASAs (configured as Auto Update clients) to notify of a client update. The list is the following: • asa5505: Cisco 5505 Adaptive Security Appliance • asa5510: Cisco 5510 Adaptive Security Appliance • asa5520: Cisco 5520 Adaptive Security Appliance • asa5540: Cisco 5540 Adaptive Security Appliance • linux: A Linux client • mac: MAC OS X client • pix-515: Cisco PIX 515 Firewall • pix-515e: Cisco PIX 515E Firewall • pix-525: Cisco PIX 525 Firewall • pix-535: Cisco PIX 535 Firewall • Windows: all windows-based platforms • WIN9X: Windows 95, Windows 98, and Windows ME platforms • WinNT: Windows NT 4.0, Windows 2000, and Windows XP platforms • vpn3002: VPN 3002 hardware client • A text string of up to 15 characters
url *url-string*	(Not available in privileged EXEC mode.) Specifies the URL for the software/firmware image. This URL must point to a file appropriate for this client. The maximum string length is 255 characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•		—
Global configuration	•	—	•		—
Tunnel-group ipsec-attributes configuration	•	—	•		—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.1(1)	Added the tunnel-group ipsec-attributes configuration mode.
7.2(1)	Added the **component**, **device-id**, and **family** keywords and their arguments to support the ASA configured as an Auto Update Server.

Usage Guidelines

In tunnel-group ipsec-attributes configuration mode, you can apply this attribute only to the IPsec remote-access tunnel-group type.

The **client-update** command lets you enable the update; specify the types and revision numbers of clients to which the update applies; provide a URL or IP address from which to get the update; and, in the case of Windows clients, optionally notify users that they should update their VPN client version. If the client is already running a software version on the list of revision numbers, it does not need to update its software. If the client is not running a software version on the list, it should update.

For Windows clients, you can provide a mechanism for users to accomplish that update. For VPN 3002 hardware client users, the update occurs automatically, with no notification. When the client type is another ASA, this ASA acts as an Auto Update server.

Note For all Windows clients and Auto Update clients, you must use the protocol “http://” or “https://” as the prefix for the URL. For the VPN 3002 hardware client, you must specify protocol “tftp://” instead.

Alternatively, for Windows clients and VPN 3002 hardware clients, you can configure client update just for individual tunnel-groups, rather than for all clients of a particular type.

Note You can have the browser automatically start an application by including the application name at the end of the URL; for example: https://support/updates/vpnclient.exe.

After you have enabled client update, you can define a set of client-update parameters for a particular IPsec- remote access tunnel group. To do this, in tunnel-group ipsec-attributes mode, specify the tunnel-group name and its type, and the URL or IP address from which to get the updated image. In addition, you must specify a revision number. If the user client revision number matches one of the specified revision numbers, there is no need to update the client; for example, to issue a client update for all Windows clients.

Optionally, you can send a notice to active users with outdated Windows clients that their VPN client needs updating. For these users, a dialog box appears, offering the opportunity to launch a browser and download the updated software from the site specified in the URL. The only part of this message that you can configure is the URL. Users who are not active get a notification message the next time they log in. You can send this notice to all active clients on all tunnel groups, or you can send it to clients on a particular tunnel group.

If the user client revision number matches one of the specified revision numbers, there is no need to update the client, and users receive no notification message. VPN 3002 clients update without user intervention, and users receive no notification message.

Note If you specify the client-update type as **windows** (specifying all Windows-based platforms) and later want to enter a client-update type of **win9x** or **winnt** for the same entity, you must first remove the windows client type with the **no** form of the command, then use new **client-update** commands to specify the new client types.

Examples

The following example, entered in global configuration mode, enables client update for all active remote clients on all tunnel groups:

```
hostname(config)# client-update enable
hostname#
```

The following example applies only to Windows (Win9x, WinNT). Entered in global configuration mode, it configures client update parameters for all Windows-based clients, including the revision number, 4.7 and the URL for retrieving the update, https://support/updates.

```
hostname(config)# client-update type windows url https://support/updates/ rev-nums 4.7
hostname(config)#
```

The following example applies only to VPN 3002 hardware clients. Entered in tunnel-group ipsec-attributes configuration mode, it configures client update parameters for the IPsec remote-access tunnel-group "salesgrp". It designates the revision number, 4.7 and uses the TFTP protocol for retrieving the updated software from the site with the IP address 192.168.1.1:

```
hostname(config)# tunnel-group salesgrp type ipsec-ra
hostname(config)# tunnel-group salesgrp ipsec-attributes
hostname(config-tunnel-ipsec)# client-update type vpn3002 url tftp:192.168.1.1 rev-nums
4.7
hostname(config-tunnel-ipsec)#
```

The following example shows how to issue a client update for clients that are Cisco 5520 ASAs configured as Auto Update clients:

```
hostname(config)# client-update type asa5520 component asdm url
http://192.168.1.114/aus/asdm501.bin rev-nums 7.2(1)
```

The following example, entered in privileged EXEC mode, sends a client-update notification to all connected remote clients in the tunnel group named "remotegrp" that need to update their client software. Clients in other groups do not get an update notification.

```
hostname# client-update remotegrp
hostname#
```

The following example, entered in privileged EXEC mode, notifies all active clients on all tunnel groups:

```
hostname# client-update all
hostname#
```

Related Commands

Command	Description
clear configure client-update	Clears the entire client-update configuration.
show running-config client-update	Shows the current client-update configuration.
tunnel-group ipsec-attributes	Configures the tunnel-group ipsec-attributes for this group.

clock set

To manually set the clock on the ASA, use the **clock set** command in privileged EXEC mode.

clock set *hh*:*mm*:*ss* {*month day* | *day month*} *year*

Syntax Description

day	Sets the day of the month, from 1 to 31. You can enter the day and month as **april 1** or as **1 april**, for example, depending on your standard date format.
hh:*mm*:*ss*	Sets the hour, minutes, and seconds in 24-hour time. For example, set **20:54:00** for 8:54 pm.
month	Sets the month. Depending on your standard date format, you can enter the day and month as **april 1** or as **1 april**.
year	Sets the year using four digits, for example, **2004**. The year range is 1993 to 2035.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If you have not entered any **clock** configuration commands, the default time zone for the **clock set** command is UTC. If you change the time zone after you enter the **clock set** command using the **clock timezone** command, the time automatically adjusts to the new time zone. However, if you enter the **clock set** command after you establish the time zone with the **clock timezone** command, then enter the time appropriate for the new time zone and not for UTC. Similarly, if you enter the **clock summer-time** command after the **clock set** command, the time adjusts for daylight saving. If you enter the **clock set** command after the **clock summer-time** command, enter the correct time for daylight saving.

This command sets the time in the hardware chip, and does not save the time in the configuration file. This time endures reboots. Unlike the other **clock** commands, this command is a privileged EXEC command. To reset the clock, you need to set a new time for the **clock set** command.

Examples

The following example sets the time zone to MST, the daylight saving time to the default period in the U.S., and the current time for MDT to 1:15 p.m. on July 27, 2004:

```
hostname(config)# clock timezone MST -7
hostname(config)# clock summer-time MDT recurring
hostname(config)# exit
hostname# clock set 13:15:0 jul 27 2004
hostname# show clock
13:15:00.652 MDT Tue Jul 27 2004
```

The following example sets the clock to 8:15 on July 27, 2004 in the UTC time zone, and then sets the time zone to MST and the daylight saving time to the default period in the U.S. The end time (1:15 in MDT) is the same as the previous example.

```
hostname# clock set 20:15:0 jul 27 2004
hostname# configure terminal
hostname(config)# clock timezone MST -7
hostname(config)# clock summer-time MDT recurring
hostname# show clock
13:15:00.652 MDT Tue Jul 27 2004
```

Related Commands

Command	Description
clock summer-time	Sets the date range to show daylight saving time.
clock timezone	Sets the time zone.
show clock	Shows the current time.

clock summer-time

To set the date range for daylight saving time for the display of the ASA time, use the **clock summer-time** command in global configuration mode. To disable the daylight saving time dates, use the **no** form of this command.

clock summer-time *zone* **recurring** [*week weekday month hh*:*mm week weekday month hh*:*mm*] [*offset*]

no clock summer-time [*zone* **recurring** [*week weekday month hh*:*mm week weekday month hh*:*mm*] [*offset*]]

clock summer-time *zone* **date** {*day month* | *month day*} *year hh*:*mm* {*day month* | *month day*} *year hh*:*mm* [*offset*]

no clock summer-time [*zone* **date** {*day month* | *month day*} *year hh*:*mm* {*day month* | *month day*} *year hh*:*mm* [*offset*]]

Syntax Description

date	Specifies the start and end dates for daylight saving time as a specific date in a specific year. If you use this keyword, you need to reset the dates each year.
day	Sets the day of the month, from 1 to 31. You can enter the day and month as **April 1** or as **1 April**, for example, depending on your standard date format.
hh:mm	Sets the hour and minutes in 24-hour time.
month	Sets the month as a string. For the **date** command, you can enter the day and month as **April 1** or as **1 April**, for example, depending on your standard date format.
offset	(Optional) Sets the number of minutes to change the time for daylight saving time. By default, the value is 60 minutes.
recurring	Specifies the start and end dates for daylight saving time, in the form of a day and time of the month, and not a specific date in a year. This keyword lets you set a recurring date range that you do not need to alter yearly. If you do not specify any dates, the ASA uses the default date range for the United States: from 2:00 a.m. on the second Sunday in March to 2:00 a.m. on the first Sunday in November.
week	(Optional) Specifies the week of the month as an integer between 1 and 4 or as the words **first** or **last**. For example, if the day might fall in the partial fifth week, then specify **last**.
weekday	(Optional) Specifies the day of the week: **Monday**, **Tuesday**, **Wednesday**, and so on.
year	Sets the year using four digits, for example, **2004**. The year range is 1993 to 2035.
zone	Specifies the time zone as a string, for example, **PDT** for Pacific Daylight Time. When the ASA shows the daylight saving time according to the date range you set with this command, the time zone changes to the value you set here. See the **clock timezone** command to set the base time zone to a zone other than UTC.

Defaults

The default offset is 60 minutes.

The default recurring date range is from 2:00 a.m. on the second Sunday in March to 2:00 a.m. on the first Sunday in November.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
8.0(2)	The default recurring date range was changed to 2:00 a.m. on the second Sunday in March to 2:00 a.m. on the first Sunday in November.

Usage Guidelines

For the Southern Hemisphere, the ASA accepts the start month to be later in the year than the end month, for example, from October to March.

Examples

The following example sets the daylight saving date range for Australia:

```
hostname(config)# clock summer-time PDT recurring last Sunday October 2:00 last Sunday
March 2:00
```

Some countries start daylight saving on a specific date. In the following example, daylight saving time is configured to start on April 1, 2008, at 3 a.m. and end on October 1, 2008, at 4 a.m.

```
hostname(config)# clock summer-time UTC date 1 April 2008 3:00 1 October 2008 4:00
```

Related Commands

Command	Description
clock set	Manually sets the clock on the ASA.
clock timezone	Sets the time zone.
ntp server	Identifies an NTP server.
show clock	Shows the current time.

clock timezone

To set the time zone for the ASA clock, use the **clock timezone** command in global configuration mode. To set the time zone back to the default of UTC, use the **no** form of this command.

clock timezone *zone* [**-**]*hours* [*minutes*]

no clock timezone [*zone* [**-**]*hours* [*minutes*]]

Syntax Description

[**-**]*hours*	Sets the number of hours of offset from UTC. For example, PST is -8 hours.
minutes	(Optional) Sets the number of minutes of offset from UTC.
zone	Specifies the time zone as a string, for example, PST for Pacific Standard Time.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To set daylight saving time, see the **clock summer-time** command.

The **clock set** command or the time derived from an NTP server sets the time in UTC. You must set the time zone as an offset of UTC using this command.

Examples

The following example sets the time zone to Pacific Standard Time, which is -8 hours from UTC:

```
hostname(config)# clock timezone PST -8
```

Related Commands

Command	Description
clock set	Manually sets the clock on the ASA.
clock summer-time	Sets the date range to show daylight saving time.

Command	Description
ntp server	Identifies an NTP server.
show clock	Shows the current time.

cluster-ctl-file

To use trustpoints that are already created from an existing CTL file stored in flash memory, use the **cluster-ctl-file** command in ctl file configuration mode. To remove the CTL file configuration so that you can create a new CTL file, use the **no** form of this command.

cluster-ctl-file *filename_path*

no cluster-ctl-file *filename_path*

Syntax Description

filename_path	Specifies the path and filename of the CTL file stored on disk or stored in flash memory.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ctl-file configuration	•	—	•	—	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Usage Guidelines

When this command is configured, the Phone Proxy parses the CTL file stored in flash memory and installs the trustpoints from that CTL file, then uses that file from flash in the creation of the new CTL file.

Examples

The following example parses the CTL file stored in flash memory to install the trustpoints from that file:

```
hostname(config-ctl-file)# cluster-ctl-file disk0:/old_ctlfile.tlv
```

Related Commands

Command	Description
ctl-file (global)	Specifies the CTL file to create for Phone Proxy configuration or the CTL file to parse from flash memory.
ctl-file (phone-proxy)	Specifies the CTL file to use for Phone Proxy configuration.
phone-proxy	Configures the Phone Proxy instance.

cluster encryption

To enable encryption for messages exchanged on the virtual load-balancing cluster, use the **cluster encryption** command in vpn load-balancing configuration mode. To disable encryption, use the **no** form of this command.

cluster encryption

no cluster encryption

Note VPN load balancing requires an active 3DES/AES license. The ASA checks for the existence of this crypto license before enabling load balancing. If it does not detect an active 3DES or AES license, the ASA prevents the enabling of load balancing and prevents internal configuration of 3DES by the load balancing system, unless the license permits this usage.

Syntax Description

This command has no arguments or keywords.

Defaults

Encryption is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Vpn load-balancing configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command turns encryption on or off for messages exchanged on the virtual load-balancing cluster.

Before configuring the **cluster encryption** command, you must have first used the **vpn load-balancing** command to enter vpn load-balancing configuration mode. You must also use the **cluster key** command to configure the cluster shared secret key before enabling cluster encryption.

Note When using encryption, you must first configure the command **isakmp enable** *inside*, where *inside* designates the load-balancing inside interface. If ISAKMP is not enabled on the load-balancing inside interface, an error message appears when you try to configure cluster encryption.

Examples

The following is an example of a VPN load-balancing command sequence that includes a **cluster encryption** command to enable encryption for the virtual load-balancing cluster:

```
hostname(config)# interface GigabitEthernet 0/1
hostname(config-if)# ip address 209.165.202.159 255.255.255.0
hostname(config)# nameif test
hostname(config)# interface GigabitEthernet 0/2
hostname(config-if)# ip address 209.165.201.30 255.255.255.0
hostname(config)# nameif foo
hostname(config)# vpn load-balancing
hostname(config-load-balancing)# interface lbpublic test
hostname(config-load-balancing)# interface lbprivate foo
hostname(config-load-balancing)# cluster ip address 209.165.202.224
hostname(config-load-balancing)# cluster key 123456789
hostname(config-load-balancing)# cluster encryption
hostname(config-load-balancing)# participate
```

Related Commands

Command	Description
cluster key	Specifies the shared-secret key for the cluster.
vpn load-balancing	Enters vpn load-balancing configuration mode.

cluster exec

To execute a command on all units in the cluster, or on a specific member, use the **cluster exec** command in privileged EXEC mode.

cluster exec [**unit** *unit_name*] *command*

Syntax Description

unit *unit_name*	(Optional) Performs the command on a specific unit. To view member names, enter **cluster exec unit ?** (to see all names except the current unit), or enter the **show cluster info** command.
command	Specifies the command you want to execute.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

Sending a **show** command to all members collects all output and displays it on the console of the current unit. Other commands, such as **capture** and **copy**, can also take advantage of cluster-wide execution.

Examples

To copy the same capture file from all units in the cluster at the same time to a TFTP server, enter the following command on the master unit:

```
hostname# cluster exec copy /pcap capture: tftp://10.1.1.56/capture1.pcap
```

Multiple PCAP files, one from each unit, are copied to the TFTP server. The destination capture file name is automatically attached with the unit name, such as capture1_asa1.pcap, capture1_asa2.pcap, and so on. In this example, asa1 and asa2 are cluster unit names.

The following sample output for the **cluster exec show port-channel** summary command shows EtherChannel information for each member in the cluster:

```
hostname# cluster exec show port-channel summary
primary(LOCAL):*********************************************************
 Number of channel-groups in use: 2

Related Commands

Command	Description
cluster group	Enters cluster group configuration mode.
show cluster info	Shows cluster information.

cluster group

To configure the cluster bootstrap parameters and other cluster settings, use the **cluster group** command in global configuration mode. To clear the cluster configuration, use the **no** form of this command.

cluster group *name*

no cluster group *name*

Syntax Description

name	Specifies the cluster name as an ASCII string from 1 to 38 characters. You can only configure one cluster group per unit. All members of the cluster must use the same name.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

Each unit in the cluster requires a bootstrap configuration to join the cluster. Typically, the first unit you configure to join the cluster will be the master unit. After you enable clustering, after an election period, the cluster elects a master unit. With only one unit in the cluster initially, that unit will become the master unit. Subsequent units that you add to the cluster will be slave units.

Before you configure clustering, you need to set the cluster interface mode using the **cluster interface-mode** command.

You must use the console port or ASDM to enable or disable clustering. You cannot use Telnet or SSH.

Examples

The following example configures a management interface, configures a device-local EtherChannel for the cluster control link, disables the health check (temporarily), and then enables clustering for the ASA called “unit1,” which will become the master unit because it is added to the cluster first:

```
ip local pool mgmt 10.1.1.2-10.1.1.9
ipv6 local pool mgmtipv6 2001:DB8::1002/32 8

interface management 0/0
    nameif management
```

```
    ip address 10.1.1.1 255.255.255.0 cluster-pool mgmt
    ipv6 address 2001:DB8::1001/32 cluster-pool mgmtipv6
    security-level 100
    management-only
    no shutdown

interface tengigabitethernet 0/6
    channel-group 1 mode active
    no shutdown

interface tengigabitethernet 0/7
    channel-group 1 mode active
    no shutdown

cluster group pod1
    local-unit unit1
    cluster-interface port-channel1 ip 192.168.1.1 255.255.255.0
    priority 1
    key chuntheunavoidable
    no health-check
    enable noconfirm
```

The following example includes the configuration for a slave unit, unit2:

```
interface tengigabitethernet 0/6
    channel-group 1 mode active
    no shutdown

interface tengigabitethernet 0/7
    channel-group 1 mode active
    no shutdown

cluster group pod1
    local-unit unit2
    cluster-interface port-channel1 ip 192.168.1.2 255.255.255.0
    priority 2
    key chuntheunavoidable
    no health-check
    enable as-slave
```

Related Commands

Command	Description
clacp system-mac	When using spanned EtherChannels, the ASA uses cLACP to negotiate the EtherChannel with the neighbor switch.
cluster-interface	Specifies the cluster control link interface.
cluster interface-mode	Sets the cluster interface mode.
conn-rebalance	Enables connection rebalancing.
console-replicate	Enables console replication from slave units to the master unit.
enable (cluster group)	Enables clustering.
health-check	Enables the cluster health check feature, which includes unit health monitoring and interface health monitoring.
key	Sets an authentication key for control traffic on the cluster control link.
local-unit	Names the cluster member.

Command	Description
mtu cluster-interface	Specifies the maximum transmission unit for the cluster control link interface.
priority (cluster group)	Sets the priority of this unit for master unit elections.

cluster ip address

To set the IP address of the virtual load-balancing cluster, use the **cluster ip address** command in vpn load-balancing configuration mode. To remove the IP address specification, use the **no** form of this command.

cluster ip address *ip-address*

no cluster ip address [*ip-address*]

Syntax Description

ip-address	The IP address that you want to assign to the virtual load-balancing cluster.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Vpn load-balancing configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You must first use the **vpn load-balancing** command to enter vpn load-balancing configuration mode and configure the interface to which the virtual cluster IP address refers.

The cluster IP address must be on the same subnet as the interface for which you are configuring the virtual cluster.

In the **no** form of the command, if you specify the optional *ip-address* value, it must match the existing cluster IP address before the **no cluster ip address** command can be completed.

Examples

The following example shows a VPN load-balancing command sequence that includes a **cluster ip address** command that sets the IP address of the virtual load-balancing cluster to 209.165.202.224:

```
hostname(config)# interface GigabitEthernet 0/1
hostname(config-if)# ip address 209.165.202.159 255.255.255.0
hostname(config)# nameif test
hostname(config)# interface GigabitEthernet 0/2
hostname(config-if)# ip address 209.165.201.30 255.255.255.0
hostname(config)# nameif foo
hostname(config)# vpn load-balancing
hostname(config-load-balancing)# interface lbpublic test
```

```
hostname(config-load-balancing)# interface lbprivate foo
hostname(config-load-balancing)# cluster ip address 209.165.202.224
hostname(config-load-balancing)# participate
```

Related Commands

Command	Description
interface	Sets the interfaces of the device.
nameif	Assigns a name to an interface.
vpn load-balancing	Enters vpn load-balancing configuration mode.

cluster key

To set the shared secret for IPsec site-to-site tunnel exchanges on the virtual load-balancing cluster, use the **cluster key** command in vpn load-balancing configuration mode. To remove this specification, use the **no** form of this command.

cluster key *shared-secret*

no cluster key [*shared-secret*]

Syntax Description

shared-secret	A 3- through 17-character string that defines the shared secret for the VPN load-balancing cluster. Special characters can appear in the string, but not spaces.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Vpn load-balancing configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You must first use the **vpn load-balancing** command to enter vpn load-balancing configuration mode. The shared secret defined in the **cluster key** command is also used for cluster encryption.

You must use the **cluster key** command to configure the shared secret before enabling cluster encryption.

If you specify a value for *shared-secret* in the **no cluster key** form of the command, the shared secret value must match the existing configuration.

Examples

The following example shows a VPN load-balancing command sequence that includes a **cluster key** command to set the shared secret of the virtual load-balancing cluster to 123456789:

```
hostname(config)# interface GigabitEthernet 0/1
hostname(config-if)# ip address 209.165.202.159 255.255.255.0
hostname(config)# nameif test
hostname(config)# interface GigabitEthernet 0/2
hostname(config-if)# ip address 209.165.201.30 255.255.255.0
hostname(config)# nameif foo
hostname(config)# vpn load-balancing
```

```
hostname(config-load-balancing)# interface lbpublic test
hostname(config-load-balancing)# interface lbprivate foo
hostname(config-load-balancing)# cluster ip address 209.165.202.224
hostname(config-load-balancing)# cluster key 123456789
hostname(config-load-balancing)# cluster encryption
hostname(config-load-balancing)# participate
```

Related Commands

Command	Description
vpn load-balancing	Enters vpn load-balancing configuration mode.

cluster master unit

To set a new unit as the master unit of an ASA cluster, use the **cluster master unit** command in privileged EXEC mode.

cluster master unit *unit_name*

Caution The best method to change the master unit is to disable clustering on the master unit (see the **no cluster enable** command), waiting for a new master election, and then re-enabling clustering. If you must specify the exact unit you want to become the master, use the **cluster master unit** command. Note, however, that for centralized features, if you force a master unit change using this command, then all connections are dropped, and you have to re-establish the connections on the new master unit.

Syntax Description

unit_name	Specifies the local unit name to be the new master unit. To view member names, enter **cluster master unit ?** (to see all names except the current unit), or enter the **show cluster info** command.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

You will need to reconnect to the main cluster IP address.

Examples

The following example sets asa2 as the master unit:

```
hostname# cluster master unit asa2
```

Related Commands

Command	Description
cluster exec	Sends a command to all cluster members.

Command	Description
cluster group	Configures a cluster.
cluster remove unit	Removes the unit from the cluster.

cluster remove unit

To remove the unit from the ASA cluster, use the cluster remove unit command in privileged EXEC mode.

cluster remove unit *unit_name*

Syntax Description

unit_name	Specifies the local unit name to removes from the cluster. To view member names, enter **cluster remove unit ?**, or enter the **show cluster info** command.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

The bootstrap configuration remains intact, as well as the last configuration synced from the master unit, so you can later re-add the unit without losing your configuration. If you enter this command on a slave unit to remove the master unit, a new master unit is elected.

Examples

The following example checks for unit names, and then removes asa2 from the cluster:

```
hostname(config)# cluster remove unit ?

Current active units in the cluster:
asa2

hostname(config)# cluster remove unit asa2
WARNING: Clustering will be disabled on unit asa2. To bring it back
to the cluster please logon to that unit and re-enable clustering
```

Related Commands

Command	Description
cluster exec	Sends a command to all cluster members.
cluster group	Configures a cluster.
cluster master unit	Sets a new unit as the master unit of an ASA cluster.

cluster-interface

To specify the cluster control link physical interface and IP address, use the **cluster-interface** command in cluster group configuration mode. To remove the cluster interface, use the **no** form of this command.

cluster-interface *interface_id* **ip** *ip_address mask*

no cluster-interface [*interface_id* **ip** *ip_address mask*]

Syntax Description

interface_id	Specifies a physical interface, an EtherChannel, or a redundant interface. Subinterfaces and Management interfaces are not allowed. This interface cannot have a **nameif** configured. For the ASA 5585-X with an IPS module, you cannot use the IPS module interfaces for the cluster control link.
ip *ip_address mask*	Specify an IPv4 address for the IP address; IPv6 is not supported for this interface. For each unit, specify a different IP address on the same network.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Cluster group configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

You need to enable the cluster control link interface before you join the cluster.

We recommend that you combine multiple cluster control link interfaces into an EtherChannel if you have enough interfaces. The EtherChannel is local to the ASA, and is not a spanned EtherChannel. We recommend that you use a Ten Gigabit Ethernet interface for the cluster control link. We recommend using the On mode for EtherChannel member interfaces to reduce unnecessary traffic on the cluster control link. The cluster control link does not need the overhead of LACP traffic because it is an isolated, stable network.

The cluster control link interface configuration is not replicated from the master unit to slave units; however, you must use the same configuration on each unit. Because this configuration is not replicated, you must configure the cluster control link interfaces separately on each unit.

See the configuration guide for more information about the cluster control link.

Examples

The following example creates an EtherChannel, Port-channel 2, for TenGigabitEthernet 0/6 and TenGigabitEthernet 0/7, and then assigns the port channel as the cluster control link. The port-channel interface is created automatically when you assign an interface to the channel group.

```
interface tengigabitethernet 0/6
    channel-group 2 mode on
    no shutdown

interface tengigabitethernet 0/7
    channel-group 2 mode on
    no shutdown

cluster group cluster1
    cluster-interface port-channel2 ip 10.1.1.1 255.255.255.0
```

Related Commands

Command	Description
clacp system-mac	When using spanned EtherChannels, the ASA uses cLACP to negotiate the EtherChannel with the neighbor switch.
cluster group	Names the cluster and enters cluster configuration mode.
cluster interface-mode	Sets the cluster interface mode.
conn-rebalance	Enables connection rebalancing.
console-replicate	Enables console replication from slave units to the master unit.
enable (cluster group)	Enables clustering.
health-check	Enables the cluster health check feature, which includes unit health monitoring and interface health monitoring.
key	Sets an authentication key for control traffic on the cluster control link.
local-unit	Names the cluster member.
mtu cluster-interface	Specifies the maximum transmission unit for the cluster control link interface.
priority (cluster group)	Sets the priority of this unit for master unit elections.

cluster-mode

To specify the security mode of the cluster, use the **cluster-mode** command in phone-proxy configuration mode. To set the security mode of the cluster to the default mode, use the **no** form of this command.

cluster-mode [**mixed** | **nonsecure**]

no cluster-mode [**mixed** | **nonsecure**]

Syntax Description

mixed	Specifies the cluster mode to be in mixed mode when configuring the Phone Proxy feature.
nonsecure	Specifies the cluster mode to be in nonsecure mode when configuring the Phone Proxy feature.

Defaults

The default cluster mode is nonsecure.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Phone-proxy configuration	•	—	•	—	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Usage Guidelines

When you are configuring the Phone Proxy to run in mixed-mode clusters (both secure and nonsecure modes), you must also configure the LDC issuer in case some phones are configured to be in authenticated or encrypted mode:

```
hostname(config)# crypto key generate rsa label ldc_signer_key modulus 1024
hostname(config)# crypto key generate rsa label phone_common modulus 1024
hostname(config)# tls-proxy my_proxy
hostname(config-tlsp)# server trust-point internal_PP_myctl
hostname(config-tlsp)# client ldc issuer ldc_server
hostname(config-tlsp)# client ldc keypair phone_common
```

Examples

The following example sets the security mode of the Phone Proxy to mixed (the IP phones will operate in secure and nonsecure modes):

```
hostname(config-phone-proxy)# cluster-mode mixed
```

Related Commands

Command	Description
phone-proxy	Configures the Phone Proxy instance.
tls-proxy	Configures the TLS Proxy instance.

cluster port

To set the UDP port for the virtual load-balancing cluster, use the **cluster port** command in vpn load-balancing configuration mode. To remove the port specification, use the **no** form of this command.

cluster port *port*

no cluster port [*port*]

Syntax Description

port	The UDP port that you want to assign to the virtual load-balancing cluster.

Defaults

The default cluster port is 9023.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Vpn load-balancing configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You must first use the **vpn load-balancing** command to enter vpn load-balancing configuration mode.

You can specify any valid UDP port number. The range is 1-65535.

If you specify a value for *port* in the **no cluster port** form of the command, the port number specified must match the existing configured port number.

Examples

The following example sets the UDP port for the virtual load-balancing cluster to 9023:

```
hostname(config)# interface GigabitEthernet 0/1
hostname(config-if)# ip address 209.165.202.159 255.255.255.0
hostname(config)# nameif test
hostname(config)# interface GigabitEthernet 0/2
hostname(config-if)# ip address 209.165.201.30 255.255.255.0
hostname(config)# nameif foo
hostname(config)# vpn load-balancing
hostname(config-load-balancing)# interface lbpublic test
hostname(config-load-balancing)# interface lbprivate foo
hostname(config-load-balancing)# cluster ip address 209.165.202.224
hostname(config-load-balancing)# cluster port 9023
hostname(config-load-balancing)# participate
```

Related Commands

Command	Description
vpn load-balancing	Enters vpn load-balancing configuration mode.

command-alias

To create an alias for a command, use the **command-alias** command in global configuration mode. To remove the alias, use the **no** form of this command.

command-alias *mode command_alias original_command*

no command-alias *mode command_alias original_command*

Syntax Description

command_alias	Specifies the new name for an existing command.
mode	Specifies the command mode in which you want to create the command alias, for example **exec** (for user and privileged EXEC modes), **configure**, or **interface**.
original_command	Specifies the existing command or command with its keywords for which you want to create the command alias.

Defaults

By default, the following user EXEC mode aliases are configured:

- **h** for **help**
- **lo** for **logout**
- **p** for **ping**
- **s** for **show**

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

When you enter the command alias, the original command is invoked. You might want to create command aliases to provide shortcuts for long commands, for example.

You can create an alias for the first part of any command and still enter the additional keywords and arguments as normal.

When you use CLI help, command aliases are indicated by an asterisk (*), and displayed in the following format:

```
*command-alias=original-command
```

For example, the **lo** command alias displays along with other privileged EXEC mode commands that start with "lo," as follows:

```
hostname# lo?
*lo=logout login  logout
```

You can use the same alias in different modes. For example, you can use "happy" in privileged EXEC mode and configuration mode to alias different commands, as follows:

```
hostname(config)# happy?

configure mode commands/options:
*happy="username employee1 password test"

exec mode commands/options:
*happy=enable
```

To list only commands and omit aliases, begin your input line with a space. Also, to circumvent command aliases, use a space before entering the command. In the following example, the alias named "happy" is not shown, because there is a space before the **happy?** command.

```
hostname(config)# alias exec test enable
hostname(config)# exit
hostname#   happy?
ERROR: % Unrecognized command
```

As with commands, you can use CLI help to display the arguments and keywords that can follow a command alias.

You must enter the complete command alias. Shortened aliases are not accepted. In the following example, the parser does not recognize the **hap** command as indicating the alias named "happy":

```
hostname# hap
% Ambiguous command: "hap"
```

Examples

The following example shows how to create a command alias named "save" for the **copy running-config startup-config** command:

```
hostname(config)# command-alias exec save copy running-config startup-config
hostname(config)# exit
hostname# save

Source filename [running-config]?
Cryptochecksum: 50d131d9 8626c515 0c698f7f 613ae54e

2209 bytes copied in 0.210 secs
hostname#
```

Related Commands

Command	Description
clear configure command-alias	Clears all nondefault command aliases.
show running-config command-alias	Displays all nondefault command aliases configured.

command-queue

To specify the maximum number of MGCP commands that are queued while waiting for a response, use the **command-queue** command in mgcp-map configuration mode. To remove the configuration, use the **no** form of this command.

command-queue *limit*

no command-queue *limit*

Syntax Description

limit	Specifies the maximum number of commands to queue, from 1 to 2147483647.

Defaults

This command is disabled by default.

The default for the MGCP command queue is 200.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Mgcp-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the **command-queue** command to specify the maximum number of MGCP commands that are queued while waiting for a response. The range of allowed values is from 1 to 4294967295. The default is 200. When the limit has been reached and a new command arrives, the command that has been in the queue for the longest time is removed.

Examples

The following example limits the MGCP command queue to 150 commands:

```
hostname(config)# mgcp-map mgcp_policy
hostname(config-mgcp-map)#command-queue 150
```

Related Commands

Commands	Description
debug mgcp	Enables the display of debugging information for MGCP.
mgcp-map	Defines an MGCP map and enables MGCP map configuration mode.

Commands	Description
show mgcp	Displays MGCP configuration and session information.
timeout	Configures the idle timeout after which an MGCP media or MGCP PAT xlate connection will be closed.

compatible rfc1583

To restore the method that is used to calculate the summary route costs per RFC 1583, use the **compatible rfc1583** command in router configuration mode. To disable RFC 1583 compatibility, use the **no** form of this command.

compatible rfc1583

no compatible rfc1583

Syntax Description

This command has no arguments or keywords.

Defaults

This command is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Only the **no** form of this command appears in the configuration.

Examples

The following example shows how to disable an RFC 1583-compatible route summary cost calculation:

```
hostname(config-router)# no compatible rfc1583
hostname(config-router)#
```

Related Commands

Command	Description
router ospf	Enters router configuration mode.
show running-config router	Displays the commands in the global router configuration.

compression

To enable compression for SVC connections and WebVPN connections, use the **compression** command in global configuration mode. To remove the command from the configuration, use the **no** form of the command.

compression {**all** | **svc** | **http-comp**}

no compression {**all** | **svc** | **http-comp**}

Syntax Description

all	Specifies enabling all available compression techniques.
http-comp	Specifies compression for WebVPN connections.
svc	Specifies compression for SVC connections.

Defaults

The default is *all*. All available compression techniques are enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•		—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

For SVC connections, the **compression** command configured in global configuration mode overrides the **svc compression** command configured in group policy webvpn and username webvpn configuration modes.

For example, if you enter the **svc compression** command for a certain group in group policy webvpn configuration mode, and then you enter the **no compression** command in global configuration mode, you override the **svc compression** command settings that you have configured for the group.

Conversely, if you turn compression back on with the **compression** command in global configuration mode, any group settings take effect, and those settings ultimately determine the compression behavior.

If you disable compression with the **no compression** command, only new connections are affected. Active connections remain unaffected.

Examples

In the following example, compression is turned on for SVC connections:

```
hostname(config)# compression svc
```

In the following example, compression is disabled for SVC and WebVPN connections:

```
hostname(config)# no compression svc http-comp
```

Related Commands

Command	Description
show webvpn svc	Displays information about the SVC installation.
svc	Enables or requires the SVC for a specific group or user.
svc compression	Enables compression of HTTP data over an SVC connection for a specific group or user.

config-register

To set the configuration register value that is used the next time you reload the ASA, use the **config-register** command in global configuration mode. To set the value back to the default, use the **no** form of this command.

config-register *hex_value*

no config-register

Syntax Description

hex_value	Sets the configuration register value as a hexadecimal number from 0x0 to 0xFFFFFFFF. This number represents 32 bits and each hexadecimal character represents 4 bits. Each bit controls a different characteristic. However, bits 32 through 20 are either reserved for future use, cannot be set by the user, or are not currently used by the ASA; therefore, you can ignore the three characters that represent those bits, because they are always set to 0. The relevent bits are represented by 5 hexadecimal characters: 0x*nnnnn*. You do not need to include preceding 0s. You do need to include trailing 0s. For example, 0x2001 is equivalent to 0x02001; but 0x10000 requires all the zeros. See Table 10-1 for more information about available values for the relevant bits.

Defaults

The default value is 0x1, which boots from the local image and startup configuration.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command is only supported on the ASA 5500 series. The configuration register value determines which image to boot from as well as other boot parameters.

The five characters are numbered from 0 to 4 from right to left, which is standard for hexadecimal and binary numbers. You can select one value for each character, and mix and match values as appropriate. For example, you can select either 0 or 2 for character number 3. Some values take priority if they conflict with other values. For example, if you set 0x2011, which sets the ASA to both boot from the

TFTP server and to boot from the local image, the ASA boots from the TFTP server. Because this value also stipulates that if the TFTP boot fails, the ASA should boot directly into ROMMON, then the action that specifies to boot from the default image is ignored.

A value of 0 means no action unless otherwise specified.

Table 10-1 lists the actions associated with each hexadecimal character; choose one value for each character:

Table 10-1 Configuration Register Values

Prefix	Hexadecimal Character Numbers 4, 3, 2, 1, and 0				
0x	**0**	**0**	**0**[1]	**0**[2]	**0**[2]
	1 Disables the 10 second ROMMON countdown during startup. Normally, you can press Escape during the countdown to enter ROMMON.	**2** If you set the ASA to boot from a TFTP server, and the boot fails, then this value boots directly into ROMMON.		**1** Boots from the TFTP server image as specified in the ROMMON Boot Parameters (which is the same as the **boot system tftp** command, if present). This value takes precedence over a value set for character 1.	**1** Boots the image specified by the first **boot system** *local_flash* command. If that image does not load, the ASA tries to boot each image specified by subsequent **boot system** commands until it boots successfully.
					2, **4**, **6**, **8** Boots the image specified by a particular **boot system** *local_flash* command. Value 3 boots the image specified in the first **boot system** command, value 5 boots the second image, and so on. If the image does not boot successfully, the ASA does not attempt to fall back to other **boot system** command images (this is the difference between using value 1 and value 3). However, the ASA has a failsafe feature that in the event of a boot failure attempts to boot from any image found in the root directory of internal flash memory. If you do not want the failsafe feature to take effect, store your images in a different directory than root.
				4[3] Ignores the startup configuration and loads the default configuration.	**2**, **4**, **6**, **8** From ROMMON, if you enter the **boot** command without any arguments, then the ASA boots the image specified by a particular **boot system** *local_flash* command. Value 3 boots the image specified in the first **boot system** command, value 5 boots the second image, and so on. This value does not automatically boot an image.
				5 Performs both actions above.	

1. Reserved for future use.
2. If character numbers 0 and 1 are not set to automatically boot an image, then the ASA boots directly into ROMMON.
3. If you disable password recovery using the **service password-recovery** command, then you cannot set the configuration register to ignore the startup configuration.

The configuration register value is not replicated to a standby unit, but the following warning is displayed when you set the configuration register on the active unit:

```
WARNING The configuration register is not synchronized with the standby, their values may
not match.
```

You can also set the configuration register value in ROMMON using the **confreg** command.

Examples

The following example sets the configuration register to boot from the default image:

```
hostname(config)# config-register 0x1
```

Related Commands

Command	Description
boot	Sets the boot image and startup configuration.
service password-recovery	Enables or disables password recovery.

configure factory-default

To restore the configuration to the factory default, use the **configure factory-default** command in global configuration mode.

configure factory-default [*ip_address* [*mask*]]

Syntax Description

ip_address	Sets the IP address of the management or inside interface, instead of using the default address, 192.168.1.1. See the "Usage Guidelines" sections for more information about which interface is configured for your model.
mask	Sets the subnet mask of the interface. If you do not set a mask, the ASA uses the mask appropriate for the IP address class.

Defaults

The default IP address and mask are 192.168.1.1 and 255.255.255.0.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	A factory default configuration was added for the ASA 5505.

Usage Guidelines

The factory default configuration is the configuration applied by Cisco to new ASAs. This command is supported on all platforms except for the PIX 525 and PIX 535 ASAs.

For the PIX 515/515E and the ASA 5510 and higher ASAs, the factory default configuration automatically configures a management interface so you can connect to it using ASDM, with which you can then complete your configuration. For the ASA 5505, the factory default configuration automatically configures interfaces and NAT so that the ASA is ready to use in your network.

This command is available only for routed firewall mode; transparent mode does not support IP addresses for interfaces, and setting the interface IP address is one of the actions this command takes. This command is also only available in single context mode; an ASA with a cleared configuration does not have any defined contexts to automatically configure using this command.

This command clears the current running configuration and then configures several commands.

If you set the IP address in the **configure factory-default** command, then the **http** command uses the subnet that you specify. Similarly, the **dhcpd address** command range consists of addresses within the subnet that you specify.

After you restore the factory default configuration, save it to internal flash memory using the **write memory** command. The **write memory** command saves the running configuration to the default location for the startup configuration, even if you previously configured the **boot config** command to set a different location; when the configuration was cleared, this path was also cleared.

Note This command also clears the **boot system** command, if present, along with the rest of the configuration. The **boot system** command lets you boot from a specific image, including an image on the external flash memory card. The next time you reload the ASA after restoring the factory configuration, it boots from the first image in internal flash memory; if you do not have an image in internal flash memory, the ASA does not boot.

To configure additional settings that are useful for a full configuration, see the **setup** command.

ASA 5505 Configuration

The default factory configuration for the ASA 5505 configures the following:

- An inside VLAN 1 interface that includes the Ethernet 0/1 through 0/7 switch ports. If you did not set the IP address in the **configure factory-default** command, then the VLAN 1 IP address and mask are 192.168.1.1 and 255.255.255.0.
- An outside VLAN 2 interface that includes the Ethernet 0/0 switch port. VLAN 2 derives its IP address using DHCP.
- The default route is also derived from DHCP.
- All inside IP addresses are translated when accessing the outside using interface PAT.
- By default, inside users can access the outside with an access list, and outside users are prevented from accessing the inside.
- The DHCP server is enabled on the ASA, so a PC connecting to the VLAN 1 interface receives an address between 192.168.1.2 and 192.168.1.254.
- The HTTP server is enabled for ASDM and is accessible to users on the 192.168.1.0 network.

The configuration consists of the following commands:

```
interface Ethernet 0/0
   switchport access vlan 2
   no shutdown
interface Ethernet 0/1
   switchport access vlan 1
   no shutdown
interface Ethernet 0/2
   switchport access vlan 1
   no shutdown
interface Ethernet 0/3
   switchport access vlan 1
   no shutdown
interface Ethernet 0/4
   switchport access vlan 1
   no shutdown
interface Ethernet 0/5
   switchport access vlan 1
   no shutdown
interface Ethernet 0/6
   switchport access vlan 1
   no shutdown
interface Ethernet 0/7
   switchport access vlan 1
   no shutdown
```

```
interface vlan2
   nameif outside
   no shutdown
   ip address dhcp setroute
interface vlan1
   nameif inside
   ip address 192.168.1.1 255.255.255.0
   security-level 100
   no shutdown
global (outside) 1 interface
nat (inside) 1 0 0
http server enable
http 192.168.1.0 255.255.255.0 inside
dhcpd address 192.168.1.2-192.168.1.254 inside
dhcpd auto_config outside
dhcpd enable inside
logging asdm informational
```

ASA 5510 and Higher Configuration

The default factory configuration for the ASA 5510 and higher configures the following:

- The management Management 0/0 interface. If you did not set the IP address in the **configure factory-default** command, then the IP address and mask are 192.168.1.1 and 255.255.255.0.
- The DHCP server is enabled on the ASA, so a PC connecting to the interface receives an address between 192.168.1.2 and 192.168.1.254.
- The HTTP server is enabled for ASDM and is accessible to users on the 192.168.1.0 network.

The configuration consists of the following commands:

```
interface management 0/0
   ip address 192.168.1.1 255.255.255.0
   nameif management
   security-level 100
   no shutdown
asdm logging informational 100
asdm history enable
http server enable
http 192.168.1.0 255.255.255.0 management
dhcpd address 192.168.1.2-192.168.1.254 management
dhcpd lease 3600
dhcpd ping_timeout 750
dhcpd enable management
```

PIX 515/515E Security Appliance Configuration

The default factory configuration for the PIX 515/515E security appliance configures the following:

- The inside Ethernet1 interface. If you did not set the IP address in the **configure factory-default** command, then the IP address and mask are 192.168.1.1 and 255.255.255.0.
- The DHCP server is enabled on the PIX security appliance, so a PC connecting to the interface receives an address between 192.168.1.2 and 192.168.1.254.
- The HTTP server is enabled for ASDM and is accessible to users on the 192.168.1.0 network.

The configuration consists of the following commands:

```
interface ethernet 1
   ip address 192.168.1.1 255.255.255.0
   nameif management
   security-level 100
   no shutdown
```

```
asdm logging informational 100
asdm history enable
http server enable
http 192.168.1.0 255.255.255.0 management
dhcpd address 192.168.1.2-192.168.1.254 management
dhcpd lease 3600
dhcpd ping_timeout 750
dhcpd enable management
```

Examples

The following example resets the configuration to the factory default, assigns the IP address 10.1.1.1 to the interface, and then saves the new configuration as the startup configuration:

```
hostname(config)# configure factory-default 10.1.1.1 255.255.255.0
Based on the inside IP address and mask, the DHCP address
pool size is reduced to 253 from the platform limit 256

WARNING: The boot system configuration will be cleared.
The first image found in disk0:/ will be used to boot the
system on the next reload.
Verify there is a valid image on disk0:/ or the system will
not boot.

Begin to apply factory-default configuration:
Clear all configuration
...
hostname(config)#
hostname(config)# copy running-config startup-config
```

Related Commands

Command	Description
boot system	Sets the software image from which to boot.
clear configure	Clears the running configuration.
copy running-config startup-config	Copies the running configuration to the startup configuration.
setup	Prompts you to configure basic settings for the ASA.
show running-config	Shows the running configuration.

configure http

To merge a configuration file from an HTTP(S) server with the running configuration, use the **configure http** command in global configuration mode.

configure http[**s**]**://**[*user*[**:***password*]@]*server*[:*port*]**/**[*path***/**]*filename*

Syntax Description

:password	(Optional) For HTTP(S) authentication, specifies the password.
:*port*	(Optional) Specifies the port. For HTTP, the default is 80. For HTTPS, the default is 443.
@	(Optional) If you enter a name and/or a password, precedes the server IP address with an at sign (@).
filename	Specifies the configuration filename.
http[**s**]	Specifies either HTTP or HTTPS.
path	(Optional) Specifies a path to the filename.
server	Specifies the server IP address or name. For IPv6 server addresses, if you specify the port, then you must enclose the IP address in brackets so that the colons in the IP address are not mistaken for the colon before the port number. For example, enter the following address and port: `[fe80::2e0:b6ff:fe01:3b7a]:8080`
user	(Optional) For HTTP(S) authentication, specifies the username.

Defaults

For HTTP, the default port is 80. For HTTPS, the default port is 443.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command supports IPv4 and IPv6 addresses. A merge adds all commands from the new configuration to the running configuration, and overwrites any conflicting commands with the new versions. For example, if a command allows multiple instances, the new commands are added to the existing commands in the running configuration. If a command allows only one instance, the new command overwrites the command in the running configuration. A merge never removes commands that exist in the running configuration, but are not set in the new configuration.

This command is the same as the **copy http running-config** command. For multiple context mode, that command is only available in the system execution space, so the **configure http** command is an alternative for use within a context.

Examples

The following example copies a configuration file from an HTTPS server to the running configuration:

```
hostname(config)# configure https://user1:pa$$w0rd@10.1.1.1/configs/newconfig.cfg
```

Related Commands

Command	Description
clear configure	Clears the running configuration.
configure memory	Merges the startup configuration with the running configuration.
configure net	Merges a configuration file from the specified TFTP URL with the running configuration.
configure factory-default	Adds commands that you enter at the CLI to the running configuration.
show running-config	Shows the running configuration.

configure memory

To merge the startup configuration with the running configuration, use the **configure memory** command in global configuration mode.

configure memory

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

A merge adds all commands from the new configuration to the running configuration, and overwrites any conflicting commands with the new versions. For example, if a command allows multiple instances, the new commands are added to the existing commands in the running configuration. If a command allows only one instance, the new command overwrites the command in the running configuration. A merge never removes commands that exist in the running configuration, but are not set in the new configuration.

If you do not want to merge the configurations, you can clear the running configuration, which disrupts any communications through the ASA, and then enter the **configure memory** command to load the new configuration.

This command is equivalent to the **copy startup-config running-config** command.

For multiple context mode, a context startup configuration is at the location specified by the **config-url** command.

Examples

The following example copies the startup configuration to the running configuration:

```
hostname(config)# configure memory
```

Related Commands

Command	Description
clear configure	Clears the running configuration.
configure http	Merges a configuration file from the specified HTTP(S) URL with the running configuration.
configure net	Merges a configuration file from the specified TFTP URL with the running configuration.
configure factory-default	Adds commands that you enter at the CLI to the running configuration.
show running-config	Shows the running configuration.

configure net

To merge a configuration file from a TFTP server with the running configuration, use the **configure net** command in global configuration mode.

configure net [*server***:**[*filename*] | **:***filename*]

Syntax Description

:*filename*	Specifies the path and filename. If you already set the filename using the **tftp-server** command, then this argument is optional. If you specify the filename in this command as well as a name in the **tftp-server** command, the ASA treats the **tftp-server** command filename as a directory, and adds the **configure net** command filename as a file under the directory. To override the **tftp-server** command value, enter a slash in front of the path and filename. The slash indicates that the path is not relative to the tftpboot directory, but is an absolute path. The URL generated for this file includes a double slash (//) in front of the filename path. If the file you want is in the tftpboot directory, you can include the path for the tftpboot directory in the filename path. If you specified the TFTP server address using the **tftp-server** command, you can enter the filename alone preceded by a colon (:).
*server***:**	Sets the TFTP server IP address or name. This address overrides the address you set in the **tftp-server** command, if present. For IPv6 server addresses, you must enclose the IP address in brackets so that the colons in the IP address are not mistaken for the colon before the filename. For example, enter the following address: [fe80::2e0:b6ff:fe01:3b7a] The default gateway interface is the highest security interface; however, you can set a different interface name using the **tftp-server** command.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command supports IPv4 and IPv6 addresses. A merge adds all commands from the new configuration to the running configuration, and overwrites any conflicting commands with the new versions. For example, if a command allows multiple instances, the new commands are added to the existing commands in the running configuration. If a command allows only one instance, the new command overwrites the command in the running configuration. A merge never removes commands that exist in the running configuration, but are not set in the new configuration.

This command is the same as the **copy tftp running-config** command. For multiple context mode, that command is only available in the system execution space, so the **configure net** command is an alternative for use within a context.

Examples

The following example sets the server and filename in the **tftp-server** command, and then overrides the server using the **configure net** command. The same filename is used.

```
hostname(config)# tftp-server inside 10.1.1.1 configs/config1
hostname(config)# configure net 10.2.2.2:
```

The following example overrides the server and the filename. The default path to the filename is /tftpboot/configs/config1. The /tftpboot/ part of the path is included by default when you do not lead the filename with a slash (/). Because you want to override this path, and the file is also in tftpboot, include the tftpboot path in the **configure net** command.

```
hostname(config)# tftp-server inside 10.1.1.1 configs/config1
hostname(config)# configure net 10.2.2.2:/tftpboot/oldconfigs/config1
```

The following example sets the server only in the **tftp-server** command. The **configure net** command specifies only the filename.

```
hostname(config)# tftp-server inside 10.1.1.1
hostname(config)# configure net :configs/config1
```

Related Commands

Command	Description
configure http	Merges a configuration file from the specified HTTP(S) URL with the running configuration.
configure memory	Merges the startup configuration with the running configuration.
show running-config	Shows the running configuration.
tftp-server	Sets a default TFTP server and path for use in other commands.
write net	Copies the running configuration to a TFTP server.

configure terminal

To configure the running configuration at the command line, use the **configure terminal** command in privileged EXEC mode.

configure terminal

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command enters global configuration mode, which lets you enter commands that change the configuration.

Examples

The following example enters global configuration mode:

```
hostname# configure terminal
hostname(config)#
```

Related Commands

Command	Description
clear configure	Clears the running configuration.
configure http	Merges a configuration file from the specified HTTP(S) URL with the running configuration.
configure memory	Merges the startup configuration with the running configuration.
configure net	Merges a configuration file from the specified TFTP URL with the running configuration.
show running-config	Shows the running configuration.

config-url

To identify the URL from which the system downloads the context configuration, use the **config-url** command in context configuration mode.

config-url *url*

Syntax Description

url	Sets the context configuration URL. All remote URLs must be accessible from the admin context. See the following URL syntax: • **disk0:/**[*path*/]*filename* For the ASA 5500 series, this URL indicates the internal flash memory. You can also use the **flash** command instead of the **disk0** command; they are aliased. • **disk1:/**[*path*/]*filename* For the ASA 5500 series, this URL indicates the external flash memory card. • **flash:/**[*path*/]*filename* This URL indicates the internal flash memory. • **ftp://**[*user*[**:***password*]@]*server*[:*port*]**/**[*path*/]*filename*[**;type=***xx*] The **type** can be one of the following keywords: – **ap**—ASCII passive mode – **an**—ASCII normal mode – **ip**—(Default) Binary passive mode – **in**—Binary normal mode • **http**[**s**]**://**[*user*[**:***password*]@]*server*[:*port*]**/**[*path*/]*filename* • **tftp://**[*user*[**:***password*]@]*server*[:*port*]**/**[*path*/]*filename*[**;int=***interface_name*] Specify the interface name if you want to override the route to the server address.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Context configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

When you add a context URL, the system immediately loads the context so that it is running.

Note Enter the **allocate-interface** command(s) before you enter the **config-url** command. The ASA must assign interfaces to the context before it loads the context configuration; the context configuration might include commands that refer to interfaces (**interface**, **nat**, **global**). If you enter the **config-url** command first, the ASA loads the context configuration immediately. If the context contains any commands that refer to interfaces, those commands fail.

The filename does not require a file extension, although we recommend using ".cfg."

The admin context file must be stored on the internal flash memory.

If you download a context configuration from an HTTP or HTTPS server, you cannot save changes back to these servers using the **copy running-config startup-config** command. You can, however, use the **copy tftp** command to copy the running configuration to a TFTP server.

If the system cannot retrieve the context configuration file because the server is unavailable, or the file does not yet exist, the system creates a blank context that is ready for you to configure with the command-line interface.

To change the URL, reenter the **config-url** command with a new URL.

The ASA merges the new configuration with the current running configuration. Reentering the same URL also merges the saved configuration with the running configuration. A merge adds any new commands from the new configuration to the running configuration. If the configurations are the same, no changes occur. If commands conflict or if commands affect the running of the context, then the effect of the merge depends on the command. You might get errors, or you might have unexpected results. If the running configuration is blank (for example, if the server was unavailable and the configuration was never downloaded), then the new configuration is used. If you do not want to merge the configurations, you can clear the running configuration, which disrupts any communications through the context, and then reload the configuration from the new URL.

Examples

The following example sets the admin context to "administrator," creates a context called "administrator" on the internal flash memory, and then adds two contexts from an FTP server:

```
hostname(config)# admin-context administrator
hostname(config)# context administrator
hostname(config-ctx)# allocate-interface gigabitethernet0/0.1
hostname(config-ctx)# allocate-interface gigabitethernet0/1.1
hostname(config-ctx)# config-url flash:/admin.cfg

hostname(config-ctx)# context test
hostname(config-ctx)# allocate-interface gigabitethernet0/0.100 int1
hostname(config-ctx)# allocate-interface gigabitethernet0/0.102 int2
hostname(config-ctx)# allocate-interface gigabitethernet0/0.110-gigabitethernet0/0.115
int3-int8
hostname(config-ctx)# config-url ftp://user1:passw0rd@10.1.1.1/configlets/test.cfg

hostname(config-ctx)# context sample
hostname(config-ctx)# allocate-interface gigabitethernet0/1.200 int1
hostname(config-ctx)# allocate-interface gigabitethernet0/1.212 int2
```

```
hostname(config-ctx)# allocate-interface gigabitethernet0/1.230-gigabitethernet0/1.235
int3-int8
hostname(config-ctx)# config-url ftp://user1:passw0rd@10.1.1.1/configlets/sample.cfg
```

Related Commands

Command	Description
allocate-interface	Allocates interfaces to a context.
context	Creates a security context in the system configuration and enters context configuration mode.
show context	Shows a list of contexts (system execution space) or information about the current context.

conn-rebalance

To enable connection rebalancing between members of a cluster, use the **conn-rebalance** command in cluster group configuration mode. To disable connection rebalancing, use the **no** form of this command.

conn-rebalance [**frequency** *seconds*]

no conn-rebalance [**frequency** *seconds*]

Syntax Description

frequency *seconds*	(Optional) Sepcifies how often the load information is exchanged, between 1 and 360 seconds. The default is 5 seconds.

Command Default

Connection rebalancing is disabled by default.

If enabled, the default frequency is 5 seconds

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Cluster group configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

If the load balancing capabilities of the upstream or downstream routers result in unbalanced flow distribution, you can configure overloaded units to redirect new flows to other units. No existing flows will be moved to other units. If enabled, ASAs exchange load information periodically, and offload new connections from more loaded devices to less loaded devices.

This command is not part of the bootstrap configuration, and is replicated from the master unit to the slave units.

Examples

The following example sets the connection rebalance frequency to 60 seconds:

```
hostname(cfg-cluster)# conn-rebalance frequency 60
```

Related Commands

Command	Description
clacp system-mac	When using spanned EtherChannels, the ASA uses cLACP to negotiate the EtherChannel with the neighbor switch.
cluster group	Names the cluster and enters cluster configuration mode.
cluster-interface	Specifies the cluster control link interface.
cluster interface-mode	Sets the cluster interface mode.
console-replicate	Enables console replication from slave units to the master unit.
enable (cluster group)	Enables clustering.
health-check	Enables the cluster health check feature, which includes unit health monitoring and interface health monitoring.
key	Sets an authentication key for control traffic on the cluster control link.
local-unit	Names the cluster member.
mtu cluster-interface	Specifies the maximum transmission unit for the cluster control link interface.
priority (cluster group)	Sets the priority of this unit for master unit elections.

console timeout

To set the inactivity timeout for an authenticated serial console session (**aaa authentication serial console**) so that a user is logged out of the console after the timeout, or for an authenticated enable session (**aaa authentication enable console**) where the user exits privileged EXEC mode and reverts to user EXEC mode after the timeout, use the **console timeout** command in global configuration mode. To disable the inactivity timeout for an authenticated serial console session, use the **no** form of this command.

console timeout [*number*]

no console timeout [*number*]

Syntax Description

number	Specifies the idle time in minutes (0 through 60) after which the console session ends. 0 means the console never times out.

Defaults

The default timeout is 0, which means the console session will not time out.

Command Modes

The following table shows the modes in which you can enter the command:

7.0(1)	This command was introduced.

Usage Guidelines

The **console timeout** command only applies to authenticated serial or enable connections. This command does not alter the Telnet, SSH, or HTTP timeouts; these access methods maintain their own timeout values. The command does not affect unauthenticated console connections.

The **no console timeout** command resets the console timeout value to the default timeout of 0, which means that the console will not time out.

Examples

The following example shows how to set the console timeout to 15 minutes:

```
hostname(config)# console timeout 15
```

Related Commands

Command	Description
clear configure console	Restores the default console connection settings.
clear configure timeout	Restores the default idle time durations in the configuration.
show running-config console timeout	Displays the idle timeout for a console connection to the ASA.

console-replicate

To enable console replication from slave units to the master unit in an ASA cluster, use the **console-replicate** command in cluster group configuration mode. To disable console replication, use the **no** form of this command.

console-replicate

no console-replicate

Syntax Description

This command has no arguments or keywords.

Command Default

Console replication is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Cluster group configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

The ASA prints out some messages directly to the console for certain critical events. If you enable console replication, slave units send the console messages to the master unit so you only need to monitor one console port for the cluster.

This command is not part of the bootstrap configuration, and is replicated from the master unit to the slave units.

Examples

The following example enables console replication:

```
hostname(config)# cluster group cluster1
hostname(cfg-cluster)# console-replicate
```

Related Commands

Command	Description
clacp system-mac	When using spanned EtherChannels, the ASA uses cLACP to negotiate the EtherChannel with the neighbor switch.
cluster group	Names the cluster and enters cluster configuration mode.

Command	Description
cluster-interface	Specifies the cluster control link interface.
cluster interface-mode	Sets the cluster interface mode.
conn-rebalance	Enables connection rebalancing.
enable (cluster group)	Enables clustering.
health-check	Enables the cluster health check feature, which includes unit health monitoring and interface health monitoring.
key	Sets an authentication key for control traffic on the cluster control link.
local-unit	Names the cluster member.
mtu cluster-interface	Specifies the maximum transmission unit for the cluster control link interface.
priority (cluster group)	Sets the priority of this unit for master unit elections.

content-length

To restrict HTTP traffic based on the length of the HTTP message body, use the **content-length** command in http-map configuration mode. To remove this command, use the **no** form of this command.

content-length { **min** *bytes* [**max** *bytes*] | **max** *bytes*] } **action** {**allow** | **reset** | **drop**} [**log**]

no content-length { **min** *bytes* [**max** *bytes*] | **max** *bytes*] } **action** {**allow** | **reset** | **drop**} [**log**]

Syntax Description

action	Specifies the action taken when a message fails this inspection.
allow	Allows the message.
bytes	Specifies the number of bytes. The permitted range is 1 to 65535 for the **min** option and 1 to 50000000 for the **max** option.
drop	Closes the connection.
log	(Optional) Generates a syslog.
max	(Optional) Specifies the maximum content length allowed.
min	Specifies the minimum content length allowed.
reset	Sends a TCP reset message to the client and server.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Http-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

After enabling the **content-length** command, the ASA only allows messages within the configured range and otherwise takes the specified action. Use the **action** keyword to cause the ASA to reset the TCP connection and create a syslog entry.

Examples

The following example restricts HTTP traffic to messages 100 bytes or larger and not exceeding 2000 bytes. If a message is outside this range, the ASA resets the TCP connection and creates a syslog entry.

```
hostname(config)# http-map inbound_http
hostname(config-http-map)# content-length min 100 max 2000 action reset log
hostname(config-http-map)# exit
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
http-map	Defines an HTTP map for configuring enhanced HTTP inspection.
debug appfw	Displays detailed information about traffic associated with enhanced HTTP inspection.
inspect http	Applies a specific HTTP map to use for application inspection.
policy-map	Associates a class map with specific security actions.

context

To create a security context in the system configuration and enter context configuration mode, use the **context** command in global configuration mode. To remove a context, use the **no** form of this command.

context *name*

no context *name* [**noconfirm**]

Syntax Description

name	Sets the name as a string up to 32 characters long. This name is case sensitive, so you can have two contexts named "customerA" and "CustomerA," for example. You can use letters, digits, or hyphens, but you cannot start or end the name with a hyphen. "System" or "Null" (in upper or lower case letters) are reserved names, and cannot be used.
noconfirm	(Optional) Removes the context without prompting you for confirmation. This option is useful for automated scripts.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

In context configuration mode, you can identify the configuration file URL and interfaces that a context can use. If you do not have an admin context (for example, if you clear the configuration), then the first context you add must be the admin context. To add an admin context, see the **admin-context** command. After you specify the admin context, you can enter the **context** command to configure the admin context.

You can only remove a context by editing the system configuration. You cannot remove the current admin context using the **no** form of this command; you can only remove it if you remove all contexts using the **clear configure context** command.

Examples

The following example sets the admin context to "administrator," creates a context called "administrator" on the internal flash memory, and then adds two contexts from an FTP server:

```
hostname(config)# admin-context administrator
hostname(config)# context administrator
hostname(config-ctx)# allocate-interface gigabitethernet0/0.1
hostname(config-ctx)# allocate-interface gigabitethernet0/1.1
hostname(config-ctx)# config-url flash:/admin.cfg

hostname(config-ctx)# context test
hostname(config-ctx)# allocate-interface gigabitethernet0/0.100 int1
hostname(config-ctx)# allocate-interface gigabitethernet0/0.102 int2
hostname(config-ctx)# allocate-interface gigabitethernet0/0.110-gigabitethernet0/0.115
int3-int8
hostname(config-ctx)# config-url ftp://user1:passw0rd@10.1.1.1/configlets/test.cfg

hostname(config-ctx)# context sample
hostname(config-ctx)# allocate-interface gigabitethernet0/1.200 int1
hostname(config-ctx)# allocate-interface gigabitethernet0/1.212 int2
hostname(config-ctx)# allocate-interface gigabitethernet0/1.230-gigabitethernet0/1.235
int3-int8
hostname(config-ctx)# config-url ftp://user1:passw0rd@10.1.1.1/configlets/sample.cfg
```

Related Commands

Command	Description
allocate-interface	Assigns interfaces to a context.
changeto	Changes between contexts and the system execution space.
config-url	Specifies the location of the context configuration.
join-failover-group	Assigns a context to a failover group.
show context	Shows context information.

copy

To copy a file from one location to another, use the **copy** command in privileged EXEC mode.

[**cluster exec**] **copy** [**/noconfirm** | **/pcap**] {*url* | **running-config** | **startup-config**} {**running-config** | **startup-config** | *url*}

Syntax Description

cluster exec	(Optional) Enables you to enter the **copy** command on one unit and then simultaneously apply it to all other units in a clustering deployment. (See the "Usage Guidelines" section for more information.)
/noconfirm	Copies the file without a confirmation prompt.
/pcap	Specifies the preconfigured TFTP server defaults. See the **tftp-server** command to configure a default TFTP server.
running-config	Specifies the running configuration stored in memory.
startup-config	Specifies the startup configuration stored in flash memory. The startup configuration for single mode or for the system in multiple context mode is a hidden file in flash memory. From within a context, the location of the startup configuration is specified by the **config-url** command. For example, if you specify an HTTP server for the **config-url** command and then enter the **copy startup-config running-config** command, the ASA copies the startup configuration from the HTTP server using the admin context interface.

url	Specifies the source or destination file to be copied between local and remote locations. (You cannot copy from a remote server to another remote server.) In a context, you can copy the running or startup configuration to a TFTP or FTP server using the context interfaces, but you cannot copy from a server to the running or startup configuration. See the **startup-config** keyword for other options. To download from a TFTP server to the running context configuration, use the **configure net** command. Use the following URL syntax for this command: • **cache:/**[*path*/]*filename*]—Indicates the cache memory in the file system. • **capture:/**[*path*/]*filename*]—Indicates the output in the capture buffer. • **disk0:/**[*path*/]*filename*] or **flash:/**[*path*/]*filename*]—ASA 5500 series only. Both **flash** and **disk0** indicate the internal flash memory. Can use either option. • **disk1:/**[*path*/]*filename*]—ASA 5500 series only. Indicates external memory. • **smb:/**[*path*/]*filename*]—Indicates a UNIX server local file system. Use Server Message Block file-system protocol in LAN managers and similar network systems to package data and exchange information with other systems. • **ftp://**[*user*[**:***password*]@]*server*[:*port*]**/**[*path*/]*filename*[**;type=***xx*]—The **type** can be one of these keywords: **ap** (ASCII passive mode), **an** (ASCII normal mode), **ip** (Default—Binary passive mode), **in** (Binary normal mode). • **http**[**s**]**://**[*user*[**:***password*]@]*server*[**:***port*]**/**[*path*/]*filename*] • **system:/**[*path*/]*filename*]—Indicates the system memory in the file system. • **tftp://**[*user*[**:***password*]@]*server*[**:***port*]**/**[*path*/]*filename*[**;int=***interface_name*] The pathname cannot contain spaces. If a pathname has spaces, set the path in the **tftp-server** command instead of in the **copy tftp** command. Specify the interface name using the **nameif interface** command if you want to override the route to the server address.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	Added support for DNS names.
8.0(2)	Added the **smb:** URL option.
9.0(1)	Added the **cluster exec** option.

Usage Guidelines

- When you copy a configuration to the running configuration, you merge the two configurations. A merge adds any new commands from the new configuration to the running configuration. If the configurations are the same, no changes occur. If commands conflict or if commands affect the running of the context, then the effect of the merge depends on the command. You might get errors, or you might have unexpected results.
  If an RSA key cannot be saved in NVRAM, the following error message appears:

  ```
  ERROR: NV RAM does not have enough space to save keypair keypair name
  ```

- After you have performed a cluster-wide capture, you can simultaneously copy the same capture file from all units in the cluster to a TFTP server by entering the following command on the master unit:

  ```
  hostname (config-cluster)# cluster exec copy /pcap capture: cap_name
  tftp://location/path/filename.pcap
  ```

  Multiple PCAP files, one from each unit, are copied to the TFTP server. The destination capture file name is automatically attached with the unit name, such as filename_A.pcap, filename_B.pcap, where A and B are cluster unit names.

  Note A different destination name gets generated if you add the unit name at the end of the filename.

Examples

The following example shows how to copy a file from the disk to a TFTP server in the system execution space:

```
hostname(config)# copy disk0:my_context/my_context.cfg
tftp://10.7.0.80/my_context/my_context.cfg
```

The following example shows how to copy a file from one location on the disk to another location on the disk. The name of the destination file can be either the name of the source file or a different name.

```
hostname(config)# copy disk0:my_context.cfg disk:my_context/my_context.cfg
```

The following example shows how to copy an ASDM file from a TFTP server to the internal flash memory:

```
hostname(config)# copy tftp://10.7.0.80/asdm700.bin disk0:asdm700.bin
```

The following example shows how to copy the running configuration in a context to a TFTP server:

```
hostname(config)# copy running-config tftp://10.7.0.80/my_context/my_context.cfg
```

The **copy** command supports DNS names as well as IP addresses, as shown in this version of the preceding example:

```
hostname(config)# copy running-config tftp://www.example.com/my_context/my_context.cfg
```

Related Commands

Command	Description
configure net	Copies a file from a TFTP server to the running configuration.
copy capture	Copies a capture file to a TFTP server.
tftp-server	Sets the default TFTP server.
write memory	Saves the running configuration to the startup configuration.
write net	Copies the running configuration to a TFTP server.

copy capture

To copy a capture file to a server, use the **copy capture** command in privileged EXEC mode.

copy [**/noconfirm**] [**/pcap**] **capture:** [*context_name/*]*buffer_name url*

Syntax Description

/noconfirm	Copies the file without a confirmation prompt.
/pcap	Copies the packet capture as raw data.
buffer_name	Unique name that identifies the capture.
context_name/	Copies a packet capture defined in a security context.
url	Specifies the destination to copy the packet capture file. See the following URL syntax: • **disk0:/**[*path/*]*filename* This option is only available for the ASA, and indicates the internal Flash card. You can also use **flash** instead of **disk0**; they are aliased. • **disk1:/**[*path/*]*filename* This option is only available for the ASA, and indicates the external Flash card. • **flash:/**[*path/*]*filename* This option indicates the internal flash card. For the ASA, **flash** is an alias for **disk0**. • **ftp://**[*user*[**:***password*]@]*server*[:*port*]**/**[*path/*]*filename*[**;type=***xx*] The **type** can be one of the following keywords: – **ap**—ASCII passive mode – **an**—ASCII normal mode – **ip**—(Default) Binary passive mode – **in**—Binary normal mode • **http**[**s**]**://**[*user*[**:***password*]@]*server*[**:***port*]**/**[*path/*]*filename* • **tftp://**[*user*[**:***password*]@]*server*[**:***port*]**/**[*path/*]*filename*[**;int=***interface_name*] Specify the interface name if you want to override the route to the server address. The pathname cannot contain spaces. If a pathname has spaces, set the path in the **tftp-server** command instead of in the **copy tftp** command.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
	Routed	Transparent	Single	Multiple Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows the prompts that are provided when you enter the **copy capture** command without specifying the full path:

```
hostname(config)# copy capture:abc tftp
Address or name of remote host [209.165.200.224]?
Source file name [username/cdisk]?
copying capture to tftp://209.165.200.224/username/cdisk:
[yes|no|again]? y
!!!!!!!!!!!!!
```

You can specify the full path as follows:

```
hostname(config)# copy capture:abc tftp:209.165.200.224/tftpboot/abc.cap
```

If the TFTP server is already configured, the location or filename can be unspecified as follows:

```
hostname(config)# tftp-server outside 209.165.200.224 tftp/cdisk
hostname(config)# copy capture:abc tftp:/tftp/abc.cap
```

Related Commands

Command	Description
capture	Enables packet capture capabilities for packet sniffing and network fault isolation.
clear capture	Clears the capture buffer.
show capture	Displays the capture configuration when no options are specified.

cpu profile activate

To start CPU profiling, use the **cpu profile activate** command in privileged EXEC mode.

cpu profile activate *n-samples* [**sample-process** *process-name*] [**trigger cpu-usage** *cpu %* [*process-name*]]

Syntax Description

n-samples	Allocates memory for storing *n* number of samples. Valid values are from 1 to 100,000.
sample-process *process-name*	Samples only a specific process.
trigger cpu-usage *cpu %*	Prevents the profiler from starting until the global 5-second CPU percentage is greater and stops the profiler if the CPU percentage drops below this value.
trigger cpu-usage *cpu % process-name*	Uses the process 5-second CPU percentage as a trigger.

Defaults

The *n-samples* default value is 1000.

The *cpu %* default value is 0.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
9.1(2)	The **sample-process** *process-name*, **trigger cpu-usage** *cpu %*, and **trigger cpu-usage** *cpu % process-name* options were added. The output format was updated.

Usage Guidelines

The CPU profiler can help you determine which process is using more CPU. Profiling the CPU captures the address of the process that was running on the CPU when the timer interrupt fired. This profiling occurs every 10 milliseconds, regardless of the CPU load. For example, if you take 5000 samples, the profiling takes exactly 50 seconds to complete. If the amount of CPU time that the CPU profiler uses is relatively low, the samples take longer to collect. The CPU profile records are sampled in a separate buffer.

Use the **show cpu profile** command in conjunction with the **cpu profile activate** command to display information that you can collect and that the TAC can use for troubleshooting CPU issues. The **show cpu profile dump** command output is in hexadecimal format.

If the CPU profiler is waiting for a starting condition to occur, the **show cpu profile** command displays the following output:

```
CPU profiling started: 12:45:57.209 UTC Wed Nov 14 2012
CPU Profiling waiting on starting condition.
Core 0: 0 out of 10 samples collected.
Core 1: 0 out of 10 samples collected.
Core 2: 0 out of 10 samples collected.
Core 3: 0 out of 10 samples collected.
CP
0 out of 10 samples collected.
```

Examples

The following example activates the profiler and instructs it to store 1000 samples.

```
hostname# cpu profile activate
Activated CPU profiling for 1000 samples.
Use "show cpu profile" to display the progress or "show cpu profile dump" to interrupt
profiling and display the incomplete results.
```

The following examples show the status of the profiing (in-progress and completed):

```
hostname# show cpu profile
CPU profiling started: 13:45:10.400 PST Fri Nov 16 2012
CPU profiling currently in progress:
Core 0: 209 out of 1000 samples collected.
Use "show cpu profile dump" to see the results after it is complete or to interrupt
profiling and display the incomplete results.

hostname# show cpu profile dump
Cisco Adaptive Security Appliance Software Version 9.1(2)
Hardware:   ASA5555
CPU profiling started: 09:13:32.079 UTC Wed Jan 30 2013
No CPU profiling process specified.
No CPU profiling trigger specified.
cores: 2

Process virtual address map:
---------------------------
…
---------------------------
End of process map
Samples for core 0 - stopped
{0x00000000007eadb6,0x000000000211ee7e} ...
```

Related Commands

Command	Description
show cpu profile	Displays the CPU profiling progress.
show cpu profile dump	Displays incomplete or completed results for profiling.

coredump enable

To enable the coredump feature, enter the **coredump enable** command. To disable the command, use the **no** form of this command.

coredump enable [**filesystem** [**disk0**: | **disk1**: | **flash**:] [**size** [**default** | **size_in_MB**]]

[**no**] **coredump enable** [**filesystem** [**disk0**: | **disk1**: | **flash**:] [**size** [**default** | **size_in_MB**]]

Syntax Description

default	Specifies the default is the suggested value to use, because the ASA calculates what this value should be.
filesystem disk0: | disk1: | flash:	Specifies the disk where the coredump file will be saved.
size	Defines the total size allocated for the coredump file system image on the ASA flash. When configuring coredump, if not enough space is available, an error message appears. It may be helpful to think of the **size** option as a container, which means that coredumps generated will never be allowed to exceed this size in disk space consumption.
size_in_MB	Specifies that the ASA will override the default value and allocate the specified value in MB for the coredump filesystem (if the space is available).

Defaults

By default, coredumps are not enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	—	—	•

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

Enabling this feature provides significant troubleshooting information. Disabling this feature results in a coredump file not being generated on a system crash for all components. In addition, disabling this feature does not delete a previous coredump filesystem image and/or the coredump filesystem image contents. When you enable coredumps, you are prompted to allow the coredump filesystem to be created. The prompt is a confirmation and includes the size (in MB) of the coredump filesystem to be created. It is important that you save your configuration after enabling or disabling coredumps.

When coredumps are enabled, the following file elements get created. You should never manipulate these file elements explicitly.

- coredumpfsys – Directory that includes coredump images
- coredumpfsysimage.bin – Coredump filesystem image used to manage coredumps
- coredumpinfo – Directory that includes the coredump log

Note Disabling coredumps has no effect on crashinfo file generation.

Cisco TAC may request that you enable the coredump feature to troubleshoot application or system crashes on the ASA.

Note Make sure that you archive the coredump files, because it is possible a subsequent coredump may result in previous coredump(s) being removed to fit the current coredump. Coredump files are located on the configured filesystem (for example, "disk0:/coredumpfsys" or "disk1:/coredumpfsys") and can be removed from the ASA.

To enable coredump, perform the following steps:

1. Make sure that you are in the /root directory. To verify your directory location on the console, enter the **pwd** command.
2. If necessary, change the directory by entering either the **cd disk0:/**, **cd disk1:/**, or **cd flash:/** command.
3. Enter the **coredump enable** command.

When using the **coredump** command to troubleshoot crashes on the ASA, it is possible that no coredump file is saved after a crash. This can occur when the coredump feature has been enabled and a coredump filesystem with preallocated disk space has been created. This condition usually appears while troubleshooting crashes that occur after a few weeks on busy ASAs that have allocated a large amount of RAM.

In the output of the **show coredump** command, something similar to the following appears:

```
Coredump Aborted as the complete coredump could not be written to flash
   Filesystem full on 'disk0', current coredump size <size> bytes too big for allocated
   filesystem
```

To alleviate this issue, you need to have a coredump filesystem card that is large enough to contain the full memory and allocate corresponding space to the coredump filesystem.

Examples

Each bang (!) in these examples represents 1 MB of the coredump filesystem being written.

The following example uses default values and **disk0:** to create the coredump filesystem.

```
hostname(config)# coredump enable
Warning: Enabling coredump on an ASA5505 platform will delay the reload of the system in
the event of software forced reload. The exact time depends on the size of the coredump
generated.
Proceed with coredump filesystem allocation of 60 MB on 'disk0:' (Note this may take a
while) [confirm]
Making coredump file system
image!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
```

The following example shows how to specify the filesystem and size by creating a 120-MB coredump filesystem on **disk1:**

```
hostname(config)# coredump enable filesystem disk1: size 120
WARNING: Enabling coredump on an ASA5540 platform will delay
the reload of the system in the event of software forced reload.
The exact time depends on the size of the coredump generated.
Proceed with coredump filesystem allocation of 120 MB
on 'disk1:' (Note this may take a while) ? [confirm]
Making coredump file system image
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
```

The following example shows how to resize the coredump filesystem from 120 MB to 100 MB:

Note The contents of the 120-MB coredump filesystem are not preserved, so make sure that you archive previous coredumps before doing this.

```
hostname(config)# coredump enable filesystem disk1: size 100
WARNING: Enabling coredump on an ASA5540 platform will delay
the reload of the system in the event of software forced reload.
The exact time depends on the size of the coredump generated.
Proceeding with resizing to 100 MB results in
deletion of current 120 MB coredump filesystem and
its contents on 'disk1:', proceed ? [confirm]
Making coredump file system
image!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
!!!!!!!!!!!!!!!
```

The following example enables coredump initially on **disk0:**, then on **disk1:**. Also note the use of the **default** keyword.

Note We do not allow two active coredump filesystems, so you must delete the previous coredump filesystem before proceeding.

```
hostname(config)# coredump enable filesystem disk1: size default
WARNING: Enabling coredump on an ASA5540 platform will delay
the reload of the system in the event of software forced reload.
The exact time depends on the size of the coredump generated.
Coredump is currently configured on 'disk0:', upon successful
configuration on 'disk1:', the coredump filesystem will be
deleted on 'disk0:', proceed ? [confirm]
Proceed with coredump filesystem allocation of 100 MB
on 'disk1:' (Note this may take a while) ? [confirm]
Making coredump file system
image!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
!!!!!!!!!!!!!!!
```

The following example shows how to disable the coredump filesystem. However, the current coredump filesystem image and its contents are not affected.

```
hostname(config)# no coredump enable
```

To reenable coredumps, reenter the command you originally used to configure the coredump filesystem.

The following examples disable and reenable coredumps:

- Using default values:

```
hostname(config)# coredump enable
```

```
hostname(config)# no coredump enable
hostname(config)# coredump enable
```

- Using explicit values:

```
hostname(config)# coredump enable filesystem disk1: size 200
hostname(config)# no coredump enable
hostname(config)# coredump enable filesystem disk1: size 200
```

Related Commands

Command	Description
clear configure coredump	Removes the coredump filesystem and its contents from your system. Also clears the coredump log.
clear coredump	Removes any coredumps currently stored on the coredump filesystem and clears the coredump log.
show coredump filesystem	Displays files on the coredump filesystem and indicates how full it might be.
show coredump log	Shows the coredump log.

crashinfo console disable

To suppress crash information from being output to the console, use the **crashinfo console disable** command in global configuration mode.

crashinfo console disable

no crashinfo console disable

Syntax Description

disable	Suppresses console output in the event of a crash.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(4)	This command was introduced.

Usage Guidelines

This command lets you suppress crash information from being output to the console. The crash information may contain sensitive information that is not appropriate for viewing by all users connected to the device. In conjunction with this command, you should also ensure crash information is written to flash, which can be examined after the device reboots. This command affects output for crash information and checkheaps, which is saved to flash and should be sufficient for troubleshooting.

Examples

The following example shows how to suppress crash information from being output to the console:

```
hostname(config)# crashinfo console disable
```

Related Commands

Command	Description
clear configure fips	Clears the system or module FIPS configuration information stored in NVRAM.
fips enable	Enables or disables policy checking to enforce FIPS compliance on the system or module.
fips self-test poweron	Executes power-on self-tests.

Command	Description
show crashinfo console	Reads, writes, and configures crash information output to flash.
show running-config fips	Displays the FIPS configuration that is running on the ASA.

crashinfo force

To force the ASA to crash, use the **crashinfo force** command in privileged EXEC mode.

crashinfo force [**page-fault** | **watchdog**]

Syntax Description

page-fault	(Optional) Forces a crash of the ASA as a result of a page fault.
watchdog	(Optional) Forces a crash of the ASA as a result of watchdogging.

Defaults

The ASA saves the crash information file to flash memory by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can use the **crashinfo force** command to test the crash output generation. In the crash output, there is nothing that differentiates a real crash from a crash resulting from the **crashinfo force page-fault** or **crashinfo force watchdog** command (because these are real crashes). The ASA reloads after the crash dump is complete.

Caution Do not use the **crashinfo force** command in a production environment. The **crashinfo force** command crashes the ASA and forces it to reload.

Examples

The following example shows the warning that displays when you enter the **crashinfo force page-fault** command:

```
hostname# crashinfo force page-fault
WARNING: This command will force the XXX to crash and reboot.
    Do you wish to proceed? [confirm]:
```

If you enter a carriage return (by pressing the Return or Enter key on your keyboard), “Y,” or “y,” the ASA crashes and reloads; any of these responses are interpreted as confirmation. Any other character is interpreted as a no, and the ASA returns to the command-line prompt.

Related Commands

clear crashinfo	Clears the contents of the crash information file.
crashinfo save disable	Disables crash information from writing to flash memory.
crashinfo test	Tests the ability of the ASA to save crash information to a file in flash memory.
show crashinfo	Displays the contents of the crash information file.

crashinfo save disable

To disable crash information from writing to flash memory, use the **crashinfo save** command in global configuration mode. To allow the crash information to be written to flash memory and return to the default behavior, use the **no** form of this command.

crashinfo save disable

no crashinfo save disable

Syntax Description

This command has no arguments or keywords.

Defaults

The ASA saves the crash information file to flash memory by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	The **crashinfo save enable** command was deprecated. Use the **no crashinfo save disable** command instead.

Usage Guidelines

Crash information writes to flash memory first, and then to the console.

Note If the ASA crashes during startup, the crash information file is not saved. The ASA must be fully initialized and running first before it can save crash information to flash memory.

Use the **no crashinfo save disable** command to reenable saving the crash information to flash memory.

Examples

The following example shows how to disable crash information from writing to flash memory:

```
hostname(config)# crashinfo save disable
```

Related Commands

clear crashinfo	Clears the contents of the crash file.
crashinfo force	Forces a crash of the ASA.

crashinfo test	Tests the ability of the ASA to save crash information to a file in flash memory.
show crashinfo	Displays the contents of the crash file.

crashinfo test

To test the ability of the ASA to save crash information to a file in flash memory, use the **crashinfo test** command in privileged EXEC mode.

crashinfo test

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If a previous crash information file already exists in flash memory, that file is overwritten.

Note Entering the **crashinfo test** command does not crash the ASA.

Examples

The following example shows the output of a crash information file test.:

```
hostname# crashinfo test
```

Related Commands

clear crashinfo	Deletes the contents of the crash file.
crashinfo force	Forces the ASA to crash.
crashinfo save disable	Disables crash information from writing to flash memory.
show crashinfo	Displays the contents of the crash file.

crl

To specify CRL configuration options, use the **crl** command in crypto ca trustpoint configuration mode.

crl {**required** | **optional** | **nocheck**}

Syntax Description

nocheck	Directs the ASA not to perform CRL checking.
optional	The ASA can still accept the peer certificate if the required CRL is not available.
required	The required CRL must be available for a peer certificate to be validated.

Defaults

The default value is **nocheck**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Crypto ca trustpoint configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	This command was deprecated. The following forms of the **revocation-check** command replace it. • **revocation-check crl none** replaces **crl optional** • **revocation-check crl** replaces **crl required** • **revocation-check none** replaces **crl nocheck**

Examples

The following example enters crypto ca trustpoint configuration mode for a trustpoint central, and requires that a CRL be available for a peer certificate to be validated for this trustpoint:

```
hostname(config)# crypto ca trustpoint central
hostname(ca-trustpoint)# crl required
hostname(ca-trustpoint)#
```

Related Commands

Command	Description
clear configure crypto ca trustpoint	Removes all trustpoints.
crypto ca trustpoint	Enters crypto ca trustpoint configuration mode.

Command	Description
crl configure	Enters crl configuration mode.
url	Specifies a URL for the CRL retrieval.

crl cache-time

To configure the amount of time (minutes) that a trustpool CRL can remain in the CRL cache before the ASA refreshes it, use the **crl cache-time** command in ca-trustpool configuration mode. To accept the default value of 60 minutes, use the **no** form of this command.

crl cache-time

no crl cache-time

Syntax Description

cache-time	Value in minutes (1-1440).

Defaults

The default value is **60**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Ca-trustpool configuration	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

This command is consistent with the version of this command supported in the trustpoint configuration mode.

Examples

```
hostname(ca-trustpool)# crl cache-time 30
```

Related Commands

Command	Description
crl enforcenextupdate	Specifies how to handle the NextUpdate CRL field.

crl configure

To enter CRL configuration mode, use the **crl configure** command in crypto ca trustpoint configuration mode.

crl configure

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca trustpoint configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example enters crl configuration mode for a trustpoint central:

```
hostname(config)# crypto ca trustpoint central
hostname(ca-trustpoint)# crl configure
hostname(ca-crl)#
```

crl enforcenextupdate

To specify how to handle the NextUpdate CRL field, use the **crl enforcenextupdate** command in ca-trustpool configuration mode. If enabled, CRLs are required to have a NextUpdate field that has not yet lapsed. To not enforce this restriction, use the **no** form of this command:

crl enforcenextupdate

no crl enforcenextupdate

Syntax Description

This command has no arguments or keywords.

Defaults

The default is enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca-trustpool configuration	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

If enabled, CRLs are required to have a NextUpdate field that has not yet elapsed. This command is consistent with the version of this command supported in the trustpoint configuration mode.

Related Commands

Command	Description
crl cache-time	Configures how long a CRL can remain in the CRL cache before ASA refreshes it.

CHAPTER 11

crypto am-disable through crypto ipsec ikev1 transform-set mode transport Commands

crypto am-disable

To disable IPsec IKEv1 inbound aggressive mode connections, use the **crypto ikev1 am-disable** command in global configuration mode. To enable inbound aggressive mode connections, use the **no** form of this command.

crypto ikev1 am-disable

no crypto ikev1 am-disable

Syntax Description

This command has no arguments or keywords.

Defaults

The default value is enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	The **isakmp am-disable** command was introduced.
7.2.(1)	The **crypto isakmp am-disable** command replaces the **isakmp am-disable** command**.**
8.4(1)	The command name was changed from **crypto isakmp am-disable** to **crypto ikev1 am-disable**.

Examples

The following example, entered in global configuration mode, disables inbound aggressive mode connections:

```
hostname(config)# crypto ikev1 am-disable
```

Related Commands

Command	Description
clear configure crypto isakmp	Clears the ISAKMP configuration.
clear configure crypto isakmp policy	Clears the ISAKMP policy configuration.
clear crypto isakmp sa	Clears the IKE runtime SA database.
show running-config crypto isakmp	Displays the active configuration.

crypto ca authenticate

To install and authenticate the CA certificates associated with a trustpoint, use the **crypto ca authenticate** command in global configuration mode. To remove the CA certificate, use the **no** form of this command.

crypto ca authenticate *trustpoint* [**fingerprint** *hexvalue*] [**nointeractive]**

no crypto ca authenticate *trustpoint*

Syntax Description

fingerprint	Specifies a hash value consisting of alphanumeric characters that the ASA uses to authenticate the CA certificate. If a fingerprint is provided, the ASA compares it to the computed fingerprint of the CA certificate and accepts the certificate only if the two values match. If there is no fingerprint, the ASA displays the computed fingerprint and asks whether to accept the certificate.
hexvalue	Identifies the hexadecimal value of the fingerprint.
nointeractive	Obtains the CA certificate for this trustpoint using no interactive mode; intended for use by the device manager only. In this case, if there is no fingerprint, the ASA accepts the certificate without question.
trustpoint	Specifies the trustpoint from which to obtain the CA certificate. The maximum name length is 128 characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced

Usage Guidelines

If the trustpoint is configured for SCEP enrollment, the CA certificate is downloaded through SCEP. If not, the ASA prompts you to paste the base-64 formatted CA certificate into the terminal.

The invocations of this command do not become part of the running configuration.

Examples

The following example shows the ASA requesting the certificate of the CA. The CA sends its certificate and the ASA prompts the administrator to verify the certificate of the CA by checking the CA certificate fingerprint. The ASA administrator should verify the fingerprint value displayed with a known, correct value. If the fingerprint displayed by the ASA matches the correct value, you should accept the certificate as valid.

```
hostname(config)# crypto ca authenticate myca
Certificate has the following attributes:
Fingerprint: 0123 4567 89AB CDEF 0123
Do you accept this certificate? [yes/no] y#
hostname(config)#
```

The following example shows the trustpoint tp9 configured for terminal-based (manual) enrollment. The ASA prompts the administrator to paste the CA certificate into the terminal. After displaying the fingerprint of the certificate, the ASA prompts the administrator to confirm that the certificate should be retained.

```
hostname(config)# crypto ca authenticate tp9
Enter the base 64 encoded CA certificate.
End with a blank line or the word "quit" on a line by itself

hostname(config)#
```

Related Commands

Command	Description
crypto ca enroll	Starts enrollment with a CA.
crypto ca import certificate	Installs a certificate received from a CA in response to a manual enrollment request.
crypto ca trustpoint	Enters crypto ca trustpoint configuration mode for the indicated trustpoint.

crypto ca certificate chain

To enter certificate chain configuration mode for the indicated trustpoint, use the **crypto ca certificate chain** command in global configuration mode.

crypto ca certificate chain *trustpoint*

Syntax Description

trustpoint	Specifies the trustpoint for configuring the certificate chain.

Defaults

No default values or behaviors.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example enters certificate chain configuration mode for the trustpoint, central:

```
hostname(config)# crypto ca certificate chain central
hostname(config-cert-chain)#
```

Related Commands

Command	Description
clear configure crypto ca trustpoint	Removes all trustpoints.

crypto ca certificate map

To maintain a prioritized list of certificate mapping rules, use the **crypto ca certificate map** command in global configuration mode. To remove a crypto CA configuration map rule, use the **no** form of the command.

crypto ca certificate map {*sequence-number* | *map-name sequence-number*}

no crypto ca certificate map {*sequence-number* | *map-name* [*sequence-number*]}

Syntax Description

map-name	Specifies a name for a certificate-to-group map.
sequence-number	Specifies a number for the certificate map rule that you are creating. The range is 1 through 65535. You can use this number when creating a tunnel group map, which maps a tunnel group to a certificate map rule.

Defaults

The default value for *map-name* is DefaultCertificateMap.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	Added the *map-name* option.

Usage Guidelines

Entering this command places the ASA in ca certificate map configuration mode, where you can configure rules based on the issuer and subject distinguished names (DNs) of the certificate. The sequence number orders the mapping rules. The general form of these rules is as follows:

- *DN match-criteria match-value*
- *DN* is either *subject-name* or *issuer-name*. DNs are defined in the ITU-T X.509 standard.
- *match-criteria* comprise the following expressions or operators:

attr *tag*	Limits the comparison to a specific DN attribute, such as common name (CN).
co	Contains
eq	Equal
nc	Does not contain
ne	Not equal

The DN matching expressions are case insensitive.

Examples

The following example enters ca certificate map mode with a map named example-map and a sequence number of 1 (rule # 1), and specifies that the common name (CN) attribute of the subject-name must match Example1:

```
hostname(config)# crypto ca certificate map example-map 1
hostname(ca-certificate-map)# subject-name attr cn eq Example1
hostname(ca-certificate-map)#
```

The following example enters ca certificate map mode with a map named example-map and a sequence number of 1, and specifies that the subject-name contain the value cisco anywhere within it:

```
hostname(config)# crypto ca certificate map example-map 1
hostname(ca-certificate-map)# subject-name co cisco
hostname(ca-certificate-map)#
```

Related Commands

Command	Description
issuer-name	Indicates that rule entry is applied to the issuer DN of the IPsec peer certificate.
subject-name (crypto ca certificate map)	Indicates that rule entry is applied to the subject DN of the IPsec peer certificate.
tunnel-group-map enable	Associates the certificate map entries created using the **crypto ca certificate map** command with tunnel groups.

crypto ca crl request

To request a CRL based on the configuration parameters of the specified trustpoint, use the **crypto ca crl request** command in crypto ca trustpoint configuration mode.

crypto ca crl request *trustpoint*

Syntax Description

trustpoint	Specifies the trustpoint. The maximum number of characters allowed is 128.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca trustpoint configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Invocations of this command do not become part of the running configuration.

Examples

The following example requests a CRL based on the trustpoint named central:

```
hostname(config)# crypto ca crl request central
hostname(config)#
```

Related Commands

Command	Description
crl configure	Enters crl configuration mode.

crypto ca enroll

To start the enrollment process with the CA, use the **crypto ca enroll** command in global configuration mode.

crypto ca enroll *trustpoint* [**noconfirm**]

Syntax Description

noconfirm	(Optional) Suppresses all prompts. Enrollment options that might have been prompted for must be preconfigured in the trustpoint. This option is for use in scripts, ASDM, or other noninteractive needs.
trustpoint	Specifies the name of the trustpoint to enroll with. The maximum number of characters allowed is 128.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

When the trustpoint is configured for SCEP enrollment, the ASA displays a CLI prompt immediately and status messages appear on the console asynchronously. When the trustpoint is configured for manual enrollment, the ASA writes a base-64-encoded PKCS10 certificate request to the console and then the CLI prompt appears.

This command generates interactive prompts that vary, depending on the configured state of the referenced trustpoint. For this command to run successfully, the trustpoint must have been configured correctly.

Examples

The following example requests enrollment for an identity certificate with trustpoint tp1 using SCEP enrollment. The ASA prompts for information not stored in the trustpoint configuration.

```
hostname(config)# crypto ca enroll tp1
%
% Start certificate enrollment ..
% Create a challenge password. You will need to verbally provide this
% password to the CA Administrator in order to revoke your certificate.
% For security reasons your password will not be saved in the configuration.
% Please make a note of it.
Password:
```

```
Re-enter password:
% The fully-qualified domain name in the certificate will be: xyz.example.com
% The subject name in the certificate will be: xyz.example.com
% Include the router serial number in the subject name? [yes/no]: no
% Include an IP address in the subject name? [no]: no
Request certificate from CA [yes/no]: yes
% Certificate request sent to Certificate authority.
% The certificate request fingerprint will be displayed.
% The 'show crypto ca certificate' command will also show the fingerprint.

hostname(config)#
```

The following example shows manual enrollment of a CA certificate:

```
hostname(config)# crypto ca enroll tp1

% Start certificate enrollment ..
% The fully-qualified domain name in the certificate will be: xyz.example.com
% The subject name in the certificate will be: wb-2600-3.example.com
if serial number not set in trustpoint, prompt:
% Include the router serial number in the subject name? [yes/no]: no
If ip-address not configured in trustpoint:
% Include an IP address in the subject name? [no]: yes
Enter Interface name or IP Address[]: 1.2.3.4
Display Certificate Request to terminal? [yes/no]: y
Certificate Request follows:

---End - This line not part of the certificate request---

Redisplay enrollment request? [yes/no]: no
hostname(config)#
```

Related Commands

Command	Description
crypto ca authenticate	Obtains the CA certificate for this trustpoint.
crypto ca import pkcs12	Installs a certificate received from a CA in response to a manual enrollment request.
crypto ca trustpoint	Enters crypto ca trustpoint configuration mode for the indicated trustpoint.

crypto ca export

To export the ASA trustpoint configuration with all associated keys and certificates in PKCS12 format, or to export the device identity certificate in PEM format, use the **crypto ca export** command in global configuration mode.

crypto ca export *trustpoint* **identity-certificate**

Syntax Description

identity-certificate	Specifies that the enrolled certificate associated with the named trustpoint is to be displayed on the console.
trustpoint	Specifies the name of the trustpoint whose certificate is to be displayed. The maximum number of characters allowed for a trustpoint name is 128.

Defaults

No default values or behaviors.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0(2)	This command was changed to accommodate certificate exporting in PEM format.

Usage Guidelines

Invocations of this command do not become part of the active configuration. The PEM or PKCS12 data is written to the console.

Web browsers use the PKCS12 format to store private keys with accompanying public key certificates protected with a password-based symmetric key. The ASA exports the certificates and keys associated with a trustpoint in base64-encoded PKCS12 format. This feature can be used to move certificates and keys between ASAs.

PEM encoding of a certificate is a base64 encoding of an X.509 certificate enclosed by PEM headers. This encoding provides a standard method for text-based transfer of certificates between ASAs. PEM encoding can be used to export the *proxy-ldc-issuer* certificate using an SSL/TLS protocol proxy when the ASA is acting as a client.

Examples

The following example exports the PEM-formatted certificate for trustpoint 222 as a console display:

```
hostname (config)# crypto ca export 222 identity-certificate
```

```
Exported 222 follows:
-----BEGIN CERTIFICATE-----
MIIGDzCCBXigAwIBAgIKFiUgwwAAAAAFPDANBgkqhkiG9w0BAQUFADCBnTEfMB0G

Related Commands

Command	Description
crypto ca authenticate	Obtains the CA certificate for this trustpoint.
crypto ca enroll	Starts enrollment with a CA.
crypto ca import	Installs a certificate received from a CA in response to a manual enrollment request.
crypto ca trustpoint	Enters crypto ca trustpoint configuration mode for the indicated trustpoint.

crypto ca import

To install a certificate received from a CA in response to a manual enrollment request or to import the certificate and key pair for a trustpoint using PKCS12 data, use the **crypto ca import** command in global configuration mode.

crypto ca import *trustpoint* **certificate** [**nointeractive**]

crypto ca import *trustpoint* **pkcs12** *passphrase* [**nointeractive**]

Syntax Description

certificate	Tells the ASA to import a certificate from the CA represented by the trustpoint.
nointeractive	(Optional) Imports a certificate using nointeractive mode, which suppresses all prompts. This option is for use in scripts, ASDM, or other noninteractive needs.
passphrase	Specifies the passphrase used to decrypt the PKCS12 data.
pkcs12	Tells the ASA to import a certificate and key pair for a trustpoint, using PKCS12 format.
trustpoint	Specifies the trustpoint with which to associate the import action. The maximum number of characters allowed is 128. If you import PKCS12 data and the trustpoint uses RSA keys, the imported key pair is assigned the same name as the trustpoint.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example manually imports a certificate for the trustpoint Main:

```
hostname (config)# crypto ca import Main certificate
% The fully-qualified domain name in the certificate will be:
securityappliance.example.com

Enter the base 64 encoded certificate.
End with a blank line or the word "quit" on a line by itself
[ certificate data omitted ]
quit
```

```
INFO: Certificate successfully imported
hostname (config)#
```

The following example manually imports PKCS12 data to a trustpoint central:

```
hostname (config)# crypto ca import central pkcs12

Enter the base 64 encoded pkcs12.
End with a blank line or the word "quit" on a line by itself:
[ PKCS12 data omitted ]
quit
INFO: Import PKCS12 operation completed successfully
hostname (config)#
```

The following example, entered in global configuration mode, generates a warning message because there is not enough space in NVRAM to save the RSA keypair:

```
hostname(config)# crypto ca import central pkcs12 mod 2048
INFO: The name for the keys will be: central
Keypair generation process begin. Please wait...
NV RAM will not have enough space to save keypair central. Remove any unnecessary keypairs
and save the running config before using this keypair.
hostname(config)#
```

Related Commands

Command	Description
crypto ca export	Exports a trustpoint certificate and key pair in PKCS12 format.
crypto ca authenticate	Obtains the CA certificate for a trustpoint.
crypto ca enroll	Starts enrollment with a CA.
crypto ca trustpoint	Enters the crypto ca trustpoint configuration mode for the indicated trustpoint.

crypto ca server

To set up and manage a local CA server on the ASA, use the **crypto ca server** command in global configuration mode. To delete the configured local CA server from the ASA, use the **no** form of this command.

crypto ca server

no crypto ca server

Syntax Description

This command has no arguments or keywords.

Defaults

A certificate authority server is not enabled on the ASA.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•		—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

There can only be one local CA on an ASA.

The **crypto ca server** command configures the CA server, but does not enable it. Use the **no** form of the **shutdown** command in ca server configuration mode to enable the local CA.

When you activate the CA server with the **no shutdown** command, you establish the RSA keypair of the CA and a trustpoint named LOCAL-CA-SERVER to hold the self-signed certificate. This newly generated self-signed certificate always has digital signature, CRL signing, and certificate signing key usage settings set.

Caution The **no crypto ca server** command deletes the configured local CA server, its RSA keypair, and the associated trustpoint, regardless of the current state of the local CA server.

Examples

The following example enters ca server configuration mode, then lists the local CA server commands available in that mode:

```
hostname(config)# crypto ca server
hostname(config-ca-server)# ?
```

```
CA Server configuration commands:
  cdp-url               CRL Distribution Point to be included in the issued
                        certificates
  database              Embedded Certificate Server database location
                        configuration
  enrollment-retrieval  Enrollment-retrieval timeout configuration
  exit                  Exit from Certificate Server entry mode
  help                  Help for crypto ca server configuration commands
  issuer-name           Issuer name
  keysize               Size of keypair in bits to generate for certificate
                        enrollments
  lifetime              Lifetime parameters
  no                    Negate a command or set its defaults
  otp                   One-Time Password configuration options
  renewal-reminder      Enrollment renewal-reminder time configuration
  shutdown              Shutdown the Embedded Certificate Server
  smtp                  SMTP settings for enrollment E-mail notifications
  subject-name-default  Subject name default configuration for issued
                        certificates
```

The following example uses the **no** form of the **crypto ca server** command in ca server configuration mode to delete the configured and enabled CA server from the ASA:

```
hostname(config-ca-server)# no crypto ca server

Certificate server 'remove server' event has been queued for processing.
hostname(config)#
```

Related Commands

Command	Description
debug crypto ca server	Shows debugging messages when you configure the local CA server.
show crypto ca server	Displays the status and parameters of the configured CA server.
show crypto ca server cert-db	Displays local CA server certificates.

crypto ca server crl issue

To force the issuance of a Certificate Revocation List (CRL), use the **crypto ca server crl issue** command in privileged EXEC mode.

crypto ca server crl issue

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca server configuration	•	—	•		—
Global configuration	•	—	•		—
Privileged EXEC	•	—	•		—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use this command to recover a lost CRL. Normally, the CRL is reissued automatically at expiration by resigning the existing CRL. The **crypto ca server crl issue** command regenerates the CRL based on the certificate database and should only be used as required to regenerate a CRL based on the certificate database contents.

Examples

The following example forces the issuance of a CRL by the local CA server:

```
hostname(config-ca-server)# crypto ca server crl issue
A new CRL has been issued.
hostname(config-ca-server)#
```

Related Commands

Command	Description
cdp-url	Specifies the certificate revocation list distribution point to be included in the certificates issued by the CA.
crypto ca server	Provides access to the ca server configuration mode command set, which allows you to configure and manage the local CA.

Command	Description
crypto ca server revoke	Marks a certificate issued by the local CA server as revoked in the certificate database and CRL.
show crypto ca server crl	Displays the current CRL of the local CA.

crypto ca server revoke

To mark a certificate issued by the local Certificate Authority (CA) server as revoked in the certificate database and the CRL, use the **crypto ca server revoke** command in privileged EXEC mode.

crypto ca server revoke *cert-serial-no*

Syntax Description

cert-serial-no	Specifies the serial number of the certificate to be revoked, which must be in hexadecimal format.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca server configuration	•	—	•		—
Global configuration	•	—	•		—
Privileged EXEC	•	—	•		—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

You revoke a specific certificate that has been issued by the local CA on an ASA by entering the **crypto ca server revoke** command on that ASA. Revocation is accomplished when this command marks the certificate as revoked in the certificate database on the CA server and in the CRL. You specify the certificate to be revoked by entering the certificate serial number in hexadecimal format.

The CRL is regenerated automatically after the specified certificate is revoked.

Examples

The following example revokes the certificate with the serial number 782ea09f issued by the local CA server:

```
hostname(config-ca-server)## crypto ca server revoke 782ea09f
Certificate with the serial number 0x782ea09f has been revoked. A new CRL has been issued.
hostname(config-ca-server)#
```

Related Commands

Command	Description
crypto ca server crl issue	Forces the issuance of a CRL.
crypto ca server unrevoke	Unrevokes a revoked certificate issued by the local CA server.
crypto ca server user-db remove	Removes a user from the CA server user database.
show crypto ca server crl	Displays the current CRL of the local CA.
show crypto ca server user-db	Displays users included in the CA server user database.

crypto ca server unrevoke

To unrevoke a revoked certificate issued by the local CA server, use the **crypto ca server unrevoke** command in privileged EXEC mode.

crypto ca server unrevoke *cert-serial-no*

Syntax Description

cert-serial-no	Specifies the serial number of the certificate to be unrevoked, which must be in hexadecimal format.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca server configuration	•	—	•		—
Global configuration	•	—	•		—
Privileged EXEC	•	—	•		—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

You unrevoke a revoked certificate issued by the local CA on an ASA by entering the **crypto ca server unrevoke** command. The validity of the certificate is restored when this command marks the certificate as valid in the certificate database and removes it from the CRL. You specify the certificate to be unrevoked by entering the certificate serial number in hexadecimal format.

The CRL is regenerated after the specified certificate is unrevoked.

Examples

The following example unrevokes the certificate with the serial number 782ea09f issued by the local CA server:

```
hostname(config-ca-server)# crypto ca server unrevoke 782ea09f
Certificate with the serial number 0x782ea09f has been unrevoked. A new CRL has been
issued.
hostname(config-ca-server)#
```

Related Commands

Command	Description
crypto ca server	Provides access to the ca server configuration mode command set, which allows you to configure and manage the local CA.
crypto ca server crl issue	Forces the issuance of a CRL.
crypto ca server revoke	Marks a certificate issued by the local CA server as revoked in the certificate database and CRL.
crypto ca server user-db add	Adds a user to the CA server user database.
show crypto ca server cert-db	Displays local CA server certificates.
show crypto ca server user-db	Displays users included in the CA server user database.

crypto ca server user-db add

To insert a new user into the CA server user database, use the **crypto ca server user-db add** command in privileged EXEC mode.

crypto ca server user-db add *user* [**dn** *dn*] [**email** *e-mail-address*]

Syntax Description

dn *dn*	Specifies a subject-name distinguished name for certificates issued to the added user. If a DN string contains a comma, enclose the value string with double quotes (for example, O=”Company, Inc.”)
email *e-mail-address*	Specifies the e-mail address for the new user.
user	Specifies a single user to whom to grant enrollment privileges. The username can be a simple username or an e-mail address.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca server configuration	•	—	•		—
Global configuration	•	—	•		—
Privileged EXEC	•	—	•		—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The *user* argument can be a simple username such as user1 or an e-mail address such as user1@example.com. The *username* must match the username specified by the end user in the enrollment page.

The *username* is added to the database as a user without privileges. You must use the **crypto ca server allow** command to grant enrollment privileges.

The *username* argument, along with the one-time password, is used to enroll the user on the enrollment interface page.

Note For e-mail notification of the one-time password (OTP), an e-mail address should be specified either in the *username* or *email-address* argument. A missing e-mail address at mailing time generates an error.

The **email** *e-mail-address* keyword-argument pair is used only as an e-mail address to notify the user for enrollment and renewal reminders and does not appear in the issued certificate.

Inclusion of the e-mail address ensures that the user can be contacted with any questions and is notified of the required one-time password for enrollment.

If an optional DN is not specified for a user, the subject name DN is formed using the *username* and the subject-name-default DN setting as cn=*username*, subject-name-default.

Examples

The following example adds a user to the user database with a username of user1@example.com with a complete subject-name DN:

```
hostname(config-ca-server)# crypto ca server user-db add dn "cn=Jane Doe, ou=engineering,
o=Example, l=RTP, st=NC, c=US"
hostname(config-ca-server)#
```

The following example grants enrollment privileges to the user named user2.

```
hostname(config-ca-server)# crypto ca server user-db allow user2
hostname(config-ca-server)
```

Related Commands

Command	Description
crypto ca server	Provides access to the ca server configuration mode command set, which allows you to configure and manage a local CA.
crypto ca server user-db allow	Permits a specific user or a subset of users in the CA server database to enroll with the CA.
crypto ca server user-db remove	Deletes a user from the CA server database.
crypto ca server user-db write	Copies the user information in the CA server database to the file specified by the **database path** command.
database path	Specifies a path or location for the local CA database. The default location is flash memory.

crypto ca server user-db allow

To permit a user or a group of users to enroll in the local CA server database, use the **crypto ca server user-db allow** command in privileged EXEC mode. This command also includes options to generate and display one-time passwords or to e-mail them to users.

crypto ca server user-db allow {*username* | **all-unenrolled** | **all-certholders**} [**display-otp**] [**email-otp**] [**replace-otp**]

Syntax Description

all-certholders	Specifies that enrollment privileges be granted to all users in the database who have been issued a certificate, whether the certificate is valid or not. This is equivalent to granting renewal privileges.
all-unenrolled	Specifies that enrollment privileges be granted to all users in the database who have not been issued a certificate.
email-otp	(Optional) Sends the specified users one-time passwords by e-mail to their configured e-mail addresses.
replace-otp	(Optional) Specifies that one-time passwords be regenerated for all specified users who originally had valid one-time passwords.
display-otp	(Optional) Displays the one-time passwords for all specified users on the console.
username	Specifies a single user to whom to grant enrollment privileges. The username can be a simple username or e-mail address.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Ca server configuration	•	—	•		—
Global configuration	•	—	•		—
Privileged EXEC	•	—	•		—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The **replace-otp** keyword generates OTPs for all specified users. These new OTPs replace any valid ones generated for the specified users.

The OTP is not stored on the ASA, but is generated and regenerated as required to notify a user or to authenticate a user during enrollment.

Examples

The following example grants enrollment privileges to all users in the database who have not enrolled yet:

```
hostname(config-ca-server)# crypto ca server user-db allow all-unenrolled
hostname(config-ca-server)#
```

The following example grants enrollment privileges to the user named user1:

```
hostname(config-ca-server)# crypto ca server user-db allow user1
hostname(config-ca-server)#
```

Related Commands

Command	Description
crypto ca server	Provides access to the ca server configuration mode command set, which allows you to configure and manage a local CA.
crypto ca server user-db add	Adds a user to the CA server user database.
crypto ca server user-db write	Copies the user information in the CA server database to the file specified by the **database path** command.
enrollment-retrieval	Specifies the time in hours that an enrolled user can retrieve a PKCS12 enrollment file.
show crypto ca server cert-db	Displays all certificates issued by the local CA.

crypto ca server user-db email-otp

To e-mail the OTP to a specific user or a subset of users in the local CA server database, use the **crypto ca server user-db email-otp** command in privileged EXEC mode.

crypto ca server user-db email-otp {*username* | **all-unenrolled** | **all-certholders**}

Syntax Description

all-certholders	Specifies that OTPs are e-mailed to all users in the database who have been issued a certificate, whether that certificate is valid or not.
all-unenrolled	Specifies that the OTPs are e-mailed to all users in the database who have never been issued a certificate, or who only hold expired or revoked certificate(s).
username	Specifies that the OTP for a single user is e-mailed to that user. The username can be a username or an e-mail address.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca server configuration	•	—	•		—
Global configuration	•	—	•		—
Privileged EXEC	•	—	•		—

Command History

Release	Modification
8.0(2)	This command was introduced.

Examples

The following example e-mails the OTP to all unenrolled users in the database:

```
hostname(config-ca-server)# crypto ca server user-db email-otp all-unenrolled
hostname(config-ca-server)#
```

The following example e-mails the OTP to the user named user1:

```
hostname(config-ca-server)# crypto ca server user-db email-otp user1
hostname(config-ca-server)#
```

Related Commands

Command	Description
crypto ca server user-db show-otp	Displays the one-time password for a specific user or a subset of users in the CA server database.
show crypto ca server cert-db	Displays all certificates issued by the local CA.
show crypto ca server user-db	Displays users included in the CA server user database.

crypto ca server user-db remove

To remove a user from the local CA server user database, use the **crypto ca server user-db remove** command in privileged EXEC mode.

crypto ca server user-db remove *username*

Syntax Description

username	Specifies the name of the user to remove in the form of a username or an e-mail address.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
CA server configuration	•	—	•		—
Global configuration	•	—	•		—
Privileged EXEC	•	—	•		—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

This command removes a username from the CA user database so that user cannot enroll. The command also provideees the option to revoke previously issued, valid certificates.

Examples

The following example removes a user with a username, user1, from the CA server user database :

```
hostname(config-ca-server)# crypto ca server user-db remove user1

WARNING: No certificates have been automatically revoked. Certificates issued to user
user1 should be revoked if necessary.

hostname(config-ca-server)#
```

Related Commands

Command	Description
crypto ca server crl issue	Forces the issuance of a CRL.
crypto ca server revoke	Marks a certificate issued by the local CA server as revoked in the certificate database and CRL.

Command	Description
show crypto ca server user-db	Displays users included in the CA server user database.
crypto ca server user-db write	Writes the user information configured in the local CA database to the file specified by the **database path** command.

crypto ca server user-db show-otp

To display the OTP for a specific user or a subset of users in the local CA server database, use the **crypto ca server user-db show-otp** command in privileged EXEC mode.

crypto ca server user-db show-otp {*username* | **all-certholders** | **all-unenrolled**}

Syntax Description

all-certholders	Displays the OTPs for all users in the database who have been issued a certificate, whether the certificate is currently valid or not.
all-unenrolled	Displays the OTPs for all users in the database who have never been issued a certificate, or who only hold expired or revoked certificate(s).
username	Specifies that the OTP for a single user be displayed. The *username* can be a username or an e-mail address.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca server configuration	•	—	•		—
Global configuration	•	—	•		—
Privileged EXEC	•	—	•		—

Command History

Release	Modification
8.0(2)	This command was introduced.

Examples

The following example displays the OTP for all users who have valid or invalid certificates in the database:

```
hostname(config-ca-server)# crypto ca server user-db show-otp all-certholders
hostname(config-ca-server)#
```

The following example displays the OTP for the user named user1:

```
hostname(config-ca-server)# crypto ca server user-db show-otp user1
hostname(config-ca-server)#
```

Related Commands

Command	Description
crypto ca server user-db add	Adds a user to the CA server user database.
crypto ca server user-db allow	Allows a specific user or a subset of users in the CA server database to enroll with the local CA.
crypto ca server user-db email-otp	E-mails the one-time password to a specific user or to a subset of users in the CA server database.
show crypto ca server cert-db	Displays all certificates issued by the local CA.

crypto ca server user-db write

To configure a directory location to store all the local CA database files, use the **crypto ca server user-db write** command in privileged EXEC mode.

crypto ca server user-db write

Syntax Description

This command has no keywords or arguments.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca server configuration	•	—	•		—
Global configuration	•	—	•		—
Privileged EXEC	•	—	•		—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The **crypto ca server user-db write** command is used to save new user-based configuration data to the storage specifed by the database path configuration. The information is generated when new users are added or allowed with the **crypto ca server user-db add** and **crypto ca server user-db allow** commands.

Examples

The following example writes the user information configured in the local CA database to storage:

```
hostname(config-ca-server)# crypto ca server user-db write
hostname(config-ca-server)#
```

Related Commands

Command	Description
crypto ca server user-db add	Adds a user to the CA server user database.
database path	Specifies a path or location for the local CA database. The default location is flash memory.

Command	Description
crypto ca server user-db remove	Removes a user from the CA server user database.
show crypto ca server cert-db	Displays all certificates issued by the local CA.
show crypto ca server user-db	Displays users included in the CA server user database.

crypto ca trustpoint

To enter the crypto ca trustpoint configuration mode for the specified trustpoint, use the **crypto ca trustpoint** command in global configuration mode. To remove the specified trustpoint, use the **no** form of this command.

crypto ca trustpoint *trustpoint-name*

no crypto ca trustpoint *trustpoint-name* [**noconfirm**]

Syntax Description

noconfirm	Suppresses all interactive prompting
ipsec	Indicates that IPsec client connections can be validated using this trustpoint.
ssl-client	Indicates that SSL client connections can be validated using this trustpoint.
trustpoint-name	Identifies the name of the trustpoint to manage. The maximum name length allowed is 128 characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	Added options to support the OCSP. These include **match certificate map**, **ocsp disable-nonce**, **ocsp url**, and **revocation-check**.
8.0(2)	Added options to support certificate validation. These include **id-usage** and **validation-policy.** The following are being deprecated: **accept-subordinates, id-cert-issuer**, and **support-user-cert-validation**.
8.0(4)	The **enrollment self** option was added to support enrollment of self-signed certificates between trusted enterprises, such as between phone proxy and TLS proxy.

Usage Guidelines

Use the **crypto ca trustpoint** command to declare a CA. Issuing this command puts you in crypto ca trustpoint configuration mode.

This command manages trustpoint information. A trustpoint represents a CA identity and possibly a device identity, based on a certificate issued by the CA. The commands within the trustpoint mode control CA-specific configuration parameters, which specify how the ASA obtains the CA certificate, how the ASA obtains its certificate from the CA, and the authentication policies for user certificates issued by the CA.

You can specify characteristics for the trustpoint using the following commands:

- **accept-subordinates**—Deprecated. Indicates whether CA certificates subordinate to the CA associated with the trustpoint are accepted if delivered during phase one IKE exchange when not previously installed on the ASA.
- **crl required | optional | nocheck**—Specifies CRL configuration options.
- **crl configure**—Enters crl configuration mode (see the **crl** command).
- **default enrollment**—Returns all enrollment parameters to their system default values. Invocations of this command do not become part of the active configuration.
- **email** *address*—During enrollment, asks the CA to include the specified email address in the subject alternative name extension of the certificate.
- **enrollment retry period** —Specifies a retry period in minutes for SCEP enrollment.
- **enrollment retry count**—Specifies a maximum number of permitted retries for SCEP enrollment.
- **enrollment terminal**—Specifies cut and paste enrollment with this trustpoint.
- **enrollment self**—Specifies enrollment that generates a self-signed certificate.
- **enrollment url** *url*—Specifies SCEP enrollment to enroll with this trustpoint and configures the enrollment URL (*url*).
- **exit**—Leaves the configuration mode.
- **fqdn** *fqdn*—During enrollment, asks the CA to include the specified FQDN in the subject alternative name extension of the certificate.
- **id-cert-issuer**—Deprecated. Indicates whether the system accepts peer certificates issued by the CA associated with this trustpoint.
- **id-usage**— Specifies how the enrolled identity of a trustpoint can be used.
- **ip-addr** *ip-address*—During enrollment, asks the CA to include the IP address of the ASA in the certificate.
- **keypair** *name*—Specifies the key pair whose public key is to be certified.
- **match certificate** *map-name* **override ocsp**—Matches a certificate map to an OCSP override rule.
- **ocsp disable-nonce**—Disables the nonce extension, which cryptographically binds revocation requests with responses to avoid replay attacks.
- **ocsp url**—Specifies that the OCSP server at this URL check all certificates associated with this trustpoint for revocation status.
- **exit**—Leaves the configuration mode.
- **password** *string*—Specifies a challenge phrase that is registered with the CA during enrollment. The CA typically uses this phrase to authenticate a subsequent revocation request.
- **revocation check**—Specifies the revocation checking method, which includes CRL, OCSP, and none.
- **serial-number**—During enrollment, asks the CA to include the ASA serial number in the certificate.

- **subject-name** *X.500 name*—During enrollment, asks the CA to include the specified subject DN in the certificate. If a DN string includes a comma, enclose the value string with double quotes (for example, O="Company, Inc.")
- **support-user-cert-validation**—Deprecated. If enabled, the configuration settings to validate a remote user certificate can be taken from this trustpoint, provided that it is authenticated to the CA that issued the remote certificate. This option applies to the configuration data associated with the subcommands **crl required | optional | nocheck** and all settings in the CRL mode.
- **validation-policy**—Specifies trustpoint conditions for validating certificates associated with user connections.

Note When you try to connect, a warning occurs to indicate that the trustpoint does not contain an ID certificate when an attempt is made to retrieve the ID certificate from the trustpoint.

Examples

The following example enters ca trustpoint configuration mode for managing a trustpoint named central:

```
hostname(config)# crypto ca trustpoint central
hostname(ca-trustpoint)#
```

Related Commands

Command	Description
clear configure crypto ca trustpoint	Removes all trustpoints.
crypto ca authenticate	Obtains the CA certificate for this trustpoint.
crypto ca certificate map	Enters crypto ca certificate map configuration mode. Defines certificate-based ACLs.
crypto ca crl request	Requests a CRL based on configuration parameters of a specified trustpoint.
crypto ca import	Installs a certificate received from a CA in response to a manual enrollment request.

crypto ca trustpool export

To export the certificates that constitute the PKI trustpool, use the **crypto ca trustpool export** command in privileged EXEC configuration mode.

crypto ca trustpool export *filename*

Syntax Description

filename	The file in which to store the exported trustpool certificates.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC configuration	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

This command copies the entire contents of the active trustpool to the indicated filepath in pem-coded format.

Examples

```
hostname# crypto ca trustpool export disk0:/exportfile.pem
Trustpool certificates exported to disk0:/exportfile.pem
hostname#
hostname# more exportfile.pem
-----BEGIN CERTIFICATE-----
MIIEMjCCAxqgAwIBAgIBATANBgkqhkiG9w0BAQUFADB7MQswCQYDVQQGEwJHQjEb

<More>
```

Related Commands

Command	Description
crypto ca trustpool import	Imports the certificates that constitute the PKI trustpool.

crypto ca trustpool import

To import the certificates that constitute the PKI trustpool, use the **crypto ca trustpool import** command in global configuration mode.

crypto ca trustpool import [clean] url *url* [**noconfirm** [**signature-required**]]

crypto ca trustpool import [clean] default [noconfirm]

Syntax Description

clean	Removes all downloaded trustpool certificates prior to import.
default	Restores the ASA's default trusted CA list.
noconfirm	Suppresses all interactive prompts.
signature-required	Indicates that only signed files are accepted.
url	The location of the trustpool file to be imported.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

This command provides the ability to validate the signature on the file when a trustpool bundle is downloaded from cisco.com. A valid signature is not mandatory when downloading bundles from other sources or in a format that does not support signatures. Users are informed of the signature status and are given the option to accept the bundle or not.

The possible interactive warnings are:

- Cisco bundle format with invalid signature
- Non-cisco bundle format
- Cisco bundle format with valid signature

The **signature-required** keyword is allowed only if the **noconfirm** option is selected. If the **signature-required** keyword is included but the signature is not present or cannot be verified, the import fails.

Note Unless you have verified the legitimacy of the file through some other means, do not install the certificates if a file signature cannot be verified,

The following example shows the behavior of the **crypto ca trustpool** import command when suppressing interactive prompting and requiring signatures:

```
hostname(config)# crypto ca trustpool import url ?

configure mode commands/options:
disk0:   Import from disk0: file system
disk1:   Import from disk1: file system
flash:   Import from flash: file system
ftp:     Import from ftp: file system
http:    Import from http: file system
https:   Import from https: file system
smb:     Import from smb: file system
system:  Import from system: file system
tftp:    Import from tftp: file system

hostname(config)# crypto ca trustpool import url http://mycompany.com ?
exec mode commands/options:
noconfirm  Specify this keyword to suppress all interactive prompting.

hostname(config)# crypto ca trustpool import url http://mycompany.com  noconfirm ?
exec mode commands/options:
signature-required  Indicate that only signed files will be accepted
```

Related Commands

Command	Description
crypto ca trustpool export	Exports the certificates that constitute the PKI trustpool.

crypto ca trustpool policy

To enter a submode that provides the commands that define the trustpool policy, use the **crypto ca trustpool policy** command in global configuration mode.

crypto ca trustpool policy

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Examples

```
hostname(config)# crypto ca trustpool ?

configure mode commands/options:
policy Define trustpool policy

hostname(config)# crypto ca trustpool policy
hostname(config-ca-trustpool)# ?

CA Trustpool configuration commands:
crl               CRL options
exit              Exit from certificate authority trustpool entry mode
match             Match a certificate map
no                Negate a command or set its defaults
revocation-check  Revocation checking options
hostname(config-ca-trustpool)#
```

Related Commands

Command	Description
show crypto ca trustpool policy	Displays the configured trustpool policy.

crypto ca trustpool remove

To remove a single specified certificate from the PKI trustpool, use the **crypto ca trustpool remove** command in privileged EXEC configuration mode.

crypto ca trustpool remove *cert fingerprint* **[noconfirm]**

Syntax Description

cert fingerprint	Hex data.
noconfirm	Specify this keyword to suppress all interactive prompting.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC configuration	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Because this command will commit a change to the trusted root certificate content, interactive users will be prompted to confirm their actions.

Examples

```
hostname# crypto ca trustpool remove ?

  Hex-data  Certificate fingerprint
hostname# crypto ca trustpool remove 497904b0eb8719ac47b0bc11519b74d0 ?
noconfirm  Specify this keyword to suppress all interactive prompting.
```

Related Commands

Command	Description
clear crypto ca trustpool	Removes all certificates from the trustpool.
crypto ca trustpool export	Exports the certificates that constitute the PKI trustpool.
crypto ca trustpool import	Imports the certificates that constitute the PKI trustpool.

crypto dynamic-map match address

To match the address of an access list for the dynamic crypto map entry, use the **crypto dynamic-map match address** command in global configuration mode. To disable the address match, use the **no** form of this command.

crypto dynamic-map *dynamic-map-name dynamic-seq-num* **match address** *acl_name*

no crypto dynamic-map *dynamic-map-name dynamic-seq-num* **match address** *acl_name*

Syntax Description

acl-name	Identifies the access list to be matched for the dynamic crypto map entry.
dynamic-map-name	Specifies the name of the dynamic crypto map set.
dynamic-seq-num	Specifies the sequence number that corresponds to the dynamic crypto map entry.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

See the **crypto map match address** command for additional information about this command.

Examples

The following example shows the use of the **crypto dynamic-map** command to match address of an access list named aclist1:

```
hostname(config)# crypto dynamic-map mymap 10 match address aclist1
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto dynamic-map	Clears all configuration for all the dynamic crypto maps.
show running-config crypto dynamic-map	Displays all configuration for all the dynamic crypto maps.

crypto dynamic-map set df-bit

To set the per-signature algorithm (SA) do-not-fragment (DF) policy, use the **crypto dynamic-map set df-bit** command in global configuration mode. To disable the DF policy, use the **no** form of this command.

crypto dynamic-map *name priority* **set df-bit** [**clear-df** | **copy-df** | **set-df**]

no crypto dynamic-map *name priority* **set df-bit** [**clear-df** | **copy-df** | **set-df**]

Syntax Description

name	Specifies the name of the crypto dynamic map set.
priority	Specifies the priority that you assign to the crypto dynamic map entry.

Defaults

The default setting is off.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

The original DF policy command is retained and acts as a global policy setting on an interface, but it is superseded for an SA by the **crypto map** command.

crypto dynamic-map set nat-t-disable

To disable NAT-T for connections based on this crypto map entry, use the **crypto dynamic-map set nat-t-disable** command in global configuration mode. To enable NAT-T for this crypto may entry, use the **no** form of this command.

crypto dynamic-map *dynamic-map-name dynamic-seq-num* **set nat-t-disable**

no crypto dynamic-map *dynamic-map-name dynamic-seq-num* **set nat-t-disable**

Syntax Description

dynamic-map-name	Specifies the name of the crypto dynamic map set.
dynamic-seq-num	Specifies the number that you assign to the crypto dynamic map entry.

Defaults

The default setting is off.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

Use the **isakmp nat-traversal** command to globally enable NAT-T. Then you can use the **crypto dynamic-map set nat-t-disable** command to disable NAT-T for specific crypto map entries.

Examples

The following command disables NAT-T for the crypto dynamic map named mymap:

```
hostname(config)# crypto dynamic-map mymap 10 set nat-t-disable
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto dynamic-map	Clears all configuration for all the dynamic crypto maps.
show running-config crypto dynamic-map	Displays all configuration for all the dynamic crypto maps.

crypto dynamic-map set peer

See the **crypto map set peer** command for additional information about this command.

crypto dynamic-map *dynamic-map-name dynamic-seq-num* **set peer** *ip_address* | *hostname*

no crypto dynamic-map *dynamic-map-name dynamic-seq-num* **set peer** *ip_address* | *hostname*

Syntax Description

dynamic-map-name	Specifies the name of the dynamic crypto map set.
dynamic-seq-num	Specifies the sequence number that corresponds to the dynamic crypto map entry.
hostname	Identifies the peer in the dynamic crypto map entry by hostname, as defined by the **name** command.
ip_address	Identifies the peer in the dynamic crypto map entry by IP address, as defined by the **name** command.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Examples

The following example shows setting a peer for a dynamic-map named mymap to the IP address 10.0.0.1:

```
hostname(config)# crypto dynamic-map mymap 10 set peer 10.0.0.1
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto dynamic-map	Clears all configuration for all the dynamic crypto maps.
show running-config crypto dynamic-map	Displays all configuration for all the dynamic crypto maps.

crypto dynamic-map set pfs

To specify the dynamic crypto map sets, use the **crypto map dynamic-map set pfs** command in global configuration mode. To remove the specified dynamic-map crypto map set, use the **no** form of this command.

See the **crypto map set pfs** command for additional information about this command.

crypto dynamic-map *dynamic-map-name dynamic-seq-num* **set pfs** [**group1 | group2 | group5**]

no crypto dynamic-map *dynamic-map-name dynamic-seq-num* **set pfs** [**group1 | group2 | group5**]

Syntax Description

dynamic-map-name	Specifies the name of the dynamic crypto map set.
dynamic-seq-num	Specifies the sequence number that corresponds to the dynamic crypto map entry.
group1	Specifies that IPsec should use the 768-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
group2	Specifies that IPsec should use the 1024-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
group5	Specifies that IPsec should use the 1536-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
set pfs	Configures IPsec to ask for perfect forward secrecy (PFS) when requesting new security associations for this dynamic crypto map entry or configures IPsec to require PFS when receiving requests for new security associations.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was modified to add Diffie-Hellman group 7.
8.0(4)	The **group 7** command option was deprecated. Attempts to configure group 7 will generate an error message and use group 5 instead.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

The **crypto dynamic-map** commands, such as **match address**, **set peer**, and **set pfs** are described with the **crypto map** commands. If the peer initiates the negotiation and the local configuration specifies PFS, the peer must perform a PFS exchange or the negotiation fails. If the local configuration does not specify a group, the ASA assumes a default of group2. If the local configuration does not specify PFS, it accepts any offer of PFS from the peer.

When interacting with the Cisco VPN Client, the ASA does not use the PFS value, but instead uses the value negotiated during Phase 1.

Examples

The following example specifies that PFS should be used whenever a new security association is negotiated for the crypto dynamic-map mymap 10. The group specified is group 2:

```
hostname(config)# crypto dynamic-map mymap 10 set pfs group2
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto dynamic-map	Clears all configuration for all the dynamic crypto maps.
show running-config crypto dynamic-map	Displays all configuration for all the dynamic crypto maps.

crypto dynamic-map set reverse route

See the **crypto map set reverse-route** command for additional information about this command.

crypto dynamic-map *dynamic-map-name dynamic-seq-num* **set reverse route**

no crypto dynamic-map *dynamic-map-name dynamic-seq-num* **set reverse route**

Syntax Description

dynamic-map-name	Specifies the name of the crypto map set.
dynamic-seq-num	Specifies the number you assign to the crypto map entry.

Defaults

The default value for this command is off.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Examples

The following command enables Reverse Route Injection for the crypto dynamic map named mymap:

```
hostname(config)# crypto dynamic-map mymap 10 set reverse route
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto dynamic-map	Clears all configuration for all the dynamic crypto maps.
show running-config crypto dynamic-map	Displays all configuration for all the dynamic crypto maps.

crypto dynamic-map set ikev1 transform-set

To specify the IKEv1 transform sets to use in a dynamic crypto map entry, use the **crypto dynamic-map set ikev1 transform-set** command in global configuration mode.

crypto dynamic-map *dynamic-map-name dynamic-seq-num* **set ikev1 transform-set** *transform-set-name1* [*… transform-set-name11*]

To remove the transform sets from the dynamic crypto map entry, specify the transform set name in the **no** form of this command:

no crypto dynamic-map *dynamic-map-name dynamic-seq-num* **set ikev1 transform-set** *transform-set-name1* [*… transform-set-name*11]

To remove the dynamic crypto map entry, use the **no** form of the command and specify all or none of the transform sets:

no crypto dynamic-map *dynamic-map-name dynamic-seq-num* **set ikev1 transform-set**

Syntax Description

dynamic-map-name	Specifies the name of the dynamic crypto map set.
dynamic-seq-num	Specifies the sequence number that corresponds to the dynamic crypto map entry.
transform-set-name1 *transform-set-name11*	Specifies one or more names of the transform sets. Any transform sets named in this command must be defined in the **crypto ipsec ikev1 transform-set** command. Each crypto map entry supports up to 11 transform sets.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0	This command was introduced.
7.2(1)	Changed the maximum number of transform sets in a crypto map entry.
8.4(1)	Added the **ikev1** keyword.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

A dynamic crypto map is a crypto map without all of the parameters configured. It acts as a policy template where the missing parameters are later dynamically learned, as the result of an IPsec negotiation, to match the peer requirements. The ASA applies a dynamic crypto map to let a peer negotiate a tunnel if its IP address is not already identified in a previous static or dynamic crypto map. This occurs with the following types of peers:

- Peers with dynamically assigned public IP addresses.

  Both LAN-to-LAN and remote access peers can use DHCP to obtain a public IP address. The ASA uses this address only to initiate the tunnel.

- Peers with dynamically assigned private IP addresses.

  Peers requesting remote access tunnels typically have private IP addresses assigned by the headend. Generally, LAN-to-LAN tunnels have a predetermined set of private networks that are used to configure static maps and therefore used to establish IPsec SAs.

As an administrator configuring static crypto maps, you might not know the IP addresses that are dynamically assigned (via DHCP or some other method), and you might not know the private IP addresses of other clients, regardless of how they were assigned. VPN clients typically do not have static IP addresses; they require a dynamic crypto map to allow IPsec negotiation to occur. For example, the headend assigns the IP address to a Cisco VPN client during IKE negotiation, which the client then uses to negotiate IPsec SAs.

Dynamic crypto maps can ease IPsec configuration and we recommend them for use in networks where the peers are not always predetermined. Use dynamic crypto maps for Cisco VPN clients (such as mobile users) and routers that obtain dynamically assigned IP addresses.

Tip Use care when using the **any** keyword in **permit** entries in dynamic crypto maps. If the traffic covered by such a **permit** entry could include multicast or broadcast traffic, insert **deny** entries for the appropriate address range into the access list. Remember to insert **deny** entries for network and subnet broadcast traffic, and for any other traffic that IPsec should not protect.

Dynamic crypto maps work only to negotiate SAs with remote peers that initiate the connection. The ASA cannot use dynamic crypto maps to initiate connections to a remote peer. With a dynamic crypto map configured, if the outbound traffic matches a permit entry in an access list and the corresponding SA does not yet exist, the ASA drops the traffic.

A crypto map set may include a dynamic crypto map. Dynamic crypto map sets should be the lowest priority crypto maps in the crypto map set (that is, they should have the highest sequence numbers) so that the ASA evaluates other crypto maps first. It examines the dynamic crypto map set only when the other (static) map entries do not match.

Similar to static crypto map sets, a dynamic crypto map set consists of all of the dynamic crypto maps with the same dynamic map name. The dynamic sequence number differentiates the dynamic crypto maps in a set. If you configure a dynamic crypto map, insert a permit ACL to identify the data flow of the IPsec peer for the crypto access list. Otherwise the ASA accepts any data flow identity the peer proposes.

Caution Do not assign static (default) routes for traffic to be tunneled to a ASA interface configured with a dynamic crypto map set. To identify the traffic that should be tunneled, add the ACLs to the dynamic crypto map. Use care to identify the proper address pools when configuring the ACLs associated with remote access tunnels. Use Reverse Route Injection to install routes only after the tunnel is up.

You can combine static and dynamic map entries within a single crypto map set.

Examples

The following example creates a dynamic crypto map entry named “dynamic0” consisting of the same ten transform sets.

```
hostname(config)# crypto dynamic-map dynamic0 1 set ikev1 transform-set 3des-md5 3des-sha
56des-md5 56des-sha 128aes-md5 128aes-sha 192aes-md5 192aes-sha 256aes-md5 256aes-sha
hostname(config)#
```

Related Commands

Command	Description
crypto ipsec ikev1 transform-set	Configures an IKEv1 transform set.
crypto map set transform-set	Specifies the transform sets to use in a crypto map entry.
clear configure crypto dynamic-map	Clears all dynamic crypto maps from the configuration.
show running-config crypto dynamic-map	Displays the dynamic crypto map configuration.
show running-config crypto map	Displays the crypto map configuration.

crypto dynamic-map set ikev2 ipsec-proposal

To specify the IPsec proposals for IKEv2 to use in a dynamic crypto map entry, use the **crypto dynamic-map set ikev2 ipsec-proposal** command in global configuration mode. To remove the names of the transform sets from a dynamic crypto map entry, use the **no** form of this command.

crypto dynamic-map *dynamic-map-name* **set ipsec-proposal** *transform-set-name1* [*… transform-set-name11*]

no crypto dynamic-map *dynamic-map-name* **set ipsec-proposal** *transform-set-name1* [*… transform-set-name11*]

Syntax Description

dynamic-map-name	Specifies the name of the dynamic crypto map set.
transform-set-name1 transform-set-name11	Specifies one or more names of the transform sets. Any transform sets named in this command must be defined in the **crypto ipsec ikev2 transform-set** command. Each crypto map entry supports up to 11 transform sets.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
8.4(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

crypto dynamic-map set ikev2 ipsec-proposal

To specify the IPsec proposals for IKEv2 to use in a dynamic crypto map entry, use the **crypto dynamic-map set ikev2 ipsec-proposal** command in global configuration mode. To remove the names of the transform sets from a dynamic crypto map entry, use the **no** form of this command.

crypto dynamic-map *dynamic-map-name* **set ipsec-proposal** *transform-set-name1* [*… transform-set-name11*]

no crypto dynamic-map *dynamic-map-name* **set ipsec-proposal** *transform-set-name1* [*… transform-set-name11*]

Syntax Description

dynamic-map-name	Specifies the name of the dynamic crypto map set.
transform-set-name1 *transform-set-name11*	Specifies one or more names of the transform sets. Any transform sets named in this command must be defined in the **crypto ipsec ikev2 transform-set** command. Each crypto map entry supports up to 11 transform sets.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
8.4(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

crypto dynamic-map set pfs

To set IPsec to ask for PFS when requesting new security associations for this dynamic crypto map entry or that IPsec requires PFS when receiving requests for new security associations, use the **crypto dynamic-map set pfs** command in global configuration mode. To specify that IPsec should not request PFS, use the **no** form of this command.

crypto dynamic-map *map-name map-index* **set pfs** [**group1 | group2 | group5 | group14 | group19 | group20 | group21 | group24**]

no crypto dynamic-map *map-name map-index* **set pfs**[**group1 | group2 | group5 | group14 | group19 | group20 | group21 | group24**]

Syntax Description

group1	Specifies that IPsec should use the 768-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
group2	Specifies that IPsec should use the 1024-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
group5	Specifies that IPsec should use the 1536-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
group14	Specifies which Diffie-Hellman key exchange group to use.
group19	Specifies which Diffie-Hellman key exchange group to use.
group20	Specifies which Diffie-Hellman key exchange group to use.
group21	Specifies which Diffie-Hellman key exchange group to use.
group24	Specifies which Diffie-Hellman key exchange group to use.
map-name	Specifies the name of the crypto map set.
map-index	Specifies the number you assign to the crypto map entry.

Defaults

By default, PFS is not set.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was modified to add Diffie-Hellman group 7.
8.0(4)	The **group 7** command option was deprecated. Attempts to configure group 7 will generate an error message and use group 5 instead.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

With PFS, every time a new security association is negotiated, a new Diffie-Hellman exchange occurs, which requires additional processing time. PFS adds another level of security because if one key is ever cracked by an attacker, only the data sent with that key is compromised.

crypto dynamic-map set tfc-packets

To enable dummy Traffic Flow Confidentiality (TFC) packets on an IPsec SA, use the **crypto dynamic-map set tfc-packets** command in global configuration mode. To disable TFC packets on an IPsec SA, use the **no** form of this command.

crypto dynamic-map *name priority* **set tfc-packets** [**burst length | auto**] [**payload-size bytes | auto**] [**timeout second | auto**]

no crypto dynamic-map *name priority* **set tfc-packets** [**burst length | auto**] [**payload-size bytes | auto**] [**timeout second | auto**]

Syntax Description

name	Specifies the name of the crypto map set.
priority	Specifies the priority that you assign to the crypto map entry.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

This command configures the existing DF policy (at an SA level) for the crypto map.

crypto dynamic-map set validate-icmp-errors

To specify whether to validate incoming ICMP error messages, received through an IPsec tunnel, that are destined for an interior host on the private network, use the **crypto dynamic-map set validate-icmp-errors** command in global configuration mode. To remove validation of incoming ICMP error messages from a crypto dynamic map entry, use the **no** form of this command.

crypto dynamic-map *name priority* **set validate-icmp-errors**

no crypto dynamic-map *name priority* **set validate-icmp-errors**

Syntax Description

name	Specifies the name of the crypto dynamic map set.
priority	Specifies the priority that you assign to the crypto dynamic map entry.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

This crypto map command is valid only for validating incoming ICMP error messages.

crypto engine accelerator-bias

To change the allocation of the cryptographic cores on Symmetric Multi-Processing (SMP) platforms, use the **crypto engine accelerator-bias** command in global configuration mode. To remove the command from the configuration, use the **no** form of this command.

crypto engine accelerator-bias [**balanced | ipsec | ssl**]

no crypto engine accelerator-bias [**balanced | ipsec | ssl**]

Syntax Description

balanced	Equally distributes cryptographic hardware resources (Admin/SSL and IPsec cores)
ipsec -client	Allocates cryptographic hardware resources to favor IPsec cores (includes SRTP encrypted voice traffic).
ssl-client	Allocates cryptographic hardware resources to favor Admin/SSL cores.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Cryptographic core rebalancing is available on the following platforms: ASA 5585, 5580, 5545/5555. and ASASM.

Examples

The following examples show the options available for configuring the crypto engine acccelerator-bias command:

```
hostname (config)# crypto engine ?

configure mode commands/options:
accelerator-bias
Specify how to allocate crypto accelerator processors

hostname (config)# crypto engine accelerator-bias ?
configure mode commands/options
balanced - Equally distribute crypto hardware resources
ipsec-client - Allocate crypto hardware resources to favor IPsec/Encrypted Voice (SRTP)
ssl-client - Allocate crypto hardware resources to favor SSL

hostname (config)# crypto engine accelerator-bias ssl
```

crypto engine large-mod-accel

To switch large modulus operations on an ASA 5510, 5520, 5540, or 5550 from software to hardware, use the **crypto engine large-mod-accel** command in global configuration mode. To remove the command from the configuration, use the **no** form of this command.

crypto engine large-mod-accel

no crypto engine large-mod-accel

Syntax Description

This command has no arguments or keywords.

Defaults

By default, the ASA performs large modulus operations in the software.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.3(2)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

This command is available only with the ASA models 5510, 5520, 5540, and 5550. It switches large modulus operations from software to hardware. The switch to hardware accelerates the following:

- 2048-bit RSA public key certificate processing.
- Diffie Hellman Group 5 (DH5) key generation.

We recommend that you use this command when necessary to improve the connections per second. Depending on the load, it might have a limited performance impact on SSL throughput.

We also recommend that you use either form of this command during a low-use or maintenance period to minimize a temporary packet loss that can occur during the transition of processing from software to hardware or hardware to software.

Note The ASA 5580/5500-X platforms already integrate this capability to switch large modulus operations; therefore, **crypto engine** commands are not applicable on these platforms.

Examples

The following example switches large modulus operations from software to hardware:

```
hostname(config)# crypto engine large-mod-accel
```

The following example removes the previous command from the configuration and switches large modulus operations back to software:

```
hostname(config)# no crypto engine large-mod-accel
```

Related Commands

Command	Description
show running-config crypto engine	Shows if large modulus operations are switched to hardware.
clear configure crypto engine	Returns large modulus operations to software. This command is equivalent to the **no crypto engine large-mod-accel** command.

crypto ikev1 enable

To enable ISAKMP IKEv1 negotiation on the interface on which the IPsec peer communicates with the ASA, use the **crypto ikev1 enable** command in global configuration mode. To disable ISAKMP IKEv1 on the interface, use the **no** form of this command.

crypto ikev1 enable *interface-name*

no crypto ikev1 enable *interface-name*

Syntax Description

interface-name	Specifies the name of the interface on which to enable or disable ISAKMP IKEv1 negotiation.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This **isakmp enable** command was introduced.
7.2(1)	The **crypto isakmp enable** command replaced the **isakmp enable** command.
8.4(1)	With the addition of IKEv2 capability, the **crypto isakmp enable** command was changed to the **crypto ikev1 enable** command.
9.0(1)	Support for multiple context mode was added.

Examples

The following example, entered in global configuration mode, shows how to disable ISAKMP on the inside interface:

```
hostname(config)# no crypto isakmp enable inside
```

Related Commands

Command	Description
clear configure crypto isakmp	Clears all the ISAKMP configuration.
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.

Command	Description
clear crypto isakmp sa	Clears the IKE runtime SA database.
show running-config crypto isakmp	Displays all the active configuration.

crypto ikev1 ipsec-over-tcp

To enable IPsec over TCP, use the **crypto ikev1 ipsec-over-tcp** command in global configuration mode. To disable IPsec over TCP, use the **no** form of this command.

crypto ikev1 ipsec-over-tcp [**port** *port1...port10*]

no crypto ikev1 ipsec-over-tcp [**port** *port1...port10*]

Syntax Description

port *port1...port10*	(Optional) Specifies the ports on which the device accepts IPsec over TCP connections. You can list up to 10 ports. Port numbers can be in the range of 1-65535. The default port number is 10000.

Defaults

The default value is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•		—

Command History

Release	Modification
7.0(1)	The **isakmp ipsec-over-tcp** command was introduced.
7.2.(1)	The **crypto isakmp ipsec-over-tcp** command replaced the **isakmp ipsec-over-tcp** command**.**
8.4(1)	The command name was changed from **crypto isakmp ipsec-over-tcp** to **crypto ikev1 ipsec-over-tcp**.

Examples

This example, entered in global configuration mode, enables IPsec over TCP on port 45:

```
hostname(config)# crypto ikev1 ipsec-over-tcp port 45
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto isakmp	Clears all the ISAKMP configuration.
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.
clear crypto isakmp sa	Clears the IKE runtime SA database.
show running-config crypto isakmp	Displays all the active configuration.

crypto ikev1 limit max-in-negotiation-sa

To limit the number of IKEv2 in-negotiation (open) SAs on the ASA, use the **crypto ikev1 limit max-in-negotiation-sa** command in global configuration mode. To disable limits on the number of open SAs, use the **no** form of this command:

crypto ikev1 limit max-in-negotiation-sa *threshold percentage*

no crypto ikev1 limit max-in-negotiation-sa *threshold percentage*

Syntax Description

threshold percentage	The percentage of the total allowed SAs for the ASA that are allowed to be in negotiation (open). After reaching the threshold, additional connections are denied. The range is 1 to 100%. The default is 100%.

Defaults

The default is disabled. The ASA does not limit the number of open SAs.

Usage Guidelines

The **crypto ikev1 limit-max-in-negotiation-sa** command limits the maximum number of SAs that can be in negotiation at any time. 1

The **crypto kev2 limit max in-negotiation-sa** command stops further connections from negotiating to protect current connections and prevent memory and/or CPU attacks that the cookie-challenge feature may be unable to thwart.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
9.1(2)	This command was introduced.

Examples

The following example limits the number of IKEv1 connections that are in negotation to 70 percent of the maximum allowable IKEv1 connections:

```
hostname(config)# crypto ikev1 limit max in-negotiation-sa 70
```

Related Commands

Command	Description
crypto ikev1 limit max-sa	Limits the number of IKEv1 connections on the ASA,
clear configure crypto isakmp	Clears all the ISAKMP configuration.
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.
clear crypto isakmp sa	Clears the IKE runtime SA database.
show running-config crypto isakmp	Displays all the active configuration.

crypto ikev1 policy

To create an IKEv1 security association (SA) for IPsec connections, use the **crypto ikev2 policy** command in global configuration mode. To remove the policy, use the **no** form of this command:

crypto ikev1 policy *priority*

no crypto ikev1 policy *priority*

Syntax Description

priority	The policy suite priority. The range is 1-65535, with 1 being the highest and 65535 the lowest

Defaults

There is no default behavior or values.

Usage Guidelines

The command enters IKEv1 policy configuration mode, in which you specify additional IKEv1 SA settings. An IKEv1 SA is a key used in phase 1 to enable IKEv1 peers to communicate securely in phase 2. After entering the **crypto ikev1 policy** command, you can use additional commands to set the SA encryption algorithm, DH group, integrity algorithm, lifetime, and hash algorithm.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
8.4(1)	This command was added.
9.0(1)	Support for multiple context mode was added.

Examples

The following example creates the priority 1 IKEv1 SA and enters enters IKEv1 policy configuration mode:

```
hostname(config)# crypto ikev1 policy 1
hostname(config-ikev2-policy)#
```

Related Commands

Command	Description
crypto ikev2 cookie-challenge	Enables the ASA to send cookie challenges to peer devices in response to SA initiate packets,
clear configure crypto isakmp	Clears all the ISAKMP configuration.
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.
clear crypto isakmp sa	Clears the IKE runtime SA database.
show running-config crypto isakmp	Displays all the active configuration.

crypto ikev2 enable

To enable ISAKMP IKEv2 negotiation on the interface on which the IPsec peer communicates with the ASA, use the **crypto ikev2 enable** command in global configuration mode. To disable ISAKMP IKEv2 on the interface, use the **no** form of this command.

crypto ikev2 enable *interface-name* [**client-services** [**port** *port*]]

no crypto ikev2 enable *interface-name* [**client-services** [**port** *port*]]

Syntax Description

interface-name	Specifies the name of the interface on which to enable or disable ISAKMP IKEv2 negotiation.
client-services	Enables client services for IKEv2 connections on the interface. Client services include enhanced Anyconnect Secure Mobility client features including software updates, client profiles, GUI localization (translation) and customization, Cisco Secure Desktop, and SCEP proxy. If you disable client services, the AnyConnect client still establishes basic IPsec connections with IKEv2.
port *port*	Specifies a port to enable client services for IKEv2 connections. The range is 1-65535. The default is port 443.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
8.4(1)	This command was added.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

Using this command alone will not enable client services.

Examples

The following example, entered in global configuration mode, shows how to enable IKEv2 on the outside interface:

```
hostname(config)# crypto ikev2 enable outside client-services port 443
```

Related Commands

Command	Description
clear configure crypto isakmp	Clears all the ISAKMP configuration.
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.
clear crypto isakmp sa	Clears the IKE runtime SA database.
show running-config crypto isakmp	Displays all the active configuration.

crypto ikev2 cookie-challenge

To enable the ASA to send cookie challenges to peer devices in response to SA initiate packets, use the **crypto ikev2 cookie-challenge** command in global configuration mode. To disable cookie challenges, use the **no** form of this command:

crypto ikev2 cookie-challenge *threshold percentage* | **always** | **never**

no crypto ikev2 cookie-challenge *threshold percentage* | **always** | **never**

Syntax Description

threshold percentage	The percentage of the total allowed SAs for the ASA that are in negotiation, which triggers cookie challenges for any future SA negotiations. The range is zero to 99%. The default is 50%.
always	Always cookie-challenges incoming SAs.
never	Never cookie-challenges incoming SAs.

Defaults

No default behavior or values.

Usage Guidelines

Cookie challenging a peer prevents possible denial-of-service (DoS) attacks. An attacker initiates a DoS attack when the peer device sends an SA initiate packet and the ASA sends its response, but the peer device does not respond further. If the peer device does this continually, all the allowed SA requests on the ASA can be used up until it stops responding.

Enabling a threshold percentage using the **crypto ikev2 cookie-challenge** command limits the number of open SA negotiations. For example, with the default setting of 50%, when 50% of the allowed SAs are in negotiation (open), the ASA cookie-challenges any additional SA initiate packets that arrive. For the Cisco ASA 5580 with 10000 allowed IKEv2 SAs, after 5000 SAs have become open, any more incoming SAs are cookie-challenged.

If used in conjunction with the **crypto kev2 limit max in-negotiation-sa** command, configure the cookie-challenge threshold lower than the maximum in-negotiation threshold for an effective cross-check.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
8.4(1)	This command was added.
9.0(1)	Support for multiple context mode was added.

Examples

In the following example, the cookie-challenge threshold is set to 30%:

```
hostname(config)# crypto ikev2 cookie-challenge 30
```

Related Commands

Command	Description
crypto ikev2 limit max-sa	Limits the number of IKEv2 connections on the ASA,
crypto ikev2 limit max-in-negotiation-sa	Limits the number of IKEv2 in-negotiation (open) SAs on the ASA.
clear configure crypto isakmp	Clears all the ISAKMP configuration.
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.
clear crypto isakmp sa	Clears the IKE runtime SA database.
show running-config crypto isakmp	Displays all the active configuration.

crypto ikev2 limit max-in-negotiation-sa

To limit the number of IKEv2 in-negotiation (open) SAs on the ASA, use the **crypto ikev2 limit max in-negotiation-sa** command in global configuration mode. To disable limits on the number of open SAs, use the **no** form of this command:

crypto ikev2 limit max in-negotiation-sa *threshold percentage*

no crypto ikev2 limit max in-negotiation-sa *threshold percentage*

Syntax Description

threshold percentage	The percentage of the total allowed SAs for the ASA that are allowed to be in negotiation (open). After reaching the threshold, additional connections are denied. The range is 1 to 100%. The default is 100%.

Defaults

The default is disabled. The ASA does not limit the number of open SAs.

Usage Guidelines

The **crypto ikev2 limit-max-in-negotiation-sa** command limits the maximum number of SAs that can be in negotiation at any time. If used in conjunction with the **crypto ikev2 cookie-challenge** command, configure the cookie-challenge threshold lower than this limit for an effective cross-check.

Unlike the **crypto ikev2 cookie-challenge** command which challenges incoming connections with a cookie, the **crypto kev2 limit max in-negotiation-sa** command stops further connections from negotiating to protect current connections and prevent memory and/or CPU attacks that the cookie-challenge feature may be unable to thwart.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
8.4(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Examples

The following example limits the number of IKEv2 connections that are in negotation to 70 percent of the maximum allowable IKEv2 connections:

```
hostname(config)# crypto ikev2 limit max in-negotiation-sa 70
```

Related Commands

Command	Description
crypto ikev2 limit max-sa	Limits the number of IKEv2 connections on the ASA,
crypto ikev2 cookie-challenge	Enables the ASA to send cookie challenges to peer devices in response to SA initiated packets,

clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.
clear crypto isakmp sa	Clears the IKE runtime SA database.
show running-config crypto isakmp	Displays all the active configuration.

crypto ikev2 limit max-sa

To limit the number of IKEv2 connections on the ASA, use the **crypto ikev2 limit max-sa** command in global configuration mode. To disable the limit on the number of connections, use the **no** form of this command:

crypto ikev2 limit max-sa *number*

no crypto ikev2 limit max-sa *number*

Syntax Description

number	The number of IKEv2 connections allowed on the ASA. After reaching the limit, additional connections are denied. The range is 1 to 10000.

Defaults

The default is disabled. The ASA does not limit the number of IKEv2 connections. The maximum number of allowed IKEv2 connections equals the maximum number of connections specified by the license.

Usage Guidelines

The **crypto ikev2 limit max-sa** command limits the maximum number of SAs on the ASA.

If used in conjunction with the **crypto ikev2 cookie-challenge** command, configure the cookie-challenge threshold lower than this limit for an effective cross-check.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
8.4(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Examples

The following example limits the number of IKEv2 connections to 5000:

```
hostname(config)# crypto ikev2 limit max-sa 5000
```

Related Commands

Command	Description
crypto ikev2 cookie-challenge	Enables the ASA to send cookie challenges to peer devices in response to SA initiated packets,
clear configure crypto isakmp	Clears all the ISAKMP configuration.
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.
clear crypto isakmp sa	Clears the IKE runtime SA database.
show running-config crypto isakmp	Displays all the active configuration.

crypto ikev2 policy

To create an IKEv2 security association (SA) for AnyConnect IPsec connections, use the **crypto ikev2 policy** command in global configuration mode. To remove the policy, use the **no** form of this command:

crypto ikev2 policy *priority policy_index*

no crypto ikev2 policy *priority policy_index*

Syntax Description

policy index	Accesses the IKEv2 policy configuration mode.
priority	The policy suite priority. The range is 1-65535, with 1 being the highest and 65535 the lowest. Group [1] [2] [5] becomes group [1] [2] [5] [14] [24] to support Diffie-Hellman groups 14 and 24 as part of IKEv2 key derivation.

Defaults

Nodefault behavior or values.

Usage Guidelines

An IKEv2 SA is a key used in phase 1 to enable IKEv2 peers to communicate securely in phase 2. After entering the **crypto ikev2 policy** command, you enter IKEv2 policy configuration mode, in which you specify additional IKEv2 SA settings. You can use additional commands to set the SA encryption algorithm, DH group, integrity algorithm, lifetime, and hash algorithm.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
8.4(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added. Added policy index option.

Examples

The following example creates the priority 1 IKEv2 SA and enters enters IKEv2 policy configuration mode:

```
hostname(config)# crypto ikev2 policy 1
hostname(config-ikev2-policy)#
```

Related Commands

Command	Description
crypto ikev2 cookie-challenge	Enables the ASA to send cookie challenges to peer devices in response to SA initiated packets,
clear configure crypto isakmp	Clears all the ISAKMP configuration.
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.
clear crypto isakmp sa	Clears the IKE runtime SA database.
show running-config crypto isakmp	Displays all the active configuration.

crypto ikev2 redirect

To specify the IKEv2 phase at which load-balancing redirection from master to cluster member occurs, use the **crypto ikev2 redirect** command in global configuration mode. To remove the command, use the **no** form of this command:

crypto ikev2 redirect {**during-init** | **during-auth**}

no crypto ikev2 redirect {**during-init** | **during-auth**}

Syntax Description

during-auth	Enables load-balancing redirection to a cluster member during the IKEv2 authentication exchange.
during-init	Enables load-balancing redirection to a cluster member during the IKEv2 SA initiated exchange.

Defaults

The default is load-balancing redirection to a cluster member, which occurs during the IKEv2 authentication exchange.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•		—

Command History

Release	Modification
8.4(1)	This command was introduced.

Examples

The following example sets the load-balancing redirection to a cluster member to occur during the IKEv2 initiated exchange:

```
hostname(config)# crypto ikev2 redirect during-init
```

Related Commands

Command	Description
crypto ikev2 cookie-challenge	Enables the ASA to send cookie challenges to peer devices in response to SA initiated packets,
clear configure crypto isakmp	Clears all the ISAKMP configuration.
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.

Command	Description
clear crypto isakmp sa	Clears the IKE runtime SA database.
show running-config crypto isakmp	Displays all the active configuration.

crypto ikev2 remote-access trust-point

To specify a global trustpoint to be referenced and used as the identity certificate trustpoint of the ASA for AnyConnect IKEv2 connections, use the **crypto ikev2 remote-access trust-point** command in tunnel group configuration mode. To remove the command from the configuration, use the **no** form of the command:

crypto ikev2 remote-access trust-point *name* [*line number*]

no crypto ikev2 remote-access trust-point *name* [*line number*]

Syntax Description

name	The name of the trustpoint, up to 65 characters.
line number	Specifies where in the line number you want the trustpoint inserted. Typically, this option is used to insert a trustpoint at the top without removing and readding the other line. If a line is not specified, the ASA adds the trustpoint at the end of the list.

Defaults

No default behavior or values.

Usage Guidelines

Use the **crypto ikev2 remote-access trust-point** command to configure a trustpoint for the ASA to authenticate itself to the AnyConnect client for all IKEv2 connections. Using this command allows the AnyConnect client to support group selection for the user.

You can configure two trustpoints at the same time: two RSA, two ECDSA, or one of each. The ASA scans the configured trustpoint list and chooses the first one that the client supports. If ECDSA is preferred, you should configure that trustpoint before the RSA trustpoint.

If you try to add a trustpoint that already exists, you receive an error. If you use the **no crypto ikev2 remote-access trustpoint** command without specifying which trustpoint name to remove, all trustpoint configuration is removed.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group configuration	•	—	•	•	—

Command History

Release	Modification
8.4(1)	This command was introduced.
9.0(1)	Support for multiple context mode and the configuration of two trustpoints were added.

Examples

The following example specifies the trustpoint *cisco_asa_trustpoint*:

```
hostname(config)# crypto ikev2 remote-access trust-point cisco_asa_trustpoint
```

crypto ipsec df-bit

To configure DF-bit policy for IPsec packets, use the **crypto ipsec df-bit** command in global configuration mode.

crypto ipsec df-bit [**clear-df** | **copy-df** | **set-df**] *interface*

Syntax Description

clear-df	(Optional) Specifies that the outer IP header will have the DF bit cleared and that the ASA may fragment the packet to add the IPsec encapsulation.
copy-df	(Optional) Specifies that the ASA will look in the original packet for the outer DF bit setting.
set-df	(Optional) Specifies that the outer IP header will have the DF bit set; however, the ASA may fragment the packet if the original packet had the DF bit cleared.
interface	Specifies an interface name.

Defaults

This command is disabled by default. If this command is enabled without a specified setting, the ASA uses the **copy-df** setting as the default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

The DF bit with IPsec tunnels feature lets you specify whether or not the ASA can clear, set, or copy the Don't Fragment (DF) bit from the encapsulated header. The DF bit within the IP header determines whether or not a device is allowed to fragment a packet.

Use the **crypto ipsec df-bit** command in global configuration mode to configure the ASA to specify the DF bit in an encapsulated header. This command treats the DF-bit setting of the clear-text packet and either clears, set, or copies it to the outer IPsec header when encryption is applied.

When encapsulating tunnel mode IPsec traffic, use the **clear-df** setting for the DF bit. This setting lets the device send packets larger than the available MTU size. Also, this setting is appropriate if you do not know the available MTU size.

Caution Packets will get dropped if you set the following conflicting configuration:
crypto ipsec fragmentation after-encryption (fragment packets)
crypto ipsec df-bit set-df outside (set the DF bit)

Examples

The following example, entered in global configuration mode, sets the IPsec DF policy to **clear-df**:

```
hostname(config)# crypto ipsec df-bit clear-df outside
hostname(config)#
```

Related Commands

Command	Description
crypto ipsec fragmentation	Configures the fragmentation policy for IPsec packets.
show crypto ipsec df-bit	Displays the DF-bit policy for a specified interface.
show crypto ipsec fragmentation	Displays the fragmentation policy for a specified interface.

crypto ipsec fragmentation

To configure the fragmentation policy for IPsec packets, use the **crypto ipsec fragmentation** command in global configuration mode.

crypto ipsec fragmentation {**after-encryption** | **before-encryption**} *interface*

Syntax Description

after-encryption	Specifies the ASA to fragment IPsec packets that are close to the maximum MTU size after encryption (disables prefragmentation).
before-encryption	Specifies the ASA to fragment IPsec packets that are close to the maximum MTU size before encryption (enables prefragmentation).
interface	Specifies an interface name.

Defaults

Before-encryption is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

When a packet is near the size of the MTU of the outbound link of the encrypting ASA, and it is encapsulated with IPsec headers, it is likely to exceed the MTU of the outbound link. This causes packet fragmentation after encryption, which makes the decrypting device reassemble in the process path. Prefragmentation for IPsec VPNs increases the performance of the device when decrypting by letting it operate in the high performance CEF path instead of the process path.

Prefragmentation for IPsec VPNs lets an encrypting device predetermine the encapsulated packet size from information available in transform sets, which are configured as part of the IPsec SA. If the device predetermines that the packet will exceed the MTU of the output interface, the device fragments the packet before encrypting it. This avoids process level reassembly before decryption and helps improve decryption performance and overall IPsec traffic throughput.

The minimum MTU allowed on an IPv6 enabled interface is 1280 bytes; however, if IPsec is enabled on the interface, the MTU value should not be set below 1380 because of the overhead of IPsec encryption. Setting the interface below 1380 bytes may result in dropped packets.

Caution Packets will get dropped if you set the following conflicting configuration:
crypto ipsec fragmentation after-encryption (fragment packets)
crypto ipsec df-bit set-df outside (set the DF bit)

Examples

The following example, entered in global configuration mode, enables prefragmentation for IPsec packets globally on the device:

```
hostname(config)# crypto ipsec fragmentation before-encryption inside
hostname(config)#
```

The following example, entered in global configuration mode, disables prefragmentation for IPsec packets on the interface:

```
hostname(config)# crypto ipsec fragmentation after-encryption inside
hostname(config)#
```

Related Commands

Command	Description
crypto ipsec df-bit	Configures the DF-bit policy for IPsec packets.
show crypto ipsec fragmentation	Displays the fragmentation policy for IPsec packets.
show crypto ipsec df-bit	Displays the DF-bit policy for a specified interface.

crypto ipsec security-association pmtu-aging

To enable path maximum transfer unit (PMTU) aging, use the **crypto ipsec security-association pmtu-aging** command in global configuration mode. To disable PMTU aging, use the no form of the command:

crypto ipsec security-association pmtu-aging *reset-interval*

[no] crypto ipsec security-association pmtu-aging *reset-interval*

Syntax Description

reset-interval	Sets the interval at which the PMTU value is reset.

Defaults

This feature is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The reset interval is specified in seconds.

crypto ipsec ikev2 ipsec-proposal

To create an IKEv2 proposal, use the **crypto ipsec ikev2 ipsec-proposal** command in global configuration mode.To remove the proposal, use the **no** form of this command.

crypto ipsec ikev2 ipsec-proposal *proposal tag proposal_name*

no crypto ipsec ikev2 ipsec-proposal *proposal tag proposal_name*

Syntax Description

proposal name	Accesses the IPsec ESP proposal sub-mode.
proposal tag	The name of the IKEv2 IPsec proposal, a string from 1 to 64 characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.4(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

This command creates a proposal and enters ipsec proposal configuration mode, in which you can specify multiple encryption and integrity types for the proposal.

Examples

The following example creates the IPsec proposal named secure, and enters IPsec proposal configuration mode:

```
hostname(config)# crypto ipsec ikev2 ipsec-proposal secure
hostname(config-ipsec-proposal)#
```

Related Commands

Command	Description
show running-config ipsec	Displays the configuration of all transform sets.
crypto map set transform-set	Specifies the transform sets to use in a crypto map entry.
crypto dynamic-map set transform-set	Specifies the transform sets to use in a dynamic crypto map entry.

Command	Description
show running-config crypto map	Displays the crypto map configuration.
show running-config crypto dynamic-map	Displays the dynamic crypto map configuration.

crypto ipsec ikev2 sa-strength-enforcement

Ensures that the strength of the IKEv2 encryption cipher is higher than the strength of its child IPsec SA's encryption ciphers. To disable this feature, use the **no** form of this command.

crypto ipsec ikev2 sa-strength-enforcement

no crypto ipsec ikev2 sa-strength-enforcement

Defaults

Enforcement is on by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.1(2)	This command was introduced.

Usage Guidelines

Security is not increased when a child SA has a stronger encryption cipher than its parent IKEv2 connection. It is good security practice to configure the IPsec so this does not happen. The strength enforcement setting only affects the encryption cipher; it does not alter the integrity or key exchange algorithms. The IKEv2 system compares the relative strength of each child SA's selected encryption cipher as follows:

When enabled, verifies that the configured encryption cipher for the child SA is not stronger than the parent IKEv2 encryption cipher. If found, then the child SA will be updated to use the parent cipher. If no compatible cipher is found, then the child SA negotiation is be aborted. The syslog and debug message logs these actions.

The supported encryption ciphers are listed below in order of strength, from highest to lowest. Ciphers on the same line have equivalent strength for purposes of this check.

- AES-GCM-256, AES-CBC-256
- AES-GCM-192, AES-CBC, 192
- AES-GCM-128, AES-CBC-128
- 3DES
- DES
- AES-GMAC (any size), NULL

Related Commands

Command	Description
show running-config ipsec	Displays crypto ipsec ikev2 sa-strength-enforcement when enabled.

crypto ipsec security-association lifetime

To configure global lifetime values, use the **crypto ipsec security-association lifetime** command in global configuration mode. To reset a global lifetime value to the default value, use the **no** form of this command.

crypto ipsec security-association lifetime {**seconds** *seconds* | **kilobytes** *kilobytes*}

no crypto ipsec security-association lifetime {**seconds** *seconds* | **kilobytes** *kilobytes*}

Syntax Description

kilobytes	Specifies the volume of traffic (in kilobytes) that can pass between peers using a given security association before that security association expires. The range is 10 to 2147483647 kbytes. The default is 4,608,000 kilobytes.
seconds	Specifies the number of seconds a security association will live before it expires. The range is 120 to 214783647 seconds. The default is 28,800 seconds (eight hours).

Defaults

The default number of kilobytes is 4,608,000; the default number of seconds is 28,800.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

The **crypto ipsec security-association lifetime** command changes global lifetime values used when negotiating IPsec security associations.

IPsec security associations use shared secret keys. These keys and their security associations time out together.

Assuming that the particular crypto map entry has no lifetime values configured, when the ASA requests new security associations during negotiation, it specifies its global lifetime value in the request to the peer; it uses this value as the lifetime of the new security associations. When the ASA receives a negotiation request from the peer, it uses the smaller of the lifetime values proposed by the peer or the locally configured lifetime value as the lifetime of the new security associations.

There are two lifetimes: a “timed” lifetime and a “traffic-volume” lifetime. The security association expires after the first of these lifetimes is reached.

The ASA lets the user change crypto map, dynamic map, and IPsec settings on the fly. If this is changed, the ASA brings down only the connections affected by the change. If the user changes an existing access list associated with a crypto map, specifically by deleting an entry within the access list, the result is that only the associated connection is brought down. Connections based on other entries in the access list are not affected.

To change the global timed lifetime, use the **crypto ipsec security-association lifetime seconds** command. The timed lifetime causes the security association to time out after the specified number of seconds have passed.

To change the global traffic-volume lifetime, use the **crypto ipsec security-association lifetime kilobytes** command. The traffic-volume lifetime causes the security association to time out after the specified amount of traffic (in kilobytes) has been protected by the security associations' key.

Shorter lifetimes can make it harder to mount a successful key recovery attack, because the attacker has less data encrypted under the same key to work with. However, shorter lifetimes require more CPU processing time for establishing new security associations.

The security association (and corresponding keys) expires according to whichever occurs sooner, either after the number of seconds has passed or after the amount of traffic in kilobytes has passed.

Examples

The following example specifies a global timed lifetime for security associations:

```
hostname(config)# crypto ipsec-security association lifetime seconds 240
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto map	Clears all IPsec configuration (that is, global lifetimes and transform sets).
show running-config crypto map	Displays all configuration for all the crypto maps.

crypto ipsec security-association replay

To configure the IPsec antireplay window size, use the **crypto ipsec security-association replay** command in global configuration mode. To reset the window size to the default value, use the **no** form of this command.

crypto ipsec security-association replay {**window-size** *n* | **disable**}

no crypto ipsec security-association replay {**window-size** *n* | **disable**}

Syntax Description

n	Sets the window size. Values can be 64, 128, 256, 512, or 1024. The default is 64.
disable	Disables antireplay checking.

Defaults

The default window size is 64.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.2(4)/8.0(4)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

Cisco IPsec authentication provides antireplay protection from an attacker duplicating encrypted packets by assigning a unique sequence number to each encrypted packet. (Security association antireplay is a security service in which the receiver can reject old or duplicate packets to protect itself from replay attacks.) The decryptor checks off the sequence numbers that it has seen before. The encryptor assigns sequence numbers in an increasing order. The decryptor remembers the value X of the highest sequence number that it has already seen. N is the window size, and the decryptor also remembers whether it has seen packets having sequence numbers from X-N+1 through X. Any packet with the sequence number X-N is discarded. Currently, N is set at 64, so only 64 packets can be tracked by the decryptor.

At times, however, the 64-packet window size is not sufficient. For example, QoS gives priority to high-priority packets, which could cause some low-priority packets to be discarded even though they could be one of the last 64 packets received by the decryptor; this event can generate warning syslog messages that are false alarms. The **crypto ipsec security-association replay** command lets you expand the window size, allowing the decryptor to keep track of more than 64 packets.

Increasing the antireplay window size has no impact on throughput and security. The impact on memory is insignificant because only an extra 128 bytes per incoming IPsec SA is needed to store the sequence number on the decryptor. It is recommended that you use the full 1024 window size to eliminate any future antireplay problems.

Examples

The following example specifies the antireplay window size for security associations:

```
hostname(config)# crypto ipsec security-association replay window-size 1024
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto map	Clears all IPsec configuration (that is, global lifetimes and transform sets).
shape	Enables traffic shaping.
priority	Enables priority queueing.
show running-config crypto map	Displays all configuration for all the crypto maps.

crypto ipsec ikev1 transform-set

To create or remove an IKEv1 transform set, use the **crypto ipsec ikev1 transform-set** command in global configuration mode. To remove a transform set, use the **no** form of this command.

crypto ipsec ikev1 transform-set *transform-set-name encryption* [*authentication*]

no crypto ipsec ikev1 transform-set *transform-set-name encryption* [*authentication*]

Syntax Description

authentication	(Optional) Specify one of the following authentication methods to ensure the integrity of IPsec data flows: **esp-md5-hmac** to use the MD5/HMAC-128 as the hash algorithm. **esp-sha-hmac** to use the SHA/HMAC-160 as the hash algorithm. **esp-none** to not use HMAC authentication.
encryption	Specify one of the following encryption methods to protect IPsec data flows: **esp-aes** to use AES with a 128-bit key. **esp-aes-192** to use AES with a 192-bit key. **esp-aes-256** to use AES with a 256-bit key. **esp-des** to use 56-bit DES-CBC. **esp-3des** to use triple DES algorithm. **esp-null** to not use encryption.
transform-set-name	Name of the transform set being created or modified. To view the transform sets already present in the configuration, enter the **show running-config ipsec** command.

Defaults

The default authentication setting is esp-none (no authentication).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0	This command was introduced.
7.2(1)	This section was rewritten.
8.4(1)	The **ikev1** keyword was added.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

This command identifes the IPsec encryption and hash algorithms to be used by the transform set.

Following the configuration of a transform set, you assign it to a crypto map. You can assign up to six transform sets to a crypto map. When the peer attempts to establish an IPsec session, the ASA evaluates the peer using the access list of each crypto map until it finds a match. The ASA then evaluates all of the protocols, algorithms, and other settings negotiated by the peer using those in the transform sets assigned to the crypto map until it finds a match. If the ASA matches the peer's IPsec negotiations to the settings in a transform set, it applies them to the protected traffic as part of its IPsec security association. The ASA terminates the IPsec session if it fails to match the peer to an access list and find an exact match of the security settings of the peer to those in a transform set assigned to the crypto map.

You can specify either the encryption or the authentication first. You can specify the encryption without specifying the authentication. If you specify the authentication in a transform set that you are creating, you must specify the encryption with it. If you specify only the authentication in a transform set that you are modifying, the transform set retains its current encryption setting.

If you are using AES encryption, we recommend that you use the **isakmp policy priority group 5** command, also in in global configuration mode, to assign Diffie-Hellman group 5 to accommodate the large key sizes provided by AES.

Tip When you apply transform sets to a crypto map or a dynamic crypto map and view the transform sets assigned to it, you will find it helpful if the names of the transform sets reflect their configuration. For example, the name "3des-md5" in the first example below shows the encryption and authentication used in the transform set. The values that follow the name are the actual encryption and authentication settings assigned to the transform set.

Examples

The following commands show all possible encryption and authentication options, excluding those that specify no encryption and no authentication:

```
hostname(config)# crypto ipsec ikev1 transform-set 3des-md5 esp-3des esp-md5-hmac
hostname(config)# crypto ipsec ikev1 transform-set 3des-sha esp-3des esp-sha-hmac
hostname(config)# crypto ipsec ikev1 transform-set 56des-md5 esp-des esp-md5-hmac
hostname(config)# crypto ipsec ikev1 transform-set 56des-sha esp-des esp-sha-hmac
hostname(config)# crypto ipsec ikev1 transform-set 128aes-md5 esp-aes esp-md5-hmac
hostname(config)# crypto ipsec ikev1 transform-set 128aes-sha esp-aes esp-sha-hmac
hostname(config)# crypto ipsec ikev1 transform-set 192aes-md5 esp-aes-192 esp-md5-hmac
hostname(config)# crypto ipsec ikev1 transform-set 192aes-sha esp-aes-192 esp-sha-hmac
hostname(config)# crypto ipsec ikev1 transform-set 256aes-md5 esp-aes-256 esp-md5-hmac
hostname(config)# crypto ipsec ikev1 transform-set 256aes-sha esp-aes-256 esp-sha-hmac
hostname(config)#
```

Related Commands

Command	Description
show running-config ipsec	Displays the configuration of all transform sets.
crypto map set transform-set	Specifies the transform sets to use in a crypto map entry.
crypto dynamic-map set transform-set	Specifies the transform sets to use in a dynamic crypto map entry.
show running-config crypto map	Displays the crypto map configuration.
show running-config crypto dynamic-map	Displays the dynamic crypto map configuration.

crypto ipsec ikev1 transform-set mode transport

To specify the transport mode for IPsec IKEv1 connections, use the **crypto ipsec ikev1 transform-set mode transport** command in global configuration mode. To remove the command, use the **no** form of this command:

crypto ipsec ikev1 transform-set *transform-set-name* **mode** {**transport**}

no crypto ipsec ikev1 transform-set *transform-set-name* **mode** {**transport**}

Syntax Description

transform-set-name	Name of the transform set being modified. To view the transform sets already present in the configuration, enter the **show running-config ipsec** command.

Defaults

The default setting for the transport mode is disabled. IPsec uses the networked tunnel mode.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	This command was rewritten.
8.4(1)	The **ikev1** keyword was added.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

Use the **crypto ipsec ikev1 transform-set mode transport** command to specify the host-to-host transport mode for IPsec, instead of the default networked tunnel mode.

Examples

The following commands show all possible encryption and authentication options, excluding those that specify no encryption and no authentication:

```
hostname(config)# crypto ipsec ikev1 transform-set
hostname(config)#
```

Related Commands

show running-config crypto map	Displays the crypto map configuration.
show running-config crypto dynamic-map	Displays the dynamic crypto map configuration.

CHAPTER 12

crypto isakmp disconnect-notify through cxsc auth-proxy port Commands

crypto isakmp disconnect-notify

To enable disconnect notification to peers, use the **crypto isakmp disconnect-notify** command in global configuration mode. To disable disconnect notification, use the **no** form of this command.

crypto isakmp disconnect-notify

no crypto isakmp disconnect-notify

Syntax Description

This command has no arguments or keywords.

Defaults

The default value is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	The **isakmp disconnect-notify** command was introduced.
7.2.(1)	The **crypto isakmp disconnect-notify** command replaced the **isakmp disconnect-notify** command**.**
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

You can enable disconnect notifications to peers with the use of the following delete reasons:

- IKE_DELETE_RESERVED = 0
  An invalid code. Do not send.
- IKE_DELETE_BY_ERROR = 1
  A transmission error for a timeout or failure when expecting a response to a keepalive or any other IKE packet ACK. The default text is “Connectivity to client lost.”
- IKE_DELETE_BY_USER_COMMAND = 2
  The SA was actively deleted with manual intervention by the user or administrator. The default text is “Manually Disconnected by Administrator.”
- IKE_DELETE_BY_EXPIRED_LIFETIME = 3
  The SA has expired. The default text is “Maximum Configured Lifetime Exceeded.”
- IKE_DELETE_NO_ERROR = 4
  An unknown error caused the delete.
- IKE_DELETE_SERVER_SHUTDOWN = 5
  The server is being shut down.

- IKE_DELETE_SERVER_IN_FLAMES = 6
  The server has some severe problems. The default text is “Peer is having heat problems.”
- IKE_DELETE_MAX_CONNECT_TIME = 7
  The maximum allowed time of an active tunnel has expired. Unlike EXPIRED_LIFETIME, this reason indicates that the entire IKE-negotiated/controlled tunnel is being disconnected, not just this one SA. The default text is “Maximum Configured Connection Time Exceeded.”
- IKE_DELETE_IDLE_TIMEOUT = 8
  The tunnel has been idle for the maximum allowed time; therefore, the entire IKE-negotiated tunnel has been disconnected, not just this one SA. The default text is “Maximum Idle Time for Session Exceeded.”
- IKE_DELETE_SERVER_REBOOT = 9
  The server is rebooting.
- IKE_DELETE_P2_PROPOSAL_MISMATCH = 10
  Phase2 proposal mismatch.
- IKE_DELETE_FIREWALL_MISMATCH = 11
  Firewall parameter mismatch.
- IKE_DELETE_CERT_EXPIRED = 12
  User certification required. The default message is “User or Root Certificate has Expired.”
- IKE_DELETE_CLIENT_NOT_ALLOWED = 13
  Client type or version not allowed.
- IKE_DELETE_FW_SERVER_FAIL = 14
  Failed to contact Zone Integrity Server.
- IKE_DELETE_ACL_ERROR = 15
  ACL downloaded from AAA cannot be inserted. The default message is “ACL parsing error.”

Examples

The following example, entered in global configuration mode, enables disconnect notification to peers:

```
hostname(config)# crypto isakmp disconnect-notify
```

Related Commands

Command	Description
clear configure crypto isakmp	Clears all the ISAKMP configuration.
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.
clear crypto isakmp sa	Clears the IKE runtime SA database.
show running-config crypto isakmp	Displays all the active configuration.

crypto isakmp identity

To set the Phase 1 ID to be sent to the peer, use the **crypto isakmp identity** command in global configuration mode. To return to the default setting, use the **no** form of this command.

crypto isakmp identity {**address** | **hostname** | **key-id** *key-id-string* | **auto**}

no crypto isakmp identity {**address** | **hostname** | **key-id** *key-id-string* | **auto**}

Syntax Description

address	Uses the IP address of the host exchanging ISAKMP identity information.
auto	Determines ISAKMP negotiation by connection type; IP address for preshared key or cert DN for certificate authentication.
hostname	Uses the fully qualified domain name of the host exchanging ISAKMP identity information (default). This name comprises the hostname and the domain name.
key-id *key_id_string*	Specifies the string used by the remote peer to look up the preshared key.

Defaults

The default ISAKMP identity is **crypto isakmp identity auto**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	The **isakmp identity** command was introduced.
7.2(1)	The **crypto isakmp identity** command replaced the **isakmp identity** command.
9.0(1)	Support for multiple context mode was added.

Examples

The following example, entered in global configuration mode, enables ISAKMP negotiation on the interface for communicating with the IPsec peer, depending on connection type:

```
hostname(config)# crypto isakmp identity auto
```

Related Commands

Command	Description
clear configure crypto isakmp	Clears all the ISAKMP configuration.
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.
clear crypto isakmp sa	Clears the IKE runtime SA database.
show running-config crypto isakmp	Displays all the active configuration.

crypto isakmp nat-traversal

To enable NAT traversal globally, check that ISAKMP is enabled (you enable it with the **crypto isakmp enable** command) in global configuration mode. To disable the NAT traversal, use the **no** form of this command.

crypto isakmp nat-traversal *natkeepalive*

no crypto isakmp nat-traversal *natkeepalive*

Syntax Description

natkeepalive	Sets the NAT keep alive interval, from 10 to 3600 seconds. The default is 20 seconds.

Defaults

By default, NAT traversal is enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	The **isakmp nat-traversal** command was introduced.
7.2.(1)	The **crypto isakmp nat-traversal** command replaced the **isakmp nat-traversal** command**.**
8.0(2)	NAT traversal is enabled by default.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

NAT including PAT is used in many networks where IPsec is also used, but there are a number of incompatibilities that prevent IPsec packets from successfully traversing NAT devices. NAT traversal enables ESP packets to pass through one or more NAT devices.

The ASA supports NAT traversal as described by Version 2 and Version 3 of the IETF "UDP Encapsulation of IPsec Packets" draft, available at http://www.ietf.org/html.charters/ipsec-charter.html, and supports NAT traversal for both dynamic and static crypto maps.

This command enables NAT-T globally on the ASA. To disable in a crypto-map entry, use the **crypto map set nat-t-disable** command.

Examples

The following example, entered in global configuration mode, enables ISAKMP and then sets NAT traversal with a keepalive interval of 30 seconds:

```
hostname(config)# crypto isakmp enable
```

```
hostname(config)# crypto isakmp nat-traversal 30
```

Related Commands

Command	Description
clear configure crypto isakmp	Clears all the ISAKMP configuration.
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.
clear crypto isakmp sa	Clears the IKE runtime SA database.
show running-config crypto isakmp	Displays all the active configuration.

crypto isakmp policy authentication

To specify an authentication method within an IKE policy, use the **crypto isakmp policy authentication** command in global configuration mode. To remove the ISAKMP authentication method, use the related **clear configure** command.

crypto isakmp policy *priority* **authentication** {**crack** | **pre-share** | **rsa-sig**}

Syntax Description

crack	Specifies IKE CRACK as the authentication method.
pre-share	Specifies preshared keys as the authentication method.
priority	Uniquely identifies the IKE policy and assigns a priority to the policy. Use an integer from 1 to 65,534, with 1 being the highest priority and 65,534 the lowest.
rsa-sig	Specifies RSA signatures as the authentication method. RSA signatures provide non-repudiation for the IKE negotiation. This basically means you can prove to a third party whether you had an IKE negotiation with the peer.

Defaults

The default ISAKMP policy authentication is **pre-share**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	The **isakmp policy authentication** command was introduced.
7.2.(1)	The **crypto isakmp policy authentication** command replaced the **isakmp policy authentication** command**.**

Usage Guidelines

IKE policies define a set of parameters for IKE negotiation.

If you specify RSA signatures, you must configure the ASA and its peer to obtain certificates from a CA server. If you specify preshared keys, you must configure these preshared keys separately within the ASA and its peer.

Examples

The following example, entered in global configuration mode, shows how to use the **crypto isakmp policy authentication** command. This example sets the authentication method of RSA signatures to be used for the IKE policy with the priority number of 40.

```
hostname(config)# crypto isakmp policy 40 authentication rsa-sig
```

Related Commands

Command	Description
clear configure crypto isakmp	Clears all the ISAKMP configuration.
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.
clear crypto isakmp sa	Clears the IKE runtime SA database.
show running-config crypto isakmp	Displays all the active configuration.

crypto isakmp policy encryption

To specify the encryption algorithm to use within an IKE policy, use the **crypto isakmp policy encryption** command in global configuration mode. To reset the encryption algorithm to the default value, which is **des,** use the **no** form of this command.

crypto isakmp policy *priority* **encryption** {**aes** | **aes-192** | **aes-256** | **des** | **3des**}

no crypto isakmp policy *priority* **encryption** {**aes** | **aes-192** | **aes-256** | **des** | **3des**}

Syntax Description

3des	Specifies that the triple DES encryption algorithm be used in the IKE policy.
aes	Specifies that the encryption algorithm to use in the IKE policy is AES with a 128-bit key.
aes-192	Specifies that the encryption algorithm to use in the IKE policy is AES with a 192-bit key.
aes-256	Specifies that the encryption algorithm to use in the IKE policy is AES with a 256-bit key.
des	Specifies that the encryption algorithm to use in the IKE policy is 56-bit DES-CBC.
priority	Uniquely identifies the IKE policy and assigns a priority to the policy. Use an integer from 1 to 65,534, with 1 being the highest priority and 65,534 the lowest.

Defaults

The default ISAKMP policy encryption is **3des**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	The **isakmp policy encryption** command was introduced.
7.2.(1)	The **crypto isakmp policy encryption** command replaced the **isakmp policy encryption** command**.**

Examples

The following example, entered in global configuration mode, shows use of the **crypto isakmp policy encryption** command; it sets 128-bit key AES encryption as the algorithm to be used within the IKE policy with the priority number of 25.

```
hostname(config)# crypto isakmp policy 25 encryption aes
```

The following example, entered in global configuration mode, sets the 3DES algorithm to be used within the IKE policy with the priority number of 40.

```
hostname(config)# crypto isakmp policy 40 encryption 3des
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto isakmp	Clears all the ISAKMP configuration.
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.
clear crypto isakmp sa	Clears the IKE runtime SA database.
show running-config crypto isakmp	Displays all the active configuration.

crypto isakmp policy group

To specify the Diffie-Hellman group for an IKE policy, use the **crypto isakmp policy group** command in global configuration mode.To reset the Diffie-Hellman group identifier to the default value, use the **no** form of this command.

crypto isakmp policy *priority* **group** {**1** | **2** | **5**}

no crypto isakmp policy *priority* **group**

Syntax Description

group 1	Specifies that the 768-bit Diffie-Hellman group be used in the IKE policy. This is the default value.
group 2	Specifies that the 1024-bit Diffie-Hellman group 2 be used in the IKE policy.
group 5	Specifies that the 1536-bit Diffie-Hellman group 5 be used in the IKE policy.
priority	Uniquely identifies the IIKE policy and assigns a priority to the policy. Use an integer from 1 to 65,534, with 1 being the highest priority and 65,534 the lowest.

Defaults

The default group policy is group 2.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	The **isakmp policy group** command was introduced.
7.2.(1)	The **crypto isakmp policy group** command replaced the **isakmp policy group** command**.**
8.0(4)	The **group 7** command option was deprecated. Attempts to configure group 7 will generate an error message and use group 5 instead.

Usage Guidelines

IKE policies define a set of parameters to use during IKE negotiation.

There are three group options: 768-bit (DH Group 1), 1024-bit (DH Group 2), and 1536-bit (DH Group 5). The 1024-bit and 1536-bit Diffie-Hellman Groups provide stronger security, but require more CPU time to execute.

Note The Cisco VPN Client Version 3.x or higher requires ISAKMP policy to use DH group 2. (If you configure DH group 1, the Cisco VPN Client cannot connect.)

AES support is available on ASAs licensed for VPN-3DES only. Due to the large key sizes provided by AES, ISAKMP negotiation should use Diffie-Hellman (DH) group 5 instead of group 1 or group 2. To configures group 5, use the **crypto isakmp policy priority group 5** command.

Examples

The following example, entered in global configuration mode, shows how to use the **crypto isakmp policy group** command. This example sets group 2, the 1024-bit Diffie Hellman, to use for the IKE policy with the priority number of 40.

```
hostname(config)# crypto isakmp policy 40 group 2
```

Related Commands

Command	Description
clear configure crypto isakmp	Clears all the ISAKMP configuration.
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.
clear crypto isakmp sa	Clears the IKE runtime SA database.
show running-config crypto isakmp	Displays all the active configuration.

crypto isakmp policy hash

To specify the hash algorithm for an IKE policy, use the **crypto isakmp policy hash** command in global configuration mode. To reset the hash algorithm to the default value of SHA-1, use the **no** form of this command.

crypto isakmp policy *priority* hash {**md5** | **sha**}

no crypto isakmp policy *priority* **hash**

Syntax Description

md5	Specifies that MD5 (HMAC variant) as the hash algorithm for the IKE policy.
priority	Uniquely identifies and assigns a priority to the policy. Use an integer from 1 to 65,534, with 1 being the highest priority and 65,534 the lowest.
sha	Specifies SHA-1 (HMAC variant) as the hash algorithm for the IKE policy.

Defaults

The default hash algorithm is SHA-1 (HMAC variant).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	The **isakmp policy hash** command was introduced.
7.2.(1)	The **crypto isakmp policy hash** command replaced the **isakmp policy hash** command**.**

Usage Guidelines

IKE policies define a set of parameters to be used during IKE negotiation.

There are two hash algorithm options: SHA-1 and MD5. MD5 has a smaller digest and is considered to be slightly faster than SHA-1.

Examples

The following example, entered in global configuration mode, shows how to use the **crypto isakmp policy hash** command. This example specifies the MD5 hash algorithm for the IKE policy, with the priority number of 40.

```
hostname(config)# crypto isakmp policy 40 hash md5
```

Related Commands

Command	Description
clear configure crypto isakmp	Clears all the ISAKMP configuration.
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.
clear crypto isakmp sa	Clears the IKE runtime SA database.
show running-config crypto isakmp	Displays all the active configuration.

crypto isakmp policy lifetime

To specify the lifetime of an IKE security association before it expires, use the **crypto isakmp policy lifetime** command in global configuration mode. To reset the security association lifetime to the default value of 86,400 seconds (one day), use the **no** form of this command .

crypto isakmp policy *priority* **lifetime** *seconds*

no crypto isakmp policy *priority* **lifetime**

Syntax Description

priority	Uniquely identifies the IKE policy and assigns a priority to the policy. Use an integer from 1 to 65,534, with 1 being the highest priority and 65,534 the lowest.
seconds	Specifies how many seconds each security association should exist before expiring. To propose a finite lifetime, use an integer from 120 to 2147483647 seconds. Use 0 seconds for an infinite lifetime.

Defaults

The default value is 86,400 seconds (one day).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	The **isakmp policy lifetime** command was introduced.
7.2.(1)	The **crypto isakmp policy lifetime** command replaced the **isakmp policy lifetime** command**.**

Usage Guidelines

When IKE begins negotiations, it seeks to agree upon the security parameters for its own session. Then the security association at each peer refers to the agreed-upon parameters. The peers retain the security association until the lifetime expires. You can specify an infinite lifetime if the peer does not propose a lifetime. Before a security association expires, subsequent IKE negotiations can use it, which can save time when setting up new IPsec security associations. The peers negotiate new security associations before current security associations expire.

With longer lifetimes, the ASA sets up future IPsec security associations more quickly. Encryption strength is great enough to ensure security without using very fast rekey times, on the order of every few minutes. We recommend that you accept the default.

Note If the IKE security association is set to an infinite lifetime, but the peer proposes a finite lifetime, then the negotiated finite lifetime from the peer is used.

Examples

The following example, entered in global configuration mode, sets the lifetime of the IKE security association to 50,4000 seconds (14 hours) for the IKE policy with the priority number of 40:

```
hostname(config)# crypto isakmp policy 40 lifetime 50400
```

The following example, entered in global configuration mode, sets the IKE security association to an infinite lifetime:

```
hostname(config)# crypto isakmp policy 40 lifetime 0
```

Related Commands

crypto isakmp reload-wait

To enable waiting for all active sessions to voluntarily terminate before rebooting the ASA, use the **crypto isakmp reload-wait** command in global configuration mode. To disable waiting for active sessions to terminate and to proceed with a reboot of the ASA, use the **no** form of this command.

crypto isakmp reload-wait

no crypto isakmp reload-wait

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	The **isakmp reload-wait** command was introduced.
7.2.(1)	The **crypto isakmp reload-wait** command replaced the **isakmp reload-wait** command**.**
9.0(1)	Support for multiple context mode was added.

Examples

The following example, entered in global configuration mode, tells the ASA to wait until all active sessions have terminated before rebooting:

```
hostname(config)# crypto isakmp reload-wait
```

Related Commands

Command	Description
clear configure crypto isakmp	Clears all the ISAKMP configuration.
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.
clear crypto isakmp sa	Clears the IKE runtime SA database.
show running-config crypto isakmp	Displays all the active configuration.

crypto key generate rsa

To generate RSA key pairs for identity certificates, use the **crypto key generate rsa** command in global configuration mode.

crypto key generate rsa [**usage-keys | general-keys**] [**label** *key-pair-label*] [**modulus** *size*] [**noconfirm**] **dsa** [**label name | elliptic-curve** [**256 | 384 | 521**]

Syntax Description

dsa [**label name**]	Uses the Suite B EDCSA algorithms when generating a keypair.
elliptic-curve [**256	384	521**]	Uses the Suite B EDCSA algorithms when generating a keypair.
general-keys	Generates a single pair of general purpose keys. This is the default key-pair type.
label *key-pair-label*	Specifies the name to be associated with the key pair(s). This key pair must be uniquely labeled. If you attempt to create another key pair with the same label, the ASA displays a warning message. If no label is provided when the key is generated, the key pair is statically named Default-RSA-Key.
modulus *size*	Specifies the modulus size of the key pair(s): 512, 768, 1024, and 2048. The default modulus size is 1024.
noconfirm	Suppresses all interactive prompting.
usage-keys	Generates two key pairs, one for signature use and one for encryption use. This implies that two certificates for the corresponding identity are required.

Defaults

The default key-pair type is **general key**. The default modulus size is 1024.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the **crypto key generate rsa** command to generate RSA key pairs to support SSL, SSH, and IPsec connections. The generated key pairs are identified by labels that you can provide as part of the command syntax. Trustpoints that do not reference a key pair can use the default one, Default-RSA-Key. SSH connections always use this key. This does not affect SSL, because SSL generates its own certificate or key dynamically, unless a trustpoint has one configured.

Note The amount of NVRAM space for storing key pairs varies depending on the ASA platform. You may reach a limit if you generate more than 30 key pairs.

Note The 4096-bit RSA keys are only supported on the ASA5580, 5585, or later platforms.

Caution Many SSL connections using identity certificates with RSA key pairs that exceed 1024 bits can cause a high CPU usage on the ASA and rejected clientless logins.

Examples

The following example, entered in global configuration mode, generates an RSA key pair with the label mypubkey:

```
hostname(config)# crypto key generate rsa label mypubkey
INFO: The name for the keys will be: mypubkey
Keypair generation process
hostname(config)#
```

The following example, entered in global configuration mode, inadvertently attempts to generate a duplicate RSA key pair with the label mypubkey:

```
hostname(config)# crypto key generate rsa label mypubkey
WARNING: You already have RSA keys defined named mypubkey
Do you really want to replace them? [yes/no] no
ERROR: Failed to create new RSA keys named mypubkey
hostname(config)#
```

The following example, entered in global configuration mode, generates an RSA key pair with the default label:

```
hostname(config)# crypto key generate rsa
INFO: The name for the keys will be: <Default-RSA-Key>
Keypair generation process begin. Please wait...
hostname(config)#
```

The following example, entered in global configuration mode, generates a warning message because there is not enough space to save the RSA keypair:

```
hostname(config)# crypto key generate rsa label mypubkey mod 2048
INFO: The name for the keys will be: mypubkey
Keypair generation process begin. Please wait...
NV RAM will not have enough space to save keypair mypubkey. Remove any unnecessary
keypairs and save the running config before using this keypair.
hostname(config)#
```

Related Commands

Command	Description
crypto key zeroize	Removes RSA key pairs.
show crypto key	Displays the RSA key pairs.

crypto key zeroize

To remove the key pairs of the indicated type (rsa or dsa), use the **crypto key zeroize** command in global configuration mode.

crypto key zeroize {**rsa** | **dsa**} [**label** *key-pair-label*] [**default**] [**noconfirm**]

Syntax Description

default	Removes RSA key pairs with no labels. This keyword is legal only with RSA key pairs.
dsa	Specifies DSA as the key type.
label *key-pair-label*	Removes the key pairs of the indicated type (**rsa** or **dsa**). If you do not provide a label, the ASA removes all key pairs of the indicated type.
noconfirm	Suppresses all interactive prompting.
rsa	Specifies RSA as the key type.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example, entered in global configuration mode, removes all RSA key pairs:

```
hostname(config)# crypto key zeroize rsa
WARNING: All RSA keys will be removed.
WARNING: All router certs issued using these keys will also be removed.

Do you really want to remove these keys? [yes/no] y
hostname(config)#
```

Related Commands

Command	Description
crypto key generate dsa	Generates DSA key pairs for identity certificates.
crypto key generate rsa	Generates RSA key pairs for identity certificates.

crypto large-cert-acceleration enable

To enable the ASA to perform 2048-bit RSA key operations in hardware, use the **crypto large-cert-acceleration enable** command in global configuration mode. To perform 2048-bit RSA key operations in software, use the **no crypto large-cert-acceleration enable** command.

crypto large-cert-acceleration enable

no crypto large-cert-acceleration enable

Syntax Description

This command has no keywords or arguments.

Defaults

By default, 2048-bit RSA key operations are performed in software.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.2(3)	This command was introduced.

Usage Guidelines

This command is only available on the ASA 5510, ASA 5520, ASA 5540, and 5550. The command is not available on the ASA 5580.

Examples

The following example shows that 2048-bit RSA key operations have been enabled in hardware:

```
hostname (config)# show running-config crypto large-cert-acceleration
crypto large-cert-acceleration enable
hostname (config)#
```

Related Commands

Command	Description
clear configure crypto	Clears the 2048-bit RSA key configuration with the rest of the crypto configuration.
show running-config crypto	Shows the 2048-bit RSA key configuration with the rest of the crypto configuration.

crypto map interface

To apply a previously defined crypto map set to an interface, use the **crypto map interface** command in global configuration mode. To remove the crypto map set from the interface, use the **no** form of this command.

crypto map *map-name* **interface** *interface-name* [**ipv6-local-address** *ipv6-address*]

no crypto map *map-name* **interface** *interface-name* [**ipv6-local-address** *ipv6-address*]

Syntax Description

interface-name	Specifies the interface for the ASA to use for establishing tunnels with VPN peers. If ISAKMP is enabled, and you are using a CA to obtain certificates, this should be the interface with the address specified in the CA certificates.
map-name	Specifies the name of the crypto map set.
ipv6-local-address *ipv6-address*	Specifies an IPv6 address.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.3(1)	The **ipv6-local-address** keyword was added.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

Use this command to assign a crypto map set to any active ASA interface. The ASA supports IPsec termination on any and all active interfaces. You must assign a crypto map set to an interface before that interface can provide IPsec services.

You can assign only one crypto map set to an interface. If multiple crypto map entries have the same map name but a different sequence number, they are part of the same set and are all applied to the interface. The ASA evaluates the crypto map entry with the lowest sequence number first.

Use the **ipv6-local-address** keyword when you have multiple IPv6 addresses configured on an interface and are configuring the ASA to support LAN-to-LAN VPN tunnels in an IPv6 environment.

Note The ASA lets you change crypto map, dynamic map, and IPsec settings on the fly. If you do so, the ASA brings down only the connections affected by the change. If you change an existing access list associated with a crypto map, specifically by deleting an entry within the accesslist, the result is that only the associated connection is brought down. Connections based on other entries in the access list are not affected.

Every static crypto map must define three parts: an access list, a transform set, and an IPsec peer. If one of these is missing, the crypto map is incomplete and the ASA moves on to the next entry. However, if the crypto map matches the access list but not either or both of the other two requirements, this ASA drops the traffic.

Use the **show running-config crypto map** command to ensure that every crypto map is complete. To fix an incomplete crypto map, remove the crypto map, add the missing entries, and reapply it.

Examples

The following example, entered in global configuration mode, assigns the crypto map set named mymap to the outside interface. When traffic passes through the outside interface, the ASA evaluates it using all the crypto map entries in the mymap set. When outbound traffic matches an access list in one of the mymap crypto map entries, the ASA forms a security association using that crypto map entry's configuration.

```
hostname(config)# crypto map mymap interface outside
```

The following example shows the minimum required crypto map configuration:

```
hostname(config)# crypto map mymap 10 ipsec-isakmp
hostname(config)# crypto map mymap 10 match address 101
hostname(config)# crypto map mymap set transform-set my_t_set1
hostname(config)# crypto map mymap set peer 10.0.0.1
```

Related Commands

Command	Description
clear configure crypto map	Clears all configuration for all crypto maps.
show running-config crypto map	Displays the crypto map configuration.

crypto map ipsec-isakmp dynamic

To require a given crypto map entry to refer to a preexisting dynamic crypto map, use the **crypto map ipsec-isakmp dynamic** command in global configuration mode. To remove the cross-reference, use the **no** form of this command.

Use the **crypto dynamic-map** command to create dynamic crypto map entries. After you create a dynamic crypto map set, use the **crypto map ipsec-isakmp dynamic** command to add the dynamic crypto map set to a static crypto map.

crypto map *map-name seq-num* **ipsec-isakmp dynamic** *dynamic-map-name*

no crypto map *map-name seq-num* **ipsec-isakmp dynamic** *dynamic-map-name*

Syntax Description

dynamic-map-name	Specifies the name of the crypto map entry that refers to a preexisting dynamic crypto map.
ipsec-isakmp	Indicates that IKE establishes the IPsec security associations for this crypto map entry.
map-name	Specifies the name of the crypto map set.
seq-num	Specifies the number you assign to the crypto map entry.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was modified to remove the **ipsec-manual** keyword.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

After you define crypto map entries, you can use the **crypto map interface** command to assign the dynamic crypto map set to interfaces.

Dynamic crypto maps provide two functions: filtering/classifying traffic to protect, and defining the policy to apply to that traffic. The first use affects the flow of traffic on an interface; the second affects the negotiation performed (via IKE) on behalf of that traffic.

IPsec dynamic crypto maps identify the following:

- The traffic to protect
- IPsec peer(s) with which to establish a security association

- Transform sets to use with the protected traffic
- How to use or manage keys and security associations

A crypto map set is a collection of crypto map entries, each with a different sequence number (*seq-num*) but the same map name. Therefore, for a given interface, you could have certain traffic forwarded to one peer with specified security applied to that traffic, and other traffic forwarded to the same or a different peer with different IPsec security applied. To accomplish this, you create two crypto map entries, each with the same map name, but each with a different sequence number.

The number you assign as the *seq-num* argument should not be arbitrary. This number ranks multiple crypto map entries within a crypto map set. A crypto map entry with a lower sequence number is evaluated before a map entry with a higher sequence number; that is, the map entry with the lower number has a higher priority.

Note When you link the crypto map to a dynamic crypto map, you must specify the dynamic crypto map. This links the crypto map to an existing dynamic crypto map that was previously defined using the **crypto dynamic-map** command. Now any changes you make to the crypto map entry after it has been converted will not take affect. For example, a change to the set peer setting does not take effect. However, the ASA stores the change while it is up. When the dynamic crypto map is converted back to the crypto map, the change is effective and appears in the output of the **show running-config crypto map** command. The ASA maintains these settings until it reboots.

Examples

The following command, entered in global configuration mode, configures the crypto map mymap to refer to a dynamic crypto map named test:

```
hostname(config)# crypto map mymap ipsec-isakmp dynamic test
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto map	Clears all configuration for all crypto maps.
show running-config crypto map	Displays the crypto map configuration.

crypto map match address

To assign an access list to a crypto map entry, use the **crypto map match address** command in global configuration mode. To remove the access list from a crypto map entry, use the **no** form of this command.

crypto map *map-name seq-num* **match address** *acl_name*

no crypto map *map-name seq-num* **match address** *acl_name*

Syntax Description

acl_name	Specifies the name of the encryption access list. This name should match the name argument of the named encryption access list being matched.
map-name	Specifies the name of the crypto map set.
seq-num	Specifies the number you assign to the crypto map entry.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

This command is required for all static crypto maps. If you are defining a dynamic crypto map (with the **crypto dynamic-map** command), this command is not required but is strongly recommended.

Use the **access-list** command to define the access lists. The access list hit counts only increase when the tunnel initiates. After the tunnel is up, the hit counts do not increase on a per-packet flow. If the tunnel drops and then reinitiates, the hit count will be increased.

The ASA uses the access lists to differentiate the traffic to protect with IPsec crypto from the traffic that does not need protection. It protects outbound packets that match a permit ACE, and ensures that inbound packets that match a permit ACE have protection.

When the ASA matches a packet to a deny statement, it skips the evaluation of the packet using the remaining ACEs in the crypto map, and resumes evaluation of the packet using the ACEs in the next crypto map in sequence. *Cascading ACLs* involves the use of deny ACEs to bypass evaluation of the remaining ACEs in an ACL, and the resumption of evaluation of traffic using the ACL assigned to the next crypto map in the crypto map set. Because you can associate each crypto map with different IPsec

settings, you can use deny ACEs to exclude special traffic from further evaluation in the corresponding crypto map, and match the special traffic to permit statements in another crypto map to provide or require different security.

Note The crypto access list does not determine whether to permit or deny traffic through the interface. An access list applied directly to the interface with the **access-group** command makes that determination.

In transparent mode, the destination address should be the IP address of the ASA, the management address. Only tunnels to the ASA are allowed in transparent mode.

Related Commands

Command	Description
clear configure crypto map	Clears all configuration for all crypto maps.
show running-config crypto map	Displays the crypto map configuration.

crypto map set connection-type

To specify the connection type for the backup Site-to-Site feature for this crypto map entry, use the **crypto map set connection-type** command in global configuration mode. To return to the default setting, use the **no** form of this command.

crypto map *map-name seq-num* **set connection-type** {**answer-only** | **originate-only** | **bidirectional**}

no crypto map *map-name seq-num* **set connection-type** {**answer-only** | **originate-only** | **bidirectional**}

Syntax Description

answer-only	Specifies that this peer only responds to inbound IKE connections first during the initial proprietary exchange to determine the appropriate peer to connect to.
bidirectional	Specifies that this peer can accept and originate connections based on this crypto map entry. This is the default connection type for all Site-to-Site connections.
map-name	Specifies the name of the crypto map set.
originate-only	Specifies that this peer initiates the first proprietary exchange to determine the appropriate peer to connect to.
seq-num	Specifies the number you assign to the crypto map entry.
set connection-type	Specifies the connection type for the backup Site-to-Site feature for this crypto map entry. There are three types of connections: answer-only, originate-only, and bidirectional.

Defaults

The default setting is bidirectional.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0	This command was introduced.
9.0	Support for multiple context mode was added.

Usage Guidelines

The **crypto map set connection-type** command specifies the connection types for the backup LAN-to-LAN feature. It allows multiple backup peers to be specified at one end of the connection.

This feature works only between the following platforms:

- Two Cisco ASA 5500 series
- A Cisco ASA 5500 series and a Cisco VPN 3000 concentrator
- A Cisco ASA 5500 series and a security appliance running Cisco PIX security appliance software Version 7.0, or higher

To configure a backup LAN-to-LAN connection, we recommend that you configure one end of the connection as originate-only using the **originate-only** keyword, and the end with multiple backup peers as answer-only using the **answer-only** keyword. On the originate-only end, use the **crypto map set peer** command to order the priority of the peers. The originate-only ASA attempts to negotiate with the first peer in the list. If that peer does not respond, the ASA works its way down the list until either a peer responds or there are no more peers in the list.

When configured in this way, the originate-only peer initially attempts to establish a proprietary tunnel and negotiate with a peer. Thereafter, either peer can establish a normal LAN-to-LAN connection and data from either end can initiate the tunnel connection.

In transparent firewall mode, you can see this command but the connection-type value cannot be set to anything other than answer-only for crypto map entries that are part of a crypto map that has been attached to the interface.

Table 12-1 lists all supported configurations. Other combinations may result in unpredictable routing issues.

Table 12-1 Supported Backup LAN-to-LAN Connection Types

Remote Side	Central Side
Originate-Only	Answer-Only
Bi-Directional	Answer-Only
Bi-Directional	Bi-Directional

Examples

The following example, entered in global configuration mode, configures the crypto map mymap and sets the connection-type to originate-only.

```
hostname(config)# crypto map mymap 10 set connection-type originate-only
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto map	Clears all configuration for all crypto maps.
show running-config crypto map	Displays the crypto map configuration.

crypto map set df-bit

To set the per-signature algorithm (SA) do-not-fragment (DF) policy, use the **crypto map set df-bit** command in global configuration mode. To disable the DF policy, use the **no** form of this command.

crypto map *name priority* **set df-bit** [**clear-df** | **copy-df** | **set-df**]

no crypto map *name priority* **set df-bit** [**clear-df** | **copy-df** | **set-df**]

Syntax Description

name	Specifies the name of the crypto map set.
priority	Specifies the priority that you assign to the crypto map entry.

Defaults

The default setting is off.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The original DF policy command is retained and acts as a global policy setting on an interface, but it is superseded for an SA by the **crypto map** command.

crypto map set ikev2 pre-shared-key

To specify a preshared key for AnyConnect IKEv2 connections, the **crypto map set ikev2 pre-shared-key** command in global configuration mode. To return to the default setting, use the **no** form of this command.

crypto map *map-name seq-num* **set ikev2 pre-shared-key** *key*

no crypto map *map-name seq-num* **set ikev2 pre-shared-key** *key*

Syntax Description

key	Alphanumeric string from 1 to 128 characters.
map-name	Specifies the name of the crypto map set.
seq-num	Specifies the number that you assign to the crypto map entry.

Defaults

There is no default value or behavior.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
8.4(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Examples

The following example configures the preshared key SKTIWHT:

```
hostname(config)# crypto map crypto_map_example set ikev2 pre-shared-key SKTIWHT
```

Related Commands

Command	Description
clear configure crypto map	Clears all configuration for all crypto maps.
show running-config crypto map	Displays the crypto map configuration.

crypto map set inheritance

To set the granularity (single or multiple) of security associations generated for this crypto map entry, use the **set inheritance** command in global configuration mode. To remove the inheritance setting for this crypto map entry, use the **no** form of this command.

crypto map *map-name seq-num* **set inheritance** {**data** | **rule**}

no crypto map *map-name seq-num* **set inheritance** {**data** | **rule**}

Syntax Description

data	Specifies one tunnel for every address pair within the address ranges specified in the rule.
map-name	Specifies the name of the crypto map set.
rule	Specifies one tunnel for each ACL entry associated with this crypto map. This is the default.
seq-num	Specifies the number that you assign to the crypto map entry.
set inheritance	Specifies the type of inheritance: **data or rule**. Inheritance allows a single security association (SA) to be generated for each security policy database (SPD) rule or multiple security SAs for each address pair in the range.

Defaults

The default value is **rule**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

This command works only when the ASA is initiating the tunnel, not when responding to a tunnel. Using the data setting may create a large number of IPsec SAs. This consumes memory and results in fewer overall tunnels. You should use the data setting only for extremely security-sensitive applications.

Examples

The following example, entered in global configuration mode, configures the crypto map mymap and sets the inheritance type to data:

```
hostname(config)# crypto map mymap 10 set inheritance data
hostname(config)#
```

Related Commands

Command	Description

crypto map set nat-t-disable

To disable NAT-T for connections based on this crypto map entry, use the **crypto map set nat-t-disable** command in global configuration mode. To enable NAT-T for this crypto map entry, use the **no** form of this command.

crypto map *map-name seq-num* **set nat-t-disable**

no crypto map *map-name seq-num* **set nat-t-disable**

Syntax Description

map-name	Specifies the name of the crypto map set.
seq-num	Specifies the number you assign to the crypto map entry.

Defaults

The default setting for this command is not on (therefore NAT-T is enabled by default).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

Use the **isakmp nat-traversal** command to globally enable NAT-T. Then you can use the **crypto map set nat-t-disable** command to disable NAT-T for specific crypto map entries.

Examples

The following command, entered in global configuration mode, disables NAT-T for the crypto map entry named mymap:

```
hostname(config)# crypto map mymap 10 set nat-t-disable
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto map	Clears all configuration for all crypto maps.
isakmp nat-traversal	Enables NAT-T for all connections.
show running-config crypto map	Displays the crypto map configuration.

crypto map set peer

To specify an IPsec peer in a crypto map entry, use the **crypto map set peer** command in global configuration mode. Use the **no** form of this command to remove an IPsec peer from a crypto map entry.

crypto map *map-name seq-num* **set peer** {*ip_address* | *hostname*}{*...ip_address10* | *hostname10*}

no crypto map *map-name seq-num* **set peer** {*ip_address* | *hostname*}{*...ip_address10* | *hostname10*}

Syntax Description

hostname	Specifies a peer by its hostname as defined by the ASA **name** command.
ip_address	Specifies a peer by its IP address (IPv4 or IPv6).
map-name	Specifies the name of the crypto map set.
peer	Specifies an IPsec peer in a crypto map entry either by hostname or IP address (IPv4 or IPv6). Multiple peers are not supported for IKEv2.
seq-num	Specifies the number that you assign to the crypto map entry.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was modified to allow up to 10 peer addresses.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

This command is required for all static crypto maps. If you are defining a dynamic crypto map (with the **crypto dynamic-map** command), this command is not required, and in most cases is not used because the peer is usually unknown.

Configuring multiple peers is equivalent to providing a fallback list. For each tunnel, the ASA attempts to negotiate with the first peer in the list. If that peer does not respond, the ASA works its way down the list until either a peer responds or there are no more peers in the list. You can set up multiple peers only when using the backup LAN-to-LAN feature (that is, when the crypto map connection type is originate-only). For more information, see the **crypto map set connection-type** command.

Note Multiple peers are not supported for IKEv2.

Examples

The following example, entered in global configuration mode, shows a crypto map configuration using IKE to establish the security associations. In this example, you can set up a security association to either the peer at 10.0.0.1 or the peer at 10.0.0.2:

```
hostname(config)# crypto map mymap 10 ipsec-isakmp
hostname(config)# crypto map mymap 10 match address 101
hostname(config)# crypto map mymap 10 set transform-set my_t_set1
hostname(config)# crypto map mymap 10 set peer 10.0.0.1 10.0.0.2
```

Related Commands

Command	Description

crypto map set pfs

Use the **crypto map set pfs** command in global configuration mode to set IPsec to ask for PFS when requesting new security associations for this crypto map entry or that IPsec requires PFS when receiving requests for new security associations. To specify that IPsec should not request PFS, use the **no** form of this command.

crypto map *map-name seq-num* **set pfs** [**group1 | group2 | group5 | group14 | group19 | group20 | group21 | group24**]

no crypto map *map-name seq-num* **set pfs** [**group1 | group2 | group5 | group14 | group19 | group20 | group21 | group24**]

Syntax Description

group1	Specifies that IPsec should use the 768-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
group2	Specifies that IPsec should use the 1024-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
group5	Specifies that IPsec should use the 1536-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
map-name	Specifies the name of the crypto map set.
seq-num	Specifies the number that you assign to the crypto map entry.

Defaults

By default PFS is not set.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was modified to add Diffie-Hellman group 7.
8.0(4)	The **group 7** command option was deprecated. Attempts to configure group 7 will generate an error message and use group 5 instead.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

With PFS, each time a new security association is negotiated, a new Diffie-Hellman exchange occurs, which requires additional processing time. PFS adds another level of security because if one key is ever cracked by an attacker, only the data sent with that key is compromised.

During negotiation, this command causes IPsec to request PFS when requesting new security associations for the crypto map entry. If the **set pfs** statement does not specify a group, the ASA sends the default (group2).

If the peer initiates the negotiation and the local configuration specifies PFS, the peer must perform a PFS exchange or the negotiation fails. If the local configuration does not specify a group, the ASA assumes a default of group2. If the local configuration specifies group2 or group5, that group must be part of the peer's offer or the negotiation fails.

For a negotiation to succeed, PFS has to be set on both ends of the LAN to LAN tunnel (with or without the Diffie-Hellman group). If set, the groups have to be an exact match. The ASA does not accept just any offer of PFS from the peer.

The 1536-bit Diffie-Hellman prime modulus group, group5, provides more security than group1 or group2, but requires more processing time than the other groups.

When interacting with the Cisco VPN Client, the ASA does not use the PFS value, but instead uses the value negotiated during Phase 1.

Examples

The following example, entered in global configuration mode, specifies that PFS should be used whenever a new security association is negotiated for the crypto map mymap 10:

```
hostname(config)# crypto map mymap 10 ipsec-isakmp
hostname(config)# crypto map mymap 10 set pfs group2
```

Related Commands

Command	Description

crypto map set ikev1 phase1-mode

To specify the IKEv1 mode for phase 1 when initiating a connection to either main or aggressive, use the **crypto map set ikev1 phase1-mode** command in global configuration mode. To remove the setting for phase 1 IKEv1 negotiations, use the **no** form of this command.

crypto map *map-name seq-num* **set ikev1 phase1-mode** {**main** | **aggressive** [**group1** | **group2** | **group5**]}

no crypto map *map-name seq-num* **set ikev1 phase1-mode** {**main** | **aggressive** [**group1** | **group2** | **group5**]}

Syntax Description

aggressive	Specifies aggressive mode for Phase 1 IKEv1 negotiations.
group1	Specifies that IPsec should use the 768-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
group2	Specifies that IPsec should use the 1024-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
group5	Specifies that IPsec should use the 1536-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
main	Specifies main mode for Phase 1 IKEv1 negotiations.
map-name	Specifies the name of the crypto map set.
seq-num	Specifies the number that you assign to the crypto map entry.

Defaults

The default Phase 1 mode is **main**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0(4)	The **group 7** command option was deprecated. Attempts to configure group 7 will generate an error message and use group 5 instead.
8.4(1)	The **ikev1** keyword was added.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

This command works only in initiator mode; not in responder mode. Including a Diffie-Hellman group with aggressive mode is optional. If one is not included, the ASA uses group 2.

Examples

The following example, entered in global configuration mode, configures the crypto map my map and sets the phase one mode to aggressive using group 2:

```
hostname(config)# crypto map mymap 10 set ikev1 phase1mode aggressive group2
hostname(config)#
```

crypto map set ikev2 phase1-mode

To specify the IKEv2 mode for Phase 1 when initiating a connection to either main or aggressive, use the **crypto map set ikev2 phase1-mode** command in global configuration mode. To remove the setting for Phase 1 IKEv2 negotiations, use the **no** form of this command.

crypto map *map-name seq-num* **set ikev2 phase1-mode** {**main** | **aggressive** [**group1** | **group2** | **group5**]}

no crypto map *map-name seq-num* **set ikev2 phase1-mode** {**main** | **aggressive** [**group1** | **group2** | **group5**]}

Syntax Description

aggressive	Specifies aggressive mode for Phase 1 IKEv2 negotiations.
group1	Specifies that IPsec should use the 768-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
group2	Specifies that IPsec should use the 1024-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
group5	Specifies that IPsec should use the 1536-bit Diffie-Hellman prime modulus group when performing the new Diffie-Hellman exchange.
main	Specifies main mode for Phase 1 IKEv2 negotiations.
map-name	Specifies the name of the crypto map set.
seq-num	Specifies the number that you assign to the crypto map entry.

Defaults

The default Phase 1 mode is **main**.

Command Modes

crypto map set reverse-route

To enable reverse route injection for any connection based on this crypto map entry, use the **crypto map set reverse-route** command in global configuration mode. To disable reverse route injection for any connection based this crypto map entry, use the **no** form of this command.

crypto map *map-name seq-num* **set reverse-route**

no crypto map *map-name seq-num s***et reverse-route**

Syntax Description

map-name	Specifies the name of the crypto map set.
seq-num	Specifies the number that you assign to the crypto map entry.

Defaults

The default setting for this command is off.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

The ASA can automatically add static routes to the routing table and announce these routes to its private network or border routers using OSPF.

Examples

The following example, entered in global configuration mode, enables reverse route injection for the crypto map named mymap.

```
hostname(config)# crypto map mymap 10 set reverse-route
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto map	Clears all configuration for all crypto maps.
show running-config crypto map	Displays the crypto map configuration.

crypto map set security-association lifetime

To override (for a particular crypto map entry) the global lifetime value, which is used when negotiating IPsec security associations, use the **crypto map set security-association lifetime** command in global configuration mode. To reset a crypto map entry's lifetime value to the global value, use the **no** form of this command.

crypto map *map-name seq-num* **set security-association lifetime** {**seconds** *seconds* | **kilobytes** *kilobytes*}

no crypto map *map-name seq-num* **set security-association lifetime** {**seconds** *seconds* | **kilobytes** *kilobytes*}

Syntax Description

kilobytes	Specifies the volume of traffic (in kilobytes) that can pass between peers using a given security association before that security association expires. The default is 4,608,000 kilobytes.
map-name	Specifies the name of the crypto map set.
seconds	Specifies the number of seconds a security association will live before it expires. The default is 28,800 seconds (eight hours).
seq-num	Specifies the number that you assign to the crypto map entry.

Defaults

The default number of kilobytes is 4,608,000; the default number of seconds is 28,800.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

The crypto map's security associations are negotiated according to the global lifetimes.

IPsec security associations use shared secret keys. These keys and their security associations time out together.

Assuming that the particular crypto map entry has lifetime values configured, when the ASA requests new security associations during security association negotiation, it specifies its crypto map lifetime values in the request to the peer; it uses these values as the lifetime of the new security associations.

When the ASA receives a negotiation request from the peer, it uses the smaller of the lifetime values proposed by the peer or the locally configured lifetime values as the lifetime of the new security associations.

There are two lifetimes: a timed lifetime and a traffic-volume lifetime. The session keys and security association expire after the first of these lifetimes is reached. You can specify both with one command.

Note The ASA lets you change crypto map, dynamic map, and IPsec settings on-the-fly. If you do so, the ASA brings down only the connections affected by the change. If you change an existing access list associated with a crypto map, specifically by deleting an entry within the access list, the result is that only the associated connection is brought down. Connections based on other entries in the access list are not affected.

To change the timed lifetime, use the **crypto map set security-association lifetime seconds** command. The timed lifetime causes the keys and security association to time out after the specified number of seconds have passed.

Examples

The following command, entered in global configuration mode, specifies a security association lifetime in seconds and kilobytes for the crypto map mymap:

```
hostname(config)# crypto map mymap 10 set security-association lifetime seconds 1400
kilobytes 3000000
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto map	Clears all configuration for all crypto maps.
show running-config crypto map	Displays the crypto map configuration.

crypto map set ikev1 transform-set

To specify the IKEv1 transform sets to use in a crypto map entry, use the **crypto map set transform-set** command in global configuration mode. To remove the names of the transform sets from a crypto map entry, use the **no** form of this command with the specified transform set name. To specify all or none of the transform sets and remove the crypto map entry, use the **no** form of the command.

crypto map *map-name seq-num* **set transform-set** *transform-set-name1* [*… transform-set-name11*]

no crypto map *map-name seq-num* **set transform-set** *transform-set-name1* [*… transform-set-name11*]

no crypto map *map-name seq-num* **set transform-set**

Syntax Description

map-name	Specifies the name of the crypto map set.
seq-num	Specifies the sequence number that corresponds to the crypto map entry.
transform-set-name1 *transform-set-name11*	Specifies one or more names of the transform sets. Any transform sets named in this command must be defined in the **crypto ipsec transform-set** command. Each crypto map entry supports up to 11 transform sets.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	The maximum number of transform sets in a crypto map entry was modified.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

This command is required for all crypto map entries.

The peer at the opposite end of the IPsec initiation uses the first matching transform set for the security association. If the local ASA initiates the negotiation, the order specified in the **crypto map** command determines the order in which the ASA presents the contents of the transform sets to the peer. If the peer initiates the negotiation, the local ASA uses the first transform set in the crypto map entry that matches the IPsec parameters sent by the peer.

If the peer at the opposite end of the IPsec initiation fails to match the values of the transform sets, IPsec does not establish a security association. The initiator drops the traffic because there is no security association to protect it.

To change the list of transform sets, specify a new list to replace the old one.

If you use this command to modify a crypto map, the ASA modifies only the crypto map entry with the same sequence number you specify. For example, the ASA inserts the transform set named 56des-sha in the last position if you enter the following commands:

```
hostname(config)# crypto map map1 1 set transform-set 128aes-md5 128aes-sha 192aes-md5
hostname(config)# crypto map map1 1 transform-set 56des-sha
hostname(config)#
```

The response to the following command shows the cumulative effect of the previous two commands:

```
hostname(config)# show running-config crypto map
crypto map map1 1 set transform-set 128aes-md5 128aes-sha 192aes-md5 56des-sha
hostname(config)#
```

To reconfigure the sequence of transform sets in a crypto map entry, delete the entry, specifying both the map name and sequence number; then recreate it. For example, the following commands reconfigure the crypto map entry named map2, sequence 3:

```
asa2(config)# no crypto map map2 3 set transform-set
asa2(config)# crypto map map2 3 set transform-set 192aes-sha 192aes-md5 128aes-sha
128aes-md5
asa2(config)#
```

Examples

The **crypto ipsec transform-set** (create or remove transform set) section shows ten transform set commands. The following example creates a crypto map entry named map2 consisting of the same ten transform sets:

```
hostname(config)# crypto map map2 10 set transform-set 3des-md5 3des-sha 56des-md5
56des-sha 128aes-md5 128aes-sha 192aes-md5 192aes-sha 256aes-md5 256aes-sha
hostname(config)#
```

The following example, entered in global configuration mode, shows the minimum required crypto map configuration when the ASA uses IKE to establish the security associations:

```
hostname(config)# crypto map map2 10 ipsec-isakmp
hostname(config)# crypto map map2 10 match address 101
hostname(config)# crypto map map2 set transform-set 3des-md5
hostname(config)# crypto map map2 set peer 10.0.0.1
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto dynamic-map	Clears all dynamic crypto maps from the configuration.
clear configure crypto map	Clears all crypto maps from the configuration.
crypto dynamic-map set transform-set	Specifies the transform sets to use in a dynamic crypto map entry.
crypto ipsec transform-set	Configures a transform set.
show running-config crypto dynamic-map	Displays the dynamic crypto map configuration.
show running-config crypto map	Displays the crypto map configuration.

crypto map set ikev2 ipsec-proposal

To specify the IKEv2 proposal to use in a crypto map entry, use the **crypto map set ikev2 ipsec-proposal** command in global configuration mode. To remove the names of the proposals from a crypto map entry, use the **no** form of this command with the specified proposal name. To specify all or none of the proposal and remove the crypto map entry, use the **no** form of the command.

crypto map *map-name seq-num* **set ikev2 ipsec-proposal** *propsal-name1* [*… proposal-name11*]

no crypto map *map-name seq-num* **set ikev2 ipsec-proposal** *propsal-name1* [*… proposal-name11*]

no crypto map *map-name seq-num* **set ikev2 ipsec-proposal**

Syntax Description

map-name	Specifies the name of the crypto map set.
seq-num	Specifies the sequence number that corresponds to the crypto map entry.
propsal-name1 *proposal-name11*	Specifies one or more names of the IPsec proposals for IKEv2. Any proposal named in this command must be defined in the **crypto ipsec ikev2 ipsec-proposal** command. Each crypto map entry supports up to 11 proposals.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.4(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

For all crypto map entries, an IKEv1 transform set or an IKEv2 proposal is required.

The peer at the opposite end of the IPsec IKEv2 initiation uses the first matching proposal for the security association. If the local ASA initiates the negotiation, the order specified in the **crypto map** command determines the order in which theASA presents the contents of the proposals to the peer. If the peer initiates the negotiation, the local ASA uses the first proposal in the crypto map entry that matches the IPsec parameters sent by the peer.

If the peer at the opposite end of the IPsec initiation fails to match the values of the proposals, IPsec does not establish a security association. The initiator drops the traffic because there is no security association to protect it.

To change the list of proposals, create a new list and specify it to replace the old one.

If you use this command to modify a crypto map, the ASA modifies only the crypto map entry with the same sequence number you specify. For example, the ASA inserts the proposal named 56des-sha in the last position if you enter the following commands:

```
hostname(config)# crypto map map1 1 set ikev2 ipsec-proposal 128aes-md5 128aes-sha
192aes-md5
hostname(config)# crypto map map1 1 set ikev2 ipsec-proposal 56des-sha
hostname(config)#
```

The response to the following command shows the cumulative effect of the previous two commands:

```
hostname(config)# show running-config crypto map
crypto map map1 1 set ipsec-proposal 128aes-md5 128aes-sha 192aes-md5 56des-sha
hostname(config)#
```

To reconfigure the sequence of proposals in a crypto map entry, delete the entry, specifying both the map name and sequence number; then recreate it. For example, the following commands reconfigure the crypto map entry named *map2*, sequence 3:

```
asa2(config)# no crypto map map2 3 set ikev2 ipsec-proposal
asa2(config)# crypto map map2 3 set ikev2 ipsec-proposal 192aes-sha 192aes-md5 128aes-sha
128aes-md5
asa2(config)#
```

Examples

The following example creates a crypto map entry named map2, consisting of ten proposals.

```
hostname(config)# crypto map map2 10 set ikev2 ipsec-proposal 3des-md5 3des-sha 56des-md5
56des-sha 128aes-md5 128aes-sha 192aes-md5 192aes-sha 256aes-md5 256aes-sha
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto dynamic-map	Clears all dynamic crypto maps from the configuration.
clear configure crypto map	Clears all crypto maps from the configuration.
crypto dynamic-map set transform-set	Specifies the transform sets to use in a dynamic crypto map entry.
crypto ipsec transform-set	Configures a transform set.
show running-config crypto dynamic-map	Displays the dynamic crypto map configuration.
show running-config crypto map	Displays the crypto map configuration.

crypto map set tfc-packets

To enable dummy Traffic Flow Confidentiality (TFC) packets on an IPsec SA, use the **crypto map set tfc-packets** command in global configuration mode. To disable TFC packets on an IPsec SA, use the **no** form of this command.

crypto map *name priority* **set tfc-packets** [**burst** *length* | *auto*] [**payload-size** *bytes* | *auto*] [**timeout** *second* | *auto*]

no crypto map *name priority* **set tfc-packets** [**burst** *length* | *auto*] [**payload-size** *bytes* | *auto*] [**timeout** *second* | *auto*]

Syntax Description

name	Specifies the name of the crypto map set.
priority	Specifies the priority that you assign to the crypto map entry.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

This command configures the existing DF policy (at an SA level) for the crypto map.

crypto map set trustpoint

To specify the trustpoint that identifies the certificate to send for authentication during Phase 1 negotiations for the crypto map entry, use the **crypto map set trustpoint** command in global configuration mode. To remove a trustpoint from a crypto map entry, use the **no** form of this command.

crypto map *map-name seq-num* **set trustpoint** *trustpoint-name* [**chain**]

no crypto map *map-name seq-num* **set trustpoint** *trustpoint-name* [**chain**]

Syntax Description

chain	(Optional) Sends a certificate chain. A CA certificate chain includes all CA certificates in a hierarchy of certificates from the root certificate to the identity certificate. The default value is disable (no chain).
map-name	Specifies the name of the crypto map set.
seq-num	Specifies the number that you assign to the crypto map entry.
trustpoint-name	Identifies the certificate to be sent during Phase 1 negotiations. The default is none.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

This crypto map command is valid only for initiating a connection. For information on the responder side, see the **tunnel-group** commands.

Examples

The following example, entered in global configuration mode, specifies a trustpoint named tpoint1 for crypto map mymap and includes the chain of certificates:

```
hostname(config)# crypto map mymap 10 set trustpoint tpoint1 chain
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto map	Clears all configuration for all crypto maps.
show running-config crypto map	Displays the crypto map configuration.
tunnel-group	Configures tunnel groups.

crypto map set validate-icmp-errors

To specify whether or not to validate incoming ICMP error messages received through an IPsec tunnel that are destined for an interior host on the private network, use the **crypto map set validate-icmp-errors** command in global configuration mode. To remove a trustpoint from a crypto map entry, use the **no** form of this command.

crypto map *name priority* **set validate-icmp-errors**

no crypto map *name priority* **set validate-icmp-errors**

Syntax Description

name	Specifies the name of the crypto map set.
priority	Specifies the priority that you assign to the crypto map entry.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

This crypto map command is valid only for validating incoming ICMP error messages.

csc

To enable the ASA to send network traffic to the CSC SSM, use the **csc** command in class configuration mode. To remove the configuration, use the **no** form of this command.

csc {**fail-open** | **fail-close**}

no csc

Syntax Description

fail-close	Specifies that the adaptive ASA should block traffic if the CSC SSM fails. This applies to the traffic selected by the class map only. Other traffic not sent to the CSC SSM is not affected by a CSC SSM failure.
fail-open	Specifies that the adaptive ASA should allow traffic if the CSC SSM fails. This applies to the traffic selected by the class map only. Other traffic not sent to the CSC SSM is not affected by a CSC SSM failure.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Class configuration mode is accessible from policy map configuration mode.

The **csc** command configures a security policy to send to the CSC SSM all traffic that is matched by the applicable class map. This occurs before the ASA allows the traffic to continue to its destination.

You can specify how the ASA treats matching traffic when the CSC SSM is not available to scan the traffic. The **fail-open** keyword specifies that the ASA permits the traffic to continue to its destination even though the CSC SSM is not available. The **fail-close** keyword specifies that the ASA never lets matching traffic continue to its destination when the CSC SSM is not available.

The CSC SSM can scan HTTP, SMTP, POP3, and FTP traffic. It supports these protocols only when the destination port of the packet requesting the connection is the well-known port for the protocol, that is, CSC SSM can scan only the following connections:

- FTP connections opened to TCP port 21
- HTTP connections opened to TCP port 80

- POP3 connections opened to TCP port 110
- SMTP connections opened to TCP port 25

If policies using the **csc** command select connections that misuse these ports for other protocols, the ASA passes the packets to the CSC SSM; however, the CSC SSM passes the packets without scanning them.

To maximize the efficiency of the CSC SSM, configure class maps used by policies implementing the **csc** command as follows:

- Select only the supported protocols that you that want the CSC SSM to scan. For example, if you do not want to scan HTTP traffic, be sure that service policies do not divert HTTP traffic to the CSC SSM.
- Select only those connections that risk trusted hosts protected by the ASA. These are connections from outside or untrusted networks to inside networks. We recommend scanning the following connections:
  - Outbound HTTP connections
  - FTP connections from clients inside the ASA to servers outside the ASA
  - POP3 connections from clients inside the ASA to servers outside the ASA
  - Incoming SMTP connections destined to inside mail servers

FTP Scanning

The CSC SSM supports scanning of FTP file transfers only if the primary channel for the FTP session uses the standard port, which is TCP port 21.

FTP inspection must be enabled for the FTP traffic that you want scanned by the CSC SSM. This is because FTP uses a dynamically assigned secondary channel for data transfer. The ASA determines the port assigned for the secondary channel and opens a pinhole to allow the data transfer to occur. If the CSC SSM is configured to scan FTP data, the ASA diverts the data traffic to the CSC SSM.

You can apply FTP inspection either globally or to the same interface that the **csc** command is applied to. By default, FTP inspection is enabled globally. If you have not changed the default inspection configuration, no further FTP inspection configuration is required to enable FTP scanning by the CSC SSM.

For more information about FTP inspection or the default inspection configuration, see the CLI configuration guide.

Examples

The ASA should be configured to divert traffic to CSC SSM requests from clients on the inside network for HTTP, FTP, and POP3 connections to the outside network and incoming SMTP connections from outside hosts to the mail server on the DMZ network. HTTP requests from the inside network to the web server on the DMZ network should not be scanned.

The following configuration creates two service policies. The first policy, csc_out_policy, is applied to the inside interface and uses the csc_out access list to ensure that all outbound requests for FTP and POP3 are scanned. The csc_out access list also ensures that HTTP connections from inside to networks on the outside interface are scanned, but the access list includes a deny ACE to exclude HTTP connections from inside to servers on the DMZ network.

The second policy, csc_in_policy, is applied to the outside interface and uses the csc_in access list to ensure that requests for SMTP and HTTP originating on the outside interface and destined for the DMZ network are scanned by the CSC SSM. Scanning HTTP requests protects the web server from HTTP file uploads.

```
hostname(config)# access-list csc_out permit tcp 192.168.10.0 255.255.255.0 any eq 21
```

```
hostname(config)# access-list csc_out deny tcp 192.168.10.0 255.255.255.0 192.168.20.0 255.255.255.0 eq 80
hostname(config)# access-list csc_out permit tcp 192.168.10.0 255.255.255.0 any eq 80
hostname(config)# access-list csc_out permit tcp 192.168.10.0 255.255.255.0 any eq 110

hostname(config)# class-map csc_outbound_class
hostname(config-cmap)# match access-list csc_out

hostname(config)# policy-map csc_out_policy
hostname(config-pmap)# class csc_outbound_class
hostname(config-pmap-c)# csc fail-close

hostname(config)# service-policy csc_out_policy interface inside

hostname(config)# access-list csc_in permit tcp any 192.168.20.0 255.255.255.0 eq 25
hostname(config)# access-list csc_in permit tcp any 192.168.20.0 255.255.255.0 eq 80

hostname(config)# class-map csc_inbound_class
hostname(config-cmap)# match access-list csc_in

hostname(config)# policy-map csc_in_policy
hostname(config-pmap)# class csc_inbound_class
hostname(config-pmap-c)# csc fail-close

hostname(config)# service-policy csc_in_policy interface outside
```

Note FTP inspection must be enabled for the CSC SSM to scan files transferred by FTP. FTP inspection is enabled by default.

Related Commands

Commands	Description
class (policy-map)	Specifies a class map for traffic classification.
class-map	Creates a traffic classification map, for use with a policy map.
match port	Matches traffic using a destination port.
policy-map	Creates a policy map by associating the traffic class with one or more actions.
service-policy	Creates a security policy by associating the policy map with one or more interfaces.

csd enable

To enable Cisco Secure Desktop (CSD) for clientless SSL VPN remote access or remote access using the AnyConnect client, use the **csd enable** command in webvpn configuration mode. To disable CSD, use the **no** form of this command.

csd enable

no csd enable

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration mode	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

CSD is enabled or disabled globally for all remote access connection attempts made to the ASA with one exception.

The **csd enable** command does the following:

1. Provides a validity check that supplements the check performed by the previous **csd image** *path* command.
2. Creates an sdesktop folder on disk0: if one is not already present.
3. Inserts a data.xml (Cisco Secure Desktop configuration) file in the sdesktop folder if one is not already present.
4. Loads the data.xml from the flash device to the running configuration.
5. Enables CSD.

Note

- You can enter the **show webvpn csd** command to determine whether or not Cisco Secure Desktop is enabled.
- The **csd image** *path* command must be in the running configuration before you enter the **csd enable** command.

- The **no csd enable** command disables CSD in the running configuration. If CSD is disabled, you cannot access CSD Manager and remote users cannot use CSD.
- If you transfer or replace the data.xml file, disable and then enable CSD to load the file into the running configuration.
- CSD is enabled or disabled globally for all remote access connection attempts made to the ASA. You cannot enable or disable CSD for an individual connection profile or group policy.

  Exception: Connection profiles for clientless SSL VPN connections can be configured so that CSD will not run on the client computer if the computer is attempting to connect to the ASA using a group URL and CSD is enabled globally. For example:

```
hostname(config)# tunnel-group group-name webvpn-attributes
hostname(config-tunnel-webvpn)# group-url https://www.url-string.com
hostname(config-tunnel-webvpn)# without-csd
```

Examples

The following commands shows how to view the status of the CSD image and enable it:

```
hostname(config-webvpn)# show webvpn csd
Secure Desktop is not enabled.
hostname(config-webvpn)# csd enable
hostname(config-webvpn)# show webvpn csd
Secure Desktop version 3.1.0.25 is currently installed and enabled.
hostname(config-webvpn)#
```

Related Commands

Command	Description
csd image	Copies the CSD image named in the command from the flash drive specified in the path to the running configuration.
show webvpn csd	Identifies the version of CSD if it is enabled. Otherwise, the CLI indicates "Secure Desktop is not enabled."
without-csd	Configures connection profiles for clientless SSL VPN sessions so that CSD will not run on the client computer if the computer is attempting to connect to the ASA using a group URL and CSD is enabled globally.

csd hostscan image

To install or upgrade the Cisco Host Scan distribution package and add it to the running configuration, use the **csd hostscan image** command in webvpn configuration mode. To remove the Host Scan distribution package from the running configuration, use the **no** form of this command:

csd hostscan image *path*

no csd hostscan image *path*

Syntax Description

path	Specifies the path and filename of the Cisco Host Scan package, up to 255 characters. The Host Scan package can be a standalone Host Scan package that has the file name convention, hostscan-*version*.pkg, or it can be the full AnyConnect Secure Mobility Client package that can be downloaded from Cisco.com and has the file name convention, anyconnect-win-*version*-k9.pkg. When customers specify the AnyConnect Secure Mobility Client, the ASA extracts the Host Scan package from the AnyConnect package and installs it. The Host Scan package contains the Host Scan software as well as the Host Scan library and support charts. This command cannot upload a CSD image. Use the **csd image** command for that operation.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.4(1)	This command was introduced.

Usage Guidelines

Enter the **show webvpn csd hostscan** command to determine the version of the Host Scan image that is currently installed and enabled.

After installing Host Scan with the **csd hostscan image** command, enable the image using the **csd enable** command.

Enter the **write memory** command to save the running configuration to ensure that the Host Scan image is available the next time that the ASA reboots.

Examples

The following commands show how to install a Cisco Host Scan package, enable it, view it, and save the configuration on the flash drive:

```
hostname> en
Password: ******
hostname# config t
hostname(config)# webvpn
hostname(config-webvpn)# show webvpn csd hostscan
Hostscan is not enabled.
hostname(config-webvpn)# csd hostscan image disk0:/hostscan_3.0.0333-k9.pkg
hostname(config-webvpn)# csd enable
hostname(config-webvpn)# show webvpn csd hostscan
Hostscan version 3.0.0333 is currently installed and enabled
hostname(config-webvpn)# write memory
Building configuration...
Cryptochecksum: 2e7126f7 71214c6b 6f3b28c5 72fa0a1e

22067 bytes copied in 3.460 secs (7355 bytes/sec)
[OK]
hostname(config-webvpn)#
```

Related Commands

Command	Description
show webvpn csd hostscan	Identifies the version of Cisco Host Scan if it is enabled. Otherwise, the CLI indicates “Secure Desktop is not enabled.”
csd enable	Enables CSD for management and remote user access.

csd image

To validate the Cisco Secure Desktop (CSD) distribution package and add it to the running configuration, effectively installing CSD, use the **csd image** command in webvpn configuration mode. To remove the CSD distribution package from the running configuration, use the **no** form of the command:

csd image *path*

no csd image *path*

Syntax Description

path	Specifies the path and filename of the CSD package, up to 255 characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Enter the **show webvpn csd** command to determine whetheror not the CSD image is enabled before entering this command. The CLI indicates the version of the CSD image that is currently installed if it is enabled.

Use the **csd image** command to install a new Cisco Secure Desktop image, or upgrade an existing image, after you download it to your computer, and transfer it to the flash drive. When downloading it, be sure to get the correct file for the ASA; it is in the form securedesktop_asa_<n>_<n>*.pkg.

Entering the **no csd image** command removes both management access to CSD Manager and remote user access to CSD. The ASA does not make any changes to the CSD software and the CSD configuration on the flash drive when you enter this command.

Note Enter the **write memory** command to save the running configuration to ensure CSD is available the next time that the ASA reboots.

Examples

The following commands show how to view the current CSD distribution package, view the contents of the flash file system, and upgrade to a new version:

```
hostname# show webvpn csd
```

```
Secure Desktop version 3.1.0.24 is currently installed and enabled.
hostname# config t
hostname(config)# webvpn

Related Commands

Command	Description
show webvpn csd	Identifies the version of CSD if it is enabled. Otherwise, the CLI indicates "Secure Desktop is not enabled."
csd enable	Enables CSD for management and remote user access.

ctl

To enable the Certificate Trust List (CTL) provider to parse the CTL file from the CTL client and install trustpoints, use the **ctl** command in ctl provider configuration mode. To remove the configuration, use the **no** form of this command.

ctl install

no ctl install

Syntax Description

This command has no arguments or keywords.

Defaults

This command is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ctl provider configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use the **ctl** command in ctl provider configuration mode to enable the CTL provider to parse the CTL file from the CTL client and install trustpoints for entries from the CTL file. Ttrustpoints installed by this command have names prefixed with "_internal_CTL_<ctl_name>."

If this command is disabled, each CallManager server and CAPFs certificate must be manually imported and installed via the **crypto ca trustpoint** and **crypto ca certificate chain** commands.

Examples

The following example shows how to create a CTL provider instance:

```
hostname(config)# ctl-provider my_ctl
hostname(config-ctl-provider)# client interface inside 172.23.45.1
hostname(config-ctl-provider)# client username CCMAdministrator password XXXXXX encrypted
hostname(config-ctl-provider)# export certificate ccm_proxy
hostname(config-ctl-provider)# ctl install
```

Related Commands

Commands	Description
ctl-provider	Defines a CTL provider instance and enters provider configuration mode.
server trust-point	Specifies the proxy trustpoint certificate to be presented during the TLS handshake.
show tls-proxy	Shows the TLS proxies.
tls-proxy	Defines a TLS proxy instance and sets the maximum sessions.

ctl-file (global)

To specify the CTL instance to create for a phone proxy or to parse the CTL file stored in flash memory, use the **ctl-file** command in global configuration mode. To remove the CTL instance, use the **no** form of this command.

ctl-file *ctl_name* **noconfirm**

no ctl-file *ctl_name* **noconfirm**

Syntax Description

ctl_name	Specifies the name of the CTL instance.
noconfirm	(Optional) Used with the **no** command, stops warnings about deleting trustpoints when the CTL file is removed from being printed to the ASA console.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Usage Guidelines

If users have phones that require LSC provisioning, you must also import the CAPF certificate into the ASA from the CUMC when configuring the CTL file instance with the **ctl-file** command. For more information,see the CLI configuration guide.

Note To create the CTL file, use the **no shutdown** command in the ctl file configuration mode. To modify or add entries to a CTL file or to delete a CTL file, use the **shutdown** command.

Using the **no** form of the command removes the CTL file and all enrolled trustpoints internally created by a phone proxy. Additionally, removing the CTL file deletes all certificates received from the related certificate authority.

Examples

The following example shows how to configure the CTL file for the phone proxy feature:

```
hostname(config)# ctl-file myctl
```

Related Commands

Command	Description
ctl-file (phone-proxy)	Specifies the CTL file to use when configuring the phone proxy instance.
cluster-ctl-file	Parses the CTL file stored in flash memory to install the trustpoints from that file.
phone-proxy	Configures the phone proxy instance.
record-entry	Specifies the trustpoints to be used for the creation of the CTL file.
sast	Specifies the number of SAST certificates to create in the CTL record.

ctl-file (phone-proxy)

To specify the CTL instance to use when configuring the Phone Proxy, use the **ctl-file** command in phone-proxy configuration mode. To remove the CTL instance, use the **no** form of this command.

ctl-file *ctl_name*

no ctl-file *ctl_name*

Syntax Description

ctl_name	Specifies the name of the CTL instance.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Phone-proxy configuration	•	—	•	—	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Examples

The following example shows the use of the **ctl-file** command to configure the CTL file for the Phone Proxy feature:

```
hostname(config-phone-proxy)# ctl-file myctl
```

Related Commands

Command	Description
ctl-file (global)	Specifies the CTL file to create for Phone Proxy configuration or the CTL file to parse from flash memory.
phone-proxy	Configures the Phone Proxy Instance.

ctl-provider

To configure a CTL provider instance in CTL provider mode, use the **ctl-provider** command in global configuration mode. To remove the configuration, use the **no** form of this command.

ctl-provider *ctl_name*

no ctl-provider *ctl_name*

Syntax Description

ctl_name	Specifies the name of the CTL provider instance.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use the **ctl-provider** command to enter CTL provider configuration mode to create a CTL provider instance.

Examples

The following example shows how to create a CTL provider instance:

```
hostname(config)# ctl-provider my_ctl
hostname(config-ctl-provider)# client interface inside 172.23.45.1
hostname(config-ctl-provider)# client username CCMAdministrator password XXXXXX encrypted
hostname(config-ctl-provider)# export certificate ccm_proxy
hostname(config-ctl-provider)# ctl install
```

Related Commands

Commands	Description
client	Specifies clients allowed to connect to the CTL provider and the username and password for client authentication.
ctl	Parses the CTL file from the CTL client and install trustpoints.
export	Specifies the certificate to be exported to the client.

Commands	Description
service	Specify the port to which the CTL provider listens.
tls-proxy	Defines a TLS proxy instance and sets the maximum sessions.

cts import-pac

To import a Protected Access Credential (PAC) file from the Cisco ISE, use the **cts import-pac** command in global configuration mode:

cts import-pac *filepath* **password** *value*

Syntax Description

filepath	Specifies one of the following **exec** mode commands and options:. **Single Mode** • **disk0**: Path and filename on disk0 • **disk1**: Path and filename on disk1 • **flash**: Path and filename on flash • **ftp**: Path and filename on FTP • **http**: Path and filename on HTTP • **https**: Path and filename on HTTPS • **smb**: Path and filename on SMB • **tftp**: Path and filename on TFTP **Multi-mode** • **http**: Path and filename on HTTP • **https**: Path and filename on HTTPS • **smb**: Path and filename on SMB • **tftp**: Path and filename on TFTP
password *value*	Specifies the password used to encrypt the PAC file. The password is independent of the password that was configured on the ISE as part of the device credentials. The password must match the one provided when the PAC file was requested, and is necessary to decrypt the PAC data. This password is not related to the one that is configured on the ISE as part of the device credentials.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Importing the PAC file to the ASA establishes the connection with the ISE. After the channel is established, the ASA initiates a secure RADIUS transaction with the ISE and downloads Cisco TrustSec environment data; specifically, the ASA downloads the security group table. The security group table maps SGTs to security group names. Security group names are created on the ISE and provide user-friendly names for security groups. No channel is established prior to the RADIUS transaction. The ASA initiates a RADIUS transaction with the ISE using the PAC for authentication.

Tip The PAC file contains a shared key that allows the ASA and ISE to secure the RADIUS transactions that occur between them. Given the sensitive nature of this key, it must be stored securely on the ASA.

After successfully importing the file, the ASA download Cisco TrustSec environment data from the ISE without requiring the device password configured in the ISE.

The ASA stores the PAC file in an area of NVRAM that is not accessible through the user interface.

Prerequisites

- The ASA must be configured as a recognized Cisco TrustSec network device in the ISE before the ASA can generate a PAC file. The ASA can import any PAC file but it will only work on the ASA when the file was generated by a properly configured ISE.
- Obtain the password used to encrypt the PAC file when generating it on the ISE.

  The ASA requires this password to import and decrypt the PAC file.
- Access to the PAC file generated by the ISE. The ASA can import the PAC file from flash or from a remote server via TFTP, FTP, HTTP, HTTPS, or SMB. (The PAC file does not have to reside on the ASA flash before you can import it.)
- The server group has been configured for the ASA.

Restrictions

- When the ASA is part of an HA configuration, you must import the PAC file to the primary ASA device.
- When the ASA is part of a clustering configuration, you must import the PAC file to the master device.

Examples

The following example imports a PAC from the ISE:

```
hostname(config)# cts import pac disk0:/pac123.pac password hideme
PAC file successfully imported
```

Related Commands

Command	Description
cts refresh environment-data	Refreshes the Cisco TrustSec environment data from the ISE when the ASA is integrated with Cisco TrustSec
cts sxp enable	Enables the SXP protocol on the ASA.

cts refresh environment-data

To refresh the Cisco TrustSec environment data from the ISE and reset the reconcile timer to the configured default value, use the **cts refresh environment-data** command in global configuration mode:

cts refresh environment-data

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

When the ASA is integrated with Cisco TrustSec, the ASA downloads environment data from the ISE, which includes the Security Group Tag (SGT) name table. The ASA automatically refreshes its environment data obtained from the ISE when you complete the following tasks on the ASA:

- Configure a AAA server to communicate with the ISE.
- Import a PAC file from the ISE.
- Identify the AAA server group that the ASA will use for retrieval of Cisco TrustSec environment data.

Normally, you will not need to manually refresh the environment data from the ISE; however, security groups can change on the ISE. These changes are not reflected on the ASA until you refresh the data in the ASA security group table. Refresh the data on the ASA to make sure any security group made on the ISE are reflected on the ASA.

Tip We recommend that you schedule policy configuration changes on the ISE and the manual data refresh on the ASA during a maintenance window. Handling policy configuration changes in this way maximizes the chances of security group names getting resolved and security policies becoming active immediately on the ASA.

Prerequisites

The ASA must be configured as a recognized Cisco TrustSec network device in the ISE and the ASA must have successfully imported a PAC file, so that the changes made for Cisco TrustSec are applied to the ASA.

Restrictions

- When the ASA is part of an HA configuration, you must refresh the environment data on the primary ASA device.
- When the ASA is part of a clustering configuration, you must refresh the environment data on the master device.

Examples

The following example downloads the Cisco TrustSec environment data from the ISE:

```
hostname(config)# cts refresh environment-data
```

Related Commands

Command	Description
cts import-pac	Imports a Protected Access Credential (PAC) file from the Cisco ISE when the ASA is integrated with Cisco TrustSec.
cts sxp enable	Enables the SXP protocol on the ASA.

cts server-group

To identify the AAA server group that the ASA uses to integrate with Cisco TrustSec for environment data retrieval, use the **cts server-group** command in global configuration mode. To disable support for the command, use the **no** form of this command.

cts server-group *aaa-server-group-name*

no cts server-group [*aaa-server-group-name*]

Syntax Description

aaa-server-group-name	Specifies the name of an existing, locally configured AAA server group.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

As part of configuring the ASA to integrate with Cisco TrustSec, you must configure the ASA so that it can communicate with the ISE. Only one instance of the server group can be configured on the ASA for Cisco TrustSec.

Prerequisites

- The referenced server group must exist. If specify a undefined server group name in the *aaa-server-group-name* argument, the ASA will display an error message.
- The referenced server group must be configured to use the RADIUS protocol. If you add a non-RADIUS server group to the ASA, the feature configuration will fail.
- If the ISE is also used for user authentication, obtain the shared secret that was entered on the ISE when you registered the ASA with the ISE. Contact your ISE administrator if you do not have this information.

Examples

The following example locally configures on the ASA the AAA server group for the ISE and configures the ASA to use that AAA server group for the ASA integration with Cisco TrustSec:

```
hostname(config)# aaa-server ISEserver protocol radius
```

```
hostname(config-aaa-server-group)# exit
hostname(config)# aaa-server ISEserver (inside) host 192.0.2.1
hostname(config-aaa-server-host)# key myexclusivemumblekey
hostname(config-aaa-server-host)# exit
hostname(config)# cts server-group ISEserver
```

Related Commands

Command	Description
aaa-server *server-tag* **protocol radius**	Creates the AAA server group and configures the AAA server parameters for the ASA to communicate with the ISE server; where *server-tag* specifies the server group name.
aaa-server *server-tag* (*interface-name*) **host** *server-ip*	Configures a AAA server as part of a AAA server group and sets host-specific connection data; where (*interface-name*) specifies the network interface where the ISE server resides, and *server-tag* is the name of the AAA server group for the Cisco TrustSec integration, and e *server-ip* specifies the IP address of the ISE server.
cts sxp enable	Enables the SXP protocol on the ASA.

cts sxp connection peer

To set up an SXP connection to an SXP peer, use the **cts sxp connection peer** command in global configuration mode. To disable support for the command, use the **no** form of this command.

cts sxp connection peer *peer_ip_address* [**source** *source_ip_address*] **password** {**default** | **mode**} [**mode** {**local** | **peer**}] {**speaker** | **listener**}

no cts sxp connection peer *peer_ip_address* [**source** *source_ip_address*] [**password** {**default** | **none**}] [**mode** {**local** | **peer**}] [**speaker** | **listener**]

Syntax Description

default	Used with the **password** keyword. Specifies to use the default password configured for SXP connections.
listener	Specifies that the ASA functions as a listener for the SXP connection; meaning that the ASA can receive IP-SGT mappings from downstream devices. Specifying a speaker or listener role for the ASA for the SPX connection is required.
local	Used with the **mode** keyword. Species to use the local SXP device.
mode	(Optional) Specifies the mode of the SXP connection.
none	Used with the **password** keyword. Specifies not to use a password for the SXP connection.
password	(Optional) Specifies whether to use the authentication key for the SXP connection.
peer	Used with the **mode** keyword. Species to use the peer SXP device.
peer_ip_address	Specifies the IPv4 or IPv6 address of the SXP peer. The peer IP address must be reachable from the ASA outgoing interface.
source *source_ip_address*	(Optional) Specifies the local IPv4 or IPv6 address of the SXP connection.
speaker	Specifies that the ASA functions as a speaker for the SXP connection; meaning that the ASA can forward IP-SGT mappings to upstream devices. Specifying a speaker or listener role for the ASA for the SPX connection is required.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

SXP connections between peers are point-to-point and use TCP as the underlying transport protocol. SXP connections are set per IP address; a single device pair can service multiple SXP connections.

Restrictions

- The ASA does not support per-connection passwords for SXP connection.
- When you use the **cts sxp default password** to configure a default SXP password, you should configure the SXP connection to use the default password; conversely, when you do not configure a default password, you should not configure a default password for the SXP connection. If you do not follow these two guidelines, SXP connections can fail.
- When you configure an SXP connection with a default password, but the ASA does not have default password configured, the SXP connection will fail.
- When you configure a source IP address for an SXP connection, you must specify the same address as the ASA outbound interface. If the source IP address does not match the address of the outbound interface, the SXP connection will fail.

  When the source IP address for an SXP connection is not configured, the ASA performs a route/ARP lookup to determine the outbound interface for the SXP connection. We recommend that you do not configure a source IP address for SXP connection and allow the ASA to perform a route/ARP lookup to determine the source IP address for the SXP connection.
- Configuring an IPv6 local link address for an SXP peer or source is not supported.
- Configuring multiple IPv6 addresses on the same interface for SXP connections is not supported.

Examples

The following example creates an SXP connection on the ASA:

```
hostname(config)# cts sxp connection peer 192.168.1.100 source 192.168.1.1 password default mode peer speaker
```

Related Commands

Command	Description
cts sxp default password	Specifies the default password for SXP connectios.
cts sxp enable	Enables the SXP protocol on the ASA.

cts sxp default password

To configure a default password for TCP MD5 authentication with SXP peers, use the **cts sxp default password** command in global configuration mode. To disable support for the command, use the **no** form of this command.

cts sxp default password [**0** | **8**] *password*

no cts sxp default password [**0** | **8**] [*password*]

Syntax Description

0	(Optional) Specifies that the default password use unencrypted cleartext for the encryption level. You can only set one encryption level for the default password.
8	(Optional) Specifies that the default password use encrypted text for the encryption level.
password	Specifies an encrypted string up to 162 characters or an ASCII key string up to 80 characters.

Defaults

By default, SXP connections do not have a password set.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

When you configure an SXP connection with a default password, but the ASA does not have default password configured, the SXP connection will fail.

Restrictions

- The ASA does not support per-connection passwords for SXP connection.
- When you use the **cts sxp default password** to configure a default SXP password, you should configure the SXP connection to use the default password; conversely, when you do not configure a default password, you should not configure a default password for the SXP connection. If you do not follow these two guidelines, SXP connections can fail.

Examples

The following example shows how to set default values for all SXP connections, including a default password for SXP connections:

```
hostname(config)# cts sxp enable
hostname(config)# cts sxp default source-ip 192.168.1.100
hostname(config)# cts sxp default password 8 ********
hostname(config)# cts sxp retry period 60
hostname(config)# cts sxp reconcile period 60
```

Related Commands

Command	Description
cts sxp connection peer	Configures an SXP connection for the ASA to an SXP peer. Specifying the **password default** keywords with this command, enables the use of the default password for that SXP connection.
cts sxp enable	Enables the SXP protocol on the ASA.

cts sxp default source-ip

To configure a default local IP address for SXP connections, use the **cts sxp default source-ip** command in global configuration mode. To disable support for the command, use the **no** form of this command.

cts sxp default source-ip *ipaddress*

no cts sxp default source-ip [*ipaddress*]

Syntax Description

ipaddress	Specifies an IPv4 or IPv6 address for the source IP address.

Defaults

By default, SXP connections do not have a default source IP address set.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

When you configure a default source IP address for SXP connections, you must specify the same address as the ASA outbound interface. If the source IP address does not match the address of the outbound interface, SXP connections will fail.

When a source IP address for an SXP connection is not configured, the ASA performs a route/ARP lookup to determine the outbound interface for the SXP connection. We recommend that you do not configure a default source IP address for SXP connections and allow the ASA to perform a route/ARP lookup to determine the source IP address for an SXP connection.

Examples

The following example shows how to set default values for all SXP connections, including a default source IP address for SXP connections:

```
hostname(config)# cts sxp enable
hostname(config)# cts sxp default source-ip 192.168.1.100
hostname(config)# cts sxp default password 8 ********
hostname(config)# cts sxp retry period 60
hostname(config)# cts sxp reconcile period 60
```

Related Commands

Command	Description
cts sxp connection peer	Configures an SXP connection for the ASA. Specifying the **source** *source_ip_address* keyword and argument with this command, enables the use of the default source IP address for that SXP connection.
cts sxp enable	Enables the SXP protocol on the ASA.

cts sxp enable

To enable the SXP protocol on the ASA, use the **cts sxp enable** command in global configuration mode. To disable support for the command, use the **no** form of this command.

cts sxp enable

no cts sxp enable

Syntax Description

This command has no arguments or keywords.

Defaults

By default, the SXP protocol is disabled on the ASA.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Examples

The following example enables the SXP protocol on the ASA:

```
hostname(config)# cts sxp enable
```

Related Commands

Command	Description
clear cts	Clears data used by the ASA when integrated with Cisco TrustSec.
cts sxp connection peer	Configures an SXP connection for the ASA to an SXP peer.

cts sxp reconciliation period

To ..., use the **cts sxp reconciliation period** command in global configuration mode. To disable support for the command, use the **no** form of this command.

cts sxp reconciliation period *timervalue*

no cts sxp reconciliation period [*timervalue*]

Syntax Description

timervalue	Specifies the default value for the reconciliation timer. Enter the number of seconds in the range of 1 to 64000 seconds.

Defaults

By default, the *timervalue* is 120 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

After an SXP peer terminates its SXP connection, the ASAstarts a hold down timer. If an SXP peer connects while the hold down timer is running, the ASA starts the reconciliation timer; then, the ASA updates the SXP mapping database to learn the latest mappings.

When the reconciliation timer expires, the ASA scans the SXP mapping database to identify stale mapping entries (entries that were learned in a previous connection session). The ASA marks these connections as obsolete. When the reconciliation timer expires, the ASA removes the obsolete entries from the SXP mapping database.

You cannot specify 0 for the timer because specifying 0 would prevent the reconciliation timer from starting. Not allowing the reconciliation timer to run would keep stale entries for an undefined time and cause unexpected results from the policy enforcement.

Examples

The following example shows how to set default values for all SXP connections, including a default reconciliation timer:

```
hostname(config)# cts sxp enable
hostname(config)# cts sxp default source-ip 192.168.1.100
hostname(config)# cts sxp default password 8 ********
hostname(config)# cts sxp retry period 60
```

```
hostname(config)# cts sxp reconcile period 60
```

Related Commands

Command	Description
cts sxp connection peer	Configures an SXP connection for the ASA to an SXP peer.
cts sxp enable	Enables the SXP protocol on the ASA.

cts sxp retry period

To specify the default time interval between ASA attempts to set up new SXP connections between SXP peers., use the **cts sxp retry period** command in global configuration mode. To disable support for the command, use the **no** form of this command.

cts sxp retry period *timervalue*

no cts sxp retry period [*timervalue*]

Syntax Description

timervalue	Specifies the default value for the retry timer. Enter the number of seconds in the range of 0 to 64000 seconds.

Defaults

By default, the *timervalue* is 120 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Specifies the default time interval between ASA attempts to set up new SXP connections between SXP peers. The ASA continues to make connection attempts until a successful connection is made.

The retry timer is triggered as long as there is one SXP connection on the ASA that is not up.

If you specify 0 seconds, the timer never expires and the ASA will not attempt to connect to SXP peers.

When the retry timer expires, the ASA goes through the connection database and if the database contains any connections that are off or in a “pending on” state, the ASA restarts the retry timer.

We recommend you configure the retry timer to a different value from its SXP peer devices.

Examples

The following example shows how to set default values for all SXP connections, including a default retry period:

```
hostname(config)# cts sxp enable
hostname(config)# cts sxp default source-ip 192.168.1.100
hostname(config)# cts sxp default password 8 ********
hostname(config)# cts sxp retry period 60
hostname(config)# cts sxp reconcile period 60
```

Related Commands

Command	Description
cts sxp connection peer	Configures an SXP connection for the ASA to an SXP peer.
cts sxp enable	Enables the SXP protocol on the ASA.

customization

To specify the customization to use for a tunnel group, group, or user, use the **customization** command in tunnel-group webvpn-attributes configuration mode or webvpn configuration mode. To not specify a customization, use the **no** form of this command.

customization ***name***

no customization *name*

customization {**none** | **value** *name*}

no customization {**none** | **value** *name*}

Syntax Description

name	Specifies the name of the WebVPN customization to apply to a group or user.
none	Disables customization for the group or user, and prevents the customization from being inherited.
value *name*	Specifies the name of a customization to apply to the group policy or user.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group webvpn-attributes configuration	•	—	•	—	—
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Before entering the **customization** command in tunnel-group webvpn-attributes configuration mode, you must name and configure the customization using the **customization** command in webvpn configuration mode.

Mode-Dependent Command Options

The keywords available with the **customization** command differ depending on the mode you are in. In group-policy attributes configuration mode and username attributes configuration mode, the additional keywords **none** and **value** appear.

For example, if you enter the **customization none** command from username attributes configuration mode, the ASA will not look for the value in the group policy or tunnel group.

Examples

The following example shows a command sequence that first establishes a WebVPN customization named "123" that defines a password prompt. The example then defines a WebVPN tunnel group named "test" and uses the **customization** command to specifies the use of the WebVPN customization named "123":

```
hostname(config)# webvpn
hostname(config-webvpn)# customization 123
hostname(config-webvpn-custom)# password-prompt Enter password
hostname(config-webvpn)# exit
hostname(config)# tunnel-group test type webvpn
hostname(config)# tunnel-group test webvpn-attributes
hostname(config-tunnel-webvpn)# customization 123
hostname(config-tunnel-webvpn)#
```

The folowing example shows the customization named "cisco" applied to the group policy named "cisco_sales." Note that the additional command option **value** is required with the **customization** command entered in group-policy attributes configuration mode via webvpn configuration mode:

```
hostname(config)# group-policy cisco_sales attributes
hostname(config-group-policy)#  webvpn
hostname(config-group-webvpn)# customization value cisco
```

Related Commands

Command	Description
clear configure tunnel-group	Removes all tunnel group configuration.
show running-config tunnel-group	Displays the current tunnel group configuration.
tunnel-group webvpn-attributes	Enters the webvpn configuration mode for configuring WebVPN tunnel group attributes.

cxsc

To redirect traffic to the ASA CX module, use the **cxsc** command in class configuration mode. To remove the ASA CX action, use the **no** form of this command.

cxsc {**fail-close** | **fail-open**} [**auth-proxy** | **monitor-only**]

no cxsc {**fail-close** | **fail-open**} [**auth-proxy** | **monitor-only**]

Syntax Description

auth-proxy	(Optional) Enables the authentication proxy, which is required for active authentication.
fail-close	Sets the ASA to block all traffic if the ASA CX module is unavailable.
fail-open	Sets the ASA to allow all traffic through, uninspected, if the ASA CX module is unavailable.
monitor-only	For demonstration purposes only, specify **monitor-only** to send a read-only copy of traffic to the ASA CX module. When you configure this option, you see a warning message similar to the following: `WARNING: Monitor-only mode should be used for demonstrations and evaluations only. This mode prevents CXSC from denying or altering traffic.`

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
8.4(4.1)	We introduced this command.
9.1(2)	We added the **monitor-only** keyword to support demonstration functionality.
9.1(3)	You can now configure ASA CX policies per context.

Usage Guidelines

You can access the class configuration mode by first entering the policy-map command.

Before or after you configure the **cxsc** command on the ASA, configure the security policy on the ASA CX module using Cisco Prime Security Manager (PRSM).

To configure the **cxsc** command, you must first configure the **class-map** command, **policy-map** command, and the **class** command.

Traffic Flow

The ASA CX module runs a separate application from the ASA. It is, however, integrated into the ASA traffic flow. When you apply the **cxsc** command for a class of traffic on the ASA, traffic flows through the ASA and the ASA CX module in the following way:

1. Traffic enters the ASA.
2. Incoming VPN traffic is decrypted.
3. Firewall policies are applied.
4. Traffic is sent to the ASA CX module over the backplane.
5. The ASA CX module applies its security policy to the traffic and takes appropriate actions.
6. Valid traffic is sent back to the ASA over the backplane; the ASA CX module might block some traffic according to its security policy, and that traffic is not passed on.
7. Outgoing VPN traffic is encrypted.
8. Traffic exits the ASA.

Information About Authentication Proxy

When the ASA CX needs to authenticate an HTTP user (to take advantage of identity policies), you must configure the ASA to act as an authentication proxy: the ASA CX module redirects authentication requests to the ASA interface IP address/proxy port. By default, the port is 885 (user configurable with the **cxsc auth-proxy port** command). Configure this feature as part of the service policy to divert traffic from the ASA to the ASA CX module. If you do not enable the authentication proxy, only passive authentication is available.

Compatibility with ASA Features

The ASA includes many advanced application inspection features, including HTTP inspection. However, the ASA CX module provides more advanced HTTP inspection than the ASA provides, as well as additional features for other applications, including monitoring and controlling application usage.

To take full advantage of the ASA CX module features, see the following guidelines for traffic that you send to the ASA CX module:

- Do not configure ASA inspection on HTTP traffic.
- Do not configure Cloud Web Security (ScanSafe) inspection. If you configure both the ASA CX action and Cloud Web Security inspection for the same traffic, the ASA only performs the ASA CX action.
- Other application inspections on the ASA are compatible with the ASA CX module, including the default inspections.
- Do not enable the Mobile User Security (MUS) server; it is not compatible with the ASA CX module.
- Do not enable ASA clustering; it is not compatible with the ASA CX module.
- If you enable failover, when the ASA fails over, any existing ASA CX flows are transferred to the new ASA, but the traffic is allowed through the ASA without being acted upon by the ASA CX module. Only new flows recieved by the new ASA are acted upon by the ASA CX module.

Monitor-Only Mode

For testing and demonstration purposes, you can configure the ASA to send a duplicate stream of read-only traffic to the ASA CX module using the **monitor-only** keyword, so you can see how the module inspects the traffic without affecting the ASA traffic flow. In this mode, the ASA CX module

inspects the traffic as usual, makes policy decisions, and generates events. However, because the packets are read-only copies, the module actions do not affect the actual traffic. Instead, the module drops the copies after inspection.

See the following guidelines:

- You cannot configure both monitor-only mode and normal inline mode at the same time on the ASA. Only one type of security policy is allowed.
- The following features are not supported in monitor-only mode:
  - Deny policies
  - Active authentication
  - Decryption policies
- The ASA CX does not perform packet buffering in monitor-only mode, and events will be generated on a best effort basis. For example, some events, such as ones with long URLs spanning packet boundaries, may be impacted by the lack of buffering.
- Be sure to configure both the ASA policy and the ASA CX to have matching modes: both in monitor-only, or both in normal inline mode.

Examples

The following example diverts all HTTP traffic to the ASA CX module and blocks all HTTP traffic if the ASA CX module card fails for any reason:

```
hostname(config)# access-list ASACX permit tcp any any eq port 80
hostname(config)# class-map my-cx-class
hostname(config-cmap)# match access-list ASACX
hostname(config-cmap)# policy-map my-cx-policy
hostname(config-pmap)# class my-cx-class
hostname(config-pmap-c)# cxsc fail-close auth-proxy
hostname(config-pmap-c)# service-policy my-cx-policy global
```

The following example diverts all IP traffic destined for the 10.1.1.0 network and the 10.2.1.0 network to the ASA CX module and allows all traffic through if the ASA CX module fails for any reason:

```
hostname(config)# access-list my-cx-acl permit ip any 10.1.1.0 255.255.255.0
hostname(config)# access-list my-cx-acl2 permit ip any 10.2.1.0 255.255.255.0
hostname(config)# class-map my-cx-class
hostname(config-cmap)# match access-list my-cx-acl
hostname(config)# class-map my-cx-class2
hostname(config-cmap)# match access-list my-cx-acl2
hostname(config-cmap)# policy-map my-cx-policy
hostname(config-pmap)# class my-cx-class
hostname(config-pmap-c)# cxsc fail-open auth-proxy
hostname(config-pmap)# class my-cx-class2
hostname(config-pmap-c)# cxsc fail-open auth-proxy
hostname(config-pmap-c)# service-policy my-cx-policy interface outside
```

Related Commands

Command	Description
class	Specifies a class map to use for traffic classification.
class-map	Identifies traffic for use in a policy map.
cxsc auth-proxy port	Sets the authentication proxy port.
debug cxsc	Enables ASA CX debugging messages.
hw-module module password-reset	Resets the module password to the default.

Command	Description
hw-module module reload	Reloads the module.
hw-module module reset	Performs a reset and then reloads the module.
hw-module module shutdown	Shuts down the module.
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
session do get-config	Gets the module configuration.
session do password-reset	Resets the module password to the default.
session do setup host ip	Configures the module management address.
show asp table classify domain cxsc	Shows the NP rules created to send traffic to the ASA CX module.
show asp table classify domain cxsc-auth-proxy	Shows the NP rules created for the authentication proxy for the ASA CX module.
show module	Shows the module status.
show running-config policy-map	Displays all current policy map configurations.
show service-policy	Shows service policy statistics.

cxsc auth-proxy port

To set the authentication proxy port for ASA CX module traffic, use the **cxsc auth-proxy port** command in global configuration mode. To set the port to the default, use the **no** form of this command.

cxsc auth-proxy port *port*

no cxsc auth-proxy port [*port*]

Syntax Description

port *port*	Sets the authentication proxy port to a value higher than 1024. The default is 885.

Command Default

The default port is 885.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.4(4.1)	We introduced this command.
9.1(3)	You can now configure ASA CX policies per context.

Usage Guidelines

If you enable the authentication proxy when you configure the **cxsc** command, you can change the port using this command.

When the ASA CX needs to authenticate an HTTP user (to take advantage of identity policies), you must configure the ASA to act as an authentication proxy: the ASA CX module redirects authentication requests to the ASA interface IP address/proxy port. By default, the port is 885. Configure this feature as part of the service policy to divert traffic from the ASA to the ASA CX module. If you do not enable the authentication proxy, only passive authentication is available.

Examples

The following example enables the authentication proxy for ASA CX traffic, then changes the port to 5000:

```
hostname(config)# access-list ASACX permit tcp any any eq port 80
hostname(config)# class-map my-cx-class
hostname(config-cmap)# match access-list ASACX
hostname(config-cmap)# policy-map my-cx-policy
hostname(config-pmap)# class my-cx-class
hostname(config-pmap-c)# cxsc fail-close auth-proxy
hostname(config-pmap-c)# service-policy my-cx-policy global
```

```
hostname(config)# cxsc auth-port 5000
```

Related Commands

hw-module module reload	Reloads the module.
hw-module module reset	Performs a reset, and then reloads the module.
hw-module module shutdown	Shuts down the module.
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
session do get-config	Gets the module configuration.
session do password-reset	Resets the module password to the default.
session do setup host ip	Configures the module management address.
show asp table classify domain cxsc	Shows the NP rules created to send traffic to the ASA CX module.
show asp table classify domain cxsc-auth-proxy	Shows the NP rules created for the authentication proxy for the ASA CX module.
show module	Shows the module status.
show running-config policy-map	Displays all current policy map configurations.
show service-policy	Shows service policy statistics.

CHAPTER 13

database path through debug cxsc Commands

database path

To specify a path or location for the local CA server database, use the **database** command in ca server configuration mode. To reset the path to flash memory, the default setting, use the **no** form of this command.

[**no**] **database path** *mount-name directory-path*

Syntax Description

directory-path	Specifies the path to a directory on the mount point where the CA files are stored.
mount-name	Specifies the mount name.

Defaults

By default, the CA server database is stored in flash memory.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Ca server configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The local CA files stored in the database include the certificate database, user database files, temporary PKCS12 files, and the current CRL file. The *mount-name* argument is the same as the *name* argument for the **mount** command that is used to specify a file system for the ASA.

Note These CA files are internal, stored files and should not be modified.

Examples

The following example defines the mount point for the CA database as cifs_share and the database files directory on the mount point as ca_dir/files_dir:

```
hostname(config)# crypto ca server
hostname(config-ca-server)# database path cifs_share ca_dir/files_dir/
hostname(config-ca-server)#
```

Related Commands

Command	Description
crypto ca server	Provides access to the ca server configuration mode CLI command set, which allows the user to configure and manage a local CA.
crypto ca server user-db write	Writes the user information configured in the local CA database to disk.
debug crypto ca server	Shows debugging messages when the user configures the local CA server.
mount	Makes the Common Internet File System (CIFS) and/or File Transfer Protocol file systems (FTPFS) accessible to the ASA.
show crypto ca server	Displays the characteristics of the CA configuration on the ASA.
show crypto ca server cert-db	Displays the certificates issued by the CA server.

ddns

To specify a Dynamic DNS (DDNS) update method type, use the **ddns** command in ddns-update-method mode. To remove an update method type from the running configuration, use the **no** form of this command.

ddns [**both**]

no ddns [**both**]

Syntax Description

both	(Optional) Specifies updates to both the DNS A and PTR resource records (RRs).

Defaults

Update only the DNS A RRs.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ddns-update-method	•	—	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

DDNS updates the name-to-address and address-to-name mapping maintained by DNS. Of the two methods for performing DDNS updates—the IETF standard defined by RFC 2136 and a generic HTTP method—the ASA supports the IETF method in this release.

Name and address mappings are contained in two types of RRs:

- The A resource record contains domain name-to-IP address mapping.
- The PTR resource record contains IP address-to-domain name mapping.

DDNS updates can be used to maintain consistent information between the DNS A and PTR RR types.

When issued in ddns-update-method configuration mode, the **ddns** command defines whether the update is just to a DNS A RR, or to both DNS A and PTR RR types.

Examples

The following example configures updates to both the DNS A and PTR RRs for the DDNS update method named ddns-2:

```
hostname(config)# ddns update method ddns-2
hostname(DDNS-update-method)# ddns both
```

Related Commands

Command	Description
ddns update	Associates a DDNS update method with an ASA interface or a DDNS update hostname.
ddns update method	Creates a method for dynamically updating DNS resource records.
dhcp-client update dns	Configures the update parameters that the DHCP client passes to the DHCP server.
dhcpd update dns	Enables a DHCP server to perform DDNS updates.
interval maximum	Configures the maximum interval between update attempts by a DDNS update method.

ddns update

To associate a dynamic DNS (DDNS) update method with an ASA interface or an update hostname, use the **ddns update** command in interface configuration mode. To remove the association between the DDNS update method and the interface or the hostname from the running configuration, use the **no** form of this command.

ddns update [*method-name* | **hostname** *hostname*]

no ddns update [*method-name* | **hostname** *hostname*]

Syntax Description

hostname	Specifies that the next term in the command string is a hostname.
hostname	Specifies a hostname to be used for updates.
method-name	Specifies a method name for association with the interface being configured.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Interface configuration	•	—	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

After defining a DDNS update method, you must associate it with an ASA interface to trigger DDNS updates.

A hostname could be a Fully Qualified Domain Name (FQDN) or just a hostname. If just a hostname, the ASA appends a domain name to the hostname to create a FQDN.

Examples

The following example associates the interface GigabitEthernet0/2 with the DDNS update method named ddns-2 and the hostname hostname1.example.com:

```
hostname(config)# interface GigabitEthernet0/2
hostname(config-if)# ddns update ddns-2
hostname(config-if)# ddns update hostname hostname1.example.com
```

Related Commands

Command	Description
ddns	Specifies a DDNS update method type for a created DDNS method.
ddns update method	Creates a method for dynamically updating DNS resource records.
dhcp-client update dns	Configures the update parameters that the DHCP client passes to the DHCP server.
dhcpd update dns	Enables a DHCP server to perform DDNS updates.
interval maximum	Configures the maximum interval between update attempts by a DDNS update method.

ddns update method

To create a method for dynamically updating DNS resource records (RRs), use the **ddns update method** command in global configuration mode. To remove a dynamic DNS (DDNS) update method from the running configuration, use the **no** form of this command.

ddns update method *name*

no ddns update method *name*

Syntax Description

name	Specifies the name of a method for dynamically updating DNS records.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

DDNS updates the name-to-address and address-to-name mapping maintained by DNS. The update method configured by the **ddns update method** command determines what and how often DDNS updates are performed. Of the two methods for performing DDNS updates—the IETF standard defined by RFC 2136 and a generic HTTP method—the ASA supports the IETF method in this release.

Name and address mapping is contained in two types of resource records (RRs):

- The A resource record contains domain name-to IP-address mapping.
- The PTR resource record contains IP address-to-domain name mapping.

DDNS updates can be used to maintain consistent information between the DNS A and PTR RR types.

Note Before the **ddns update method** command will work, you must configure a reachable default DNS server using the **dns** command with domain lookup enabled on the interface.

Examples

The following example configures the DDNS update method named ddns-2:

```
hostname(config)# ddns update method ddns-2
```

Related Commands

Command	Description
ddns	Specifies a DDNS update method type for a created DDNS method.
ddns update	Associates a DDNS update method with an ASA interface or a DDNS update hostname.
dhcp-client update dns	Configures the update parameters that the DHCP client passes to the DHCP server.
dhcpd update dns	Enables a DHCP server to perform dynamic DNS updates.
interval maximum	Configures the maximum interval between update attempts by a DDNS update method.

debug aaa

To show debugging messages for AAA, use the **debug aaa** command in privileged EXEC mode. To disable the display of AAA messages, use the **no** form of this command.

debug aaa [**accounting | authentication | authorization | common | internal | vpn** [*level*]]

no debug aaa

Syntax Description

accounting	(Optional) Show debugging messages for accounting only.
authentication	(Optional) Show debugging messages for authentication only.
authorization	(Optional) Show debugging messages for authorization only.
common	(Optional) Show debugging messages for different states within the AAA feature.
internal	(Optional) Show debugging messages for AAA functions supported by the local database only.
level	(Optional) Specifies the debugging level. Valid with the **vpn** keyword only.
vpn	(Optional) Show debugging messages for VPN-related AAA functions only.

Defaults

The default debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was modified to include new keywords.

Usage Guidelines

The **debug aaa** command displays detailed information about AAA activity. The **no debug all** and **undebug all** commands turn off all enabled debugging commands.

Examples

The following is sample output from the **debug aaa internal** command:

```
hostname(config)# debug aaa internal
debug aaa internal enabled at level 1
hostname(config)# uap allocated. remote address: 10.42.15.172, Session_id: 2147483841
uap freed for user . remote address: 10.42.15.172, session id: 2147483841
```

Related Commands

Command	Description
show running-config aaa	Displays the running configuration related to AAA.

debug acl filter

To enable VPN filter debugging, use the **debug acl filter** command in privileged EXEC mode. To disable VPN filter debugging, use the **no** form of this command.

debug acl filter

no debug acl filter

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
8.2(2)	This command was introduced.

Usage Guidelines

Use the **debug acl filter** command to help troubleshoot installation of the VPN filters into the ASP Filter table and removal of the VPN filters from the ASP Filter table.

Examples

The following is sample output from the **debug acl filter** command when a user 1 connects:

```
hostname(config)# debug acl filter
ACL FILTER INFO: first reference to inbound filter vpnfilter(2): Installing rule into NP.
 ACL FILTER INFO: first reference to outbound filter vpnfilter(2): Installing rule into
NP.
```

The following is sample output from the **debug acl filter** command when a user 1 disconnects:

```
hostname(config)# debug acl filter

ACL FILTER INFO: releasing last reference from inbound filter vpnfilter(2): Removing rule
into NP.
 ACL FILTER INFO: releasing last reference from outbound filter vpnfilter(2): Removing
rule into NP.
```

Related Commands

Command	Description
show asp table filter	Debugs the accelerated security path filter tables.
clear asp table filter	Clears the hit counters for the ASP filter table entries.

debug appfw

To display detailed information about application inspection, use the **debug appfw** command in privileged EXEC mode. To disable debugging, use the **no** form of this command.

debug appfw [**chunk** | **event** | **eventverb** | **regex**]

no debug appfw [**chunk** | **event** | **eventverb** | **regex**]

Syntax Description

chunk	(Optional) Displays runtime information about processing of chunked transfer encoded packets.
event	(Optional) Displays debug information about packet inspection events.
eventverb	(Optional) Displays the action taken by the ASA in response to an event.
regex	(Optional) Displays information about matching patterns with predefined signatures.

Defaults

All options are enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **debug appfw** command displays detailed information about HTTP application inspection. The **no debug all** and **undebug all** commands turn off all enabled **debug** commands.

Examples

The following example enables the display of detailed information about application inspection:

```
hostname# debug appfw
```

Related Commands

Commands	Description
http-map	Defines an HTTP map for configuring enhanced HTTP inspection.
inspect http	Applies a specific HTTP map to use for application inspection.

debug arp

To show debugging messages for ARP, use the **debug arp** command in privileged EXEC mode. To stop showing debugging messages for ARP, use the **no** form of this command.

debug arp

no debug arp

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debugging messages for ARP:

```
hostname# debug arp
```

Related Commands

Command	Description
arp	Adds a static ARP entry.
show arp statistics	Shows ARP statistics.
show debug	Shows all enabled debuggers.

debug arp-inspection

To show debugging messages for ARP inspection, use the **debug arp-inspection** command in privileged EXEC mode. To stop showing debugging messages for ARP inspection, use the **no** form of this command.

debug arp-inspection

no debug arp-inspection

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	—	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debugging messages for ARP inspection:

```
hostname# debug arp-inspection
```

Related Commands

Command	Description
arp	Adds a static ARP entry.
arp-inspection	For transparent firewall mode, inspects ARP packets to prevent ARP spoofing.
show debug	Shows all enabled debuggers.

debug asdm history

To view debugging information for ASDM, use the **debug asdm history** command in privileged EXEC mode.

debug asdm history *level*

Syntax Description

level	(Optional) Specifies the debugging level.

Defaults

The default debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was changed from the **debug pdm history** command to the **debug asdm history** command.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables level 1 debugging of ASDM:

```
hostname# debug asdm history
debug asdm history enabled at level 1

hostname#
```

Related Commands

Command	Description
show asdm history	Displays the contents of the ASDM history buffer.

debug auto-update

To display auto-update client and server debugging information, use the **debug auto-update** command in privileged EXEC mode. To disable the display of auto-update client and server debugging information, use the **no** form of this command.

debug auto-update client | server [*level*]

no debug auto-update client | server [*level*]

Syntax Description

client	Identifies the auto-update client.
level	(Optional) Sets the level at which to display debugging messages. The range of values is between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.
server	Identifies the auto-update server.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug auto-update** and the **show debug auto-update** commands.

```
hostname# debug auto-update client
hostname# debug auto-update server
hostname# show debug auto-update
debug auto-update client enabled at level 1
debug auto-update server enabled at level 1
```

Related Commands

Command	Description
show debug auto	Displays the current auto-update debugging configuration.

debug boot-mem

To display boot memory debugging information, use the **debug boot-mem** command in privileged EXEC mode. To disable the display of debugging information, use the **no** form of this command.

debug boot-mem [*level*]

no debug boot-mem [*level*]

Syntax Description

level	(Optional) Sets the level at which to display debugging messages. The range of values is between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug boot-mem** and the **show debug boot-mem** commands.

```
hostname# debug boot-mem
debug boot-mem enabled at level 1
hostname# show debug boot-mem
debug boot-mem enabled at level 1
```

Related Commands

Command	Description
show debug boot	Displays the current boot memory debugging configuration.

debug boot-module

To display boot module (SSM) debugging information, use the **debug boot-module** command in privileged EXEC mode. To disable the display of debugging information, use the **no** form of this command.

debug boot-module [*level*]

no debug boot-module [*level*]

Syntax Description

level	(Optional) Sets the level to display debugging messages. The range of values is between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.0(2)	This command was introduced.
8.6(1)	Supports software modules such as IPS. Supports the ASA 5512-X, 5515-X, 5525-X, 5545-X, and 5555-X.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug boot-module** command:

```
hostname# debug boot-module
debug boot-module enabled at level 1
```

Related Commands

Command	Description
show debug boot-mem	Displays the current boot memory debugging configuration.

debug cluster

To display ASA cluster debug information, use the **debug cluster** command in privileged EXEC mode. To disable the display of debug information, use the **no** form of this command.

debug cluster [**ccp** | **datapath** | **fsm** | **general** | **hc** | **license** | **rpc** | **transport**] [*level*]

no debug cluster [**ccp** | **datapath** | **fsm** | **general** | **hc** | **license** | **rpc** | **transport**]

Syntax Description

level	(Optional) Sets the debug message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.
ccp	(Optional) Displays debug messages for the cluster control protocol.
datapath	(Optional) Displays debug messages for the datapath.
fsm	(Optional) Displays debug messages for the finite state machine.
general	(Optional) Displays general clustering debug messages.
hc	(Optional) Displays debug messages for the health check.
license	(Optional) Displays debug messages for the cluster license.
rpc	(Optional) Displays debug messages for the RPC module.
transport	(Optional) Displays debug messages for the transport service.

Command Default

If you do not specify a debug type when enabling debug messages, then all types are enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables debug messages for all types:

```
hostname# debug cluster
```

Related Commands

Command	Description
debug lacp cluster	Enables debug messages for cluster Link Aggregation Control Protocol (cLACP).

debug context

To show debugging messages when you add or delete a security context, use the **debug context** command in privileged EXEC mode. To stop showing debugging messages for contexts, use the **no** form of this command.

debug context [*level*]

no debug context [*level*]

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debug messages for context management:

```
hostname# debug context
```

Related Commands

Command	Description
context	Creates a security context in the system configuration and enters context configuration mode.
show context	Shows context information.
show debug	Shows all enabled debuggers.

debug cplane

To show debugging messages about the control plane that connects internally to an SSM, use the **debug cplane** command in privileged EXEC mode. To stop showing debugging messages for the control plane, use the **no** form of this command.

debug cplane [*level*]

no debug cplane [*level*]

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debugging messages for the control plane:

```
hostname# debug cplane
```

Related Commands

Command	Description
hw-module module recover	Recovers an intelligent SSM by loading a recovery image from a TFTP server.
hw-module module reset	Shuts down an SSM and performs a hardware reset.
hw-module module reload	Reloads the intelligent SSM software.

Command	Description
hw-module module shutdown	Shuts down the SSM software in preparation for being powered off without losing configuration data.
show module	Shows SSM information.

debug crypto ca

To show debugging messages for PKI activity (used with CAs), use the **debug crypto ca** command in privileged EXEC mode. To disable the display of debugging messages for PKI, use the **no** form of this command.

debug crypto ca [**messages** | **transactions**] [*level*]

no debug crypto ca [**messages** | **transactions**] [*level*]

Syntax Description

messages	(Optional) Shows only debugging messages for PKI input and output messages.
transactions	(Optional) Shows only debugging messages for PKI transactions.
level	(Optional) Sets the level to display debugging messages.The range is between 1 and 255. To display additional messages at higher levels, set the level to a higher number. Level 1 (the default) shows messages only when errors occur. Level 2 shows warnings. Level 3 shows informational messages. Levels 4 and up show additional information for troubleshooting.

Defaults

By default, this command shows all debugging messages. The default level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debugging messages for PKI:

```
hostname# debug crypto ca
```

Related Commands

Command	Description
debug crypto engine	Shows debugging messages for the crypto engine.
debug crypto ipsec	Shows debugging messages for IPsec.
debug crypto isakmp	Shows debugging messages for ISAKMP.

debug crypto condition

To filter debugging messages for IPSec and ISAKMP based on the specified conditions, use the **debug crypto condition** command in privileged EXEC mode. To disable a single filtering condition without affecting other conditions, use the **no** form of this command.

debug crypto condition [[**peer [address** *peer_addr*] **subnet** *subnet_mask*]] | [**user** *user_name*] | [**group** *group_name*] | [spi *spi*] | [**reset**]

[no] debug crypto condition [[**peer [address** *peer_addr*] **subnet** *subnet_mask*]] | [**user** *user_name*] | [**group** *group_name*] | [**spi** *spi*] | [**reset**]

Syntax Description

group *group_name*	Specifies the group being used and the client group name.
peer *peer_addr*	Specifies the IPsec peer and its IP address
reset	Clears all filtering conditions and disables filtering.
spi *spi*	Specifies the IPsec SPI.
subnet *subnet_mask*	Specifies the subnet and subnet mask that are associated with the specified IP address.
user *user_name*	Specifies the client being used and the client username.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The **debug crypto condition** command does not affect the display or logging of syslog messages. This feature is not stored in the configuration, and must be reset after each power cycle.

Examples

The following examples configure a filter for the network, 10.1.1.0 and for the peer, 10.2.2.2:

```
hostname# debug crypto condition peer address 10.1.1.0 subnet 255.255.255.0
hostname# debug crypto condition peer address 10.2.2.2
```

The following example configures a filter for the user, “example_user”:

```
hostname# debug crypto condition user example_user
```

The following example clears the debugging filters:

```
hostname# debug crypto condition reset
```

Related Commands

Command	Description
debug crypto condition error	Shows debugging messages whether or not filtering conditions have been specified.
debug crypto condition unmatched	Shows debugging messages for IPsec and ISAKMP that do not include sufficient context information for filtering.
show crypto debug-condition	Shows the configured filters for IPsec and ISAKMP debugging messages.

debug crypto condition error

To show debugging messages for IPSec and ISAKMP whether or not they match any of the configured filters, use the **debug crypto condition error** command in privileged EXEC mode. To disable the display of debugging messages for IPsec and ISAKMP whether or not they match any of the configured filters, use the **no** form of this command.

debug crypto condition error [[**ipsec | isakmp**]

[**no**] **debug crypto condition error** [**ipsec | isakmp**]

Syntax Description

ipsec	Specifies the IPsec debugging messaging system.
isakmp	Specifies the ISAKMP debugging messaging system.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The **debug crypto condition error** command does not affect the display or logging of syslog messages. This feature is not stored in the configuration, and must be reset after each power cycle.

Examples

The following example configures IPsec messages to appear whether or not filtering conditions have been specified:

```
hostname# debug crypto condition error ipsec
```

Related Commands

Command	Description
debug crypto condition	Sets filtering conditions for IPsec and ISAKMP debugging messages.

Command	Description
debug crypto condition unmatched	Shows debugging messages for IPsec and ISAKMP that do not include sufficient context information for filtering.
show crypto debug-condition	Shows the configured filters for IPsec and ISAKMP debugging messages.

debug crypto condition unmatched

To show debugging messages for IPsec and ISAKMP that do not include sufficient context information for filtering, use the **debug crypto condition unmatched** command in privileged EXEC mode. To filter debugging messages for IPSec and ISAKMP that do not include sufficient context information, use the **no** form of this command.

debug crypto condition unmatched [[**ipsec | isakmp**]

[**no**] **debug crypto condition unmatched** [**ipsec | isakmp**]

Syntax Description

ipsec	Specifies the IPSec debugging messaging system.
isakmp	Specifies the ISAKMP debugging messaging system.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The **debug crypto condition unmatched** command does not affect the display or logging of syslog messages. This feature is not stored in the configuration, and must be reset after each power cycle.

Examples

The following example configures the filter to allow IPsec messages with insufficient context to appear:

```
hostname# debug crypto condition unmatched ipsec
```

Related Commands

Command	Description
debug crypto condition	Sets filtering conditions for IPsec and ISAKMP debugging messages.

Command	Description
debug crypto condition error	Shows debugging messages whether or not filtering conditions have been specified.
show crypto debug-condition	Shows the configured filters for IPsec and ISAKMP debugging messages.

debug crypto ca server

To set the local CA server debugging message level and begin listing associated debugging messages, use the **debug crypto ca server** command in ca server configuration mode. To disable the display of all debugging messages, use the **no** form of the command.

debug crypto ca server [*level*]

no debug crypto ca server [*level*]

Syntax Description

level	Sets the level to display associated debugging messages. The range of values is between 1 and 255.

Defaults

The default debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca server configuration	•	—	•	—	—
Global configuration	•	—	•	—	—
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks. Levels 5 and higher are reserved for raw data dumps and should be avoided during normal debugging because of excessive debugging output.

Examples

The following example sets the debugging level to 3:

```
hostname(config-ca-server)# debug crypto ca server 3
hostname(config-ca-server)#
```

The following example turns off all debugging:

```
hostname(config-ca-server)# no debug crypto ca server
hostname(config-ca-server)#
```

Related Commands

Command	Description
cdp-url	Specifies the certificate revocation list (CRL) distribution point (CDP) to be included in the certificates issued by the CA.
crypto ca server	Provides access to the ca server configuration mode CLI command set, which allows you to configure and manage the local CA.
database path	Specifies a path or location for the local CA server database.
show crypto ca server	Displays the characteristics of the certificate authority configuration on the ASA in ASCII text format.
show crypto ca server certificate	Displays the local CA configuration in base64 format.
show crypto ca server crl	Displays the current CRL of the local CA.

debug crypto condition error

To show debugging messages for IPsec and ISAKMP whether or not they match any of the configured filters, use the **debug crypto condition error** command in privileged EXEC mode. To disable the display of debugging messages for IPsec and ISAKMP whether or not they match any of the configured filters, use the **no** form of this command.

debug crypto condition error [**ipsec | isakmp**]

[**no**] **debug crypto condition error** [**ipsec | isakmp**]

Syntax Description

ipsec	Specifies the IPsec debugging messaging system.
isakmp	Specifies the ISAKMP debugging messaging system.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

The **debug crypto condition error** command does not affect the display or logging of syslog messages. This feature is not stored in the configuration, and must be reset after each power cycle.

Examples

The following example configures IPsec messages to appear whether or not filtering conditions have been specified:

```
hostname# debug crypto condition error ipsec
```

Related Commands

Command	Description
debug crypto condition	Sets filtering conditions for IPsec and ISAKMP debugging messages.
debug crypto condition unmatched	Shows debugging messages for IPsec and ISAKMP that do not include sufficient context information for filtering.
show crypto debug-condition	Shows the configured filters for IPsec and ISAKMP debugging messages.

debug crypto engine

To show debugging messages for the crypto engine, use the **debug crypto engine** command in privileged EXEC mode. To disable the display of debugging messages for the crypto engine, use the **no** form of this command.

debug crypto engine [*level*]

no debug crypto engine [*level*]

Syntax Description

level	(Optional) Sets the level to display debugging messages. The range of values is between 1 and 255. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debugging messages for the crypto engine:

```
hostname# debug crypto engine
```

Related Commands

Command	Description
debug crypto ca	Shows debugging messages for the CA.
debug crypto ipsec	Shows debugging messages for IPsec.
debug crypto ikev1	Shows debugging messages for IKEv1.
debug crypto ikev2	Shows debugging messages for IKEv2.

debug crypto ike-common

To show debugging processes that involve the IKE protocol, use the **debug crypto ike-common** command in privileged EXEC mode. To stop showing the debugging messages, use the **no** form of this command:

debug crypto ike-common [*level*]

no debug crypto ike-common [*level*]

Syntax Descriptiong

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number. Level 1 (the default) shows messages only when errors occur. Levels 2 through 7 show additional information. Level 254 shows decrypted IKE packets in a human readable format. Level 255 shows hexadecimal dumps of decrypted IKE packets.

ing

Defaults

The default level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(1)	The command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debugging messages processes involving the IKE protocol:

```
hostname# debug crypto ike-common
```

Related Commands

Command	Description
debug crypto ca	Shows debugging messages for the CA.
debug crypto engine	Shows debugging messages for the crypto engine.

Command	Description
debug crypto ipsec	Shows debugging messages for IPsec.
debug crypto ikev1	Shows debugging messages for IKEv1.
debug crypto ikev2	Shows debugging messages for IKEv2.

debug crypto ikev1

To show debug messages for IKEv1, use the **debug crypto ikev1** command in privileged EXEC mode. To stop showing the debugging messages, use the **no** form of this command:

debug crypto ikev1 [*level*] [**timers**]

no debug crypto ikev1 [*level*] [**timers**]

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number. Level 1 (the default) shows messages only when errors occur. Levels 2 through 7 show additional information. Level 254 shows decrypted IKEv1 packets in a human readable format. Level 255 shows hexadecimal dumps of decrypted IKEv1 packets.
timers	(Optional) Shows debugging messages for IKEv1 timer expiration.

Defaults

The default level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.4(1)	The command name changed from **debug crypto isakmp** to **debug crypto ikev1**.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debugging messages for IKEv1:

```
hostname# debug crypto ikev1
```

Related Commands

Command	Description
debug crypto ca	Shows debugging messages for the CA.
debug crypto engine	Shows debugging messages for the crypto engine.
debug crypto ipsec	Shows debugging messages for IPsec.
debug crypto ikev2	Shows debugging messages for IKEv2.

debug crypto ikev2

To show debugging messages for IKEv2, use the **debug crypto ikev2** command in privileged EXEC mode. To stop showing the debugging messages, use the **no** form of this command:

debug crypto ikev2 {**ha** | **platform** | **protocol** | **timers**} [*level*]

no debug crypto ikev2 {**ha** | **platform** | **protocol** | **timers**} [*level*]

Syntax Description

ha	Shows debugging messages for IKEv1 high availability.
level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number. Level 1 (the default) shows messages only when errors occur. Levels 2 through 7 show additional information. Level 254 shows decrypted IKEv1 packets in a human-readable format. Level 255 shows hexadecimal dumps of decrypted IKEv1 packets.
platform	Shows debugging messages about ASA processing of IKEv2 vs. protocol specific exchanges, such as AAA interfacing, session manager, and the ASA cryptographic module performing encryption and decryption.
protocol	Shows debugging messages about the IKEv1 protocol.
timers	(Optional) Shows debugging messages for IKEv1 timer expiration.

Defaults

The default level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(1)	The command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debug messages for IKEv2 protocol:

```
hostname# debug crypto ikev1 protocol
```

Related Commands

Command	Description
debug crypto ca	Shows debugging messages for the CA.
debug crypto engine	Shows debugging messages for the crypto engine.
debug crypto ipsec	Shows debugging messages for IPsec.
debug crypto ikev1	Shows debugging messages for IKEv1.

debug crypto ss-api

To show debugging messages for the crypto secure socket API, use the **debug crypto ss-api** command in privileged EXEC mode. To disable the display of these debugging messages, use the **no** form of this command.

debug crypto ss-api [*level*]

no debug crypto ss-api [*level*]

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debugging messages for the crypto secure socket API:

```
hostname# debug crypto ss-api
```

Related Commands

Command	Description
debug crypto ca	Shows debugging messages for the CA.
debug crypto engine	Shows debugging messages for the crypto engine.
debug crypto ikev1	Shows debugging messages for IKEv1.
debug crypto ikev2	Shows debugging messages for IKEv2.

debug crypto vpnclient

To show crypto debugging messages for the EasyVPN client, use the **debug crypto vpnclient** command in privileged EXEC mode. To stop showing the debugging messages, use the **no** form of this command:

debug crypto vpnclient [*level*]

no debug crypto vpnclient [*level*]

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables crypto debugging messages for the Easy VPN client:

```
hostname# debug crypto vpnclient
```

Related Commands

Command	Description
debug crypto ca	Shows debugging messages for the CA.
debug crypto engine	Shows debugging messages for the crypto engine.
debug crypto ikev1	Shows debugging messages for IKEv1.
debug crypto ikev2	Shows debugging messages for IKEv2.

debug crypto ipsec

To show debugging messages for IPsec, use the **debug crypto ipsec** command in privileged EXEC mode. To stop showing debugging messages for IPsec, use the **no** form of this command.

debug crypto ipsec [*level*]

no debug crypto ipsec [*level*]

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debugging messages for IPsec:

```
hostname# debug crypto ipsec
```

Related Commands

Command	Description
debug crypto ca	Shows debugging messages for the CA.
debug crypto engine	Shows debugging messages for the crypto engine.
debug crypto ikev1	Shows debugging messages for IKEv1.
debug crypto ikev2	Shows debugging messages for IKEv2.

debug ctiqbe

To show debugging messages for CTIQBE application inspection, use the **debug ctiqbe** command in privileged EXEC mode. To stop showing debugging messages for CTIQBE application inspection, use the **no** form of this command.

debug ctiqbe [*level*]

no debug ctiqbe [*level*]

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To see the current debugging command settings, enter the **show debug** command. To stop the debugging output, enter the **no debug** command. To stop all debugging messages from being displayed, enter the **no debug all** command.

Note Enabling the **debug ctiqbe** command may slow down traffic on busy networks.

Examples

The following example enables debugging messages at the default level (1) for CTIQBE application inspection:

```
hostname# debug ctiqbe
```

Related Commands

Command	Description
inspect ctiqbe	Enables CTIQBE application inspection.
show ctiqbe	Displays information about CTIQBE sessions established through the ASA.
show conn	Displays the connection state for different connection types.
timeout	Sets the maximum idle time duration for different protocols and session types.

debug ctl-provider

To show debugging messages for Certificate Trust List (CTL) providers, use the **debug ctl-provider** command in privileged EXEC mode. To stop showing debugging messages, use the **no** form of this command.

debug ctl-provider [**errors** | **events** | **parser**]

no debug ctl-provider [**errors** | **events** | **parser**]

Syntax Description

errors	Specifies CTL provider error debugging.
events	Specifies CTL provider event debugging.
parser	Specifies CTL provider parser debugging.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debugging messages for CTL provider:

```
hostname# debug ctl-provider
```

Related Commands

Command	Description
ctl	Parses the CTL file from the CTL client and install trustpoints.
ctl-provider	Configures a CTL provider instance in CTL provider mode.
export	Specifies the certificate to be exported to the client.
service	Specifies the port to which the CTL provider listens.

debug cxsc

To show debugging messages for the ASA CX module, use the **debug cxsc** command in privileged EXEC mode. To stop showing debugging messages, use the **no** form of this command.

debug cxsc [**error** | **event** | **message**]

no debug cxsc [**error** | **event** | **message**]

Syntax Description

error	Enables error-level debugging.
event	Enables event-level debugging.
message	Enables message-level debugging.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(4.1)	This command was introduced.
9.1(3)	You can now configure ASA CX policies per context.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

When you enable the authentication proxy, the ASA generates a debugging messge when it sends an authentication proxy TLV to the ASA CX module, giving details of the IP and port:

```
DP CXSC Event: Sent Auth proxy tlv for adding Auth Proxy on interface: inside4.
DP CXSC Event: Sent Auth proxy tlv for adding Auth Proxy on interface: cx_inside.
DP CXSC Event: Sent Auth proxy tlv for adding Auth Proxy on interface: cx_outside.
```

When the interface IP address is changed, auth-proxy tlv updates are sent to CXSC:

```
DP CXSC Event: Sent Auth proxy tlv for removing Auth Proxy for interface inside.
DP CXSC Event: Sent Auth proxy tlv for adding Auth Proxy on interface: inside.
```

When a flow is freed on the ASA, the ASA CX module is notified so it can clean up the flow:

```
DP CXSC Msg: Notifying CXSC that flow (handle:275233990) is being freed  for
192.168.18.5:2213 -> 10.166.255.18:80.
```

When the ASA CX module sends a redirect to a client to authenticate, and that redirect is sent to the ASA, the ASA sends it to the ASA CX module. In this example, 192.168.18.3 is the interface address and port 8888 is the authentication proxy port reserved on that interface for the authentication proxy feature:

```
DP CXSC Msg: rcvd authentication proxy data from 192.168.18.5:2214 -> 192.168.18.3:8888,
forwarding to cx
```

When a VPN connection is established on the ASA, and the ASA sends connection information to the ASA CX module:

```
CXSC Event:   Dumping attributes from the vpn session record
CXSC Event:   tunnel->Protocol:        17
CXSC Event:   tunnel->ClientVendor:    SSL VPN Client
CXSC Event:   tunnel->ClientVersion:   Cisco AnyConnect VPN Agent for Windows 2.4.1012
CXSC Event:   Sending VPN RA session data to CXSC
CXSC Event:   sess index:      0x3000
CXSC Event:   sess type id:    3
CXSC Event:   username:        devuser
CXSC Event:   domain:          CN=Users,DC=test,DC=priv
CXSC Event:   directory type:  1
CXSC Event:   login time:      1337124762
CXSC Event:   nac result:      0
CXSC Event:   posture token:
CXSC Event:   public IP:       172.23.34.108
CXSC Event:   assigned IP:     192.168.17.200
CXSC Event:   client OS id:    1
CXSC Event:   client OS:
CXSC Event:   client type:     Cisco AnyConnect VPN Agent for Windows 2.4.1012
CXSC Event:   anyconnect data: , len: 0
```

Related Commands

Command	Description
class	Specifies a class map to use for traffic classification.
class-map	Identifies traffic for use in a policy map.
cxsc	Redirects traffic to the ASA CX module.
cxsc auth-proxy port	Sets the authentication proxy port.
hw-module module password-reset	Resets the module password to the default.
hw-module module reload	Reloads the module.
hw-module module reset	Performs a reset and then reloads the module.
hw-module module shutdown	Shuts down the module.
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
session do get-config	Gets the module configuration.
session do password-reset	Resets the module password to the default.
session do setup host ip	Configures the module management address.
show asp table classify domain cxsc	Shows the NP rules created to send traffic to the ASA CX module.
show asp table classify domain cxsc-auth-proxy	Shows the NP rules created for the authentication proxy for the ASA CX module.
show module	Shows the module status.

Command	Description
show running-config policy-map	Displays all current policy map configurations.
show service-policy	Shows service policy statistics.

CHAPTER 14

debug dap through debug http-map Commands

debug dap

To enable logging of Dynamic Access Policy events, use the **debug dap** command in privileged EXEC mode. To disable the logging of DAP debugging messages, use the **no** form of this command.

debug dap {**errors** | **trace**}

no debug dap {**errors** | **trace**}

Syntax Description

errors	Specifies DAP processing errors.
trace	Specifies a DAP function trace.

Defaults

No default value or behaviors.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The high priority assigned to debugging output can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example shows how to enable DAP trace debugging:

```
hostname # debug dap trace
hostname #
```

Related Commands

Command	Description
dynamic-access-policy-record	Creates a DAP record.

debug ddns

To show debugging messages for DDNS, use the **debug ddns** command in privileged EXEC mode. To disable debugging messages, use the **no** form of this command.

debug ddns

no debug ddns

Syntax Description

This command has no arguments or keywords.

Defaults

The default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The **debug ddns** command displays detailed information about DDNS. The **undebug ddns** command and the **no debug ddns** command turn off DDNS debugging information.

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example shows an example of enabling DDNS debugging messages:

```
hostname# debug ddns
debug ddns enabled at level 1
```

Related Commands

Command	Description
ddns (DDNS-update-method mode)	Specifies a DDNS update method type for a created DDNS method.
ddns update (interface config mode)	Associates a DDNS update method with a ASA interface or a DDNS update hostname.
ddns update method (global config mode)	Creates a method for dynamically updating DNS resource records.
show running-config ddns	Displays the type and interval of all configured DDNS methods in the running configuration.

debug dhcpc

To enable debugging of the DHCP client, use the **debug dhcpc** command in privileged EXEC mode. To disable debugging, use the **no** form of this command.

debug dhcpc {**detail** | **packet** | **error**} [*level*]

no debug dhcpc {**detail** | **packet** | **error**} [*level*]

Syntax Description

detail	Displays detail event information that is associated with the DHCP client.
error	Displays error messages that are associated with the DHCP client.
level	(Optional) Specifies the debugging level. Valid values range from 1 to 255.
packet	Displays packet information that is associated with the DHCP client.

Defaults

The default debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command displays DHCP client debugging information.

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example shows how to enable debugging for the DHCP client:

```
hostname# debug dhcpc detail 5
debug dhcpc detail enabled at level 5
```

Related Commands

Command	Description
show ip address dhcp	Displays detailed information about the DHCP lease for an interface.
show running-config interface	Displays the running configuration of the specified interface.

debug dhcpd

To enable debugging of the DHCP server, use the **debug dhcpd** command in privileged EXEC mode. To disable debugging, use the **no** form of this command.

debug dhcpd {**event** | **packet**} [*level*]

no debug dhcpd {**event** | **packet**} [*level*]

Syntax Description

event	Displays event information that is associated with the DHCP server.
level	(Optional) Specifies the debugging level. Valid values range from 1 to 255.
packet	Displays packet information that is associated with the DHCP server.

Defaults

The default debug level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **debug dhcpd event** command displays event information about the DHCP server. The **debug dhcpd packet** command displays packet information about the DHCP server.

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example shows an example of enabling DHCP event debugging:

```
hostname# debug dhcpd event
debug dhcpd event enabled at level 1
```

Related Commands

Command	Description
show dhcpd	Displays DHCP binding, statistical, or state information.
show running-config dhcpd	Displays the current DHCP server configuration.

debug dhcpd ddns

To enable debugging of the DHCP DDNS, use the **debug dhcpd ddns** command in privileged EXEC mode. To disable debugging, use the **no** form of this command.

debug dhcpd ddns [*level*]

no debug dhcpd ddns [*level*]

Syntax Description

level	(Optional) Specifies the debugging level. Valid values range from 1 to 255.

Defaults

The default debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The **debug dhcpd ddns** command displays detailed information about DHCP and DDNS. The **undebug dhcpd ddns** command and the **no debug dhcpd ddns** command turn off DHCP and DDNS debugging information.

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example shows DHCP DDNS debugging being enabled:

```
hostname# debug dhcpd ddns
debug dhcpd ddns enabled at level 1
```

Related Commands

Command	Description
dhcpd update dns	Enables a DHCP server to perform DDNS updates.
show running-config dhcpd	Displays the current DHCP server configuration.
show running-config ddns	Display the DDNS update methods of the running configuration.

debug dhcprelay

To enable debugging of the DHCP relay server, use the **debug dhcpreleay** command in privileged EXEC mode. To disable debugging, use the **no** form of this command.

debug dhcprelay {**event** | **packet** | **error**} [*level*]

no debug dhcprelay {**event** | **packet** | **error**} [*level*]

Syntax Description

error	Displays error messages that are associated with the DHCP relay agent.
event	Displays event information that is associated with the DHCP relay agent.
level	(Optional) Specifies the debugging level. Valid values range from 1 to 255.
packet	Displays packet information that is associated with the DHCP relay agent.

Defaults

The default debug level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example shows how to enable debugging for DHCP relay agent error messages:

```
hostname# debug dhcprelay error
debug dhcprelay error enabled at level 1
```

Related Commands

Command	Description
clear configure dhcprelay	Removes all DHCP relay agent settings.
clear dhcprelay statistics	Clears the DHCP relay agent statistic counters.
show dhcprelay statistics	Displays DHCP relay agent statistic information.
show running-config dhcprelay	Displays the current DHCP relay agent configuration.

debug disk

To display file system debugging information, use the **debug disk** command in privileged EXEC mode. To disable the display of debugging information, use the **no** form of this command.

debug disk {**file** | **file-verbose** | **filesystem**} [*level*]

no debug disk {**file** | **file-verbose** | **filesystem**}

Syntax Description

file	Enables file-level disk debugging messages.
file-verbose	Enables verbose file-level disk debugging messages.
filesystem	Enables file system debugging messages.
level	(Optional) Sets the level to display debugging messages. The range of values is between 1 and 255. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug disk** and the **show debug** commands:

```
hostname# debug disk file
debug disk file enabled at level 1
hostname# show debug
debug vpn-sessiondb  enabled at level 1
hostname# dir
IFS: Opening: file flash:/, flags 1, mode 0
IFS: Opened: file flash:/ as fd 3
```

```
IFS: Getdent: fd 3
IFS: Getdent: fd 3
IFS: Getdent: fd 3
IFS: Getdent: fd 3

Directory of flash:/
IFS: Close: fd 3
IFS: Opening: file flash:/, flags 1, mode 0

4      -rw-  5124096     14:42:27 Apr 04 2005  cdisk.binIFS: Opened: file flash:/ as fd 3

IFS: Getdent: fd 3
IFS: Getdent: fd 3
IFS: Getdent: fd 3
IFS: Close: fd 3

16128000 bytes total (5047296 bytes free)
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug dns

To show debugging messages for DNS, use the **debug dns** command in privileged EXEC mode. To stop showing debugging messages for DNS, use the **no** form of this command.

debug dns [**resolver** | **all**] [*level*]

no debug dns [**resolver** | **all**] [*level*]

Syntax Description

all	(Default) Shows all messages, including messages about the DNS cache.
level	(Optional) Sets the debugging message level to display, which can be either 1 or 2. The default is 1. To display additional messages at higher levels, set the level to a higher number.
resolver	(Optional) Shows only DNS resolver messages.

Defaults

The default level is 1. If you do not specify any keywords, the ASA shows all mesages.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debugging messages for DNS:

```
hostname# debug dns
```

Related Commands

Command	Description
class-map	Defines the traffic class to which to apply security actions.
inspect dns	Enables DNS application inspection.
policy-map	Associates a class map with specific security actions.
service-policy	Applies a policy map to one or more interfaces.

debug eap

To enable logging of EAP events to debug NAC messaging, use the **debug eap** command in privileged EXEC mode. To disable the logging of EAP debugging messages, use the **no** form of this command.

debug eap {**all** | **errors** | **events** | **packets** | **sm**}

no debug eap {**all** | **errors** | **events** | **packets** | **sm**}

Syntax Description

all	Enables logging of debugging messages about all EAP information.
errors	Enables logging of EAP packet errors.
events	Enables logging of EAP session events.
packets	Enables logging of debugging messages about EAP packet information.
sm	Enables logging of debugging messages about EAP state machine information.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

When you use this command, the ASA records EAP session state changes and EAP status query events, and generates a complete record of EAP and packet contents in hexadecimal format.

The high priority assigned to debugging output can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables the logging of all EAP session events:

```
hostname# debug eap events
hostname#
```

The following example enables the logging of all EAP debugging messages:

```
hostname# debug eap all
hostname#
```

The following example disables the logging of all EAP debugging messages:

```
hostname# no debug eap
hostname#
```

Related Commands

Command	Description
debug eou	Enables logging of EAPoUDP events to debug NAC messaging.
debug nac	Enables logging of NAC events.
eou initialize	Clears the resources assigned to one or more NAC sessions and initiates a new, unconditional posture validation for each of the sessions.
eou revalidate	Forces immediate posture revalidation of one or more NAC sessions.
show debug	Displays a current debugging configuration.

debug eigrp fsm

To display debugging information the DUAL finite state machine, use the **debug eigrp fsm** command in privileged EXEC mode. To disable the debugging information display, use the **no** form of this command.

debug eigrp fsm

no debug eigrp fsm

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

This command lets you observe EIGRP feasible successor activity and to determine whether or not route updates are being installed and deleted by the routing process.

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug eigrp fsm** command:

```
hostname# debug eigrp fsm

DUAL: dual_rcvupdate(): 172.25.166.0 255.255.255.0 via 0.0.0.0 metric 750080/0
DUAL: Find FS for dest 172.25.166.0 255.255.255.0. FD is 4294967295, RD is 4294967295
found
DUAL: RT installed 172.25.166.0 255.255.255.0 via 0.0.0.0
DUAL: dual_rcvupdate(): 192.168.4.0 255.255.255.0 via 0.0.0.0 metric 4294967295/4294967295
DUAL: Find FS for dest 192.168.4.0 255.255.255.0. FD is 2249216, RD is 2249216
DUAL:   0.0.0.0 metric 4294967295/4294967295not found Dmin is 4294967295
```

```
DUAL: Dest 192.168.4.0 255.255.255.0 not entering active state.
DUAL: Removing dest 192.168.4.0 255.255.255.0, nexthop 0.0.0.0
DUAL: No routes. Flushing dest 192.168.4.0 255.255.255.0
```

In the fist line, DUAL stands for diffusing update algorithm. It is the basic mechanism within EIGRP that makes the routing decisions. The next three fields are the Internet address, mask of the destination network, and the address through which the update was received. The metric field shows the metric stored in the routing table and the metric advertised by the neighbor sending the information. If shown, the term “Metric... inaccessible” usually means that the neighbor router no longer has a route to the destination, or the destination is in a hold-down state.

In the following output, EIGRP is attempting to find a feasible successor for the destination. Feasible successors are part of the DUAL loop avoidance methods. The FD field includes more loop avoidance state information. The RD field is the reported distance, which is the metric used in update, query, or reply packets. The indented line with the “not found” message means a feasible successor was not found for 192.168.4.0, and EIGRP must start a diffusing computation. This means it begins to actively probe (sends query packets about destination 192.168.4.0) the network looking for alternate paths to 192.164.4.0.

```
DUAL: Find FS for dest 192.168.4.0 255.255.255.0. FD is 2249216, RD is 2249216
DUAL:   0.0.0.0 metric 4294967295/4294967295not found Dmin is 4294967295
```

The following output indicates the route DUAL successfully installed into the routing table:

```
DUAL: RT installed 172.25.166.0 255.255.255.0 via 0.0.0.0
```

The following output shows that no routes to the destination were discovered and that the route information is being removed from the topology table:

```
DUAL: Dest 192.168.4.0 255.255.255.0 not entering active state.
DUAL: Removing dest 192.168.4.0 255.255.255.0, nexthop 0.0.0.0
DUAL: No routes. Flushing dest 192.168.4.0 255.255.255.0
```

Related Commands

Command	Description
show eigrp topology	Displays the EIGRP topology table.

debug eigrp neighbors

To display debugging information for neighbors discovered by EIGRP, use the **debug eigrp neighbors** command in privileged EXEC mode. To disable the debugging information display, use the **no** form of this command.

debug eigrp neighbors [**siatimer** | **static**]

no debug eigrp neighbors [**siatimer** | **static**]

Syntax Description

siatimer	(Optional) Displays EIGRP stuck-in-active (SIA) messages.
static	(Optional) Displays EIGRP static neighbor messages.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug eigrp neighbors static** command. The example shows a static neighbor being added and then removed, and the corresponding debugging messages.

```
hostname# debug eigrp neighbors static

EIGRP Static Neighbors debugging is on

hostname# configure terminal
hostname(config) router eigrp 100
hostname(config-router)# neighbor 10.86.194.3 interface outside
hostname(config-router)#
```

```
EIGRP: Multicast Hello is disabled on Ethernet0/0!
EIGRP: Add new static nbr 10.86.194.3 to AS 100 Ethernet0/0

hostname(config-router)# no neighbor 10.86.194.3 interface outside
hostname(config-router)#

EIGRP: Static nbr 10.86.194.3 not in AS 100 Ethernet0/0 dynamic list
EIGRP: Delete static nbr 10.86.194.3 from AS 100 Ethernet0/0
EIGRP: Multicast Hello is enabled on Ethernet0/0!

hostname(config-router)# no debug eigrp neighbors static

EIGRP Static Neighbors debugging is off
```

Related Commands

Command	Description
neighbor	Defines an EIGRP neighbor.
show eigrp neighbors	Displays the EIGRP neighbor table.

debug eigrp packets

To display debugging information for EIGRP packets, use the **debug eigrp packets** command in privileged EXEC mode. To disable the debugging information display, use the **no** form of this command.

debug eigrp packets [**SIAquery | SIAreply | ack | hello | probe | query | reply | request | retry | stub | terse | update | verbose**]

no debug eigrp packets [**SIAquery | SIAreply | ack | hello | probe | query | reply | request | retry | stub | terse | update | verbose**]

Syntax Description

ack	(Optional) Limits the debugging output to EIGRP ack packets.
hello	(Optional) Limits the debugging output to EIGRP hello packets.
probe	(Optional) Limits the debugging output to EIGRP probe packets.
query	(Optional) Limits the debugging output to EIGRP query packets.
reply	(Optional) Limits the debugging output to EIGRP reply packets.
request	(Optional) Limits the debugging output to EIGRP request packets.
retry	(Optional) Limits the debugging output to EIGRP retry packets.
SIAquery	(Optional) Limits the debugging output to EIGRP stuck in active query packets.
SIAreply	(Optional) Limits the debugging output to EIGRP stuck in active reply packets.
stub	(Optional) Limits the debugging output to EIGRP stub routing packets.
terse	(Optional) Displays all EIGRP packets except hello packets.
update	(Optional) Limits the debugging output to EIGRP update packets.
verbose	(Optional) Outputs all packet debugging messages.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

You can specify more than one packet type in a single command, for example:

```
hostname# debug eigrp packets query reply
```

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug eigrp packets** command:

```
hostname# debug eigrp packets

EIGRP: Sending HELLO on Ethernet0/1
       AS 109, Flags 0x0, Seq 0, Ack 0
EIGRP: Sending HELLO on Ethernet0/1
       AS 109, Flags 0x0, Seq 0, Ack 0
EIGRP: Sending HELLO on Ethernet0/1
       AS 109, Flags 0x0, Seq 0, Ack 0
EIGRP: Received UPDATE on Ethernet0/1 from 192.195.78.24,
       AS 109, Flags 0x1, Seq 1, Ack 0
EIGRP: Sending HELLO/ACK on Ethernet0/1 to 192.195.78.24,
       AS 109, Flags 0x0, Seq 0, Ack 1
EIGRP: Sending HELLO/ACK on Ethernet0/1 to 192.195.78.24,
       AS 109, Flags 0x0, Seq 0, Ack 1
EIGRP: Received UPDATE on Ethernet0/1 from 192.195.78.24,
       AS 109, Flags 0x0, Seq 2, Ack 0
```

The output shows the transmission and receipt of EIGRP packets. The sequence and acknowledgment numbers used by the EIGRP reliable transport algorithm are shown in the output. Where applicable, the network-layer address of the neighboring router is also included.

Related Commands

Command	Description
show eigrp traffic	Displays the number of EIGRP packets sent and received.

debug eigrp transmit

To display transmission messages sent by EIGRP, use the **debug eigrp transmit** command in privileged EXEC mode. To disable the debugging information display, use the **no** form of this command.

debug eigrp transmit [**ack**] [**build**] [**detail**] [**link**] [**packetize**] [**peerdown**] [**sia**] [**startup**] [**strange**]

no debug eigrp transmit [**ack**] [**build**] [**detail**] [**link**] [**packetize**] [**peerdown**] [**sia**] [**startup**] [**strange**]

Syntax Description

ack	(Optional) Displays information for acknowledgment (ACK) messages sent by the system.
build	(Optional) Displays build information messages (messages that indicate that a topology table was either successfully built or could not be built).
detail	(Optional) Displays additional detail for debugging output.
link	(Optional) Displays information regarding topology table linked-list management.
packetize	(Optional) Displays information regarding packetized events.
peerdown	(Optional) Displays information regarding the effect on packet generation when a peer is down.
sia	(Optional) Displays stuck-in-active messages.
startup	(Optional) Displays information regarding peer startup and initialization packets that have been transmitted.
strange	(Optional) Displays unusual events relating to packet processing.

Defaults

If at least one transmission event is not specified, all transmission events are shown in the debugging output.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

You can specify more than one transmission event in a single command, For example:

```
hostname# debug eigrp ack build link
```

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug eigrp transmit** command. The example shows a **network** command being entered and the transmission event debugging message that is generated.

```
hostname# debug eigrp transmit

EIGRP Transmission Events debugging is on

    (ACK, PACKETIZE, STARTUP, PEERDOWN, LINK, BUILD, STRANGE, SIA, DETAIL)

hostname# configure terminal
hostname(config)# router eigrp 100
hostname(config-router)# network 10.86.194.0 255.255.255.0

DNDB UPDATE 10.86.194.0 255.255.255.0, serno 0 to 1, refcount 0

hostname(config-router)# no debug eigrp transmit

EIGRP Transmission Events debugging is off
```

Related Commands

Command	Description
show eigrp traffic	Displays the number of EIGRP packets sent and received.

debug eigrp user-interface

To display debugging information for EIGRP user events, use the **debug eigrp user-interface** command in privileged EXEC mode. To disable the debugging information display, use the **no** form of this command.

debug eigrp user-interface

no debug eigrp user-interface

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug eigrp user-interface** command. The output is caused by an administrator removing a **passive-interface** command from an EIGRP configuration.

```
hostname# debug eigrp user-interface

EIGRP UI Events debugging is on

hostname# configure terminal
hostname(config) router eigrp 100
hostname(config-router)# no passive-interface inside

CSB2AF: FOUND (AS=100, Name=, VRF=0, AFI=ipv4)
```

```
hostname(config-router)# no debug eigrp user-interface

EIGRP UI Events debugging is off
```

Related Commands

Command	Description
router eigrp	Enables an EIGRP routing process and enters router configuration mode.
show running-config eigrp	Displays the EIGRP commands in the running configuration.

debug email

To display e-mail debugging information, use the **debug email** command in privileged EXEC mode. To disable the display of e-mail debugging information, use the **no** form of this command.

debug email [*level*]

no debug email [*level*]

Syntax Description

level	(Optional) Sets the level to display debugging messages. The range of values is between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug email** and the **show debug email** commands:

```
hostname# debug email
debug email enabled at level 1
hostname# show debug email
debug email enabled at level 1
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug entity

To display MIB debugging information, use the **debug entity** command in privileged EXEC mode. To disable the display of debugging information, use the **no** form of this command.

debug entity [*level*]

no debug entity

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables MIB debugging messages. The **show debug** command indicates that MIB debugging messages are enabled.

```
hostname# debug entity
debug entity enabled at level 1
hostname# show debug
debug entity enabled at level 1
hostname#
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug eou

To enable logging of EAPoUDP events to debug NAC messaging, use the **debug eou** command in privileged EXEC mode. To disable the logging of EAPoUDP debugging messages, use the **no** form of this command.

debug eou {**all** | **eap** | **errors** | **events** | **packets** | **sm**}

no debug eou [**all** | **eap** | **errors** | **events** | **packets** | **sm**]

Syntax Description

all	Enables logging of debugging messages about all EAPoUDP information.
eap	Enables logging of debugging messages about EAPoUDP packets.
errors	Enables logging of EAPoUDP packet errors.
events	Enables logging of EAPoUDP session events.
packets	Enables logging of debugging messages about EAPoUDP packet information.
sm	Enables logging of debugging messages about EAPoUDP state machine information.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

When you use this command, the ASA records EAPoUDP session state changes and timer events, and generates a complete record of EAPoUDP header and packet contents in hexadecimal format.

The high priority assigned to debugging output can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables the logging of all EAPoUDP session events:

```
hostname# debug eou events
hostname#
```

The following example enables the logging of all EAPoUDP debugging messages:

```
hostname# debug eou all
hostname#
```

The following example disables the logging of all EAPoUDP debugging messages:

```
hostname# no debug eou
hostname#
```

Related Commands

Command	Description
debug eap	Enables logging of EAP events to debug NAC messaging.
debug nac	Enables logging of NAC events.
eou initialize	Clears the resources assigned to one or more NAC sessions and initiates a new, unconditional posture validation for each of the sessions.
eou revalidate	Forces immediate posture revalidation of one or more NAC sessions.
show debug	Displays the current debugging configuration.

debug esmtp

To show debugging messages for SMTP/ESMTP application inspection, use the **debug esmtp** command in privileged EXEC mode. To stop showing debugging messages for SMTP/ESMTP application inspection, use the **no** form of this command.

debug esmtp [*level*]

no debug esmtp [*level*]

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To see the current debugging command settings, enter the **show debug** command. To stop the debugging output, enter the **no debug** command. To stop all debugging messages from being displayed, enter the **no debug all** command.

Note Enabling the **debug esmtp** command may slow down traffic on busy networks.

Examples

The following example enables debugging messages at the default level (1) for SMTP/ESMTP application inspection:

```
hostname# debug esmtp
```

Related Commands

Command	Description
class-map	Defines the traffic class to which to apply security actions.
inspect esmtp	Enables ESMTP application inspection.
policy-map	Associates a class map with specific security actions.
service-policy	Applies a policy map to one or more interfaces.
show conn	Displays the connection state for different connection types, including SMTP.

debug etherchannel

To display EtherChannel debugging information, use the **debug etherchannel** command in privileged EXEC mode. To disable the display of debugging information, use the **no** form of this command.

debug etherchannel [**all** | **error** | **event**]

no debug etherchannel [**all** | **error** | **event**]

Syntax Description

all	(Optional) Displays all EtherChannel information.
event	(Optional) Displays major EtherChannel events.
error	(Optional) Displays EtherChannel errors.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.4(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables EtherChannel debug messages for events. The **show debug** command indicates that EtherChannel debugging messages are enabled.

```
hostname# debug etherchannel event
hostname# show debug
debug etherchannel event enabled
hostname#
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug fixup

To display detailed information about application inspection, use the **debug fixup** command in privileged EXEC mode. To disable debugging, use the **no** form of this command.

debug fixup

no debug fixup

Defaults

All options are enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **debug fixup** command displays detailed information about application inspection. The **no debug all** or **undebug all** command turns off all enabled **debug** commands.

Examples

The following example enables the display of detailed information about application inspection:

```
hostname# debug fixup
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
inspect *protocol*	Enables application inspection for specific protocols.
policy-map	Associates a class map with specific security actions.

debug fover

To display failover debug information, use the **debug fover** command in privileged EXEC mode. To disable the display of debug information, use the **no** form of this command.

debug fover {**cable** | **cmd-exec** | **fail** | **fmsg** | **ifc** | **open** | **rx** | **rxdmp** | **rxip** | **switch** | **sync** | **tx** | **txdmp** | **txip** | **verify**}

no debug fover {**cable** | **fail** | **fmsg** | **ifc** | **open** | **rx** | **rxdmp** | **rxip** | **switch** | **sync** | **tx** | **txdmp** | **txip** | **verify**}

Syntax Description

cable	Failover LAN status or serial cable status.
cmd-exec	**failover exec** command execution trace.
fail	Failover internal exception.
fmsg	Failover message.
ifc	Network interface status trace.
open	Failover device open.
rx	Failover message receive.
rxdmp	Failover receive message dump (serial console only).
rxip	IP network failover packet receive.
switch	Failover switching status.
sync	Failover configuration/command replication.
tx	Failover message transmit.
txdmp	Failover transmit message dump (serial console only).
txip	IP network failover packet transmit.
verify	Failover message verify.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was modified to include additional debugging keywords.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug fover cmd-exec** command. After debugging is enabled, a **failover exec** command is entered. The results of the **failover exec** command are shown after the debugging output.

```
hostname(config)# debug fover cmd-exec

fover event trace on

hostname(config)# failover exec mate show running-config failover

ci/console: Sending cmd: show runn failovero to peer for execution, seq = 4
ci/console: frep_execv_cmd: replicating exec cmd: show runn failover...

ci/console: Fover rexec waiting at clock tick 2670960
fover_parse: Fover rexec ack: seq = 4, ret_val = 0
ci/console: Fover rexec conteinuer at clock tick: 2671040
ci/console: Fover exec succeeded, seq = 5

failover
failover lan interface failover GigabitEthernet0/3
failover polltime unit 1 holdtime 3
failover key *****
failover link failover GigabitEthernet0/3
failover interface ip failover 10.0.5.1 255.255.255.0 standby 10.0.5.2
ciscoasa(config)#
```

Related Commands

Command	Description
show failover	Displays information about the failover configuration and operational statistics.

debug fsm

To display FSM debugging information, use the **debug fsm** command in privileged EXEC mode. To disable the display of debugging information, use the **no** form of this command.

debug fsm [*level*]

no debug fsm

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables FSM debugging messages. The **show debug** command indicates that FSM debugging messages are enabled.

```
hostname# debug fsm
debug fsm enabled at level 1
hostname# show debug
debug fsm enabled at level 1
hostname#
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug ftp client

To show debugging messages for FTP, use the **debug ftp client** command in privileged EXEC mode. To disable the display of debugging messages for FTP, use the **no** form of this command.

debug ftp client [*level*]

no debug ftp client [*level*]

Syntax Description

level	(Optional) Sets the level to display debugging messages. The range of values is between 1 and 255. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To see the current debugging command settings, enter the **show debug** command. To disable the debugging message output, enter the **no debug** command. To stop all debugging messages from being displayed, enter the **no debug all** command.

Note Enabling the **debug ftp client** command may slow down traffic on busy networks.

Examples

The following example enables debugging messages at the default level (1) for FTP:

```
hostname# debug ftp client
```

Related Commands

Command	Description
copy	Uploads or downloads image files or configuration files to or from an FTP server.
ftp mode passive	Configures the mode for FTP sessions.
show running-config ftp mode	Displays the FTP client configuration.

debug generic

To display miscellaneous debugging information, use the **debug generic** command in privileged EXEC mode. To disable the display of miscellaneous debugging information, use the **no** form of this command.

debug generic [*level*]

no debug generic

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables miscellaneous debug messages. The **show debug** command indicates that miscellaneous debugging messages are enabled.

```
hostname# debug generic
debug generic  enabled at level 1
hostname# show debug
debug generic  enabled at level 1
hostname#
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug gtp

To display detailed information about GTP inspection, use the **debug gtp** command in privileged EXEC mode. To disable debugging, use the **no** form of this command.

debug gtp {**error** | **event** | **ha** | **parser**}

no debug gtp {**error** | **event** | **ha** | **parser**}

Syntax Description

error	Displays debugging information on errors encountered while processing the GTP message.
event	Displays debugging information on GTP events.
ha option	Debugs information on GTP HA events.
parser	Displays debugging information for parsing the GTP messages.

Defaults

All options are enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **debug gtp** command displays detailed information about GTP inspection. The **no debug all** or **undebug all** command turns off all enabled **debug** commands.

Note GTP inspection requires a special license.

Examples

The following example enables the display of detailed information about GTP inspection:

```
hostname# debug gtp
```

Related Commands

Commands	Description
clear service-policy inspect gtp	Clears global GTP statistics.
gtp-map	Defines a GTP map and enables GTP map configuration mode.
inspect gtp	Applies a GTP map to use for application inspection.
show service-policy inspect gtp	Displays the GTP configuration.
show running-config gtp-map	Shows the GTP maps that have been configured.

debug h323

To show debugging messages for H.323, use the **debug h323** command in privileged EXEC mode. To stop showing debugging messages for H.323, use the **no** form of this command.

debug h323 {**h225** | **h245** | **ras**} [**asn** | **event**]

no debug h323 {**h225** | **h245** | **ras**} [**asn** | **event**]

Syntax Description

h225	Specifies H.225 signaling.
h245	Specifies H.245 signaling.
ras	Specifies the registration, admission, and status protocol.
asn	(Optional) Displays the output of the decoded protocol data units (PDU)s.
event	(Optional) Displays the signaling events or turns on both traces.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To see the current debugging command settings, enter the **show debug** command. To stop the debugging output, enter the **no debug** command. To stop all debugging messages from being displayed, enter the **no debug all** command.

Note Enabling the **debug h323** command may slow down traffic on busy networks.

Examples

The following example enables debugging messages at the default level (1) for H.225 signaling:

```
hostname# debug h323 h225
```

Related Commands

Command	Description
inspect h323	Enables H.323 application inspection.
show h225	Displays information for H.225 sessions established across the ASA.
show h245	Displays information for H.245 sessions established across the ASA by endpoints using slow start.
show h323-ras	Displays information for H.323 RAS sessions established across the ASA.
timeout h225 | h323	Configures the idle time after which an H.225 signalling connection or an H.323 control connection will be closed.

debug http

To display detailed information about HTTP traffic, use the **debug http** command in privileged EXEC mode. To disable debugging, use the **no** form of this command.

debug http [*level*]

no debug http [*level*]

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **debug http** command displays detailed information about HTTP traffic. The **no debug all** or **undebug all** command turns off all enabled **debug** commands.

Examples

The following example enables the display of detailed information about HTTP traffic:

```
hostname# debug http
```

Related Commands

Commands	Description
http	Specifies hosts that can access the HTTP server internal to the ASA.
http-proxy	Configures an HTTP proxy server.
http redirect	Redirects HTTP traffic to HTTPS.
http server enable	Enables the ASA HTTP server.

debug http-map

To show debugging messages for HTTP application inspection maps, use the **debug http-map** command in privileged EXEC mode. To stop showing debugging messages for HTTP application inspection, use the **no** form of this command.

debug http-map

no debug http-map

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To see the current debugging command settings, enter the **show debug** command. To stop the debugging output, enter the **no debug** command. To stop all debugging messages from being displayed, enter the **no debug all** command.

Note Enabling the **debug http-map** command may slow down traffic on busy networks.

Examples

The following example enables debugging messages at the default level (1) for HTTP application inspection:

```
hostname# debug http-map
```

Related Commands

Command	Description
class-map	Defines the traffic class to which to apply security actions.
debug appfw	Displays detailed information about HTTP application inspection.
http-map	Defines an HTTP map for configuring enhanced HTTP inspection.
inspect http	Applies a specific HTTP map to use for application inspection.
policy-map	Associates a class map with specific security actions.

CHAPTER 15

debug icmp through debug ospfv3 Commands

debug icmp

To display detailed information about ICMP inspection, use the **debug icmp** command in privileged EXEC mode. To disable debugging, use the **no** form of this command.

debug icmp trace [*level*]

no debug icmp trace [*level*]

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.
trace	Displays debugging information about ICMP trace activity.

Defaults

All options are enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **debug icmp** command displays detailed information about ICMP inspection. The **no debug all** or **undebug all** command turns off all enabled debugs.

Examples

The following example enables the display of detailed information about ICMP inspection:

```
hostname# debug icmp
```

Related Commands

Commands	Description
clear configure icmp	Clears the ICMP configuration.
icmp	Configures access rules for ICMP traffic that terminates at a ASA interface.
show conn	Displays the state of connections through the ASA for different protocols and session types.

Commands	Description
show icmp	Displays the ICMP configuration.
timeout icmp	Configures the idle timeout for ICMP.

debug idprom

To enable the display of IDPROM-related debugging information, use the **debug idprom** command in privileged EXEC mode. To disable the display of IDPROM-related debugging information, use the **no** form of this command.

debug idprom

no debug idprom

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.6(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables the display of debugging information for IDPROM-related errors:

```
hostname# debug idprom
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug igmp

To display IGMP debugging message information, use the **debug igmp** command in privileged EXEC mode. To disable the display of debugging message information, use the **no** form of this command.

debug igmp [**group** *group_id* | **interface** *if_name*]

no debug igmp [**group** *group_id* | **interface** *if_name*]

Syntax Description

group *group_id*	Displays IGMP debugging message information for the specified group.
interface *if_name*	Display IGMP debugging message information for the specified interface.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug igmp** command:

```
hostname# debug igmp

IGMP debugging is on
IGMP: Received v2 Query on outside from 192.168.3.2
IGMP: Send v2 general Query on dmz
IGMP: Received v2 Query on dmz from 192.168.4.1
IGMP: Send v2 general Query on outside
IGMP: Received v2 Query on outside from 192.168.3.1
IGMP: Send v2 general Query on inside
IGMP: Received v2 Query on inside from 192.168.1.1
IGMP: Received v2 Report on inside from 192.168.1.6 for 224.1.1.1
IGMP: Updating EXCLUDE group timer for 224.1.1.1
```

Related Commands

Command	Description
show igmp groups	Displays the multicast groups with receivers that are directly connected to the ASA and that were learned through IGMP.
show igmp interface	Displays multicast information for an interface.

debug ils

To show debugging messages for ILS, use the **debug ils** command in privileged EXEC mode. To stop showing debugging messages for ILS, use the **no** form of this command.

debug ils [*level*]

no debug ils [*level*]

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To see the current **debug** command settings, enter the **show debug** command. To stop the debugging output, enter the **no debug** command. To stop all debugging messages from being displayed, enter the **no debug all** command.

Note Enabling the **debug ils** command may slow down traffic on busy networks.

Examples

The following example enables debugging messages at the default level (1) for ILS application inspection:

```
hostname# debug ils
```

Related Commands

Command	Description
class-map	Defines the traffic class to which to apply security actions.
inspect ils	Enables ILS application inspection.
policy-map	Associates a class map with specific security actions.
service-policy	Applies a policy map to one or more interfaces.

debug imagemgr

To display Image Manager debugging information, use the **debug imagemgr** command in privileged EXEC mode. To disable the display of debugging information, use the **no** form of this command.

debug imagemgr [*level*]

no debug imagemgr [*level*]

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug imagemgr** and the **show debug** commands:

```
hostname# debug imagemgr
debug imagemgr  enabled at level 1
hostname# show debug
debug imagemgr  enabled at level 1
hostname#
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug inspect tls-proxy

To show debugging messages for TLS proxy inspection, use the **debug inspect tls-proxy** command in privileged EXEC mode. To stop showing debugging messages, use the **no** form of this command.

debug inspect tls-proxy [**all** | **errors** | **events** | **packets**]

no debug inspect tls-proxy [**all** | **errors** | **events** | **packets**]

Syntax Description

all	Specifies all TLS proxy debugging.
errors	Specifies TLS proxy error debugging.
events	Specifies TLS proxy event debugging.
packets	Specifies TLS proxy packet debugging.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debugging messages for TLS proxy:

```
hostname# debug inspect tls-proxy
```

Related Commands

Command	Description
client	Defines a cipher suite and sets the local dynamic certificate issuer or keypair.
ctl-provider	Defines a CTL provider instance and enters provider configuration mode.
show tls-proxy	Shows the TLS proxies.
tls-proxy	Defines a TLS proxy instance and sets the maximum sessions.

debug ip eigrp

To display debugging message information EIGRP protocol packets, use the **debug ip eigrp** command in privileged EXEC mode. To disable the debugging message information display, use the **no** form of this command.

debug ip eigrp [*as-number*] [*ip-addr mask* | **neighbor** *nbr-addr* | **notifications** | **summary**]

no debug ip eigrp [*as-number*] [*ip-addr mask* | **neighbor** *nbr-addr* | **notifications** | **summary**]

Syntax Description

as-number	(Optional) Specifies the autonomous system number of the EIGRP process for which you are viewing the event log. Because the ASA only supports one EIGRP routing process, you do not need to specify the autonomous system number.
ip-addr mask	(Optional) Limits debugging message output to messages that fall within the range defined by the IP address and network mask.
neighbor *nbr-addr*	(Optional) Limits debugging message output to the specified neighbor.
notifications	(Optional) Limits debugging message output to EIGRP protocol events and notifications.
summary	(Optional) Limits debugging message output to summary route processing.
user-interface	(Optional) Limits debugging message output to user events.

Defaults

If no keywords or arguments are specified, only debugging messages from the IPv4 ASDM appear.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

This command helps you analyze the packets that are sent and received on an interface.

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug ip eigrp** command:

```
hostname# debug ip eigrp

IP-EIGRP Route Events debugging is on

Table 15-1describes the significant fields shown in the display.

Table 15-1 debug ip eigrp Field Descriptions

Field	Description
IP-EIGRP:	Indicates IP EIGRP messages.
Ext	Indicates that the following address is an external route rather than an internal route, which would be labeled as Int.
M	Displays the computed metric, which includes the value in the SM field and the cost between this router and the neighbor. The first number is the composite metric. The next two numbers are the inverse bandwidth and the delay, respectively.
SM	Displays the metric as reported by the neighbor.

Related Commands

Command	Description
debug eigrp packets	Displays debugging information for EIGRP packets.

debug ipsec-over-tcp

To display IPsec-over-TCP debugging information, use the **debug ipsec-over-tcp** command in privileged EXEC mode. To disable the display of debugging information, use the **no** form of this command.

debug ipsec-over-tcp [*level*]

no debug ipsec-over-tcp

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables IPsec-over-TCP debugging messages. The **show debug** command reveals that IPsec-over-TCP debugging messages are enabled.

```
hostname# debug ipsec-over-tcp
debug ipsec-over-tcp  enabled at level 1
hostname# show debug
debug ipsec-over-tcp  enabled at level 1
hostname#
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug ipv6

To display IPv6 debugging messages, use the **debug ipv6** command in privileged EXEC mode. To stop the display of debugging messages, use the **no** form of this command.

debug ipv6 {**icmp** | **interface** | **mld** | **nd** | **packet** | **routing**}

no debug ipv6 {**icmp** | **interface** | **nd** | **packet** | **routing**}

Syntax Description

icmp	Displays debugging messages for IPv6 ICMP transactions, excluding ICMPv6 neighbor discovery transactions.
interface	Displays debugging information for IPv6 interfaces.
mld	Displays debugging messages for Multicast Listener Discovery (MLD).
nd	Displays debugging messages for ICMPv6 neighbor discovery transactions.
packet	Displays debugging messages for IPv6 packets.
routing	Displays debugging messages for IPv6 routing table updates and route cache updates.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output for the **debug ipv6 icmp** command:

```
hostname# debug ipv6 icmp
13:28:40:ICMPv6:Received ICMPv6 packet from 2000:0:0:3::2, type 136
13:28:45:ICMPv6:Received ICMPv6 packet from FE80::203:A0FF:FED6:1400, type 135
13:28:50:ICMPv6:Received ICMPv6 packet from FE80::203:A0FF:FED6:1400, type 136
```

```
13:28:55:ICMPv6:Received ICMPv6 packet from FE80::203:A0FF:FED6:1400, type 135
```

Related Commands

Command	Description
ipv6 icmp	Defines access rules for ICMP messages that terminate on an ASA interface.
ipv6 address	Configures an interface with an IPv6 address or addresses.
ipv6 nd dad attempts	Defines the number of neighbor discovery attempts performed during duplicate address detection.
ipv6 route	Defines a static entry in the IPv6 routing table.

debug ipv6 dhcp

To enable and disable generic IPv6 DHCP debugging messages, use the **debug ipv6 dhcp** command in privileged EXEC mode. To stop the display of debugging messages, use the **no** form of this command.

debug ipv6 dhcp

no debug ipv6 dhcp

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output for the **debug ipv6 dhcp** command:

```
hostname# debug ipv6 dhcp
IPv6 DHCP: Received RELAY-REPLY from fe80::2a0:c9ff:fe5d:41ed on cnr

IPv6 DHCP: detailed packet contents

    link 2002::1
    peer fe80::204:23ff:febb:b094
    option INTERFACE-ID(18), len 4
    0x00000003
    option RELAY-MSG(9), len 58
    type REPLY(7), xid 3718228
    option CLIENTID(1), len 14
```

```
  000100010f9a59d1000423bbb094
option SERVERID(2), len 14
  0001000147f28f15000cf1fcecac
option STATUS-CODE(13), len 14
  status code SUCCESS(0)
  status message: All on link!
```

Related Commands

Command	Description
debug ipv6 dhcprelay	Enables and disables IPv6 DHCP relay agent debugging.
show ipv6 dhcprelay binding	Displays the relay binding entries created by the relay agent.

debug ipv6 dhcprelay

To enable and disable IPv6 DHCP relay agent debugging messages, use the **debug ipv6 dhcprelay** command in privileged EXEC mode. To stop the display of debugging messages, use the **no** form of this command.

debug ipv6 dhcprelay

no debug ipv6 dhcprelay

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output for the **debug ipv6 dhcprelay** command:

```
hostname# debug ipv6 dhcprelay
IPv6 DHCP_RELAY: Relaying CONFIRM from fe80::204:23ff:febb:b094 on client
IPv6 DHCP_RELAY: Creating relay binding for fe80::204:23ff:febb:b094 at interface client
IPv6 DHCP_RELAY:   to fe80::2a0:c9ff:fe5d:41ed using cnr
IPv6 DHCP_RELAY:   to 2005::11 via 2005::11 using router
IPv6 DHCP_RELAY:   to fe80::204:23ff:febb:b094 using server
IPv6 DHCP_RELAY: Relaying RELAY-REPLY from fe80::2a0:c9ff:fe5d:41ed on cnr
IPv6 DHCP_RELAY:   relayed msg: REPLY
IPv6 DHCP_RELAY:   to fe80::204:23ff:febb:b094
IPv6 DHCP_RELAY: Deleting binding for fe80::204:23ff:febb:b094 at interface client
```

Related Commands

Command	Description
debug ipv6 dhcp	Enables and disables generic IPv6 DHCP debugging messages.
show ipv6 dhcprelay binding	Displays the relay binding entries created by the relay agent.

debug iua-proxy

To display IUA proxy debugging information, use the **debug iua-proxy** command in privileged EXEC mode. To disable the display of debugging information, use the **no** form of this command.

debug iua-proxy [*level*]

no debug iua-proxy

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables IUA-proxy debugging messages. The **show debug** command indicates that IUA-proxy debugging messages are enabled.

```
hostname# debug iua-proxy
debug iua-proxy  enabled at level 1
hostname# show debug
debug iua-proxy  enabled at level 1
hostname#
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug kerberos

To display Kerberos authentication debugging information, use the **debug kerberos** command in privileged EXEC mode. To disable the display of debugging information, use the **no** form of this command.

debug kerberos [*level*]

no debug kerberos

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging lvel is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables Kerberos debugging messages. The **show debug** command reveals that Kerberos debugging messages are enabled.

```
hostname# debug kerberos
debug kerberos enabled at level 1
hostname# show debug
debug kerberos enabled at level 1
hostname#
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug l2tp

To display L2TP debugging information, use the **debug l2tp** command in privileged EXEC mode. To disable the display of debugging information, use the **no** form of this command.

debug l2tp {**data** | **error** | **event** | **packet**} *level*

no debug l2tp {**data** | **error** | **event** | **packet**} *level*

Syntax Description

data	Displays data packet trace information.
error	Displays error events.
event	Displays L2TP connection events.
level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.
packet	Displays packet trace information.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables L2TP debugging messages for connection events. The **show debug** command indicates that L2TP debugging messages are enabled.

```
hostname# debug l2tp event 1
hostname# show debug
debug l2tp event enabled at level 1
hostname#
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug lacp

To display EtherChannel LACP debugging information, use the **debug lacp** command in privileged EXEC mode. To disable the display of debugging information, use the **no** form of this command.

debug lacp [**all** | **event** | **fsm** | **misc** | **packet** | **periodic**]

no debug lacp [**all** | **event** | **fsm** | **misc** | **packet** | **periodic**]

Syntax Description

all	(Optional) Displays all LACP information.
event	(Optional) Displays LACP events.
fsm	(Optional) Displays LACP finite state machine eventd.
misc	(Optional) Displays LACP miscellaneous events.
packet	(Optional) Displays LACP packet activity.
periodic	(Optional) Displays periodic events.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.4(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables LACP debugging messages for events. The **show debug** command indicates that LACP debugging messages are enabled.

```
hostname# debug lacp event
hostname# show debug
debug lacp event enabled
hostname#
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug lacp cluster

To display cluster Link Aggregation Control Protocol (cLACP) debug information, use the **debug lacp cluster** command in privileged EXEC mode. To disable the display of debug information, use the **no** form of this command.

debug lacp cluster [**all** | **ccp** | **misc** | **protocol**] [*level*]

no debug lacp cluster [**all** | **ccp** | **misc** | **protocol**]

Syntax Description

level	(Optional) Sets the debug message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.
ccp	(Optional) Displays debug messages for the cluster control process.
all	(Optional) Displays messages for all debug types.
misc	(Optional) Displays miscellaneous clustering debug messages.
protocol	(Optional) Displays debug messages for the protocol.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables debug messages for all types:

```
hostname# debug lacp cluster all
```

Related Commands

Command	Description
debug cluster	Enables debug messages for clustering.

debug ldap

To display LDAP debugging information, use the **debug ldap** command in privileged EXEC mode. To disable the display of debugging information, use the **no** form of this command.

debug ldap [*level*]

no debug ldap

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables LDAP debugging messages. The **show debug** command indicates that LDAP debugging messages are enabled.

```
hostname# debug ldap
debug ldap enabled at level 1
hostname# show debug
debug ldap enabled at level 1
hostname#
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug license

To show debugging messages for licenses, use the **debug license** command in privileged EXEC mode. To stop showing debugging messages for licenses, use the **no** form of this command.

debug license [*level*]

[no] debug license [*level*]

Syntax Description

level	Indicates the privilege level assigned to the specified user.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debugging for licenses:

```
hostname# debug lioense 255
debug license enabled at level 255
```

Related Commands

Command	Description
license server-enable	Identifies a unit as a shared licensing server.
show activation-key	Shows the current licenses installed.
show debug	Shows all enabled debuggers.

debug mac-address-table

To show debugging messages for the MAC address table, use the **debug mac-address-table** command in privileged EXEC mode. To stop showing debugging messages for the MAC address table, use the **no** form of this command.

debug mac-address-table [*level*]

no debug mac-address-table [*level*]

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	—	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debugging messages for the MAC address table:

```
hostname# debug mac-address-table
```

Related Commands

Command	Description
mac-address-table aging-time	Sets the timeout for dynamic MAC address entries.
mac-address-table static	Adds static MAC address entries to the MAC address table.
mac-learn	Disables MAC address learning.

Command	Description
show debug	Shows all enabled debuggers.
show mac-address-table	Shows MAC address table entries.

debug menu

To display detailed debugging information for specific features, use the **debug menu** command in privileged EXEC mode.

debug menu [**aaa | ak47 | coredump | crashinfo | ctm | cts | dap | email | fw | ike-common | ikev1 | ikev2 | ipaddrutl | ipsec-over-tcp | ipv6 | license | memory | nac | npshim | pki | ppp | qos | quota | regex | sessmgr | splitdns | ssl | syslog | vpnfo | vpnlib | webvpn**]

Syntax Description

aaa	(Optional) Specifies debugging information for the AAA feature.
ak47	(Optional) Specifies debugging information for the Application Kernel layer 4 to 7 framework feature.
coredump	(Optional) Specifies debugging information for the coredump feature.
crashinfo	(Optional) Specifies debugging information for the crashinfo feature.
ctm	(Optional) Specifies debugging information for the CTM feature.
cts	(Optional) Specifies debugging information for the CTS feature.
dap	(Optional) Specifies debugging information for the DAP feature.
email	(Optional) Specifies debugging information for the e-mail feature.
fw	(Optional) Specifies debugging information for the firewall feature.
ike-common	(Optional) Specifies debugging information for the IKE feature.
ikev1	(Optional) Specifies debugging information for the IKEv1 feature.
ikev2	(Optional) Specifies debugging information for the IKEv2 feature.
ipaddrutl	(Optional) Specifies debugging information for the IP address utilityfeature.
ipsec-over-tcp	(Optional) Specifies debugging information for the IPsec over TCP feature.
ipv6	(Optional) Specifies debugging information for the IPv6 feature.
license	(Optional) Specifies debugging information for the licensing feature.
memory	(Optional) Specifies debugging information for the memory feature.
nac	(Optional) Specifies debugging information for the NAC feature.
npshim	(Optional) Specifies debugging information for the NPSHIM feature.
pki	(Optional) Specifies debugging information for the PKI feature.
ppp	(Optional) Specifies debugging information for the PPP feature.
qos	(Optional) Specifies debugging information for the QoS feature.
quota	(Optional) Specifies debugging information for the quota feature.
regex	(Optional) Specifies debugging information for the registered expression feature.
sessmgr	(Optional) Specifies debugging information for the session manager feature.
splitdns	(Optional) Specifies debugging information for the split DNS feature.
ssl	(Optional) Specifies debugging information for the SSL feature.
syslog	(Optional) Specifies debugging information for the syslog feature.
vpnfo	(Optional) Specifies debugging information for the VPN failover feature.
vpnlib	(Optional) Specifies debugging information for the VPN library feature.
webvpn	(Optional) Specifies debugging information for the WebVPN feature.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
9.1(4)	The **ak47** option was added.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Caution The **debug menu** command should be used only under the supervision of Cisco TAC.

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug mfib

To display MFIB debugging information, use the **debug mfib** command in privileged EXEC mode. To disable the display of debugging information, use the **no** form of this command.

debug mfib {**db** | **init** | **mrib** | **pak** | **ps** | **signal**} [*group*] [**cluster**]

no debug mfib {**db** | **init** | **mrib** | **pak** | **ps** | **signal**} [*group*] [**cluster**]

Syntax Description

cluster	(Optional) Displays debugging information for the MFIB epoch number and the current timer value for the cluster.
group	(Optional) Displays the IP address of the multicast group.
init	(Optional) Displays system initialization activity.
mrib	(Optional) Displays debugging information for communication with MFIB.
pak	(Optional) Displays debugging information for packet forwarding operations.
ps	(Optional) Displays debugging information for process switching operations.
signal	(Optional) Displays debugging information for MFIB signaling to routing protocols.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	The **cluster** keyword was added.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug mfib db** command:

```
hostname# debug mfib db
MFIB IPv4 db debugging enabled
```

The following is sample output from the **debug mfib cluster** command:

```
hostname# debug mfib cluster

MFIB CLUSTER: MFIB CLUSTER: mfib_cluster_send_update_msg sync DB entry add:
s=172.23.57.98, g=229.111.112.12, mask_len=32, epoch=1, attr=0x20

MFIB CLUSTER: MFIB CLUSTER: mfib_cluster_send_update_msg sync DB entry add:
s=172.23.57.98, g=229.111.112.12, mask_len=32, epoch=1, attr=0x20

MFIB CLUSTER: MFIB CLUSTER: mfib_cluster_send_update_msg sync DB entry add:
s=172.23.57.98, g=229.111.112.12, mask_len=32, epoch=1, attr=0x20

MFIB CLUSTER: MFIB CLUSTER: mfib_cluster_send_update_msg sync DB entry add:
s=172.23.57.98, g=229.111.112.12, mask_len=32, epoch=1, attr=0x20
```

Related Commands

Command	Description
show mfib	Displays MFIB forwarding entries and interfaces.

debug mgcp

To display detailed information about MGCP application inspection, use the **debug mgcp** command in privileged EXEC mode. To disable debugging, use the **no** form of this command.

debug mgcp {**messages** | **parser** | **sessions**}

no debug mgcp {**messages** | **parser** | **sessions**}

Syntax Description

messages	Displays debugging information about MGCP messages.
parser	Displays debugging information for parsing MGCP messages.
sessions	Displays debugging information about MGCP sessions.

Defaults

All options are enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **debug mgcp** command displays detailed information about MGCP inspection. The **no debug all** or **undebug all** command turns off all enabled debugging.

Examples

The following example enables the display of detailed information about MGCP application inspection:

```
hostname# debug mgcp
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
inspect mgcp	Enables MGCP application inspection.
mgcp-map	Defines an MGCP map and enables MGCP map configuration mode.
show mgcp	Displays information about MGCP sessions established through the ASA.
show conn	Displays the connection state for different connection types.

debug mmp

To display inspect MMP events, use the **debug mmp** command in privileged EXEC mode. To stop the display of inspect MMP events, use the **no** form of this command.

debug mmp

no debug mmp

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Examples

The following example shows how to display inspect MMP events:

```
hostname# debug mmp
ciscoasa5520-tfw-cuma/admin(config-pmap)# MMP:: received 28 bytes from outside:1

```

Related Commands

Command	Description
inspect mmp	Configures the MMP inspection engine.
show debug mmp	Displays the current debugging settings for the MMP inspection module.
show mmp	Displays information about existing MMP sessions.

debug module-boot

To show debugging messages about the SSM booting process, use the **debug module-boot** command in privileged EXEC mode. To disable the display of debugging messages for the SSM booting process, use the **no** form of this command.

debug module-boot [*level*]

no debug module-boot [*level*]

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debugging messages for the SSM booting process:

```
hostname# debug module-boot
```

Related Commands

Command	Description
hw-module module recover	Recovers an intelligent SSM by loading a recovery image from a TFTP server.
hw-module module reset	Shuts down an SSM and performs a hardware reset.
hw-module module reload	Reloads the intelligent SSM software.

Command	Description
hw-module module shutdown	Shuts down the SSM software in preparation for being powered off without losing configuration data.
show module	Shows SSM information.

debug mrib

To display MRIB debugging information, use the **debug mrib** command in privileged EXEC mode. To disable the display of debugging information, use the **no** form of this command.

debug mrib {**client** | **io** | **route** [*group*] | **table**}

no debug mrib {**client** | **io** | **route** [*group*] | **table**}

Syntax Description

client	Enables debugging for MRIB client management activity.
io	Enables debugging of MRIB I/O events.
route	Enables debugging of MRIB routing entry activity.
group	Enables debugging of MRIB routing entry activity for the specified group.
table	Enables debugging of MRIB table management activity.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug mrib** io command:

```
hostname# debug mrib io
IPv4 MRIB io debugging is on
```

Related Commands

Command	Description
show mrib client	Displays information about the MRIB client connections.
show mrib route	Displays MRIB table entries.

debug nac

To enable logging of NAC Framework events, use the **debug nac** command in privileged EXEC mode. To disable the logging of NAC debugging messages, use the **no** form of this command.

debug nac {**all** | **auth** | **errors** | **events**}

no debug nac {**all** | **auth** | **errors** | **events**}

Syntax Description

all	Enables logging of debugging messages about all NAC information.
auth	Enables logging of debugging messages about NAC authentication requests and responses.
errors	Enables logging of NAC session errors.
events	Enables logging of NAC session events.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

When you use this command, the ASA logs the following types of NAC events: initializations, exception list matches, ACS transactions, clientless authentications, default ACL applications, and revalidations.

The high priority assigned to debugging output can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables the logging of all NAC session events:

```
hostname# debug nac events
hostname#
```

The following example enables the logging of all NAC debugging messages:

```
hostname# debug nac all
```

```
hostname#
```

The following example disables the logging of all NAC debugging messages:

```
hostname# no debug nac
hostname#
```

Related Commands

Command	Description
debug eap	Enables logging of Extensible Authentication Protocol events to debug NAC Framework messaging.
debug eou	Enables logging of EAP over UDP events to debug NAC Framework messaging.
show vpn-session_summary.db	Displays the number of IPsec, WebVPN, and NAC sessions.
show vpn-session.db	Displays information about VPN sessions, including NAC results.

debug ntdomain

To display NT domain authentication debugging information, use the **debug ntdomain** command in privileged EXEC mode. To disable the display of NT domain debugging information, use the **no** form of this command.

debug ntdomain [*level*]

no debug ntdomain

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables NT domain debugging messages. The **show debug** command indicates that NT domain debugging messages are enabled.

```
hostname# debug ntdomain
debug ntdomain enabled at level 1
hostname# show debug
debug ntdomain enabled at level 1
hostname#
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug ntp

To show debugging messages for NTP, use the **debug ntp** command in privileged EXEC mode. To stop showing debugging messages for NTP, use the **no** form of this command.

debug ntp {**adjust** | **authentication** | **events** | **loopfilter** | **packets** | **params** | **select** | **sync** | **validity**}

no debug ntp {**adjust** | **authentication** | **events** | **loopfilter** | **packets** | **params** | **select** | **sync** | **validity**}

Syntax Description

adjust	Shows messages about NTP clock adjustments.
authentication	Shows messages about NTP authentication.
events	Shows messages about NTP events.
loopfilter	Shows messages about NTP loop filter.
packets	Shows messages about NTP packets.
params	Shows messages about NTP clock parameters.
select	Shows messages about NTP clock selection.
sync	Shows messages about NTP clock synchronization.
validity	Shows messages about NTP peer clock validity.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debugging messages for NTP:

```
hostname# debug ntp events
```

Related Commands

Command	Description
ntp authenticate	Enables NTP authentication.
ntp server	Identifies an NTP server.
show debug	Shows all enabled debuggers.
show ntp associations	Shows the NTP servers with which the ASA is associated.
show ntp status	Shows the status of the NTP association.

debug ospf

To display debugging information about the OSPF routing processes, use the **debug ospf** command in privileged EXEC mode. To disable the display of debugging information, use the **no** form of this command.

debug ospf [**adj** | **database-timer** | **events** | **flood** | **hello** | **ipsec** | **lsa** | **lsa-generation** | **lsa-maxage** | **lsdb** | **packet** | **rate-limit** | **retransmission** | **spf** | **tree**] [**external**]

no debug ospf [**adj** | **database-timer** | **events** | **flood** | **hello** | **ipsec** | **lsa** | **lsa-generation** | **lsa-maxage** | **lsdb** | **packet** | **rate-limit** | **retransmission** | **spf** | **tree**] [**external**]

Syntax Description

adj	(Optional) Enables the debugging of OSPF adjacency events.
database-timer	(Optional) Enables the debugging of OSPF database timer events.
events	(Optional) Enables the debugging of OSPF events.
external	(Optional) Limits SPF debugging to external events.
flood	(Optional) Enables the debugging of OSPF flooding events.
hello	(Optional) Enables the debugging of OSPF hello events.
ipsec	(Optional) Enables the debugging of OSPF IPsec events.
lsa	(Optional) Enables SPF debugging of LSA events.
lsa-generation	(Optional) Enables the debugging of OSPF summary LSA generation events.
lsa-maxage	(Optional) Enables the debugging of OSPF summary LSA maximum age events.
lsdb	(Optional) Enables the debugging of OSPF summary LSA database events.
packet	(Optional) Enables the debugging of received OSPF packets.
rate-limit	(Optional) Enables the debugging of received OSPF rate limits.
retransmission	(Optional) Enables the debugging of OSPF retransmission events.
spf	(Optional) Enables the debugging of OSPF shortest path first calculations.
tree	(Optional) Enables the debugging of OSPF database events.

Defaults

Displays all OSPF debugging information if no keyword is provided.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	The following keywords have been added: **hello, ipsec, lsa, lsa-maxage, lsdb,** and **rate-limit.**

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug ospf events** command:

```
hostname# debug ospf events
ospf event debugging is on

OSPF:hello with invalid timers on interface Ethernet0
hello interval received 10 configured 10
net mask received 255.255.255.0 configured 255.255.255.0
dead interval received 40 configured 30
```

Related Commands

Command	Description
show ospf	Displays general information about the OSPF routing process.

debug ospfv3

To display debugging information about the OSPFv3 routing processes, use the **debug ospfv3** command in privileged EXEC mode. To disable the display of debugging information, use the **no** form of this command.

debug ospfv3 [**adj** | **database-timer** | **events** | **flood** | **hello** | **lsa-generation** | **packet** | **retransmission** | **spf**]

no debug ospfv3 [**adj** | **database-timer** | **events** | **flood** | **hello** | **lsa-generation** | **packet** | **retransmission** | **spf**]

Syntax Description

adj	(Optional) Enables the debugging of OSPFv3 adjacency events.
database-timer	(Optional) Enables the debugging of OSPFv3 timer events.
events	(Optional) Enables the debugging of OSPFv3 events.
flood	(Optional) Enables the debugging of OSPFv3 flooding.
hello	(Optional) Enables the debugging of OSPFv3 hello events.
lsa-generation	(Optional) Enables the debugging of OSPFv3 summary LSA generation.
packet	(Optional) Enables the debugging of received OSPv3F packets.
retransmission	(Optional) Enables the debugging of OSPFv3 retransmission events.
spf	(Optional) Enables the debugging of OSPFv3 SPF calculations.

Defaults

Displays all OSPFv3 debugging information if no keyword is provided.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug ospf events** command:

```
hostname# debug ospfv3 events
ospfv3 event debugging is on

OSPFv3:hello with invalid timers on interface Ethernet0
hello interval received 10 configured 10
net mask received 255.255.255.0 configured 255.255.255.0
dead interval received 40 configured 30
```

Related Commands

Command	Description
show ipv6 ospf	Displays general information about the OSPFv3 routing process.

CHAPTER 16

debug parser cache through debug xml Commands

debug parser cache

To display CLI parser debugging information, use the **debug parser cache** command in privileged EXEC mode. To disable the display of CLI parser debugging information, use the **no** form of this command.

debug parser cache [*level*]

no debug parser cache

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables CLI parser debugging messages. The **show debug** command indicates the current debugging configuration. The CLI parser debugging messages appear before and after the output of the **show debug** command.

```
hostname# debug parser cache
debug parser cache enabled at level 1
hostname# show debug
parser cache: try to match 'show debug' in exec mode
debug parser cache enabled at level 1
parser cache: hit at index 8
hostname#
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug phone-proxy

To show debugging messages for the Phone Proxy instance, use the **debug phone-proxy** command in privileged EXEC mode. To stop displaying Phone Proxy messages, use the **no** form of this command.

debug phone-proxy [**media** | **signaling** | **tftp** [**errors** | **events**]]

no debug phone-proxy [**media** | **signaling** | **tftp** [**errors** | **events**]]

Syntax Description

errors	(Optional) Show debugging messages of phone-proxy errors.
events	(Optional) Show debugging messages of phone-proxy events.
media	(Optional) Show debugging messages of media sessions for SIP and Skinny inspections.
signaling	(Optional) Show debugging messages of signaling sessions for SIP and Skinny inspections.
tftp	(Optional) Show debugging messages of TFTP inspection, including creation of the CTL file and configuration file parsing.

Defaults

If no options are specified with the **debug phone-proxy** command, all phone-proxy debugging messages are displayed.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Usage Guidelines

The **debug phone-proxy** command displays detailed information about Phone Proxy activity. The **no debug phone-proxy** commands turn off all enabled debugging.

Examples

The following example shows successful TFTP transactions for the configuration file request for the Phone Proxy:

```
hostname(config)# debug phone-proxy tftp
PP: 98.208.49.30/1028 requesting SEP00070E364804.cnf.xml.sgn
PP: opened 0x33952aa2
PP: Received data from 192.168.200.101 to outside:98.208.49.30/1028
        Received Block 1
```

```
PP: Acked Block #1 from 98.208.49.30/1028 to 192.168.200.101/39514
           .... [snip].....
PP: Received data from 192.168.200.101 to outside:98.208.49.30/1028
       Received Block 10
PP: Acked Block #10 from 98.208.49.30/1028 to 192.168.200.101/39514
PP: Installed application redirect rule from 98.208.49.30 to 192.168.200.101 using
redirect port 2000 and secure port 2443
PP: Modifying to TLS as the transport layer protocol.
PP: Modifying to encrypted mode.
PP: Data Block 1 forwarded from 192.168.200.101/39514 to 98.208.49.30/1028
PP: Received ACK Block 1 from outside:98.208.49.30/1028 to inside:192.168.200.101
           ..... [snip] ....
PP: Data Block 11 forwarded to 98.208.49.30/1028
PP: Received ACK Block 11 from outside:98.208.49.30/1028 to inside:192.168.200.101
PP: TFTP session complete, all data sent
```

Related Commands

Command	Description
phone-proxy	Configures the Phone Proxy instance.
show running-config phone-proxy	Displays Phone Proxy-specific information.

debug pim

To display PIM debugging information, use the **debug pim** command in privileged EXEC mode. To disable the display of debugging information, use the **no** form of this command.

debug pim [**df-election** [**interface** *if_name* | **rp** *rp*] | **group** *group* | **interface** *if_name* | **neighbor**]

no debug pim [**df-election** [**interface** *if_name* | **rp** *rp*] | **group** *group* | **interface** *if_name* | **neighbor**]

Syntax Description

df-election	(Optional) Displays debugging messages for PIM bidirectional DF-election message processing.
group *group*	(Optional) Displays debugging information for the specified group. The value for *group* can be one of the following: • Name of the multicast group, as defined in the DNS hosts table or with the domain **ipv4 host** command. • IP address of the multicast group, which is a multicast IP address in four-part, dotted-decimal notation.
interface *if_name*	(Optional) When used with the **df-election** keyword, limits the DF election debugging display to information for the specified interface. When used without the **df-election** keyword, displays PIM error messages for the specified interface. **Note** The **debug pim interface** command does not display PIM protocol activity messages; it only displays error messages. To see debugging information for PIM protocol activity, use the **debug pim** command without the **interface** keyword. You can use the **group** keyword to limit the display to the specified multicast group.
neighbor	(Optional) Displays only the sent and received PIM hello messages.
rp *rp*	(Optional) Can be either one of the following: • Name of the RP, as defined in the DNS hosts table or with the domain **ipv4 host** command. • IP address of the RP, which is a multicast IP address in four-part, dotted-decimal notation.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command logs PIM packets received and transmitted and PIM-related events.

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug pim** command:

```
hostname# debug pim
PIM: Received Join/Prune on Ethernet1 from 172.24.37.33
PIM: Received Join/Prune on Ethernet1 from 172.24.37.33
PIM: Received Join/Prune on Tunnel0 from 10.3.84.1
PIM: Received Join/Prune on Ethernet1 from 172.24.37.33
PIM: Received Join/Prune on Ethernet1 from 172.24.37.33
PIM: Received RP-Reachable on Ethernet1 from 172.16.20.31
PIM: Update RP expiration timer for 224.2.0.1
PIM: Forward RP-reachability packet for 224.2.0.1 on Tunnel0
PIM: Received Join/Prune on Ethernet1 from 172.24.37.33
PIM: Prune-list (10.221.196.51/32, 224.2.0.1)
PIM: Set join delay timer to 2 seconds for (10.221.0.0/16, 224.2.0.1) on Ethernet1
PIM: Received Join/Prune on Ethernet1 from 172.24.37.6
PIM: Received Join/Prune on Ethernet1 from 172.24.37.33
PIM: Received Join/Prune on Tunnel0 from 10.3.84.1
PIM: Join-list: (*, 224.2.0.1) RP 172.16.20.31
PIM: Add Tunnel0 to (*, 224.2.0.1), Forward state
PIM: Join-list: (10.0.0.0/8, 224.2.0.1)
PIM: Add Tunnel0 to (10.0.0.0/8, 224.2.0.1), Forward state
PIM: Join-list: (10.4.0.0/16, 224.2.0.1)
PIM: Prune-list (172.24.84.16/28, 224.2.0.1) RP-bit set RP 172.24.84.16
PIM: Send Prune on Ethernet1 to 172.24.37.6 for (172.24.84.16/28, 224.2.0.1), RP
PIM: For RP, Prune-list: 10.9.0.0/16
PIM: For RP, Prune-list: 10.16.0.0/16
PIM: For RP, Prune-list: 10.49.0.0/16
PIM: For RP, Prune-list: 10.84.0.0/16
PIM: For RP, Prune-list: 10.146.0.0/16
PIM: For 10.3.84.1, Join-list: 172.24.84.16/28
PIM: Send periodic Join/Prune to RP via 172.24.37.6 (Ethernet1)
```

Related Commands

Command	Description
show pim group-map	Displays the group-to-protocol mapping table.
show pim interface	Displays interface-specific information for PIM.
show pim neighbor	Displays entries in the PIM neighbor table.

debug pix acl

To show PIX ACL debugging messages, use the **debug pix acl** command in privileged EXEC mode. To stop showing debugging messages, use the **no** form of this command.

debug pix acl

no debug pix acl

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables debugging messages for PIX ACLs:

```
hostname# debug pix acl
```

Related Commands

Command	Description
debug pix process	Shows debugging messages for xlate and secondary connections processing.
show debug	Shows all enabled debuggers.

debug pix cls

To show PIX CLS debugging messages, use the **debug pix cls** command in privileged EXEC mode. To stop showing debugging messages, use the **no** form of this command.

debug pix cls

no debug pix cls

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables debugging messages for PIX CLS:

```
hostname# debug pix cls
```

Related Commands

Command	Description
debug pix process	Shows debug messages for xlate and secondary connections processing.
show debug	Shows all enabled debuggers.

debug pix pkt2pc

To show debugging messages that trace packets sent to the uauth code and that trace the event where the uauth proxy session is cut through to the data path, use the **debug pix pkt2pc** command in privileged EXEC mode. To stop showing debugging messages, use the **no** form of this command.

debug pix pkt2pc

no debug pix pkt2pc

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debugging messages that trace packets sent to the uauth code and that trace the event where the uauth proxy session is cut through to the data path:

```
hostname# debug pix pkt2pc
```

Related Commands

Command	Description
debug pix process	Shows debugging messages for xlate and secondary connections processing.

debug pix uauth

To show PIX uauth debugging messages, use the **debug pix uauth** command in privileged EXEC mode. To stop showing debugging messages, use the **no** form of this command.

debug pix uauth

no debug pix uauth

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables debugging messages for PIX uauth:

```
hostname# debug pix uauth
```

Related Commands

Command	Description
debug pix process	Shows debugging messages for xlate and secondary connections processing.
show debug	Shows all enabled debuggers.

debug pptp

To show debugging messages for PPTP application inspection, use the **debug pptp** command in privileged EXEC mode. To stop showing debugging messages for PPTP, use the **no** form of this command.

debug pptp [*level*]

no debug pptp [*level*]

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To see the current debugging command settings, enter the **show debug** command. To stop the debugging output, enter the **no debug** command. To stop all debugging messages from being displayed, enter the **no debug all** command.

Note Enabling the **debug pptp** command may slow down traffic on busy networks.

Examples

The following example enables debugging messages at the default level (1) for PPTP application inspection:

```
hostname# debug pptp
```

Related Commands

Command	Description
class-map	Defines the traffic class to which to apply security actions.
inspect pptp	Enables PPTP application inspection.
policy-map	Associates a class map with specific security actions.
service-policy	Applies a policy map to one or more interfaces.

debug radius

To show RADIUS messages between the ASA and a RADIUS AAA server, use the **debug radius** command in privileged EXEC mode. To stop showing RADIUS messages, use the **no** form of this command.

debug radius [**all** | **decode** | **session** | **user** *username*]]

no debug radius

Syntax Description

all	(Optional) Show RADIUS debugging messages for all users and sessions, including decoded RADIUS messages.
decode	(Optional) Show decoded content of RADIUS messages. Content of all RADIUS packets display, including hexadecimal values and the decoded, eye-readable versions of these values.
session	(Optional) Show session-related RADIUS messages. Packet types for sent and received RADIUS messages appear, but not the packet content.
user	(Optional) Show RADIUS debugging messages for a specific user.
username	Specifies the user whose messages you want to see. Valid with the **user** keyword only.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **debug radius** command displays detailed information about RADIUS messaging between the ASA and a RADIUS AAA server. The **no debug all** or **undebug all** command turns off all enabled debugging.

Examples

The following example shows decoded RADIUS messages, which happen to be accounting packets:

```
hostname(config)# debug radius decode
hostname(config)# RADIUS packet decode (accounting request)

-------------------------------------
```

```
Raw packet data (length = 216).....

Related Commands

Command	Description
show running-config	Displays the configuration that is running on the ASA.

debug redundant-interface

To show debugging messages about redundant interfaces, use the **debug redundant-interface** command in privileged EXEC mode. To stop showing debugging messages for redundant interfaces, use the **no** form of this command.

debug redundant-interface [*level*]

no debug redundant-interfac [*level*]

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debugging messages for redundant interfaces:

```
hostname# debug redundant-interface
```

Related Commands

Command	Description
interface redundant	Creates a redundant interface.
member-interface	Assigns a physical interface to a redundant interface.
redundant-interface	Changes the active interface in a redundant interface pair.
show debug	Shows all enabled debuggers.

debug rip

To display debugging information for RIP, use the **debug rip** command in privileged EXEC mode. To disable the debugging information display, use the **no** form of this command.

debug rip [**database** | **events**]

no debug rip [**database** | **events**]

Syntax Description

database	Displays RIP database events.
events	Displays RIP processing events.

Defaults

All RIP events are shown in the debugging output.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	The **database** and **events** keywords were added.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug rip** command:

```
hostname# debug rip

RIP: broadcasting general request on GigabitEthernet0/1
RIP: broadcasting general request on GigabitEthernet0/2
RIP: Received update from 10.89.80.28 on GigabitEthernet0/1
    10.89.95.0 in 1 hops
    10.89.81.0 in 1 hops
    10.89.66.0 in 2 hops
    172.31.0.0 in 16 hops (inaccessible)
    0.0.0.0 in 7 hops
RIP: Sending update to 255.255.255.255 via GigabitEthernet0/1 (10.89.64.31)
```

```
    subnet 10.89.94.0, metric 1
    172.31.0.0 in 16 hops (inaccessible)
RIP: Sending update to 255.255.255.255 via GigabitEthernet0/2 (10.89.94.31)
    subnet 10.89.64.0, metric 1
    subnet 10.89.66.0, metric 3
    172.31.0.0 in 16 hops (inaccessible)
    default 0.0.0.0, metric 8
RIP: bad version 128 from 192.168.80.43
```

Related Commands

Command	Description
router rip	Configures a RIP process.
show running-config rip	Displays the RIP commands in the running configuration.

debug route

To display debugging information for general routing and failover debugging messages for routing, use the **debug route** command in privileged EXEC mode. To disable the debugging information display, use the **no** form of this command.

debug route [**ha** | **events**]

no debug route [**ha** | **events**]

Syntax Description

events	Displays general routing-related debugging messages.
ha	Displays Stateful Failover-related debugging messages for dynamic routing protocols.

Defaults

All general routing events and failover events for routing are shown in the debugging output.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.4(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

To display general routing debugging information, such as adding or deleting routes in the CP routing table, use the **debug route events** command.

Examples

The following is sample output from the **debug route events** command:

```
hostname# debug route events
add 10.0.3.0 255.255.255.0 via 10.1.1.10, ospf metric [110/40]
```

The following is sample output from the **debug route ha** command on the active unit:

```
ROUTE HA: Route HA start bulk sync
ROUTE HA: Sending Message Version: 1 Action: add Object: route Address: 10.0.0.0 Mask:
255.0.0.0
ROUTE HA: Sending Message Version: 1 Action: add Object: route Address: 10.0.1.0 Mask:
255.0.0.0
ROUTE HA: Sending Message Version: 1 Action: add Object: route Address: 10.0.3.0 Mask:
255.255.255.0
```

The following is sample output from the **debug route ha** command on the standby unit:

```
ROUTE HA: Processing rcvd msg with address: 10.0.3.0 mask: 255.255.255.0 gateway:
10.10.0.10
ROUTE HA: Received Msg ADD address: 10.0.3.0 mask: 255.255.255.0 gateway: 10.0.1.10
metric: 40
ROUTE HA: RIB Epoch number 0 assigned to NDB: 10.0.0.0
ROUTE HA: RIB epoch number 0 assigned to SDB: 10.0.3.0
```

Related Commands

Command	Description
debug rip	Displays RIP debugging information.
show debug route	Displays the general routing debugging configuration.

debug route cluster

To display debugging information for RIB table replication and dynamic updates through trace messages to determine whether or not the RIB table is correctly synchronized to slave units, use the **debug route cluster** command in privileged EXEC mode. To disable the debugging information display, use the **no** form of this command.

debug route cluster

no debug route cluster

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced. Applies only to the ASA 5580 and 5585-X.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug route cluster** command:

```
hostname# debug route cluster
ROUTE CLUSTER: old ndb_epoch=1, RIB Epoch number 1 assigned to NDB: 192.168.33.0
ROUTE CLUSTER: old ndb_epoch=1, RIB Epoch number 1 assigned to NDB: 172.16.0.0
ROUTE CLUSTER: old ndb_epoch=1, RIB Epoch number 1 assigned to NDB: 192.168.32.0
ROUTE CLUSTER ip_route_delete: del 172.31.32.1 255.255.255.255 via 172.16.32.4, ospf
metric [110/13]
ROUTE CLUSTER ip_route_delete: delete subnet route to 172.31.32.1 255.255.255.255
ROUTE CLUSTER ip_route_delete: delete network route to 172.31.0.0
ROUTE CLUSTER: old ndb_epoch=1, RIB Epoch number 1 assigned to NDB: 172.16.0.0
ROUTE CLUSTER: old ndb_epoch=1, RIB Epoch number 1 assigned to NDB: 172.17.0.0
ROUTE CLUSTER: old ndb_epoch=1, RIB Epoch number 1 assigned to NDB: 172.18.0.0
```

```
ROUTE CLUSTER: old ndb_epoch=1, RIB Epoch number 1 assigned to NDB: 172.20.0.0
ROUTE CLUSTER: old ndb_epoch=1, RIB Epoch number 1 assigned to NDB: 172.30.0.0
ROUTE CLUSTER: old ndb_epoch=1, RIB Epoch number 1 assigned to NDB: 172.31.0.0
ROUTE CLUSTER: old ndb_epoch=1, RIB Epoch number 1 assigned to NDB: 192.168.32.0
```

Related Commands

Command	Description
debug route	Displays general routing and failover debugging messages for routing.
show debug route	Displays the general routing debugging configuration.

debug rtp

To display debugging information and error messages for RTP packets associated with H.323 and SIP inspection, use the **debug rtp** command in privileged EXEC mode. To disable the display of debugging information, use the **no** form of this command.

debug rtp [*level*]

no debug rtp [*level*]

Syntax Description

level	(Optional) Specifies the level of debugging.

Defaults

The default level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example shows how to enable debugging for RTP packets using the **debug rtp** command:

```
hostname# debug rtp 255
debug rtp  enabled at level 255
```

Related Commands

Command	Description
policy-map	Creates a Layer 3/4 policy map.

Command	Description
rtp-conformance	Checks RTP packets flowing on the pinholes for protocol conformance in H.323 and SIP.
show running-config policy-map	Displays all current policy map configurations.

debug rtsp

To show debugging messages for RTSP application inspection, use the **debug rtsp** command in privileged EXEC mode. To stop showing debugging messages for RTSP application inspection, use the **no** form of this command.

debug rtsp [*level*]

no debug rtsp [*level*]

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To see the current debugging command settings, enter the **show debug** command. To stop the debugging output, enter the **no debug** command. To stop all debugging messages from being displayed, enter the **no debug all** command.

Note Enabling the **debug rtsp** command may slow down traffic on busy networks.

Examples

The following example enables debugging messages at the default level (1) for RTSP application inspection:

```
hostname# debug rtsp
```

Related Commands

Command	Description
class-map	Defines the traffic class to which to apply security actions.
inspect rtsp	Enables RTSP application inspection.
policy-map	Associates a class map with specific security actions.
service-policy	Applies a policy map to one or more interfaces.

debug sdi

To display SDI authentication debugging information, use the **debug sdi** command in privileged EXEC mode. To disable the display of SDI debugging information, use the **no** form of this command.

debug sdi [*level*]

no debug sdi

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables SDI debugging messages. The **show debug** command indicates that SDI debugging messages are enabled.

```
hostname# debug sdi
debug sdi  enabled at level 1
hostname# show debug
debug sdi  enabled at level 1
hostname#
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug sequence

To add a sequence number to the beginning of all debugging messages, use the **debug sequence** command in privileged EXEC mode. To disable the use of debugging sequence numbers, use the **no** form of this command.

debug sequence [*level*]

no debug sequence

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The defaults are as follows:

- Debugging message sequence numbers are disabled.
- The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables sequence numbers in debugging messages. The **debug parser cache** command enables CLI parser debugging messages. The **show debug** command indicates the current debugging configuration. The CLI parser debugging messages shown include sequence numbers before each message.

```
hostname# debug sequence
debug sequence  enabled at level 1
hostname# debug parser cache
```

```
debug parser cache enabled at level 1
hostname# show debug
0: parser cache: try to match 'show debug' in exec mode
debug parser cache enabled at level 1
debug sequence  enabled at level 1
1: parser cache: hit at index 8
hostname#
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug session-command

To show debugging messages for a session to an SSM, use the **debug session-command** command in privileged EXEC mode. To disable the display of debugging messages for sessions, use the **no** form of this command.

debug session-command [*level*]

no debug session-command [*level*]

Syntax Description

level	(Optional) Sets the level to display debugging messages. The range of values is between 1 and 255. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debugging messages for sessions:

```
hostname# debug session-command
```

Related Commands

Command	Description
session	Sessions to an SSM.

debug sip

To show debugging messages for SIP application inspection, use the **debug sip** command in privileged EXEC mode. To stop showing debugging messages for SIP application inspection, use the **no** form of this command.

debug sip [**ha**]

no debug sip [**ha**]

Syntax Description

ha	(Optional) Displays SIP Stateful Failover messages. When this keyword is used with the **debug sip** command on the active unit, debugging messages are displayed when SIP state information is sent to the standby unit. When this keyword is used with the **debug sip** command on the standby unit, debugging messages are displayed with state updates that are received from the active unit.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0(2)	The **ha** keyword was added.

Usage Guidelines

To see the current **debug** command settings, enter the **show debug** command. To stop the debugging output, enter the **no debug** command. To stop all debugging messages from being displayed, enter the **no debug all** command.

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug sip** command for the active unit or failover group in a failover pair:

```
hostname# debug sip ha
SIP HA:    Sending    update SESSION message from faddr 10.132.80.120/5060 laddr
10.130.80.4/50295 Call-id: 001201e8-8a36000d-196df7f1-17cfef14@10.130.80.4 From:
sip:1004@10.132.80.120:001201e88a3600124a7fad61-640406c0 To: sip:1009@10.132.80.120:

SIP HA:    Created    SIP Transaction    for faddr 10.132.80.120/5060 to   laddr
10.130.80.4/50295CSeq 101 INVITEState Transaction Calling
```

Related Commands

Command	Description
class-map	Defines the traffic class to which to apply security actions.
inspect sip	Enables SIP application inspection.
show conn	Displays the connection state for different connection types.
show sip	Displays information about SIP sessions established through the ASA.
timeout	Sets the maximum idle time duration for different protocols and session types.

debug skinny

To show debugging messages for SCCP (Skinny) application inspection, use the **debug skinny** command in privileged EXEC mode. To stop showing debugging messages for SCCP application inspection, use the **no** form of this command.

debug skinny [*level*]

no debug skinny [*level*]

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To see the current **debug** command settings, enter the **show debug** command. To stop the debugging output, enter the **no debug** command. To stop all debugging messages from being displayed, enter the **no debug all** command.

Note Enabling the **debug skinny** command may slow down traffic on busy networks.

Examples

The following example enables debugging messages at the default level (1) for SCCP application inspection:

```
hostname# debug skinny
```

Related Commands

Command	Description
class-map	Defines the traffic class to which to apply security actions.
inspect skinny	Enables SCCP application inspection.
show skinny	Displays information about SCCP sessions established through the ASA.
show conn	Displays the connection state for different connection types.
timeout	Sets the maximum idle time duration for different protocols and session types.

debug sla monitor

To display debugging messages for the SLA monitor operation, use the **debug sla monitor** command in privileged EXEC mode. To disable debugging, use the **no** form of this command.

debug sla monitor [**error** | **trace**] [*sla-id*]

no debug sla monitor [*sla-id*]

Syntax Description

error	(Optional) Shows the output of IP SLA monitor error messages.
sla-id	(Optional) Shows the ID of the SLA to debug.
trace	(Optional) Shows the output of IP SLA monitor trace messages.

Defaults

Both error and trace messages are shown by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Only 32 SLA operations can be debugged at one time.

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables SLA operation error debugging:

```
hostname(config)# debug sla monitor error
```

The following example shows how to display SLA operation trace messages for the specified SLA operation:

```
hostname(config)# debug sla monitor trace 123
```

Related Commands

Command	Description
clear configure route	Removes statically configured **route** commands.
clear route	Removes routes learned through dynamic routing protocols such as RIP.
show route	Displays route information.
show running-config route	Displays configured routes.

debug sqlnet

To show debugging messages for SQL*Net application inspection, use the **debug sqlnet** command in privileged EXEC mode. To stop showing debugging messages for SQL*Net application inspection, use the **no** form of this command.

debug sqlnet [*level*]

no debug sqlnet [*level*]

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To see the current **debug** command settings, enter the **show debug** command. To stop the debugging output, enter the **no debug** command. To stop all debugging messages from being displayed, enter the **no debug all** command.

Note Enabling the **debug sqlnet** command may slow down traffic on busy networks.

Examples

The following example enables debugging messages at the default level (1) for SQL*Net application inspection:

```
hostname# debug sqlnet
```

Related Commands

Command	Description
class-map	Defines the traffic class to which to apply security actions.
inspect sqlnet	Enables SQL*Net application inspection.
policy-map	Associates a class map with specific security actions.
service-policy	Applies a policy map to one or more interfaces.
show conn	Displays the connection state for different connection types, including SQL*Net.

debug ssh

To display debugging information and error messages associated with SSH, use the **debug ssh** command in privileged EXEC mode. To disable the display of debugging information, use the **no** form of this command.

debug ssh [*level*]

no debug ssh [*level*]

Syntax Description

level	(Optional) Specifies the level of debugging.

Defaults

The default level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug ssh 255** command:

```
hostname# debug ssh 255
debug ssh  enabled at level 255
SSH2 0: send: len 64 (includes padlen 17)
SSH2 0: done calc MAC out #239
SSH2 0: send: len 32 (includes padlen 7)
SSH2 0: done calc MAC out #240
SSH2 0: send: len 64 (includes padlen 15)
SSH2 0: done calc MAC out #241
SSH2 0: send: len 32 (includes padlen 16)
SSH2 0: done calc MAC out #242
SSH2 0: send: len 64 (includes padlen 7)
SSH2 0: done calc MAC out #243
```

```
SSH2 0: send: len 64 (includes padlen 18)
SSH2 0: done calc MAC out #244
SSH2 0: send: len 64 (includes padlen 8)
SSH2 0: done calc MAC out #245

SSH2 0: done calc MAC out #246
SSH2 0: send: len 64 (includes padlen 7)
SSH2 0: done calc MAC out #247
SSH2 0: send: len 64 (includes padlen 18)
SSH2 0: done calc MAC out #248
SSH2 0: send: len 64 (includes padlen 7)
SSH2 0: done calc MAC out #249
SSH2 0: send: len 64 (includes padlen 18)
SSH2 0: done calc MAC out #250
SSH2 0: send: len 64 (includes padlen 8)
SSH2 0: done calc MAC out #251
SSH2 0: send: len 64 (includes padlen 18)
SSH2 0: done calc MAC out #252
SSH2 0: send: len 64 (includes padlen 7)
SSH2 0: done calc MAC out #253
SSH2 0: send: len 64 (includes padlen 18)
SSH2 0: done calc MAC out #254
SSH2 0: send: len 64 (includes padlen 8)
SSH2 0: done calc MAC out #255
SSH2 0: send: len 64 (includes padlen 18)
SSH2 0: done calc MAC out #256
SSH2 0: send: len 64 (includes padlen 7)
SSH2 0: done calc MAC out #257
SSH2 0: send: len 64 (includes padlen 18)
SSH2 0: done calc MAC out #258
```

Related Commands

Command	Description
clear configure ssh	Clears all SSH commands from the running configuration.
show running-config ssh	Displays the current SSH commands in the running configuration.
show ssh sessions	Displays information about active SSH sessions to the ASA.
ssh	Allows SSH connectivity to the ASA from the specified client or network.

debug sunrpc

To show debugging messages for RPC application inspection, use the **debug sunrpc** command in privileged EXEC mode. To stop showing debugging messages for RPC application inspection, use the **no** form of this command.

debug sunrpc [*level*]

no debug sunrpc [*level*]

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To see the current debugging command settings, enter the **show debug** command. To stop the debugging output, enter the **no debug** command. To stop all debugging messages from being displayed, enter the **no debug all** command.

Note Enabling the **debug sunrpc** command may slow down traffic on busy networks.

Examples

The following example enables debugging messages at the default level (1) for RPC application inspection:

```
hostname# debug sunrpc
```

Related Commands

Command	Description
class-map	Defines the traffic class to which to apply security actions.
inspect sunrpc	Enables Sun RPC application inspection.
policy-map	Associates a class map with specific security actions.
show conn	Displays the connection state for different connection types, including RPC.
timeout	Sets the maximum idle time duration for different protocols and session types.

debug switch ilpm

To show debugging messages for models with a built-in switch, such as the ASA 5505, show debugging messages for PoE, use the **debug switch ilpm** command in privileged EXEC mode. To stop showing debugging messages for PoE, use the **no** form of this command.

debug switch ilpm [**events** | **errors**] [*level*]

no debug switch ilpm [**events** | **errors**] [*level*]

Syntax Description

errors	(Optional) Shows troubleshooting information when there is an error.
events	(Optional) Shows PoE events.
level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

By default, both events and errors are shown if you do not specify a keyword. The default level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debugging messages for PoE ports:

```
hostname# debug switch ilpm
```

Related Commands

Command	Description
interface vlan	Adds a VLAN interface.
debug switch manager	Shows debugging messages for VLAN assignment and **switchport** command-caused events and errors.
show debug	Shows all enabled debuggers.

debug switch manager

To show debugging messages for switch port models with a built-in switch, such as the ASA 5505, show debugging messages for VLAN assignment, and **switchport** command-caused events and errors, use the **debug switch manager** command in privileged EXEC mode. To stop showing debugging messages for switch ports, use the **no** form of this command.

debug switch manager [**events** | **errors**] [*level*]

no debug switch manager [**events** | **errors**] [*level*]

Syntax Description

errors	(Optional) Shows troubleshooting information when there is an error.
events	(Optional) Shows the switch manager events.
level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

By default, both events and errors are shown if you do not specify a keyword. The default level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Using **debug** commands might slow down traffic on busy networks.

Examples

The following example enables debugging messages for switch ports:

```
hostname# debug switch manager
```

Related Commands

Command	Description
interface vlan	Adds a VLAN interface.
debug switch ilpm	Shows debugging messages for PoE.
show debug	Shows all enabled debuggers.

debug tacacs

To display TACACS+ debugging information, use the **debug tacacs** command in privileged EXEC mode. To disable the display of TACACS+ debugging information, use the **no** form of this command.

debug tacacs [**session** | **user** *username*]

no debug tacacs [**session** | **user** *username*]

Syntax Description

session	Displays session-related TACACS+ debugging messages.
user	Displays user-specific TACACS+ debugging messages. You can display TACACS+ debugging messages for only one user at a time.
username	Specifies the user whose TACACS+ debugging messages you want to view.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables TACACS+ debugging messages and provides sample output from the **show debug** command:

```
hostname# debug tacacs user admin342
hostname# show debug
debug tacacs user admin342
hostname#
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug tcp-map

To show debugging messages for TCP application inspection maps, use the **debug tcp-map** command in privileged EXEC mode. To stop showing debugging messages for TCP application inspection, use the **no** form of this command.

debug tcp-map

no debug tcp-map

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables debugging messages for TCP application inspection maps. The **show debug** command indicates that debugging messages for TCP application inspection maps are enabled.

```
hostname# debug tcp-map
debug tcp-map enabled at level 1.
hostname# show debug
debug tcp-map enabled at level 1.
hostname#
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug timestamps

To add timestamp information to the beginning of all debugging messages, use the **debug timestamps** command in privileged EXEC mode. To disable the use of debugging timestamps, use the **no** form of this command.

debug timestamps [*level*]

no debug timestamps

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The defaults are as follows:

- Debugging timestamp information is disabled.
- The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables timestamps in debugging messages. The **debug parser cache** command enables CLI parser debugging messages. The **show debug** command indicates the current debugging configuration. The CLI parser debugging messages shown include timestamps before each message.

```
hostname# debug timestamps
debug timestamps  enabled at level 1
hostname# debug parser cache
debug parser cache enabled at level 1
```

```
hostname# show debug
1982769.770000000: parser cache: try to match 'show debug' in exec mode
1982769.770000000: parser cache: hit at index 8
hostname#
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug user-identity

To debug the Identity Firewall, use the **debug user-identity** command in privileged EXEC mode. To disable the use of debug command, use the **no** form of this command.

debug user-identity {**acl** | **ad-agent** | **all** | **debug** | **error** | **fqdn** | **ha** | **ldap** | **logout-probe** | **process** | **tmatch** | **user** *user_name* | **user-group** *user_group_name*}

no debug user-identity {**acl** | **ad-agent** | **all** | **debug** | **error** | **fqdn** | **ha** | **ldap** | **logout-probe** | **process** | **tmatch** | **user** *user_name* | **user-group** *user_group_name*}

Syntax Description

acl	Enables debugging messages related to access list changes.
ad-agent	Enables debugging messages for the connection between the ASA and the Windows server on which the AD Agent is installed.
all	Enables all debugging messages for all aspects of the Identity Firewall.
debug	Enables debugging information about the debugging-level messages for the Identity Firewall.
error	Enables debugging information about errors in the user identity module or the Identity Firewall.
fqdn	Enables debugging messages about FQDN to IP address updates.
ha	Enables debugging messages for your high availablity deployment of the Identity Firewall. See the CLI configuration guide for information about the types of Identity Firewall deployments.
ldap	Enables debugging messages for the LDAP query that the ASA sends to Microsoft Active Directory for the user groups configured on the AD Server and for the reply that the ASA receives from Active Directory.
logout-probe	Enables debugging messages for logout probing.
process	Enables debugging messages for the user identity process of the Identity Firewall.
tmatch	Enables debugging messages related to tmatch changes.
user *user_name*	Enables debugging messages for the specified user in all domains.
user-group *user_group_name*	Enables debugging messages for the specified user group in all domains.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
8.4(2)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

debug user-identity logout-probe

Using the **debug user-identity logout-probe** command enables debugging messages for logout probing, including NetBIOS handling and inactive user check. The client logs onto the network through Microsoft Active Directory. The AD Server authenticates users and generates user login security logs. The ASA probes the NetBIOS of the client to pass inactive and no-response users. Enabling NetBIOS probing configures how often the ASA probes the user client IP address to determine whether the client is still active.

To minimize the NetBIOS packets, the ASA only sends a NetBIOS probe to a client when the user has been idle for more than the specified number of minutes. By default, NetBIOS probing is disabled.

debug user-identity tmatch

When the ASA resolves an FQDN network object, it populates the resolved IP addresses and other fields, such as the IP address of a user or user-group of an access-list in the tmatch lookup table.

Depending on the Identity Firewall configuration, the ASA updates IP addresses from the DNS server periodically or when the TTL of DNS entries expire, whichever comes first. When the ASA finds new IP addresses, it adds them to the tmatch lookup table. When existing IP addresses expire, the ASA removes them from the tmatch lookup table.

You can configure a longer DNS expire-entry timer to balance degradation of system performance because of tmatch recompilation; you must balance system performance with the security risk caused by the gap between DNS entries TTL expiration and the actual time when expired entries are removed from tmatch table.

Even when you configure the ASA with reasonable expire-DNS-entry value, the ASA can still recompile the tmatch lookup table periodically when DNS load balancing is configured; however, this does not guarantee that all valid IP addresses will be refreshed within any defined time period.

Some FQDN hosts can have very short TTL, which leads to frequent recompilation of the tmatch lookup table and a performance impact.

When the Identity Firewall process is disabled (no identity-firewall enable), the tmatch lookup table is not updated for new or changed IP-user mappings, and user-identity rules have any effect at all on security policies.

Examples

The following example shows how to turn off debugging for all aspects of the Identity Firewall, and then turn on debugging of the Identity Firewall process:

```
hostname# debug user-identity ?
  acluser-identity ACL message
  ad-agent              user-identity ad-agent message
  all                   All user-identity messages
  debug                 user-identity debug message
  error                 user-identity error message
```

```
  fqdn                  user-identity fqdn message
  ha                    user-identity HA message
  ldap                  user-identity ldap message
  logout-probe          user-identity logout-probe message
  process               user-identity process message
  tmatch                user-identity tmatch message
  user                  user-identity user message
  user-group            user-identity user-group message
hostname# no debug user-identity all
debug user-identity process enabled
hostname# debug user-identity process
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug vpn-sessiondb

To display VPN-session database debugging information, use the **debug vpn-sessiondb** command in privileged EXEC mode. To disable the display of VPN-session database debugging information, use the **no** form of this command.

debug vpn-sessiondb [*level*]

no debug vpn-sessiondb

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables VPN-session database debugging messages. The **show debug** command indicates that VPN-session database debugging messages are enabled.

```
hostname# debug vpn-sessiondb
debug vpn-sessiondb enabled at level 1
hostname# show debug
debug vpn-sessiondb enabled at level 1
hostname#
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug wccp

To enable logging of WCCP events, use the **debug wccp** command in privileged EXEC mode. To disable the logging of WCCP debugging messages, use the **no** form of this command.

debug wccp {**events | packets | subblocks**}

no debug wccp {**events | packets | subblocks**}

Syntax Description

events	Enables logging of WCCP session events.
packets	Enables logging of debugging messages about WCCP packet information.
subblocks	Enables logging of debugging messages about WCCP subblocks.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The high priority assigned to debugging output can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables the logging of all WCCP session events:

```
hostname# debug wccp events
hostname#
```

The following example enables the logging of WCCP packet debugging messages:

```
hostname# debug wccp packets
hostname#
```

The following example disables the logging of WCCP debugging messages:

```
hostname# no debug wccp
```

```
hostname#
```

Related Commands

Command	Description
wccp	Enables support of WCCP.
show debug	Displays the current debugging configuration.

debug webvpn

To log WebVPN debugging messages, use the **debug webvpn** command in privileged EXEC mode. To disable the logging of WebVPN debugging messages, use the **no** form of this command.

debug webvpn [**chunk** | **cifs** | **citrix** | **failover** | **html** | **javascript** | **request** | **response** | **svc** | **transformation** | **url** | **util** | **xml**] [*level*]

no debug webvpn [**chunk** | **cifs** | **citrix** | **failover** | **html** | **javascript** | **request** | **response** | **svc** | **transformation** | **url** | **util** | **xml**] [*level*]

Syntax Description

chunk	Displays debugging messages about memory blocks used to support WebVPN connections.
cifs	Displays debugging messages about connections between CIFS)servers and WebVPN users.
citrix	Displays debug messages about connections between Citrix Metaframe Servers and Citrix ICA clients over WebVPN.
failover	Displays debugging messages about equipment failovers affecting WebVPN connections.
html	Displays debugging messages about HTML pages sent over WebVPN connections.
javascript	Displays debugging messages about JavaScript sent over WebVPN connections.
level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.
request	Displays debugging messages about requests issued over WebVPN connections.
response	Displays debugging messages about responses issued over WebVPN connections.
svc	Displays debugging messages about connections to SSL VPN clients over WebVPN.
transformation	Displays debugging messages about WebVPN content transformation.
url	Displays debugging messages about website requests issued over WebVPN connections.
util	Displays debugging messages about CPU utilization dedicated to support connections to WebVPN remote users.
xml	Displays debugging messages about JavaScript sent over WebVPN connections.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

The high priority assigned to debugging output can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following example enables WebVPN debugging messages for CIFS. The **show debug** command indicates that CIFS debugging messages are enabled.

```
hostname# debug webvpn cifs
INFO: debug webvpn cifs enabled at level 1.
hostname# show debug
debug webvpn cifs enabled at level 1
hostname#
```

Related Commands

Command	Description
show debug	Displays the current debugging configuration.

debug xdmcp

To show debugging messages for XDMCP application inspection, use the **debug xdmcp** command in privileged EXEC mode. To stop showing debugging messages for XDMCP application inspection, use the **no** form of this command.

debug xdmcp [*level*]

no debug xdmcp [*level*]

Syntax Description

level	(Optional) Sets the debugging message level to display, between 1 and 255. The default is 1. To display additional messages at higher levels, set the level to a higher number.

Defaults

The default value for the debugging level is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To see the current debugging command settings, enter the **show debug** command. To stop the debugging output, enter the **no debug** command. To stop all debugging messages from being displayed, enter the **no debug all** command.

Note Enabling the **debug xdmcp** command may slow down traffic on busy networks.

Examples

The following example enables debugging messages at the default level (1) for XDMCP application inspection:

```
hostname# debug xdmcp
```

Related Commands

Command	Description
class-map	Defines the traffic class to which to apply security actions.
inspect xdmcp	Enables XDMCP application inspection.
policy-map	Associates a class map with specific security actions.
service-policy	Applies a policy map to one or more interfaces.

debug xml

To display debugging information for the XML parser, use the **debug xml** command in privileged EXEC mode. To disable the display of debugging information, use the **no** form of this command.

debug xml [**element** | **event**]

no debug xml [**element** | **event**]

Syntax Description

element	(Optional) Displays debugging events related to processing individual XML elements.
event	(Optional) Displays XML parsing or error events.

Defaults

If no keywords are specified, all XML parser debugging messages are shown.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The following is sample output from the **debug xml element** command:

```
hostname# debug xml element
debug xml element enabled at level 1

XML Executes cmd: hostname hostname
XML Executes cmd: domain-name example.com
XML Executes cmd: names
XML Executes cmd: dns-guard
XML Executes cmd: !
XML Executes cmd: interface Ethernet0
XML Executes cmd:  nameif outside
XML Executes cmd:  security-level 0
```

```
XML Executes cmd:  ip address 192.168.5.151 255.255.255.0 standby 192.168.5.152
XML Executes cmd: interface Ethernet1
XML Executes cmd:  nameif inside
XML Executes cmd:  security-level 100

XML Executes cmd: crashinfo save disable
```

The following is sample output from the **debug xml event** command:

```
hostname# debug xml event
debug xml event enabled at level 1

XML parsing: data = <con... len = 3176
Exit XML parser, ret code = 0
```

Related Commands

Command	Description
show debug	Displays the debugging status for the various **debug** commands.

default through dhcp-server Commands

default (crl configure)

To return all CRL parameters to their system default values, use the **default** command in crl configure configuration mode.

default

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crl configure configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Invocations of this command do not become part of the active configuration. The crl configure configuration mode is accessible from the crypto ca trustpoint configuration mode. These parameters are used only when the LDAP server requires them.

Examples

The following example enters ca-crl configuration mode and returns CRL command values to their defaults:

```
hostname(config)# crypto ca trustpoint central
hostname(ca-trustpoint)# crl configure
hostname(ca-crl)# default
hostname(ca-crl)#
```

Related Commands

Command	Description
crl configure	Enters crl configure configuration mode.
crypto ca trustpoint	Enters trustpoint configuration mode.
protocol ldap	Specifies LDAP as a retrieval method for CRLs.

default (interface)

To return an interface command to its system default value, use the **default** command in interface configuration mode.

default *command*

Syntax Description

command	Specifies the command that you want to set to the default. For example: `default activation key`

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command is a runtime command; when you enter it, it does not become part of the active configuration.

Examples

The following example enters interface configuration mode and returns the security level to its default:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# default security-level
```

Related Commands

Command	Description
interface	Enters interface configuration mode.

default (OSPFv3)

To return an OSPFv3 parameter to its default value, use the **default** command in router configuration mode.

default [**area** | **auto-cost** | **default-information** | **default-metric** | **discard-route** | **distance** | **distribute-list** | **ignore** | **log-adjacency-changes** | **maximum-paths** | **passive-interface** | **redistribute** | **router-id** | **summary-prefix** | **timers**]

Syntax Description

area	(Optional) Specifies the OSPFv3 area parameters.
auto-cost	(Optional) Specifies the OSPFv3 interface cost according to the bandwidth.
default-information	(Optional) Distributes default information.
default-metric	(Optional) Specifies the metric for a redistributed route.
discard-route	(Optional) Enables or disables discard-route installation.
distance	(Optional) Specifies the administrative distance.
distribute-list	(Optional) Filters networks in routing updates.
ignore	(Optional) Ignores a specific event.
log-adjacency-changes	(Optional) Logs changes in the adjacency state.
maximum-paths	(Optional) Forwards packets over multiple paths.
passive-interface	(Optional) Suppresses routing updates on an interface.
redistribute	(Optional) Redistributes IPv6 prefixes from another routing protocol.
router-id	(Optional) Specifies the router ID for the specified routing process.
summary-prefix	(Optional) Specifies the OSPFv3 summary prefix.
timers	(Optional) Spoecifies the OSPFv3 timers.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Router configuration	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to reset OSPFv3 parameter default values.

Examples

The following example resets OSPFv3 timer parameters to their default values:

```
hostname(config-router)# default timers spf
```

Related Commands

Command	Description
distance	Specifies the administrative distance for OSPFv3 routing processes.
default-information originate	Generates a default external route into an OSPFv3 routing domain.
log-adjacency-changes	Configures the router to send a syslog message when an OSPFv3 neighbor goes up or down.

default (time-range)

To restore default settings for the **absolute** and **periodic** commands, use the **default** command in time-range configuration mode.

default {**absolute** | **periodic** *days-of-the-week time* **to** [*days-of-the-week*] *time*}

Syntax Description

absolute	Defines an absolute time when a time range is in effect.
days-of-the-week	The first occurrence of this argument is the starting day or day of the week that the associated time range is in effect. The second occurrence is the ending day or day of the week the associated statement is in effect. This argument is any single day or combinations of days: Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, and Sunday. Other possible values are: • daily—Monday through Sunday • weekdays—Monday through Friday • weekend—Saturday and Sunday If the ending days of the week are the same as the starting days of the week, you can omit them.
periodic	Specifies a recurring (weekly) time range for functions that support the time range feature.
time	Specifies the time in the format HH:MM. For example, 8:00 is 8:00 a.m. and 20:00 is 8:00 p.m.
to	Entry of the **to** keyword is required to complete the range "from start-time to end-time."

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Time-range configuration	•	•	•	•	

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If the end days-of-the-week value is the same as the start value, you can omit them.

If a **time-range** command has both **absolute** and **periodic** values specified, then the **periodic** commands are evaluated only after the absolute start time is reached, and are not further evaluated after the absolute end time is reached.

The time-range feature relies on the system clock of the ASA; however, the feature works best with NTP synchronization.

Examples

The following example shows how to restore the default behavior of the **absolute** keyword:

```
hostname(config-time-range)# default absolute
```

Related Commands

Command	Description
absolute	Defines an absolute time when a time range is in effect.
periodic	Specifies a recurring (weekly) time range for functions that support the time range feature.
time-range	Defines access control to the ASA based on time.

default user group

For Cloud Web Security, to specify the default username and/or group if the ASA cannot determine the identity of the user coming into the ASA, use the **default user group** command in parameters configuration mode. To remove the default user or group, use the **no** form of this command. You can access the parameters configuration mode by first entering the **policy-map type inspect scansafe** command.

default {[**user** *username*] [**group** *groupname*]}

no default [**user** *username*] [**group** *groupname*]

Syntax Description

username	Specifies the default username.
groupname	Specifies the default group name.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

If the ASA cannot determine the identity of the user coming into the ASA, then the default user and/or group is included in the HTTP header.

Examples

The following example sets a default name as “Boulder” and a group name as “Cisco”:

```
hostname(config)# policy-map type inspect scansafe cws_inspect_pmap1
hostname(config-pmap)# parameters
hostname(config-pmap-p)# http
hostname(config-pmap-p)# default name Boulder group Cisco
```

Related Commands

Command	Description
class-map type inspect scansafe	Creates an inspection class map for whitelisted users and groups.
http[**s**] (parameters)	Specifies the service type for the inspection policy map, either HTTP or HTTPS.
inspect scansafe	Enables Cloud Web Security inspection on the traffic in a class.
license	Configures the authentication key that the ASA sends to the Cloud Web Security proxy servers to indicate from which organization the request comes.
match user group	Matches a user or group for a whitelist.
policy-map type inspect scansafe	Creates an inspection policy map so you can configure essential parameters for the rule and also optionally identify the whitelist.
retry-count	Enters the retry counter value, which is the amount of time that the ASA waits before polling the Cloud Web Security proxy server to check its availability.
scansafe	In multiple context mode, allows Cloud Web Security per context.
scansafe general-options	Configures general Cloud Web Security server options.
server {**primary** | **backup**}	Configures the fully qualified domain name or IP address of the primary or backup Cloud Web Security proxy servers.
show conn scansafe	Shows all Cloud Web Security connections, as noted by the capitol Z flag.
show scansafe server	Shows the status of the server, whether it's the current active server, the backup server, or unreachable.
show scansafe statistics	Shows total and current http connections.
user-identity monitor	Downloads the specified user or group information from the AD agent.
whitelist	Performs the whitelist action on the class of traffic.

default-acl

To specify the ACL to be used as the default ACL for NAC Framework sessions that fail posture validation, use the **default-acl** command in nac-policy-nac-framework configuration mode. To remove the command from the NAC policy, use the **no** form of the command.

[**no**] **default-acl** *acl-name*

Syntax Description

acl-name	Names the access control list to be applied to the session.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Nac-policy-nac-framework configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.
8.0(2)	"nac-" was removed from the command name. The command moved from group-policy configuration mode to nac-policy-nac-framework configuration mode.

Usage Guidelines

Each group policy points to a default ACL to be applied to hosts that match the policy and are eligible for NAC. The ASA applies the NAC default ACL before posture validation. After posture validation, the ASA replaces the default ACL with the one obtained from the Access Control Server for the remote host. It retains the default ACL if posture validation fails.

The ASA also applies the NAC default ACL if clientless authentication is enabled (which is the default setting).

Examples

The following example identifies acl-1 as the ACL to be applied before posture validation succeeds:

```
hostname(config-group-policy)# default-acl acl-1
hostname(config-group-policy)
```

The following example inherits the ACL from the default group policy:

```
hostname(config-group-policy)# no default-acl
hostname(config-group-policy)
```

Related Commands

Command	Description
nac-policy	Creates and accesses a Cisco NAC policy, and specifies its type.
nac-settings	Assigns a NAC policy to a group policy.
debug nac	Enables logging of NAC Framework events.
show vpn-session_summary.db	Displays the number of IPsec, WebVPN, and NAC sessions.
show vpn-session.db	Displays information about VPN sessions, including NAC results.

default enrollment

To return all enrollment parameters to their system default values, use the **default enrollment** command in crypto ca trustpoint configuration mode.

default enrollment

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca trustpoint configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Invocations of this command do not become part of the active configuration.

Examples

The following example enters crypto ca trustpoint configuration mode for trustpoint central, and returns all enrollment parameters to their default values within trustpoint central:

```
hostname(config)# crypto ca trustpoint central
hostname(ca-trustpoint)# default enrollment
hostname(ca-trustpoint)#
```

Related Commands

Command	Description
clear configure crypto ca trustpoint	Removes all trustpoints.
crl configure	Enters crl configuration mode.
crypto ca trustpoint	Enters trustpoint configuration mode.

default-domain

To set a default domain name for users of the group policy, use the **default-domain** command in group-policy configuration mode. To delete a domain name, use the **no** form of this command.

default-domain {**value** *domain-name* | **none**}

no default-domain [*domain-name*]

Syntax Description

none	Indicates that there is no default domain name. Sets a default domain name with a null value, thereby disallowing a default domain name. Prevents inheriting a default domain name from a default or specified group policy.
value *domain-name*	Identifies the default domain name for the group.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To prevent users from inheriting a domain name, use the **default-domain none** command.

The ASA passes the default domain name to the AnyConnect Secure Mobility Client or the legacy VPN client (IPsec/IKEv1) to append to DNS queries that omit the domain field. This domain name applies only to tunneled packets. When there are no default domain names, users inherit the default domain name in the default group policy.

You can use only alphanumeric characters, hyphens (-), and periods (.) in default domain names.

Examples

The following example shows how to set a default domain name of FirstDomain for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# default-domain value FirstDomain
```

Related Commands

Command	Description
split-dns	Provides a list of domains to be resolved through the split tunnel.
split-tunnel-network-list	Identifies the access list the ASA uses to distinguish networks that require tunneling and those that do not.
split-tunnel-policy	Lets an IPsec client conditionally direct packets over an IPsec tunnel in encrypted form, or to a network interface in clear text form.

default-group-policy

To specify the set of attributes that the user inherits by default, use the **default-group-policy** command in tunnel-group general-attributes configuration mode. To eliminate a default group policy name, use the **no** form of this command.

default-group-policy *group-name*

no default-group-policy *group-name*

Syntax Description

group-name	Specifies the name of the default group.

Defaults

The default group name is DfltGrpPolicy.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group general-attributes configuration	•	—	•	—	—

Command History

Version	Modification
7.0(1)	This command was introduced.
7.1(1)	The **default-group-policy** command in webvpn configuration mode was deprecated. The **default-group-policy** command in tunnel-group general-attributes mode replaced it.

Usage Guidelines

In Version 7.1(1), if you enter this command in webvpn configuration mode, it is transformed to the same command in tunnel-group general-attributes mode.

The default group policy DfltGrpPolicy comes with the initial configuration of the ASA. You can apply this attribute to all tunnel group types.

Examples

The following example entered in config-general configuration mode, specifies a set of attributes for users to inherit by default for an IPsec LAN-to-LAN tunnel group named "standard-policy." This set of commands defines the accounting server, the authentication server, the authorization server, and the address pools.

```
hostname(config)# tunnel-group standard-policy type ipsec-ra
hostname(config)# tunnel-group standard-policy general-attributes
hostname(config-tunnel-general)# default-group-policy first-policy
hostname(config-tunnel-general)# accounting-server-group aaa-server123
hostname(config-tunnel-general)# address-pool (inside) addrpool1 addrpool2 addrpool3
hostname(config-tunnel-general)# authentication-server-group aaa-server456
```

```
hostname(config-tunnel-general)# authorization-server-group aaa-server78
hostname(config-tunnel-general)#
```

Related Commands

Command	Description
clear-configure tunnel-group	Clears all configured tunnel groups.
group-policy	Creates or edits a group policy
show running-config tunnel group	Shows the tunnel group configuration for all tunnel groups or for a particular tunnel group.
tunnel-group general-attributes	Specifies the general attributes for the named tunnel group.

default-group-policy (webvpn)

To specify the name of the group policy to use when the WebVPN or e-mail proxy configuration does not specify a group policy, use the **default-group-policy** command in various configuration modes. To remove the attribute from the configuration, use the **no** form of this command.

default-group-policy *groupname*

no default-group-policy

Syntax Description

groupname	Identifies the previously configured group policy to use as the default group policy. Use the **group-policy** command to configure a group policy.

Defaults

A default group policy, named *DfltGrpPolicy*, always exists on the ASA. This **default-group-policy** command lets you substitute a group policy that you create as the default group policy for WebVPN and e-mail proxy sessions. An alternative is to edit the DfltGrpPolicy.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—
Imap4s configuration	•	—	•	—	—
Pop3s configuration	•	—	•	—	—
Smtps configuration	•	—	•	—	—

Command History

Version	Modification
7.0(1)	This command was introduced.
7.1(1)	This command was deprecated in webvpn configuration mode and moved to tunnel-group general-attributes configuration mode.

Usage Guidelines

WebVPN, IMAP4S, POP3S, and SMTPS sessions require either a specified or a default group policy. For WebVPN, use this command in webvpn configuration mode. For e-mail proxy, use this command in the applicable e-mail proxy mode.

In Version 7.1(1), if you enter this command in webvpn configuration mode, it is transformed to the same command in tunnel-group general-attributes configuration mode.

You can edit, but not delete the system DefaultGroupPolicy. It has the following AVPs:

Attribute	Default Value
wins-server	none
dns-server	none
dhcp-network-scope	none
vpn-access-hours	unrestricted
vpn-simultaneous-logins	3
vpn-idle-timeout	30 minutes
vpn-session-timeout	none
vpn-filter	none
vpn-tunnel-protocol	WebVPN
ip-comp	disable
re-xauth	disable
group-lock	none
pfs	disable
client-access-rules	none
banner	none
password-storage	disabled
ipsec-udp	disabled
ipsec-udp-port	0
backup-servers	keep-client-config
split-tunnel-policy	tunnelall
split-tunnel-network-list	none
default-domain	none
split-dns	none
intercept-dhcp	disable
client-firewall	none
secure-unit-authentication	disabled
user-authentication	disabled
user-authentication-idle-timeout	none
ip-phone-bypass	disabled
leap-bypass	disabled
nem	disabled
webvpn attributes	
filter	none
functions	disabled
homepage	none
html-content-filter	none
port-forward	disabled
port-forward-name	none
url-list	none

Examples

The following example shows how to specify a default group policy called WebVPN7 for WebVPN:

```
hostname(config)# webvpn
hostname(config-webvpn)# default-group-policy WebVPN7
```

default-idle-timeout

To set a default idle timeout value for WebVPN users, use the **default-idle-timeout** command in webvpn configuration mode. To remove the default idle timeout value from the configuration and reset the default, use the **no** form of this command.

default-idle-timeout *seconds*

no default-idle-timeout

Syntax Description

seconds	Specifies the number of seconds for the idle time out. The minimum is 60 seconds, maximum is 1 day (86400 seconds).

Defaults

1800 seconds (30 minutes).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The ASA uses the value you set here if there is no idle timeout defined for a user, if the value is 0, or if the value does not fall into the valid range. The default idle timeout prevents stale sessions.

We recommend that you set this command to a short time period, because a browser set to disable cookies (or one that prompts for cookies and then denies them) can result in a user not connecting but nevertheless appearing in the sessions database. If the maximum number of connections permitted is set to one (via the **vpn-simultaneous-logins** command), the user cannot log back in because the database indicates that the maximum number of connections already exists. Setting a low idle timeout removes such phantom sessions quickly, and lets a user log in again.

Examples

The following example shows how to set the default idle timeout to 1200 seconds (20 minutes):

```
hostname(config)# webvpn
hostname(config-webvpn)# default-idle-timeout 1200
```

Related Commands

Command	Description
vpn-simultaneous-logins	Sets the maximum number of simultaneous VPN sessions permitted.

default-information (EIGRP)

To control the candidate default route information for the EIGRP routing process, use the **default-information** command in router configuration mode. To suppress EIGRP candidate default route information in incoming or outbound updates, use the **no** form of this command.

default-information {**in** | **out**} [*acl-name*]

no default-information {**in** | **out**}

Syntax Description

acl-name	(Optional) Specifies the named standard access list.
in	Configures EIGRP to accept exterior default routing information.
out	Configures EIGRP to advertise external routing information.

Defaults

Exterior routes are accepted and sent.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

Only the **no** form of the command or **default-information** commands with an access list specified will appear in the running configuration because, by default, the candidate default routing information is accepted and sent. The **no** form of the command does not take an *acl-name* argument.

Examples

The following example disables the receipt of exterior or candidate default route information:

```
hostname(config)# router eigrp 100
hostname(config-router)# no default-information in
```

Related Commands

Command	Description
router eigrp	Creates an EIGRP routing process and enters configuration mode for that process.

default-information originate (OSPFv2 and OSPFv3)

To generate a default external route into an OSPFv2 or OSPFv3 routing domain, use the **default-information originate** command in router configuration mode or IPv6 router configuration mode. To disable this feature, use the **no** form of this command.

default-information originate [**always**] [**metric** *value*] [**metric-type** {**1** | **2**}] [**route-map** *map-name*]

no default-information originate [[**always**] [**metric** *value*] [**metric-type** {**1** | **2**}] [**route-map** *map-name*]]

Syntax Description

always	(Optional) Always advertises the default route whether or not the software has a default route.
metric *value*	(Optional) Specifies the OSPF default metric value, from 0 to 16777214.
metric-type {**1** | **2**}	(Optional) Specifies the external link type associated with the default route advertised into the OSPF routing domain. Valid values are as follows: • **1**—Type 1 external route. • **2**—Type 2 external route.
route-map *map-name*	(Optional) Specifies the name of the route map to apply.

Defaults

The default values are as follows:

- **metric** *value* is 1.
- **metric-type** is 2.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
IPv6 router configuration	•	—	•	—	—
Router configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Added support for OSPFv3.

Usage Guidelines

Using the **no** form of this command with optional keywords and arguments only removes the optional information from the command. For example, entering the **no default-information originate metric** *3* command removes the **metric** *3* option from the command in the running configuration. To remove the complete command from the running configuration, use the **no** form of the command without any options: **no default-information originate**.

Examples

The following example shows how to use the **default-information originate** command with an optional metric and metric type:

```
hostname(config-rtr)# default-information originate always metric 3 metric-type 2
hostname(config-rtr)#
```

Related Commands

Command	Description
router ospf	Enters router configuration mode.
show running-config router	Displays the OSPFv2 commands in the global router configuration.
ipv6 router ospf	Enters IPv6 router configuration mode.
show running-config ipv6 router	Displays the OSPFv3 commands in the global router configuration.

default-information originate (RIP)

To generate a default route into RIP, use the **default-information originate** command in router configuration mode. To disable this feature, use the **no** form of this command.

default-information originate [**route-map** *name*]

no default-information originate [**route-map** *name*]]

Syntax Description

route-map *name*	(Optional) Name of the route map to apply. The routing process generates the default route if the route map is satisfied.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The route map referenced in the **default-information originate** command cannot use an extended access list; it can use only a standard access list.

Examples

The following example shows how to generate a default route into RIP:

```
hostname(config)# router rip
hostname(config-router)# network 10.0.0.0
hostname(config-router)# default-information originate
```

Related Commands

Command	Description
router rip	Enters router configuration mode for the RIP routing process.
show running-config router	Displays the commands in the global router configuration.

default-language

To set the default language displayed on the Clientless SSL VPN pages, use the **default-language** command in webvpn configuration mode.

default-language *language*

Syntax Description

language	Specifies the name of a previously imported translation table.

Defaults

The default language is en-us (English spoken in the United States).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The ASA provides language translation for the portal and screens displayed to users that initiate browser-based, clientless SSL VPN connections, as well as the user interface displayed to AnyConnect VPN Client users.

The default language is displayed to Clientless SSL VPN users when they initially connect to the ASA, before logging in. Thereafter, the language displayed is affected by the tunnel group or group policy settings and any customization that they reference.

Examples

The following example changes the default language to Chinese with the name *Sales*:

```
hostname(config-webvpn)# default-language zh
```

Related Commands

Command	Description
import webvpn translation-table	Imports a translation table.
revert	Removes translation tables from cache memory.
show import webvpn translation-table	Displays information about imported translation tables.

default-metric

To specify the EIGRP metrics for redistributed routes, use the **default-metric** command in router configuration mode. To restore the default values, use the **no** form of this command.

default-metric *bandwidth delay reliability loading mtu*

no default-metric *bandwidth delay reliability loading mtu*

Syntax Description

bandwidth	The minimum bandwidth of the route in kilobytes per second. Valid values are from 1 to 4294967295.
delay	The route delay in tens of microseconds. Valid values are 1 to 4294967295.
loading	The effective bandwidth of the route expressed as a number from 1 to 255 (255 is 100 percent loading).
mtu	The smallest allowed value for the MTU, expressed in bytes. Valid values are from 1 to 65535.
reliability	The likelihood of successful packet transmission expressed as a number from 0 through 255. The value 255 means 100 percent reliability; 0 means no reliability.

Defaults

Only connected routes can be redistributed without a default metric. The metric of redistributed connected routes is set to 0.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

You must use a default metric to redistribute a protocol into EIGRP unless you use the **metric** keyword and attributes in the **redistribute** command. Metric defaults have been carefully set to work for a wide variety of networks. Take great care when changing these values. Keeping the same metrics is supported only when you are redistributing from static routes.

The minimum MTU allowed on an IPv6 enabled interface is 1280 bytes; however, if IPsec is enabled on the interface, the MTU value should not be set below 1380 because of the overhead of IPsec encryption. Setting the interface below 1380 bytes may result in dropped packets.

Examples

The following example shows how the redistributed RIP route metrics are translated into EIGRP metrics with values as follows: bandwidth = 1000, delay = 100, reliability = 250, loading = 100, and MTU = 1500.

```
hostname(config)# router eigrp 100
hostname(config-router)# network 172.16.0.0
hostname(config-router)# redistribute rip
hostname(config-router)# default-metric 1000 100 250 100 1500
```

Related Commands

Command	Description
router eigrp	Creates an EIGRP routing process and enters router configuration mode for that process.
redistribute (EIGRP)	Redistributes routes into the EIGRP routing process.

delay

To set a delay value for an interface, use the **delay** command in interface configuration mode. To restore the default delay value, use the **no** form of this command.

delay *delay-time*

no delay

Syntax Description

delay-time	The delay time in tens of microseconds. Valid values are from 1 to 16777215.

Defaults

The default delay depends upon the interface type. Use the **show interface** command to see the delay value for an interface.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The value entered is in tens of microseconds. The delay value displayed in the **show interface** output is in microseconds.

Examples

The following example changes the delay on an interface from the default 1000 to 2000. Truncated **show interface** command output is included before and after the **delay** command to show how the command affects the delay values. The delay value is noted in the second line of the **show interface** output, after the DLY label.

Notice that the command entered to change the delay value to 2000 is **delay 200**, not **delay 2000**. This is because the value entered with the **delay** command is in tens of microseconds, and the **show interface** output displays microseconds.

```
hostname(config)# interface Ethernet0/0
hostname(config-if)# show interface Ethernet0/0

Interface Ethernet0/0 "outside", is up, line protocol is up
  Hardware is i82546GB rev03, BW 100 Mbps, DLY 1000 usec
        Auto-Duplex(Half-duplex), Auto-Speed(100 Mbps)
```

```
        MAC address 0013.c480.7e16, MTU 1500
        IP address 10.86.194.224, subnet mask 255.255.254.0
! Remainder of the output removed

hostname(config-if)# delay 200
hostname(config-if)# show interface Ethernet0/0

Interface Ethernet0/0 "outside", is up, line protocol is up
  Hardware is i82546GB rev03, BW 100 Mbps, DLY 2000 usec
        Auto-Duplex(Half-duplex), Auto-Speed(100 Mbps)
        MAC address 0013.c480.7e16, MTU 1500
        IP address 10.86.194.224, subnet mask 255.255.254.0
! Remainder of the output removed
```

Related Commands

Command	Description
show interface	Displays interface statistics and settings.

delete

To delete a file from flash memory, use the **delete** command in privileged EXEC mode.

delete [**/noconfirm**] [**/recursive**] [**disk0: | disk1: | flash:**] [*path/*] *filename*

Syntax Description

/noconfirm	(Optional) Does not prompt for confirmation.
/recursive	(Optional) Deletes the specified file recursively in all subdirectories.
disk0:	(Optional) Specifies the internal flash memory.
disk1:	(Optional) Specifies the external flash memory card.
filename	Specifies the name of the file to delete.
flash:	(Optional) Specifies the internal flash memory. This keyword is the same as **disk0**.
path/	(Optional) Specifies to the path to the file.

Defaults

If you do not specify a directory, the directory is the current working directory by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The file is deleted from the current working directory if a path is not specified. Wildcards are supported when deleting files. When deleting files, you are prompted with the filename and must confirm the deletion.

Examples

The following example shows how to delete a file named test.cfg in the current working directory:

```
hostname# delete test.cfg
```

Related Commands

Command	Description
cd	Changes the current working directory to the one specified.

Command	Description
rmdir	Removes a file or directory.
show file	Displays the specified file.

deny-message

To change the message delivered to a remote user who logs into WebVPN successfully, but has no VPN privileges, use the **deny-message value** command in group-webvpn configuration mode. To remove the string so that the remote user does not receive a message, use the **no** form of this command.

deny-message value *string*

no deny-message value

Syntax Description

string	Allows up to 491 alphanumeric characters, including special characters, spaces, and punctuation.

Defaults

The default deny message is: “Login was successful, but because certain criteria have not been met or due to some specific group policy, you do not have permission to use any of the VPN features. Contact your IT administrator for more information.”

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.1(1)	This command moved from tunnel-group webvpn configuration mode to group-webvpn configuration mode.

Usage Guidelines

Before entering this command, you must enter the **group-policy** *name* **attributes** command in global configuration mode, then the **webvpn** command. (This step assumes you already have created the policy name.)

The **no deny-message none** command removes the attribute from the group-webvpn configuration. The policy inherits the attribute value.

When typing the string in the **deny-message value** command, continue typing even if the command wraps.

The text appears on the remote user’s browser upon login, independent of the tunnel policy used for the VPN session.

Examples

The following example shows the first command that creates an internal group policy named group2. The subsequent commands modify the deny message associated with that policy:

```
hostname(config)# group-policy group2 internal
hostname(config)# group-policy group2 attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# deny-message value "Your login credentials are OK. However,
you have not been granted rights to use the VPN features. Contact your administrator for
more information."
hostname(config-group-webvpn)
```

Related Commands

Command	Description
clear configure group-policy	Removes all group policy configuration.
group-policy	Creates a group policy.
group-policy attributes	Enters the group-policy attribute configuration mode.
show running-config group-policy	Displays the running group policy configuration for the policy named.
webvpn	Enters group-policy webvpn configuration mode.

deny version

To deny a specific version of SNMP traffic, use the **deny version** command in snmp-map configuration mode. To disable this command, use the **no** form of this command.

deny version *version*

no deny version *version*

Syntax Description

version	Specifies the version of SNMP traffic that the ASA drops. The permitted values are **1**, **2**, **2c**, and **3**.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Snmp-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the **deny version** command to restrict SNMP traffic to specific versions of SNMP. Earlier versions of SNMP were less secure, so restricting SNMP traffic to Version 2 may be specified by your security policy. You use the **deny version** command within an SNMP map, which you configure using the **snmp-map** command, which is accessible by entering the **snmp-map** command in global configuration mode. After creating the SNMP map, you enable the map using the **inspect snmp** command, and then apply it to one or more interfaces using the **service-policy** command.

Examples

The following example shows how to identify SNMP traffic, define a SNMP map, define a policy, and apply the policy to the outside interface:

```
hostname(config)# access-list snmp-acl permit tcp any any eq 161
hostname(config)# access-list snmp-acl permit tcp any any eq 162
hostname(config)# class-map snmp-port
hostname(config-cmap)# match access-list snmp-acl
hostname(config-cmap)# exit
hostname(config)# snmp-map inbound_snmp
hostname(config-snmp-map)# deny version 1
hostname(config-snmp-map)# exit
hostname(config)# policy-map inbound_policy
hostname(config-pmap)# class snmp-port
```

```
hostname(config-pmap-c)# inspect snmp inbound_snmp
hostname(config-pmap-c)# exit
hostname(config-pmap)# exit
hostname(config)# service-policy inbound_policy interface outside
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
inspect snmp	Enables SNMP application inspection.
policy-map	Associates a class map with specific security actions.
snmp-map	Defines an SNMP map and enables SNMP map configuration mode.
service-policy	Applies a policy map to one or more interfaces.

description

To add a description for a named configuration unit (for example, for a context or for an object group, or for a DAP record), use the **description** command in various configuration modes. To remove the description, use the **no** form of this command.

description *text*

no description

Syntax Description

text	Sets the description as a text string of up to 200 characters in length. The description adds helpful notes in your configuration. For dynamic-access-policy-record mode, the maximum length is 80 characters. If you want to include a question mark (?) in the string, you must type **Ctrl-V** before typing the question mark so you do not inadvertently invoke CLI help.

Defaults

No default behavior or values.

Command Modes

This command is available in various configuration modes.

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0(2)	Support was added for the dynamic-access-policy-record configuration mode.

Examples

The following example adds a description to the "Administration" context configuration:

```
hostname(config)# context administrator
hostname(config-context)# description This is the admin context.
hostname(config-context)# allocate-interface gigabitethernet0/0.1
hostname(config-context)# allocate-interface gigabitethernet0/1.1
hostname(config-context)# config-url flash://admin.cfg
```

Related Commands

Command	Description
class-map	Identifies traffic to which you apply actions in the **policy-map** command.
context	Creates a security context in the system configuration and enters context configuration mode.
gtp-map	Controls parameters for the GTP inspection engine.
interface	Configures an interface and enters interface configuration mode.
object-group	Identifies traffic to include in the **access-list** command.
policy-map	Identifies actions to apply to traffic identified by the **class-map** command.

dhcp client route distance

To configure an administrative distance for routes learned through DHCP, use the **dhcp client route distance** command in interface configuration mode. To restore the default setting, use the **no** form of this command.

dhcp client route distance *distance*

no dhcp client route distance *distance*

Syntax Description

distance	The administrative distance to apply to routes learned through DHCP. Valid values are from 1 to 255.

Defaults

Routes learned through DHCP are given an administrative distance of 1 by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The **dhcp client route distance** command is checked only when a route is learned from DHCP. If the **dhcp client route distance** command is entered after a route is learned from DHCP, the administrative distance specified does not affect the existing learned route. Only routes learned after the command was entered have the specified administrative distance.

You must specify the **setroute** option in the **ip address dhcp** command to obtain routes through DHCP.

If DHCP is configured on multiple interfaces, you must use the **dhcp client route distance** command on each of the interfaces to indicate the priority of the installed routes.

Examples

The following example obtains the default route through DHCP on GigabitEhternet0/2. The route is tracked by tracking entry object 1. The SLA operation monitors the availability of the 10.1.1.1 gateway off of the outside interface. If the SLA operation fails, then the backup route obtained through DHCP on GigabitEthernet0/3 is used. The backup route is assigned an administrative distance of 254.

```
hostname(config)# sla monitor 123
hostname(config-sla-monitor)# type echo protocol ipIcmpEcho 10.1.1.1 interface outside
hostname(config-sla-monitor-echo)# timeout 1000
hostname(config-sla-monitor-echo)# frequency 3
```

```
hostname(config)# sla monitor schedule 123 life forever start-time now
hostname(config)# track 1 rtr 123 reachability
hostname(config)# interface GigabitEthernet0/2
hostname(config-if)# dhcp client route track 1
hostname(config-if)# ip address dhcp setroute
hostname(config)# interface GigabitEthernet0/3
hostname(config-if)# dhcp client route track 1
hostname(config-if)# dhcp client route distance 254
hostname(config-if)# ip address dhcp setroute
```

Related Commands

Command	Description
dhcp client route track	Associates routes learned through DHCP with a tracking entry object.
ip address dhcp	Configures the specified interface with an IP address obtained through DHCP.
sla monitor	Defines an SLA monitoring operation.
track rtr	Creates a tracking entry to poll the SLA.

dhcp client route track

To configure the DHCP client to associate added routes with a specified tracked object number, use the **dhcp client route track** command in interface configuration mode. To disable DHCP client route tracking, use the **no** form of this command.

dhcp client route track *number*

no dhcp client route track

Syntax Description

number	The tracking entry object ID. Valid values are from 1 to 500.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The **dhcp client route track** command is checked only when a route is learned from DHCP. If the **dhcp client route track** command is entered after a route is learned from DHCP, the existing learned routes are not associated with a tracking object. You must put the following two commands in the correct order. Make sure that you always enter the **dhcp client route track** command first, followed by the **ip address dhcp setroute** command, If you have already entered the **ip address dhcp setroute** command, then remove it and reenter it in the order previously described. Only routes learned after the command was entered are associated with the specified tracking object.

You must specify the **setroute** option in the **ip address dhcp** command to obtain routes through DHCP.

If DHCP is configured on multiple interfaces, you must use the **dhcp client route distance** command on each of the interfaces to indicate the priority of the installed routes.

Examples

The following example obtains the default route through DHCP on GigabitEhternet0/2. The route is tracked by tracking entry object 1. The SLA operation monitors the availability of the 10.1.1.1 gateway off of the outside interface. If the SLA operation fails, then the backup route obtained through DHCP on GigabitEthernet0/3 is used. The backup route is assigned an administrative distance of 254.

```
hostname(config)# sla monitor 123
hostname(config-sla-monitor)# type echo protocol ipIcmpEcho 10.1.1.1 interface outside
```

```
hostname(config-sla-monitor-echo)# timeout 1000
hostname(config-sla-monitor-echo)# frequency 3
hostname(config)# sla monitor schedule 123 life forever start-time now
hostname(config)# track 1 rtr 123 reachability
hostname(config)# interface GigabitEthernet0/2
hostname(config-if)# dhcp client route track 1
hostname(config-if)# ip address dhcp setroute
hostname(config)# interface GigabitEthernet0/3
hostname(config-if)# dhcp client route distance 254
hostname(config-if)# ip address dhcp setroute
```

Related Commands

Command	Description
dhcp client route distance	Assigns an administrative distance to routes learned through DHCP.
ip address dhcp	Configures the specified interface with an IP address obtained through DHCP.
sla monitor	Defines an SLA monitoring operation.
track rtr	Creates a tracking entry to poll the SLA.

dhcp-client broadcast-flag

To allow the ASA to set the broadcast flag in the DHCP client packet, use the **dhcp-client broadcast-flag** command in global configuration mode. To disallow the broadcast flag, use the **no** form of this command.

dhcp-client broadcast-flag

no dhcp-client broadcast-flag

Syntax Description

This command has no arguments or keywords.

Defaults

By default, the broadcast flag is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

If you enable the DHCP client for an interface using the **ip address dhcp** command, then you can use this command to set the broadcast flag to 1 in the DHCP packet header when the DHCP client sends a discover requesting an IP address. The DHCP server listens to this broadcast flag and broadcasts the reply packet if the flag is set to 1.

If you enter the **no dhcp-client broadcast-flag** command, the broadcast flag is set to 0, and the DHCP server unicasts the reply packets to the client with the offered IP address.

The DHCP client can receive both broadcast and unicast offers from the DHCP server.

Examples

The following example enables the broadcast flag:

```
hostname(config)# dhcp-client broadcast-flag
```

Related Commands

Command	Description
ip address dhcp	Enables the DHCP client for an interface.
interface	Enters interface configuration mode so you can set the IP address.

dhcp-client client-id	Sets DHCP request packet option 61 to include the interface MAC address.
dhcp-client update dns	Enables DNS updates for the DHCP client.

dhcp-client client-id

To force a MAC address to be stored inside a DHCP request packet for option 61 instead of the default internally generated string, use the **dhcp-client client-id** command in global configuration mode. To disallow the MAC address, use the **no** form of this command.

dhcp-client client-id interface *interface_name*

no dhcp-client client-id interface *interface_name*

Syntax Description

interface *interface_name*	Specifies the interface on which you want to enable the MAC address for option 61.

Defaults

By default, an internally-generated ASCII string is used for option 61.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

If you enable the DHCP client for an interface using the **ip address dhcp** command, some ISPs expect option 61 to be the interface MAC address. If the MAC address is not included in the DHCP request packet, then an IP address will not be assigned. Use the **dhcp-client client-id** command to include the interface MAC address for option 61.

Examples

The following example enables the MAC address for option 61 for the outside interface:

```
hostname(config)# dhcp-client client-id interface outside
```

Related Commands

Command	Description
ip address dhcp	Enables the DHCP client for an interface.
interface	Enters interface configuration mode so you can set the IP address.

dhcp-client broadcast-flag	Sets the broadcast flag in the DHCP client packet.
dhcp-client update dns	Enables DNS updates for the DHCP client.

dhcp-client update dns

To configure the update parameters that the DHCP client passes to the DHCP server, use the **dhcp-client update dns** command in global configuration mode. To remove the parameters that the DHCP client passes to the DHCP server, use the **no** form of this command.

dhcp-client update dns [**server** {**both** | **none**}]

no dhcp-client update dns [**server** {**both** | **none**}]

Syntax Description

both	The client requests that the DHCP server update both the DNS A and PTR resource records.
none	The client requests that the DHCP server perform no DDNS updates.
server	Specifies the DHCP server to receive the client requests.

Defaults

By default, the ASA requests that the DHCP server perform PTR RR updates only. The client does not send the FQDN option to the server.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can also be entered in interface configuration mode, but it is not hyphenated. See the **dhcp client update dns** command. When entered in interface mode, the **dhcp client update dns** command overrides settings configured by this command in global configuration mode.

Examples

The following example configures the client to request that the DHCP server update neither the A and the PTR RRs:

```
hostname(config)# dhcp-client update dns server none
```

The following example configures the client to request that the server update both the A and PTR RRs:

```
hostname(config)# dhcp-client update dns server both
```

Related Commands

Command	Description
ddns	Specifies a DDNS update method type for a created DDNS method.
ddns update	Associates a DDNS update method with a ASA interface or a DDNS update hostname.
ddns update method	Creates a method for dynamically updating DNS resource records.
dhcpd update dns	Enables a DHCP server to perform DDNS updates.
interval maximum	Configures the maximum interval between update attempts by a DDNS update method.

dhcp-network-scope

To specify the range of IP addresses the ASA DHCP server should use to assign addresses to users of this group policy, use the **dhcp-network-scope** command in group-policy configuration mode. To remove the attribute from the running configuration, use the **no** form of this command.

dhcp-network-scope {*ip_address*} | **none**

no dhcp-network-scope

Syntax Description

ip_address	Specifies the IP subnetwork the DHCP server should use to assign IP addresses to users of this group policy.
none	Sets the DHCP subnetwork to a null value, thereby allowing no IP addresses. Prevents inheriting a value from a default or specified group policy.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command allows inheritance of a value from another group policy. To prevent inheriting a value, use the **dhcp-network-scope none** command.

Examples

The following example shows how to set an IP subnetwork of 10.10.85.1 for the group policy named First Group:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# dhcp-network-scope 10.10.85.1
```

dhcp-server

To configure support for DHCP servers that assign IP addresses to clients as a VPN tunnel is established, use the **dhcp-server** command in tunnel-group general-attributes configuration mode. To return this command to the default, use the **no** form of this command.

dhcp-server [**link-selection** | **subnet-selection**] **ip1** [**ip2-ip10**]

[**no**] **dhcp-server** [**link-selection** | **subnet-selection**] **ip1** [**ip2-ip10**]

Syntax Description

ip1	Address of a DHCP server
ip2-ip10	(Optional) Addresses of additional DHCP servers. Up to ten may be specified in the same command or spread over multiple commands.
link-selection	(Optional) Specifies that the ASA should send DHCP suboption 5, the Link Selection Suboption for the Relay Information Option 82, defined by RFC 3527. This should only be used with servers that support this RFC.
subnet-selection	(Optional) Specifies that the ASA should send DHCP Option 118, the IPv4 Subnet Selection Option, defined by RFC 3011. This should only be used with servers that support this RFC.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Tunnel-group general attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0(5)	Added the **link-selection** and **subnet-selection** keywords.

Usage Guidelines

You can apply this attribute to remote access tunnel group types only.

Examples

The following command, entered in config-general configuration mode, adds three DHCP servers (dhcp1, dhcp2, and dhcp3) to the IPsec remote access tunnel group “remotegrp”:

```
hostname(config)# tunnel-group remotegrp type remote-access
hostname(config)# tunnel-group remotegrp general
hostname(config-tunnel-general)# default-group-policy remotegrp
```

```
hostname(config-tunnel-general)# dhcp-server dhcp1 dhcp2 dhcp3
hostname(config-tunnel-general)
```

Related Commands

Command	Description
clear-configure tunnel-group	Clears all configured tunnel groups.
show running-config tunnel group	Shows the tunnel group configuration for all tunnel groups or for a particular tunnel group.
tunnel-group general-attributes	Specifies the general attributes for the named tunnel group.

dhcpd address through distribute-list out Commands

dhcpd address

To define the IP address pool used by the DHCP server, use the **dhcpd address** command in global configuration mode. To remove an existing DHCP address pool, use the **no** form of this command.

dhcpd address *IP_address1*[*-IP_address2*] *interface_name*

no dhcpd address *interface_name*

Syntax Description

interface_name	Interface to which the address pool is assigned.
IP_address1	Start address of the DHCP address pool.
IP_address2	End address of the DHCP address pool.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The address pool of an ASA DHCP server must be within the same subnet of the ASA interface on which it is enabled, and you must specify the associated ASA interface using *interface_name*.

The size of the address pool is limited to 256 addresses per pool on the ASA. If the address pool range is larger than 253 addresses, the netmask of the ASA interface cannot be a Class C address (for example, 255.255.255.0) and needs to be something larger, for example, 255.255.254.0.

DHCP clients must be physically connected to the subnet of the ASA DCHP server interface.

The **dhcpd address** command cannot use interface names with a "-" (dash) character because this character is interpreted as a range specifier instead of as part of the object name.

The **no dhcpd address** *interface_name* command removes the DHCP server address pool that you configured for the specified interface.

See the CLI configuration guide for information about how to implement the DHCP server feature in the ASA.

Examples

The following example shows how to configure an address pool and DNS server for the DHCP clients on the DMZ interface of the ASA:

```
hostname(config)# dhcpd address 10.0.1.100-10.0.1.108 dmz
hostname(config)# dhcpd dns 209.165.200.226
hostname(config)# dhcpd enable dmz
```

The following example shows how to configure a DHCP server on the inside interface. The **dhcpd address** command assigns a pool of 10 IP addresses to the DHCP server on that interface.

```
hostname(config)# dhcpd address 10.0.1.101-10.0.1.110 inside
hostname(config)# dhcpd dns 198.162.1.2 198.162.1.3
hostname(config)# dhcpd wins 198.162.1.4
hostname(config)# dhcpd lease 3000
hostname(config)# dhcpd ping_timeout 1000
hostname(config)# dhcpd domain example.com
hostname(config)# dhcpd enable inside
```

Related Commands

Command	Description
clear configure dhcpd	Removes all DHCP server settings.
dhcpd enable	Enables the DHCP server on the specified interface.
show dhcpd	Displays DHCP binding, statistical, or state information.
show running-config dhcpd	Displays the current DHCP server configuration.

dhcpd auto_config

To enable the ASA to automatically configure DNS, WINS and domain name values for the DHCP server based on the values obtained from an interface running a DHCP or PPPoE client, or from a VPN server, use the **dhcpd auto_config** command in global configuration mode. To discontinue the automatic configuration of DHCP parameters, use the **no** form of this command.

dhcpd auto_config *client_if_name* [[**vpnclient-wins-override**] **interface** *if_name*]

no dhcpd auto_config *client_if_name* [[**vpnclient-wins-override**] **interface** *if_name*]

Syntax Description

client_if_name	Specifies the interface running the DHCP client that supplies the DNS, WINS, and domain name parameters.
interface *if_name*	Specifies the interface to which the action will apply.
vpnclient-wins-override	Overrides the interface DHCP or PPPoE client WINS parameter with the vpnclient parameter.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If you specify DNS, WINS, or domain name parameters using the CLI commands, then the CLI-configured parameters overwrite the parameters obtained by automatic configuration.

Examples

The following example shows how to configure DHCP on the inside interface. The **dhcpd auto_config** command is used to pass DNS, WINS, and domain information obtained from the DHCP client on the outside interface to the DHCP clients on the inside interface.

```
hostname(config)# dhcpd address 10.0.1.101-10.0.1.110 inside
hostname(config)# dhcpd auto_config outside
hostname(config)# dhcpd enable inside
```

Related Commands

Command	Description
clear configure dhcpd	Removes all DHCP server settings.
dhcpd enable	Enables the DHCP server on the specified interface.
show ip address dhcp server	Displays detailed information about the DHCP options provided by a DHCP server to an interface acting as a DHCP client.
show running-config dhcpd	Displays the current DHCP server configuration.

dhcpd dns

To define the DNS servers for DHCP clients, use the **dhcpd dns** command in global configuration mode. To clear defined servers, use the **no** form of this command.

dhcpd dns *dnsip1* [*dnsip2*] [**interface** *if_name*]

no dhcpd dns *dnsip1* [*dnsip2*] [**interface** *if_name*]

Syntax Description

dnsip1	Specifies the IP address of the primary DNS server for the DHCP client.
dnsip2	(Optional) Specifies the IP address of the alternate DNS server for the DHCP client.
interface *if_name*	Specifies the interface to which values entered to the server apply. If no interface is specified, values are applied to all servers.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **dhcpd dns** command lets you specify the IP address or addresses of the DNS server(s) for the DHCP client. You can specify two DNS servers. The **no dhcpd dns** command lets you remove the DNS IP address(es) from the configuration.

Examples

The following example shows how to configure an address pool and DNS server for the DHCP clients on the DMZ interface of the ASA.

```
hostname(config)# dhcpd address 10.0.1.100-10.0.1.108 dmz
hostname(config)# dhcpd dns 192.168.1.2
hostname(config)# dhcpd enable dmz
```

Related Commands

Command	Description
clear configure dhcpd	Removes all DHCP server settings.
dhcpd address	Specifies the address pool used by the DHCP server on the specified interface.
dhcpd enable	Enables the DHCP server on the specified interface.
dhcpd wins	Defines the WINS servers for DHCP clients.
show running-config dhcpd	Displays the current DHCP server configuration.

dhcpd domain

To define the DNS domain name for DHCP clients, use the **dhcpd domain** command in global configuration mode. To clear the DNS domain name, use the **no** form of this command.

dhcpd domain *domain_name* [**interface** *if_name*]

no dhcpd domain [*domain_name*] [**interface** *if_name*]

Syntax Description

domain_name	Specifies the DNS domain name (example.com).
interface *if_name*	Specifies the interface to which values entered to the server apply. If no interface is specified, values are applied to all servers.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **dhcpd domain** command lets you specify the DNS domain name for the DHCP client. The **no dhcpd domain** command lets you remove the DNS domain server from the configuration.

Examples

The following example shows how to configure the domain name supplied to DHCP clients by the DHCP server on the ASA:

```
hostname(config)# dhcpd address 10.0.1.101-10.0.1.110 inside
hostname(config)# dhcpd dns 198.162.1.2 198.162.1.3
hostname(config)# dhcpd wins 198.162.1.4
hostname(config)# dhcpd lease 3000
hostname(config)# dhcpd ping_timeout 1000
hostname(config)# dhcpd domain example.com
hostname(config)# dhcpd enable inside
```

Related Commands

Command	Description
clear configure dhcpd	Removes all DHCP server settings.
show running-config dhcpd	Displays the current DHCP server configuration.

dhcpd enable

To enable the DHCP server, use the **dhcpd enable** command in global configuration mode. To disable the DHCP server, use the **no** form of this command.

dhcpd enable *interface*

no dhcpd enable *interface*

Syntax Description

interface	Specifies the interface on which to enable the DHCP server.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The DHCP server provides network configuration parameters to DHCP clients. Support for the DHCP server within the ASA means that the ASA can use DHCP to configure connected clients. The **dhcpd enable** *interface* command lets you enable the DHCP daemon to listen for the DHCP client requests on the DHCP-enabled interface. The **no dhcpd enable** command disables the DHCP server feature on the specified interface.

Note For multiple context mode, you cannot enable the DHCP server on an interface that is used by more than one context (a shared VLAN).

When the ASA responds to a DHCP client request, it uses the IP address and subnet mask of the interface at which the request was received as the IP address and subnet mask of the default gateway in the response.

Note The ASA DHCP server daemon does not support clients that are not directly connected to an ASA interface.

See the CLI configuration guide for information about how to implement the DHCP server feature in the ASA.

Examples

The following example shows how to enable the DHCP server on the inside interface:

```
hostname(config)# dhcpd address 10.0.1.101-10.0.1.110 inside
hostname(config)# dhcpd dns 198.162.1.2 198.162.1.3
hostname(config)# dhcpd wins 198.162.1.4
hostname(config)# dhcpd lease 3000
hostname(config)# dhcpd ping_timeout 1000
hostname(config)# dhcpd domain example.com
hostname(config)# dhcpd enable inside
```

Related Commands

Command	Description
debug dhcpd	Displays debugging information for the DHCP server.
dhcpd address	Specifies the address pool used by the DHCP server on the specified interface.
show dhcpd	Displays DHCP binding, statistical, or state information.
show running-config dhcpd	Displays the current DHCP server configuration.

dhcpd lease

To specify the DHCP lease length, use the **dhcpd lease** command in global configuration mode. To restore the default value for the lease, use the **no** form of this command.

dhcpd lease *lease_length* [**interface** *if_name*]

no dhcpd lease [*lease_length*] [**interface** *if_name*]

Syntax Description

interface *if_name*	Specifies the interface to which values entered to the server apply. If no interface is specified, values are applied to all servers.
lease_length	Specifies the length of the IP address lease, in seconds, granted to the DHCP client from the DHCP server. Valid values are from 300 to 1048575 seconds.

Defaults

The default *lease_length* is 3600 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **dhcpd lease** command lets you specify the length of the lease, in seconds, that is granted to the DHCP client. This lease indicates how long the DHCP client can use the assigned IP address that the DHCP server granted.

The **no dhcpd lease** command lets you remove the lease length that you specified from the configuration and replaces this value with the default value of 3600 seconds.

Examples

The following example shows how to specify the length of the lease of DHCP information for DHCP clients:

```
hostname(config)# dhcpd address 10.0.1.101-10.0.1.110 inside
hostname(config)# dhcpd dns 198.162.1.2 198.162.1.3
hostname(config)# dhcpd wins 198.162.1.4
hostname(config)# dhcpd lease 3000
hostname(config)# dhcpd ping_timeout 1000
hostname(config)# dhcpd domain example.com
hostname(config)# dhcpd enable inside
```

Related Commands

Command	Description
clear configure dhcpd	Removes all DHCP server settings.
show running-config dhcpd	Displays the current DHCP server configuration.

dhcpd option

To configure DHCP options, use the **dhcpd option** command in global configuration mode. To clear the option, use the **no** form of this command.

dhcpd option *code* {**ascii** *string*} | {**ip** *IP_address* [*IP_address*]} | {**hex** *hex_string*} [**interface** *if_name*]

no dhcpd option *code* [**interface** *if_name*]

Syntax Description

ascii *string*	Specifies that the option parameter is an ASCII character string without spaces.
code	Specifies anumber representing the DHCP option being set. Valid values are 0 to 255 with several exceptions. See the Usage Guidelines section for the list of DHCP option codes that are not supported.
hex *hex_string*	Specifies that the option parameter is a hexadecimal string with an even number of digits and no spaces. You do not need to use a 0x prefix.
interface *if_name*	Specifies the interface to which values entered to the server apply. If no interface is specified, values are applied to all servers.
ip	Specifies that the option parameter is an IP address. You can specify a maximum of two IP addresses with the **ip** keyword.
IP_address	Specifies a dotted-decimal IP address.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can use the **dhcpd option** command to provide TFTP server information to Cisco IP Phones and routers.

When a DHCP option request arrives at the ASA DHCP server, the ASA places the value or values that are specified by the **dhcpd option** command in the response to the client.

The **dhcpd option 66** and **dhcpd option 150** commands specify TFTP servers that Cisco IP Phones and routers can use to download configuration files. Use these commands as follows:

- **dhcpd option 66 ascii** *string*, where *string* is either the IP address or hostname of the TFTP server. Only one TFTP server can be specified for option 66.
- **dhcpd option 150 ip** *IP_address* [*IP_address*], where *IP_address* is the IP address of the TFTP server. You can specify a maximum of two IP addresses for option 150.

Note The **dhcpd option 66** command only takes an **ascii** parameter, and the **dhcpd option 150** only takes an **ip** parameter.

Use the following guidelines when specifying an IP address for the **dhcpd option 66 | 150** commands:

- If the TFTP server is located on the DHCP server interface, use the local IP address of the TFTP server.
- If the TFTP server is located on a less secure interface than the DHCP server interface, then general outbound rules apply. Create a group of NAT, global, and access list entries for the DHCP clients, and use the actual IP address of the TFTP server.
- If the TFTP server is located on a more secure interface, then general inbound rules apply. Create a group of static and access list statements for the TFTP server and use the global IP address of the TFTP server.

For information about other DHCP options, see RFC 2132.

Note The ASA does not verify that the option type and value that you provide match the expected type and value for the option code as defined in RFC 2132. For example, you can enter the **dhcpd option 46 ascii hello** command, and the ASA accepts the configuration although option 46 is defined in RFC 2132 as a single-digit, hexadecimal value.

You cannot configure the following DHCP options with the **dhcpd option** command:

Option Code	Description
0	DHCPOPT_PAD
1	HCPOPT_SUBNET_MASK
12	DHCPOPT_HOST_NAME
50	DHCPOPT_REQUESTED_ADDRESS
51	DHCPOPT_LEASE_TIME
52	DHCPOPT_OPTION_OVERLOAD
53	DHCPOPT_MESSAGE_TYPE
54	DHCPOPT_SERVER_IDENTIFIER
58	DHCPOPT_RENEWAL_TIME
59	DHCPOPT_REBINDING_TIME
61	DHCPOPT_CLIENT_IDENTIFIER
67	DHCPOPT_BOOT_FILE_NAME

Option Code	Description
82	DHCPOPT_RELAY_INFORMATION
255	DHCPOPT_END

Examples

The following example shows how to specify a TFTP server for DHCP option 66:

```
hostname(config)# dhcpd option 66 ascii MyTftpServer
```

Related Commands

Command	Description
clear configure dhcpd	Removes all DHCP server settings.
show running-config dhcpd	Displays the current DHCP server configuration.

dhcpd ping_timeout

To change the default timeout for DHCP ping, use the **dhcpd ping_timeout** command in global configuration mode. To return to the default value, use the **no** form of this command.

dhcpd ping_timeout *number* [**interface** *if_name*]

no dhcpd ping_timeout [**interface** *if_name*]

Syntax Description

interface *if_name*	Specifies the interface to which values entered to the server apply. If no interface is specified, values are applied to all servers.
number	The timeout value of the ping, in milliseconds. The minimum value is 10, the maximum is 10000. The default is 50.

Defaults

The default number of milliseconds for *number* is 50.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To avoid address conflicts, the DHCP server sends two ICMP ping packets to an address before assigning that address to a DHCP client. The ASA waits for both ICMP ping packets to time out before assigning an IP address to a DHCP client. For example, if the default value is used, the ASA waits for 1500 milliseconds (750 milliseconds for each ICMP ping packet) before assigning an IP address.

A long ping timeout value can adversely affect the performance of the DHCP server.

Examples

The following example shows how to use the **dhcpd ping_timeout** command to change the ping timeout value for the DHCP server:

```
hostname(config)# dhcpd address 10.0.1.101-10.0.1.110 inside
hostname(config)# dhcpd dns 198.162.1.2 198.162.1.3
hostname(config)# dhcpd wins 198.162.1.4
hostname(config)# dhcpd lease 3000
hostname(config)# dhcpd ping_timeout 1000
hostname(config)# dhcpd domain example.com
hostname(config)# dhcpd enable inside
```

Related Commands

Command	Description
clear configure dhcpd	Removes all DHCP server settings.
show running-config dhcpd	Displays the current DHCP server configuration.

dhcpd update dns

To enable a DHCP server to perform DDNS updates, use the **dhcpd update dns** command in global configuration mode. To disable DDNS by a DHCP server, use the **no** form of this command.

dhcpd update dns [**both**] [**override**] [**interface** *srv_ifc_name*]

no dhcpd update dns [**both**] [**override**] [**interface** *srv_ifc_name*]

Syntax Description

both	Specifies that the DHCP server updates both A and PTR DNS RRs.
interface	Specifies the ASA interface to which the DDNS updates apply.
override	Specifies that the DHCP server overrides DHCP client requests.
srv_ifc_name	Specifies an interface to apply this option to.

Defaults

By default, the DHCP server performs PTR RR updates only.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

DDNS updates the name-to-address and address-to-name mapping maintained by DNS. Updates are performed in conjunction with a DHCP server. The **dhcpd update dns** command enables updates by the server.

Name and address mapping is contained in two types of RRs:

- The A resource record contains domain name-to IP-address mapping.
- The PTR resource record contains IP addres- to-domain name mapping.

DDNS updates can be used to maintain consistent information between the A and PTR RR types.

Using the **dhcpd update dns** command, the DHCP server can be configured to perform both A and PRT RR updates or PTR RR updates only. It can also be configured to override update requests from the DHCP client.

Examples

The following example configures the DDNS server to perform both A and PTR updates and override requests from the DHCP client:

```
hostname(config)# dhcpd update dns both override
```

Related Commands

Command	Description
ddns	Specifies a DDNS update method type for a created DDNS method.
ddns update	Associates a DDNS update method with an ASA interface or a DDNS update hostname.
ddns update method	Creates a method for dynamically updating DNS resource records.
dhcp-client update dns	Configures the update parameters that the DHCP client passes to the DHCP server.
interval maximum	Configures the maximum interval between update attempts by a DDNS update method.

dhcpd wins

To define the WINS server IP addresses for DHCP clients, use the **dhcpd wins** command in global configuration mode. To remove the WINS server IP addresses from the configuration, use the **no** form of this command.

dhcpd wins *server1* [*server2*] [**interface** *if_name*]

no dhcpd wins [*server1* [*server2*]] [**interface** *if_name*]

Syntax Description

interface *if_name*	Specifies the interface to which values entered to the server apply. If no interface is specified, values are applied to all servers.
server1	Specifies the IP address of the primary Microsoft NetBIOS name server (WINS server).
server2	(Optional) Specifies the IP address of the alternate Microsoft NetBIOS name server (WINS server).

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **dhcpd wins** command lets you specify the addresses of the WINS servers for the DHCP client. The **no dhcpd wins** command removes the WINS server IP addresses from the configuration.

Examples

The following example shows how to specify WINS server information that is sent to DHCP clients:

```
hostname(config)# dhcpd address 10.0.1.101-10.0.1.110 inside
hostname(config)# dhcpd dns 198.162.1.2 198.162.1.3
hostname(config)# dhcpd wins 198.162.1.4
hostname(config)# dhcpd lease 3000
hostname(config)# dhcpd ping_timeout 1000
hostname(config)# dhcpd domain example.com
hostname(config)# dhcpd enable inside
```

Related Commands

Command	Description
clear configure dhcpd	Removes all DHCP server settings.
dhcpd address	Specifies the address pool used by the DHCP server on the specified interface.
dhcpd dns	Defines the DNS servers for DHCP clients.
show dhcpd	Displays DHCP binding, statistical, or state information.
show running-config dhcpd	Displays the current DHCP server configuration.

dhcprelay enable

To enable the DHCP relay agent, use the **dhcprelay enable** command in global configuration mode. To disable the DHCP relay agent, use the **no** form of this command.

dhcprelay enable *interface_name*

no dhcprelay enable *interface_name*

Syntax Description

interface_name	Name of the interface on which the DHCP relay agent accepts client requests.

Defaults

The DHCP relay agent is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The DHCP relay agent allows DHCP requests to be forwarded from a specified ASA interface to a specified DHCP server.

For the ASA to start the DHCP relay agent with the **dhcprelay enable** *interface_name* command, you must have a **dhcprelay server** command already in the configuration. Otherwise, the ASA displays an error message similar to the following:

```
DHCPRA: Warning - There are no DHCP servers configured!
        No relaying can be done without a server!
        Use the 'dhcprelay server <server_ip> <server_interface>' command
```

You cannot enable DHCP relay under the following conditions:

- You cannot enable DHCP relay and the DHCP relay server on the same interface.
- You cannot enable DCHP relay and a DHCP server (**dhcpd enable**) on the same interface.
- The DHCP relay agent cannot be enabled if the DHCP server is also enabled.
- For multiple context mode, you cannot enable DHCP relay on an interface that is used by more than one context (a shared VLAN).

The **no dhcprelay enable** *interface_name* command removes the DHCP relay agent configuration for the interface that is specified by the *interface_name* argument only.

Examples

The following example shows how to configure the DHCP relay agent for a DHCP server with an IP address of 10.1.1.1 on the outside interface of the ASA, client requests on the inside interface of the ASA, and a timeout value up to 90 seconds:

```
hostname(config)# dhcprelay server 10.1.1.1 outside
hostname(config)# dhcprelay timeout 90
hostname(config)# dhcprelay enable inside
hostname(config)# show running-config dhcprelay
dhcprelay server 10.1.1.1 outside
dhcprelay enable inside
dhcprelay timeout 90
```

The following example shows how to disable the DHCP relay agent:

```
hostname(config)# no dhcprelay enable inside
hostname(config)# show running-config dhcprelay
dhcprelay server 10.1.1.1 outside
dhcprelay timeout 90
```

Related Commands

Command	Description
clear configure dhcprelay	Removes all DHCP relay agent settings.
debug dhcp relay	Displays debugging information for the DHCP relay agent.
dhcprelay server	Specifies the DHCP server to which the DHCP relay agent forwards DHCP requests.
dhcprelay setroute	Defines IP address that the DHCP relay agent uses as the default router address in DHCP replies.
show running-config dhcprelay	Displays the current DHCP relay agent configuration.

dhcprelay information trust-all

To configure a specified interface as trusted, use the **dhcprelay information trust-all** command in global configuration mode.

dhcprelay information trust-all

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
9.1(2)	This command was introduced.

Usage Guidelines

This command configures a given interface as trusted. To view the interface-specific trusted configuration, use the **show running-config dhcprelay interface** command in interface configuration mode. To configure a given interface as trusted in interface configuration mode, use the **dhcprelay information trusted** command. To view a given interface as trusted in global configuration mode, use the **show running-config dhcprelay** command.

Examples

The following example shows how to configure a specified interface as trusted in global configuration mode:

```
hostname(config-if)# interface vlan501
hostname(config-if)# nameif inside
hostname(config)# dhcprelay information trust-all
hostname(config)# show running-config dhcprelay
dhcprelay information trust-all
```

Related Commands

Command	Description
clear configure dhcprelay	Removes all DHCP relay agent settings.
dhcprelay enable	Enables the DHCP relay agent on the specified interface.

Command	Description
dhcprelay setroute	Defines IP address that the DHCP relay agent uses as the default router address in DHCP replies.
dhcprelay timeout	Specifies the timeout value for the DHCP relay agent.
show running-config dhcprelay	Displays the current DHCP relay agent configuration.

dhcprelay information trusted

To configure a specified interface as trusted, use the **dhcprelay information trusted** command in interface configuration mode.

dhcprelay information trusted

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
9.1(2)	This command was introduced.

Usage Guidelines

This command configures a given interface as trusted. To view the interface-specific trusted configuration, use the **show running-config dhcprelay interface** command in interface configuration mode. To configure a given interface as trusted in global configuration mode, use the **dhcprelay information trust-all** command. To view a given interface as trusted in global configuration mode, use the **show running-config dhcprelay** command.

Examples

The following example shows how to configure a specified interface as trusted:

```
hostname(config-if)# interface gigabitEthernet 0/0
hostname(config-if)# nameif inside
hostname(config-if)# dhcprelay information trusted
hostname(config)# show running-config dhcprelay
interface gigabitEthernet 0/0
nameif inside
dhcprelay information trusted
```

Related Commands

Command	Description
clear configure dhcprelay	Removes all DHCP relay agent settings.
dhcprelay enable	Enables the DHCP relay agent on the specified interface.
dhcprelay setroute	Defines IP address that the DHCP relay agent uses as the default router address in DHCP replies.
dhcprelay timeout	Specifies the timeout value for the DHCP relay agent.
show running-config dhcprelay	Displays the current DHCP relay agent configuration.

dhcprelay server (global)

To specify the DHCP server to which DHCP requests are forwarded, use the **dhcpreplay server** command in global configuration mode. To remove the DHCP server from the DHCP relay configuration, use the **no** form of this command.

dhcprelay server [*interface_name*]

no dhcprelay server [*interface_name*]

Syntax Description

interface_name	Specifies the name of the ASA interface on which the DHCP server resides.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The DHCP relay agent allows DHCP requests to be forwarded from a specified ASA interface to a specified DHCP server. You can add up to ten DHCP relay servers per interface. You must add at least one **dhcprelay server** command to the ASA configuration before you can enter the **dhcprelay enable** command. You cannot configure a DHCP client on an interface that has a DHCP relay server configured.

The **dhcprelay server** command opens UDP port 67 on the specified interface and starts the DHCP relay task as soon as the **dhcprelay enable** command is added to the configuration.

Examples

The following example shows how to configure the DHCP relay agent for a DHCP server with an IP address of 10.1.1.1 on the outside interface of the ASA, client requests on the inside interface of the ASA, and a timeout value of up to 90 seconds:

```
hostname(config)# dhcprelay server 10.1.1.1 outside
hostname(config)# dhcprelay timeout 90
hostname(config)# dhcprelay enable inside
hostname(config)# show running-config dhcprelay
dhcprelay server 10.1.1.1 outside
dhcprelay enable inside
dhcprelay timeout 90
```

Related Commands

Command	Description
clear configure dhcprelay	Removes all DHCP relay agent settings.
dhcprelay enable	Enables the DHCP relay agent on the specified interface.
dhcprelay setroute	Defines IP address that the DHCP relay agent uses as the default router address in DHCP replies.
dhcprelay timeout	Specifies the timeout value for the DHCP relay agent.
show running-config dhcprelay	Displays the current DHCP relay agent configuration.

dhcprelay server (interface) (9.1(2) and later)

To specify the DHCP relay interface server to which DHCP requests are forwarded, use the **dhcpreplay server** command in interface configuration mode. To remove the DHCP relay interface server from the DHCP relay configuration, use the **no** form of this command.

dhcprelay server *ip_address*

no dhcprelay server *ip_address*

Syntax Description

ip_address	Specifies the IP address of the DHCP relay interface server to which the DHCP relay agent forwards client DHCP requests.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
9.1(2)	This command was introduced.

Usage Guidelines

The DHCP relay agent allows DHCP requests to be forwarded from a specified ASA interface to a specified DHCP server. You can add up to four DHCP relay servers per interface. You must add at least one **dhcprelay server** command to the ASA configuration before you can enter the **dhcprelay enable** command. You cannot configure a DHCP client on an interface that has a DHCP relay server configured.

The **dhcprelay server** command opens UDP port 67 on the specified interface and starts the DHCP relay task as soon as the **dhcprelay enable** command is added to the configuration.

In the interface configuration mode, you can use the **dhcprelay server** *ip_address* command to configure a DHCP relay server (called a helper) address on a per-interface basis. This means that when a DHCP request is received on an interface and it has helper addresses configured, then the request is forwarded to only those servers.

When you use the **no dhcprelay server** *ip_address* command, the interface stops forwarding DHCP packets to that server and removes the DHCP relay agent configuration for the DHCP server that is specified by the *ip_address* argument only.

This command takes precedence over a DHCP relay server that has been configured in global configuration mode. This means that the DHCP relay agent forwards the client discovery message first to the DHCP relay interface server, then to the DHCP global relay server.

Examples

The following example shows how to configure the DHCP relay agent for a DHCP relay interface server with an IP address of 10.1.1.1 on the outside interface of the ASA, client requests on the inside interface of the ASA, and a timeout value of up to 90 seconds:

```
hostname(config)# interface vlan 10
hostname(config-if)# nameif inside
hostname(config-if)# dhcprelay server 10.1.1.1
hostname(config-if)# exit
hostname(config)# dhcprelay timeout 90
hostname(config)# dhcprelay enable inside
hostname(config)# show running-config dhcprelay
dhcprelay enable inside
dhcprelay timeout 90

interface vlan 10
nameif inside
dhcprelay server 10.1.1.1
```

Related Commands

Command	Description
clear configure dhcprelay	Removes all DHCP relay agent settings.
dhcprelay enable	Enables the DHCP relay agent on the specified interface.
dhcprelay setroute	Defines IP address that the DHCP relay agent uses as the default router address in DHCP replies.
dhcprelay timeout	Specifies the timeout value for the DHCP relay agent.
show running-config dhcprelay	Displays the current DHCP relay agent configuration.

dhcprelay setroute

To set the default gateway address in the DHCP reply, use the **dhcprelay setroute** command in global configuration mode. To remove the default router, use the **no** form of this command.

dhcprelay setroute *interface*

no dhcprelay setroute *interface*

Syntax Description

interface	Configures the DHCP relay agent to change the first default IP address (in the packet sent from the DHCP server) to the address of *interface*.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command causes the default IP address of the DHCP reply to be substituted with the address of the specified ASA interface. The **dhcprelay setroute** *interface* command lets you enable the DHCP relay agent to change the first default router address (in the packet sent from the DHCP server) to the address of *interface*.

If there is no default router option in the packet, the ASA adds one containing the address of *interface*. This action allows the client to set its default route to point to the ASA.

When you do not configure the **dhcprelay setroute** *interface* command (and there is a default router option in the packet), it passes through the ASA with the router address unaltered.

Examples

The following example shows how to set the default gateway in the DHCP reply from the external DHCP server to the inside interface of the ASA:

```
hostname(config)# dhcprelay server 10.1.1.1 outside
hostname(config)# dhcprelay timeout 90
hostname(config)# dhcprelay setroute inside
hostname(config)# dhcprelay enable inside
```

Related Commands

Command	Description
clear configure dhcprelay	Removes all DHCP relay agent settings.
dhcprelay enable	Enables the DHCP relay agent on the specified interface.
dhcprelay server	Specifies the DHCP server that the DHCP relay agent forwards DHCP requests to.
dhcprelay timeout	Specifies the timeout value for the DHCP relay agent.
show running-config dhcprelay	Displays the current DHCP relay agent configuration.

dhcprelay timeout

To set the DHCP relay agent timeout value, use the **dhcprelay timeout** command in global configuration mode. To restore the timeout value to its default value, use the **no** form of this command.

dhcprelay timeout *seconds*

no dhcprelay timeout

Syntax Description

seconds	Specifies the number of seconds that are allowed for DHCP relay address negotiation.

Defaults

The default value for the DHCP relay timeout is 60 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **dhcprelay timeout** command lets you set the amount of time, in seconds, allowed for responses from the DHCP server to pass to the DHCP client through the relay binding structure.

Examples

The following example shows how to configure the DHCP relay agent for a DHCP server with an IP address of 10.1.1.1 on the outside interface of the ASA, client requests on the inside interface of the ASA, and a timeout value up to 90 seconds:

```
hostname(config)# dhcprelay server 10.1.1.1 outside
hostname(config)# dhcprelay timeout 90
hostname(config)# dhcprelay enable inside
hostname(config)# show running-config dhcprelay
dhcprelay server 10.1.1.1 outside
dhcprelay enable inside
dhcprelay timeout 90
```

Related Commands

Command	Description
clear configure dhcprelay	Removes all DHCP relay agent settings.
dhcprelay enable	Enables the DHCP relay agent on the specified interface.
dhcprelay server	Specifies the DHCP server to which the DHCP relay agent forwards DHCP requests.
dhcprelay setroute	Defines IP address that the DHCP relay agent uses as the default router address in DHCP replies.
show running-config dhcprelay	Displays the current DHCP relay agent configuration.

dialog

To customize dialog box messages displayed to WebVPN users, use the **dialog** command in webvpn customization configuration mode. To remove the command from the configuration and cause the value to be inherited, use the **no** form of this command.

dialog {**title** | **message** | **border**} **style** *value*

no dialog {**title** | **message** | **border**} **style** *value*

Syntax Description

border	Specifies a change to the border.
message	Specifies a change to the message.
style	Specifies a change to the style.
title	Specifies a change to the title.
value	The actual text or or CSS parameters to display (the maximum is 256 characters).

Defaults

The default title style is background-color:#669999;color:white.

The default message style is background-color:#99CCCC;color:black.

The default border style is border:1px solid black;border-collapse:collapse.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Webvpn customization configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The **style** option is expressed as any valid CSS parameters. Describing these parameters is beyond the scope of this document. For more information about CSS parameters, consult CSS specifications at the World Wide Web Consortium website at www.w3.org. Appendix F of the CSS 2.1 Specification contains a convenient list of CSS parameters, and is available at www.w3.org/TR/CSS21/propidx.html.

Here are some tips for making the most common changes to the WebVPN pages—the page colors:

- You can use a comma-separated RGB value, an HTML color value, or the name of the color if recognized in HTML.
- The RGB format is 0,0,0, a range of decimal numbers from 0 to 255 for each color (red, green, blue); the comma-separated entry indicates the level of intensity of each color to combine with the others.

- The HTML format is #000000, six digits in hexadecimal format; the first and second represent red, the third and fourth green, and the fifth and sixth represent blue.

Note To easily customize the WebVPN pages, we recommend that you use ASDM, which has convenient features for configuring style elements, including color swatches and preview capabilities.

Examples

The following example customizes the dialog box message, changing the foreground color to blue:

```
hostname(config)# webvpn
hostname(config-webvpn)# customization cisco
hostname(config-webvpn-custom)# dialog message style color:blue
```

Related Commands

Command	Description
application-access	Customizes the Application Access box of the WebVPN Home page.
browse-networks	Customizes the Browse Networks box of the WebVPN Home page.
web-bookmarks	Customizes the Web Bookmarks title or links on the WebVPN Home page.
file-bookmarks	Customizes the File Bookmarks title or links on the WebVPN Home page.

dir

To display the directory contents, use the **dir** command in privileged EXEC mode.

dir [/all] [all-filesystems] [/recursive] [disk0: | disk1: | flash: | system:] [*path]*

Syntax Description

/all	(Optional) Displays all files.
/recursive	(Optional) Displays the directory contents recursively.
all-filesystems	(Optional) Displays the files of all filesystems.
disk0:	(Optional) Specifies the internal flash memory, followed by a colon.
disk1:	(Optional) Specifies the external flash memory card, followed by a colon.
flash:	(Optional) Displays the directory contents of the default flash partition.
path	(Optional) Specifies a specific path.
system:	(Optional) Displays the directory contents of the file system.

Defaults

If you do not specify a directory, the directory is the current working directory by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **dir** command without keywords or arguments displays the directory contents of the current directory.

Examples

The following example shows how to display the directory contents:

```
hostname# dir
Directory of disk0:/

1      -rw-  1519        10:03:50 Jul 14 2003    my_context.cfg
2      -rw-  1516        10:04:02 Jul 14 2003    my_context.cfg
3      -rw-  1516        10:01:34 Jul 14 2003    admin.cfg
60985344 bytes total (60973056 bytes free)
```

The following example shows how to display recursively the contents of the entire file system:

```
hostname# dir /recursive disk0:
Directory of disk0:/*
1      -rw-  1519        10:03:50 Jul 14 2003    my_context.cfg
2      -rw-  1516        10:04:02 Jul 14 2003    my_context.cfg
3      -rw-  1516        10:01:34 Jul 14 2003    admin.cfg
60985344 bytes total (60973056 bytes free)
```

The following example shows how to display the contents of the flash partition:

```
hostname# dir flash:
Directory of disk0:/*
1      -rw-  1519        10:03:50 Jul 14 2003    my_context.cfg
2      -rw-  1516        10:04:02 Jul 14 2003    my_context.cfg
3      -rw-  1516        10:01:34 Jul 14 2003    admin.cfg
60985344 bytes total (60973056 bytes free)
```

Related Commands

Command	Description
cd	Changes the current working directory to the one specified.
pwd	Displays the current working directory.
mkdir	Creates a directory.
rmdir	Removes a directory.

disable

To exit privileged EXEC mode and return to unprivileged EXEC mode, use the **disable** command in privileged EXEC mode.

disable

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the **enable** command to enter privileged mode. The **disable** command allows you to exit privileged mode and returns you to an unprivileged mode.

Examples

The following example shows how to enter privileged mode:

```
hostname> enable
hostname#
```

The following example shows how to exit privileged mode:

```
hostname# disable
hostname>
```

Related Commands

Command	Description
enable	Enables privileged EXEC mode.

disable (cache)

To disable caching for WebVPN, use the **disable** command in cache configuration mode. To reenable caching, use the **no** version of this command.

disable

no disable

Defaults

Caching is enabled with default settings for each cache attribute.

Command Modes

The following table shows the modes in which you enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Cache configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Caching stores frequently reused objects in the system cache, which reduces the need to perform repeated rewriting and compressing of content. It reduces traffic between WebVPN and both the remote servers and end-user browsers, with the result that many applications run much more efficiently.

Examples

The following example shows how to disable caching, and then how to reenable it.

```
hostname(config)# webvpn
hostname(config-webvpn)# cache
hostname(config-webvpn-cache)# disable
hostname(config-webvpn-cache)# no disable
hostname(config-webvpn-cache)#
```

Related Commands

Command	Description
cache	Enters webvpn cache configuration mode.
cache-compressed	Configures WebVPN cache compression.
expiry-time	Configures the expiration time for caching objects without revalidating them.
lmfactor	Sets a revalidation policy for caching objects that have only the last-modified timestamp.

Command	Description
max-object-size	Defines the maximum size of an object to cache.
min-object-size	Defines the minimum sizze of an object to cache.

disable service-settings

To disable the service settings on IP phones when using the Phone Proxy feature, use the **disable service-settings** command in phone-proxy configuration mode. To preserve the settings on the IP phones, use the **no** form of this command.

disable service-settings

no disable service-settings

Syntax Description

There are no arguments or keywords for this command.

Defaults

The service settings are disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Phone-proxy configuration	•	—	•	—	—

Command History

Release	Modification
8.0(4)	This command was introduced.

Usage Guidelines

By default, the following settings are disabled on the IP phones:

- PC Port
- Gratuitous ARP
- Voice VLAN access
- Web Access
- Span to PC Port

To preserve the settings configured on the CUCM for each IP phone configured, configure the **no disable service-settings** command.

Examples

The following example shows how to preserve the settings of the IP phones that use the Phone Proxy feature on the ASA:

```
hostname(config-phone-proxy)# no disable service-settings
```

Related Commands

Command	Description
phone-proxy	Configures the Phone Proxy instance.
show phone-proxy	Displays Phone Proxy specific information.

display

To display attribute value pairs that the ASA writes to the DAP attribute database, enter the **display** command in dap test attributes mode.

display

Command Default

No default value or behaviors.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Dap test attributes	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Normally the ASA retrieves user authorization attributes from the AAA server and retrieves endpoint attributes from Cisco Secure Desktop, Host Scan, CNA or NAC. For the test command, you specify the user authorization and endpoint attributes in this attributes mode. The ASA writes them to an attribute database that the DAP subsystem references when evaluating the AAA selection attributes and endpoint select attributes for a DAP record. The **display** command lets you display these attributes to the console.

Related Commandsl

Command	Description
attributes	Enters attributes configuration mode, in which you can set attribute value pairs.
dynamic-access-policy-record	Creates a DAP record.
test dynamic-access-policy attributes	Enters attributes submode.
test dynamic-access-policy execute	Executes the logic that generates DAP and displays the resulting access policies to the console.

distance eigrp

To configure the administrative distances of internal and external EIGRP routes, use the **distance eigrp** command in router configuration mode. To restore the default values, use the **no** form of this command.

distance eigrp *internal-distance external-distance*

no distance eigrp

Syntax Description

external-distance	Administrative distance for EIGRP external routes. External routes are those for which the best path is learned from a neighbor external to the autonomous system. Valid values are from 1 to 255.
internal-distance	Administrative distance for EIGRP internal routes. Internal routes are those that are learned from another entity within the same autonomous system. Valid values are from 1 to 255.

Defaults

The default values are as follows:

- *external-distance* is 170
- *internal-distance* is 90

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

Because every routing protocol has metrics based on algorithms that are different from the other routing protocols, it is not always possible to determine the “best path” for two routes to the same destination that were generated by different routing protocols. Administrative distance is a route parameter that the ASA uses to select the best path when there are two or more different routes to the same destination from two different routing protocols.

If you have more than one routing protocol running on the ASA, you can use the **distance eigrp** command to adjust the default administrative distances of routes discovered by the EIGRP routing protocol in relation to the other routing protocols. Table 18-1 lists the default administrative distances for the routing protocols supported by the ASA.

Table 18-1 Default Administrative Distances

Route Source	Default Administrative Distance
Connected interface	0
Static route	1
EIGRP summary route	5
Internal EIGRP	90
OSPF	110
RIP	120
EIGRP external route	170
Unknown	255

The **no** form of the command does not take any keywords or arguments. Using the **no** form of the command restores the default administrative distance for both internal and external EIGRP routes.

Examples

The following example uses the **distance eigrp** command to set the administrative distance of all EIGRP internal routes to 80 and all EIGRP external routes to 115. Setting the EIGRP external route administrative distance to 115 would give routes discovered by EIGRP to a specific destination preference over the same routes discovered by RIP but not by OSPF.

```
hostname(config)# router eigrp 100
hostname(config-router)# network 192.168.7.0
hostname(config-router)# network 172.16.0.0
hostname(config-router)# distance eigrp 90 115
```

Related Commands

Command	Description
router eigrp	Creates an EIGRP routing process and enters configuration mode for that process.

distance (OSPFv3)

To define OSPFv3 route administrative distances based on route type, use the **distance** command in IPv6 router configuration mode. To restore the default values, use the **no** form of this command.

distance [**ospf** {**external | intra-area | inter-area**}] *distance*

no distance [**ospf** {**external | intra-area | inter-area**}] *distance*

Syntax Description

distance	Specifies the administrative distance. Valid values range from 10 to 254.
external	(Optional) Specifies external type 5 and type 7 routes for OSPFv3 routes.
inter-area	(Optional) Specifies the inter-area routes for OSPFv3 routes.
intra-area	(Optional) Specifies the intra-area routes for OSPFv3 routes.
ospf	(Optional) Specifies the administrative distance for OSPFv3 routes.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
IPv6 router configuration	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to set the administrative distance for OSPFv3 routes.

Examples

The following example sets the administrative distance for external type 5 and type 7 routes for OSPFv3 to 200:

```
hostname(config-if)# ipv6 router ospf
hostname(config-router)# distance ospf external 200
```

Related Commands

Command	Description
default-information originate	Generates a default external route into an OSPFv3 routing domain.
redistribute	Redistributes IPv6 routes from one routing domain into another routing domain.

distance ospf (OSPFv2)

To define OSPFv2 route administrative distances based on route type, use the **distance ospf** command in router configuration mode. To restore the default values, use the **no** form of this command.

distance ospf [**intra-area** *d1*] [**inter-area** *d2*] [**external** *d3*]

no distance ospf

Syntax Description

d1, *d2*, and *d3*	Specifies the distance for each route type. Valid values range from 1 to 255.
external	(Optional) Sets the distance for routes from other routing domains that are learned by redistribution.
inter-area	(Optional) Sets the distance for all routes from one area to another area.
intra-area	(Optional) Sets the distance for all routes within an area.

Defaults

The default values for *d1*, *d2*, and *d3* are 110.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You must specify at least one keyword and argument. You can enter the commands for each type of administrative distance separately, however they appear as a single command in the configuration. If you reenter an administrative distance, the administrative distance for only that route type changes; the administrative distances for any other route types remain unaffected.

The **no** form of the command does not take any keywords or arguments. Using the **no** form of the command restores the default administrative distance for all of the route types. If you want to restore the default administrative distance for a single route type when you have multiple route types configured, you can do one of the following:

- Manually set that route type to the default value.
- Use the **no** form of the command to remove the entire configuration and then reenter the configurations for the route types that you want to keep.

Examples

The following example sets the administrative distance of external routes to 150:

```
hostname(config-router)# distance ospf external 105
hostname(config-router)#
```

The following example shows how entering separate commands for each route type appears as a single command in the router configuration:

```
hostname(config-rtr)# distance ospf intra-area 105 inter-area 105
hostname(config-rtr)# distance ospf intra-area 105
hostname(config-rtr)# distance ospf external 105
hostname(config-rtr)# exit
hostname(config)# show running-config router ospf 1
!
router ospf 1
 distance ospf intra-area 105 inter-area 105 external 105
!
hostname(config)#
```

The following example shows how to set each administrative distance to 105, and then change only the external administrative distance to 150. The **show running-config router ospf** command shows how only the external route type value changed, while the other route types retained the value previously set.

```
hostname(config-rtr)# distance ospf external 105 intra-area 105 inter-area 105
hostname(config-rtr)# distance ospf external 150
hostname(config-rtr)# exit
hostname(config)# show running-config router ospf 1
!
router ospf 1
 distance ospf intra-area 105 inter-area 105 external 150
!
hostname(config)#
```

Related Commands

Command	Description
router ospf	Enters router configuration mode for OSPFv2.
show running-config router	Displays the OSPFv2 commands in the global router configuration.

distribute-list in

To filter incoming routing updates, use the **distribute-list in** command in router configuration mode. To remove the filtering, use the **no** form of this command.

distribute-list *acl* **in** [**interface** *if_name*]

no distribute-list *acl* **in** [**interface** *if_name*]

Syntax Description

acl	Name of a standard access list.
interface *if_name*	(Optional) The interface on which to apply the incoming routing updates. Specifying an interface causes the access list to be applied only to routing updates received on that interface.

Defaults

Networks are not filtered in incoming updates.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

If no interface is specified, the access list will be applied to all incoming updates.

Examples

The following example filters RIP routing updates received on the outside interface. It accepts routes in the 10.0.0.0 network and discards all others.

```
hostname(config)# access-list ripfilter permit 10.0.0.0
hostname(config)# access-list ripfilter deny any
hostname(config)# router rip
hostname(config-router)# network 10.0.0.0
hostname(config-router)# distribute-list ripfilter in interface outside
```

The following example filters EIGRP routing updates received on the outside interface. It accepts routes in the 10.0.0.0 network and discards all others.

```
hostname(config)# access-list eigrp_filter permit 10.0.0.0
hostname(config)# access-list eigrp_filter deny any
hostname(config)# router eigrp 100
```

```
hostname(config-router)# network 10.0.0.0
hostname(config-router)# distribute-list eigrp_filter in interface outside
```

Related Commands

Command	Description
distribute-list out	Filters outgoing routing updates.
router eigrp	Enters router configuration mode for the EIGRP routing process.
router rip	Enters router configuration mode for the RIP routing process.
show running-config router	Displays the commands in the global router configuration.

distribute-list out

To filter outgoing routing updates, use the **distribute-list out** command in router configuration mode. To remove the filtering, use the **no** form of this command.

distribute-list *acl* **out** [**interface** *if_name*] [**eigrp** *as_number* | **rip** | **ospf** *pid* | **static** | **connected**]

no distribute-list *acl* **out** [**interface** *if_name*] [**eigrp** *as_number* | **rip** | **ospf** *pid* | **static** | **connected**]

Syntax Description

acl	Name of a standard access list.
connected	(Optional) Filters only connected routes.
eigrp *as_number*	(Optional) Filters only EIGRP routes from the specified autonomous system number. The *as_number* argument is the autonomous system number of the EIGRP routing process on the ASA.
interface *if_name*	(Optional) The interface on which to apply the outgoing routing updates. Specifying an interface causes the access list to be applied only to routing updates received on that interface.
ospf *pid*	(Optional) Filters only OSPF routes discovered by the specified OSPF process.
rip	(Optional) Filters only RIP routes.
static	(Optional) Filters only static routes.

Defaults

Networks are not filtered in sent updates.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.
8.0(2)	The **eigrp** keyword was added.

Usage Guidelines

If no interface is specified, the access list will be applied to all outgoing updates.

Examples

The following example prevents the 10.0.0.0 network from being advertised in RIP updates sent out of any interface:

```
hostname(config)# access-list ripfilter deny 10.0.0.0
hostname(config)# access-list ripfilter permit any
```

```
hostname(config)# router rip
hostname(config-router)# network 10.0.0.0
hostname(config-router)# distribute-list ripfilter out
```

The following example prevents the EIGRP routing process from advertising the 10.0.0.0 network on the outside interface:

```
hostname(config)# access-list eigrp_filter deny 10.0.0.0
hostname(config)# access-list eigrp_filter permit any
hostname(config)# router eigrp 100
hostname(config-router)# network 10.0.0.0
hostname(config-router)# distribute-list eigrp_filter out interface outside
```

Related Commands

Command	Description
distribute-list in	Filters incoming routing updates.
router eigrp	Enters router configuration mode for the EIGRP routing process.
router rip	Enters router configuration mode for the RIP routing process.
show running-config router	Displays the commands in the global router configuration.

CHAPTER 19

dns domain-lookup through dynamic-filter whitelist Commands

dns domain-lookup

To enable the ASA to send DNS requests to a DNS server to perform a name lookup for supported commands, use the **dns domain-lookup** command in global configuration mode. To disable DNS requests, use the **no** form of this command.

dns domain-lookup *interface_name*

no dns domain-lookup *interface_name*

Syntax Description

interface_name	Specifies the name of the configured interface.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.4(2)	This command was introduced.

Usage Guidelines

The command enable the ASA to send DNS requests to a DNS server to perform a name lookup for supported commands.

Examples

The following example enable the ASA to send DNS requests to a DNS server to perform a name lookup for the inside interface:

```
hostname(config)# dns domain-lookup inside
```

Related Commands

Command	Description
clear configure dns	Removes all DNS commands.
dns server-group	Enters dns-server-group mode, in which you can configure a DNS server group.
show running-config dns-server group	Shows one or all the existing DNS server group configurations.

dns expire-entry-timer

To remove the IP address of a resolved FQDN after its TTL expires, use the **dns expire-entry-timer** command in global configuration mode. To remove the timer, use the **no** form of this command.

dns expire-entry-timer minutes *minutes*

no dns expire-entry-timer minutes *minutes*

Syntax Description

minutes *minutes*	Specifies the timer time in minutes. Valid values range from 1 to 65535 minutes.

Defaults

By default, the DNS expire-entry-timer value is 1 minute.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration mode	•	—	•	—	—

Command History

Release	Modification
8.4(2)	This command was introduced.

Usage Guidelines

The command specifies the time to remove the IP address of a resolved FQDN after its TTL expires. When the IP address is removed, the ASA recompiles the tmatch lookup table.

Specifying this command is only effective when the associated network object for the DNS is activated.

The default DNS expire-entry-timer value is 1 minute, which means that IP addresses are removed 1 minute after the TTL of the DNS entry expires.

Note The default setting might result in frequent recompilation of the tmatch lookup table when the resolved TTL of common FQDN hosts, such as www.sample.com, is a short time period. You can specify a long DNS expire-entry timer value to reduce the frequency of recompilation of the tmatch lookup table while maintaining security.

Examples

The following example removes resolved entries after 240 minutes:

```
hostname(config)# dns expire-entry-timer minutes 240
```

Related Commands

Command	Description
clear configure dns	Removes all DNS commands.
dns server-group	Enters dns-server-group mode, in which you can configure a DNS server group.
show running-config dns-server group	Shows one or all the existing DNS server group configurations.

dns name-server

To configure a DNS server for the ASA, user the **dns name-server** command in global configuration mode. To remove the configuration, use the **no** form of this command.

dns name-server *ipv4_addr* | *ipv6_addr*

no dns name-server *ipv4_addr* | *ipv6_addr*

Syntax Description

ipv4_addr	Specifies the IPv4 address of the DNS server.
ipv6_addr	Specifies the IPv6 address of the DNS server.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.4(2)	This command was introduced.
9.0(1)	Support of IPv6 addresses was added.

Usage Guidelines

Use this command to identify a DNS server address for the ASA. The ASA supports both IPv4 and IPv6 addresses for DNS servers.

Examples

The following example configures a DNS server with an IPv6 address:

```
hostname(config)# dns domain-lookup
hostname(config)# dns name-server 8080:1:2::2
hostname(config)# dns retries 4
hostname(config)# dns timeout 10
```

Related Commands

Command	Description
clear configure dns	Removes all DNS commands.

Command	Description
dns server-group	Enters dns-server-group mode, in which you can configure a DNS server group.
show running-config dns-server group	Shows one or all the existing DNS server group configurations.

dns poll-timer

To specify the timer during which the ASA queries the DNS server to resolve fully qualified domain names (FQDN) that are defined in a network object group, use the **dns poll-timer** command in global configuration mode. To remove the timer, use the **no** form of this command.

dns poll-timer minutes *minutes*

no dns poll-timer minutes *minutes*

Syntax Description

minutes *minutes*	Specifies the timer in minutes. Valid values are from 1 to 65535 minutes.

Defaults

By default, the DNS timer is 240 minutes or 4 hours.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.4(2)	This command was introduced.

Usage Guidelines

This command specifies the timer during which the ASA queries the DNS server to resolve the FQDN that was defined in a network object group. A FQDN is resolved periodically when the poll DNS timer has expired or when the TTL of the resolved IP entry has expired, whichever comes first.

This command has effect only when at least one network object group has been activated.

Examples

The following example sets the DNS poll timer to 240 minutes:

```
hostname(config)# dns poll-timer minutes 240
```

Related Commands

Command	Description
clear configure dns	Removes all DNS commands.
dns server-group	Enters dns-server-group mode, in which you can configure a DNS server group.
show running-config dns-server group	Shows one or all the existing DNS server-group configurations.

dns update

To start DNS lookup to resolve the designated hostnames without waiting for the expiration of the DNS poll timer, use the **dns update** command in privileged EXEC mode.

dns update [**host** *fqdn_name*] [**timeout seconds** *seconds*]

Syntax Description

host *fqdn_name*	Specifies the fully qualified domain name of the host on which to run DNS updates.
timeout seconds *seconds*	Specifies the timeout in seconds.

Defaults

By default, the timeout is 30 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC mode	•	—	•	—	—

Command History

Release	Modification
8.4(2)	This command was introduced.

Usage Guidelines

This command immediately starts a DNS lookup to resolve the designated hostnames without waiting for the expiration of the DNS poll timer. When you run DNS update without specifying an option, all activated host groups and FQDN hosts are selected for DNS lookup. When the command finishes running, the ASA displays [Done] at the command prompt and generates a syslog message.

When the update operation starts, a starting update log is created. When the update operation finishes or is aborted after the timer has expired, another syslog message is generated. Only one outstanding DNS update operation is allowed. If you reissue the command, an error message appears.

Examples

The following example performs a DNS update:

```
hostname# dns update
hostname# …
hostname# [Done] dns update
```

Related Commands

Command	Description
clear configure dns	Removes all DNS commands.
dns server-group	Enters dns-server-group mode, in which you can configure a DNS server group.
show running-config dns-server group	Shows one or all the existing DNS server group configurations.

dns-group

To specify the DNS server to use for a WebVPN tunnel group, use the **dns-group** command in tunnel-group webvpn configuration mode. To restore the default DNS group, use the **no** form of this command.

dns-group *name*

no dns-group

Syntax Description

name	Specifies the name of the DNS server group configuration to use for the tunnel group.

Defaults

The default value is DefaultDNS.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group webvpn-attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The name can specify any DNS group. The **dns-group** command resolves the hostname to the appropriate DNS server for the tunnel group.

You configure the DNS group using the **dns server-group** command.

Examples

The following example shows a customization command that specifies the use of the DNS group named "dnsgroup1":

```
hostname(config)# tunnel-group test type webvpn
hostname(config)# tunnel-group test webvpn-attributes
hostname(config-tunnel-webvpn)# dns-group dnsgroup1
hostname(config-tunnel-webvpn)#
```

Related Commands

Command	Description
clear configure dns	Removes all DNS commands.
dns server-group	Enters dns-server-group mode, in which you can configure a DNS server group.
show running-config dns-server group	Shows one or all the existing DNS server group configurations.
tunnel-group webvpn-attributes	Enters the config-webvpn mode for configuring WebVPN tunnel group attributes.

dns-guard

To enable the DNS guard function, which enforces one DNS response per query, use the **dns-guard** command in parameters configuration mode. To disable this feature, use the **no** form of this command.

dns-guard

no dns-guard

Syntax Description

This command has no arguments or keywords.

Defaults

DNS guard is enabled by default. This feature can be enabled when the **inspect dns** command is configured even if a **policy-map type inspect dns** command is not defined. To disable, the **no dns-guard** command must explicitly be stated in the policy map configuration. If the **inspect dns** command is not configured, the behavior is determined by the **global dns-guard** command.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The identification field in the DNS header is used to match the DNS response with the DNS header. One response per query is allowed through the ASA.

Examples

The following example shows how to enable DNS guard in a DNS inspection policy map:

```
hostname(config)# policy-map type inspect dns preset_dns_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# dns-guard
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.

Command	Description
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

dns-server

To set the IP address of the primary and secondary DNS servers, use the **dns-server** command in group-policy configuration mode. To remove the attribute from the running configuration, use the **no** form of this command.

dns-server {**value** *ip_address* [*ip_address*] | **none**}

no dns-server

Syntax Description

none	Sets the **dns-server** command to a null value, thereby allowing no DNS servers. Prevents inheriting a value from a default or specified group policy.
value *ip_address*	Specifies the IP address of the primary and secondary DNS servers.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command allows inheritance of a DNS server from another group policy. To prevent inheriting a server, use the **dns-server none** command.

Each time you issue the **dns-server** command, you overwrite the existing setting. For example, if you configure DNS server x.x.x.x and then configure DNS server y.y.y.y, the second command overwrites the first, and y.y.y.y becomes the sole DNS server. The same holds true for multiple servers. To add a DNS server rather than overwrite previously configured servers, include the IP addresses of all DNS servers when you enter this command.

Examples

The following example shows how to configure DNS servers with the IP addresses 10.10.10.15, 10.10.10.30, and 10.10.10.45 for the group policy named FirstGroup.

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# dns-server value 10.10.10.15 10.10.10.30 10.10.10.45
```

Related Commands

Command	Description
clear configure dns	Removes all DNS commands.
show running-config dns server-group	Shows the current running DNS server group configuration.

dns server-group

To specify the domain name, name server, number of retries, and timeout values for a DNS server to use for a tunnel group, use the **dns server-group** command in global configuration mode. To remove a particular DNS server group, use the **no** form of this command.

dns server -group *name*

no dns server-group

Syntax Description

name	Specifies the name of the DNS server group configuration to use for the tunnel group.

Defaults

The default value is DefaultDNS.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The name can specify any DNS group. You configure the DNS group using the **dns server-group** command.

Examples

The following example configures a DNS server group named “eval”:

```
hostname(config)# dns server-group eval
hostname(config-dns-server-group)# domain-name cisco.com
hostname(config-dns-server-group)# name-server 192.168.10.10
hostname(config-dns-server-group)# retries 5
hostname(config-dns-server-group)# timeout 7
hostname(config-dns-server-group)#
```

Related Commands

Command	Description
clear configure dns	Removes all DNS commands.
show running-config dns server-group	Shows the current running DNS server group configuration.

domain-name

To set the default domain name, use the **domain-name** command in global configuration mode. To remove the domain name, use the **no** form of this command.

domain-name *name*

no domain-name [*name*]

Syntax Description

name	Sets the domain name, up to 63 characters.

Defaults

The default domain name is default.domain.invalid.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The ASA appends the domain name as a suffix to unqualified names. For example, if you set the domain name to "example.com" and specify a syslog server by the unqualified name of "jupiter," then the ASA qualifies the name to "jupiter.example.com." For multiple context mode, you can set the domain name for each context, as well as within the system execution space.

Examples

The following example sets the domain to example.com:

```
hostname(config)# domain-name example.com
```

Related Commands

Command	Description
dns domain-lookup	Enables the ASA to perform a name lookup.
dns name-server	Identifies a DNS server for the ASA.
hostname	Sets the ASA hostname.
show running-config domain-name	Shows the domain name configuration.

domain-name (dns server-group)

To set the default domain name, use the **domain-name** command in dns server-group configuration mode. To remove the domain name, use the **no** form of this command.

domain-name *name*

no domain-name [*name*]

Syntax Description

name	Sets the domain name, up to 63 characters.

Defaults

The default domain name is default.domain.invalid.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Dns server-group configuration	•	•	•	•	•

Command History

Release	Modification
7.1(1)	This command replaces the **dns domain-lookup** command, which has been deprecated.

Usage Guidelines

The ASA appends the domain name as a suffix to unqualified names. For example, if you set the domain name to "example.com," and specify a syslog server by the unqualified name of "jupiter," then the ASA qualifies the name to "jupiter.example.com." For multiple context mode, you can set the domain name for each context, as well as within the system execution space.

Examples

The following example sets the domain to "example.com" for "dnsgroup1":

```
hostname(config)# dns server-group dnsgroup1
hostname(config-dns-server-group)# domain-name example.com
```

Related Commands

Command	Description
clear configure dns	Removes all DNS commands.
dns server-group	Enters dns-server-group configuration mode, in which you can configure a DNS server group.

Command	Description
domain-name	Sets the default domain name globally.
show running-config dns-server group	Shows one or all the current DNS server group configurations.

downgrade

To downgrade your software version, use the **downgrade** command in global configuration mode.

downgrade [**/noconfirm**] *old_image_url old_config_url* [**activation-key** *old_key*]

Syntax Description

activation-key *old_key*	(Optional) If you need to revert the activation key, then you can enter the old activation key.
old_config_url	Specifies the path to the saved, pre-migration configuration (by default this was saved on disk0).
old_image_url	Specifies the path to the old image on disk0, disk1, tftp, ftp, or smb.
/noconfirm	(Optional) Downgrades without prompting.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	—	•

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

This command is a shortcut for completing the following functions:

1. Clearing the boot image configuration (**clear configure boot**).
2. Setting the boot image to be the old image (**boot system**).
3. (Optional) Entering a new activation key (**activation-key**).
4. Saving the running configuration to startup (**write memory**). This sets the BOOT environment variable to the old image, so when you reload, the old image is loaded.
5. Copying the old configuration to the startup configuration (**copy** *old_config_url* **startup-config**).
6. Reloading (**reload**).

Examples

The following example downgrades without confirming:

```
hostname(config)# downgrade /noconfirm disk0:/asa821-k8.bin disk0:/8_2_1_0_startup_cfg.sav
```

Related Commands

Command	Description
activation-key	Enters an activation key.
boot system	Sets the image to boot from.
clear configure boot	Clears the boot image configuration.
copy startup-config	Copies a configuration to the startup configuration.

download-max-size

To specify the maximum size allowed for an object to download, use the **download-max-size** command in group-policy webvpn configuration mode. To remove this object from the configuration, use the **no** version of this command.

download-max-size *size*

no download-max-size

Syntax Description

size	Specifies the maximum size allowed for a downloaded object. The range is 0 through 2147483647.

Defaults

The default size is 2147483647.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy webvpn configuration mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Setting the size to 0 effectively disallows object downloading.

Examples

The following example sets the maximum size for a downloaded object to 1500 bytes:

```
hostname(config)# group-policy test attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# download-max-size 1500
```

Related Commands

Command	Description
post-max-size	Specifies the maximum size of an object to post.
upload-max-size	Specifies the maximum size of an object to upload.

Command	Description
webvpn	Use in group-policy configuration mode or in username configuration mode. Lets you enter webvpn mode to configure parameters that apply to group policies or usernames.
webvpn	Use in global configuration mode. Lets you configure global settings for WebVPN.

drop

To drop all packets that match the **match** command or **class** command, use the **drop** command in match or class configuration mode. To disable this action, use the **no** form of this command.

drop [**send-protocol-error**] [**log**]

no drop [**send-protocol-error**] [**log**]

Syntax Description

log	Logs the match. The syslog message number depends on the application.
send-protocol-error	Sends a protocol error message.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Match and class configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

When using the Modular Policy Framework, drop packets that match a **match** command or class map by using the **drop** command in match or class configuration mode. This drop action is available in an inspection policy map (the **policy-map type inspect** command) for application traffic; however, not all applications allow this action.

An inspection policy map consists of one or more **match** and **class** commands. The exact commands available for an inspection policy map depends on the application. After you enter the **match** or **class** command to identify application traffic (the **class** command refers to an existing **class-map type inspect** command that in turn includes **match** commands), you can enter the **drop** command to drop all packets that match the **match** command or **class** command.

If you drop a packet, then no further actions are performed in the inspection policy map. For example, if the first action is to drop the packet, then it will never match any further **match** or **class** commands. If the first action is to log the packet, then a second action, such as dropping the packet, can occur. You can configure both the **drop** and the **log** action for the same **match** or **class** command, in which case the packet is logged before it is dropped for a given match.

When you enable application inspection using the **inspect** command in a Layer 3/4 policy map (the **policy-map** command), you can enable the inspection policy map that contains this action, for example, enter the **inspect http http_policy_map** command where http_policy_map is the name of the inspection policy map.

Examples

The following example drops packets and sends a log when they match the HTTP traffic class map. If the same packet also matches the second **match** command, it will not be processed because it was already dropped.

```
hostname(config-cmap)# policy-map type inspect http http-map1
hostname(config-pmap)# class http-traffic
hostname(config-pmap-c)# drop log
hostname(config-pmap-c)# match req-resp content-type mismatch
hostname(config-pmap-c)# reset log
```

Related Commands

Commands	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
policy-map type inspect	Defines special actions for application inspection.
show running-config policy-map	Display all current policy map configurations.

drop-connection

When using the Modular Policy Framework, drop packets and close the connection for traffic that matches a **match** command or class map by using the **drop-connection** command in match or class configuration mode. To disable this action, use the **no** form of this command.

drop-connection [**send-protocol-error**] [**log**]

no drop-connection [**send-protocol-error**] [**log**]

Syntax Description

send-protocol-error	Sends a protocol error message.
log	Logs the match. The system log message number depends on the application.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Match and class configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The connection will be removed from the connection database on the ASA. Any subsequent packets entering the ASA for the dropped connection will be discarded. This drop-connection action is available in an inspection policy map (the **policy-map type inspect** command) for application traffic; however, not all applications allow this action. An inspection policy map consists of one or more **match** and **class** commands. The exact commands available for an inspection policy map depends on the application. After you enter the **match** or **class** command to identify application traffic (the **class** command refers to an existing **class-map type inspect** command that in turn includes **match** commands), you can enter the **drop-connection** command to drop packets and close the connection for traffic that matches the **match** command or **class** command.

If you drop a packet or close a connection, then no further actions are performed in the inspection policy map. For example, if the first action is to drop the packet and close the connection, then it will never match any further **match** or **class** commands. If the first action is to log the packet, then a second action, such as dropping the packet, can occur. You can configure both the **drop-connection** and the **log** action for the same **match** or **class** command, in which case the packet is logged before it is dropped for a given match.

When you enable application inspection using the **inspect** command in a Layer 3/4 policy map (the **policy-map** command), you can enable the inspection policy map that contains this action. For example, enter the **inspect http http_policy_map** command, where http_policy_map is the name of the inspection policy map.

Examples

The following example drops packets, closes the connection, and sends a log when they match the http-traffic class map. If the same packet also matches the second **match** command, it will not be processed because it was already dropped.

```
hostname(config-cmap)# policy-map type inspect http http-map1
hostname(config-pmap)# class http-traffic
hostname(config-pmap-c)# drop-connection log
hostname(config-pmap-c)# match req-resp content-type mismatch
hostname(config-pmap-c)# reset log
```

Related Commands

Commands	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
policy-map type inspect	Defines special actions for application inspection.
show running-config policy-map	Display all current policy map configurations.

dtls port

To specify a port for DTLS connections, use the **dtls port** command from webvpn configuration mode. To remove the command from the configuration, use the **no** form of this command:

dtls port *number*

no dtls port *number*

Syntax Description

number	The UDP port number, from 1 to 65535.

Defaults

The default port number is 443.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

This command specifies the UDP port to be used for SSL VPN connections using DTLS.

DTLS avoids latency and bandwidth problems associated with some SSL connections and improves the performance of real-time applications that are sensitive to packet delays.

Examples

The following example enters webvpn configuration mode and specifies port 444 for DTLS:

```
hostname(config)# webvpn
hostname(config-webvpn)# dtls port 444
```

Related Commands

Command	Description
dtls enable	Enables DTLS on an interface.
svc dtls	Enables DTLS for groups or users establishing SSL VPN connections.
vpn-tunnel-protocol	Specifies VPN protocols that the ASA allows for remote access, including SSL.

duplex

To set the duplex of a copper (RJ-45) Ethernet interface, use the **duplex** command in interface configuration mode. To restore the duplex setting to the default, use the **no** form of this command.

duplex {**auto** | **full** | **half**}

no duplex

Syntax Description

auto	Auto-detects the duplex mode.
full	Sets the duplex mode to full duplex.
half	Sets the duplex mode to half duplex.

Defaults

The default is auto detect.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was moved from a keyword of the **interface** command to an interface configuration mode command.

Usage Guidelines

Set the duplex mode on the physical interface only.

The **duplex** command is not available for fiber media.

If your network does not support auto detection, set the duplex mode to a specific value.

For RJ-45 interfaces on the ASA 5500 series, the default auto-negotiation setting also includes the Auto-MDI/MDIX feature. Auto-MDI/MDIX eliminates the need for crossover cabling by performing an internal crossover when a straight cable is detected during the auto-negotiation phase. Either the speed or duplex must be set to auto-negotiate to enable Auto-MDI/MDIX for the interface. If you explicitly set both the speed and duplex to a fixed value, thus disabling auto-negotiation for both settings, then Auto-MDI/MDIX is also disabled.

If you set the duplex to anything other than **auto** on PoE ports, if available, then Cisco IP phones and Cisco wireless access points that do not support IEEE 802.3af will not be detected and supplied with power.

Examples

The following example sets the duplex mode to full duplex:

```
hostname(config)# interface gigabitethernet0/1
hostname(config-if)# speed 1000
hostname(config-if)# duplex full
hostname(config-if)# nameif inside
hostname(config-if)# security-level 100
hostname(config-if)# ip address 10.1.1.1 255.255.255.0
hostname(config-if)# no shutdown
```

Related Commands

Command	Description
clear configure interface	Clears all configuration for an interface.
interface	Configures an interface and enters interface configuration mode.
show interface	Displays the runtime status and statistics of interfaces.
show running-config interface	Shows the interface configuration.
speed	Sets the interface speed.

dynamic-access-policy-config

To configure a DAP record and the access policy attributes associated with it, use the **dynamic-access-policy-config** command in global configuration mode. To remove an existing DAP configuration, use the **no** form of this command.

dynamic-access-policy-config *name* | *activate*

no dynamic-access-policy-config

Syntax Description

activate	Activates the DAP selection configration file.
name	Specifies the name of the DAP record. The name can be up to 64 characters long and cannot contain spaces.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration (name)	•	•	•	•	—
Privileged EXEC (activate)	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

Use the **dynamic-access-policy-config** command in global configuration mode to create one or more DAP records. To activate a DAP selection configuration file, use the **dynamic-access-policy-config** command with the *activate* argument.

When you use this command, you enter dynamic-access-policy-record mode, in which you can set attributes for the named DAP record. The commands you can use in dynamic-access-policy-record mode include the following:

- **action**
- **description**
- **network-acl**
- **priority**
- **user-message**

- **webvpn**

Examples

The following example shows how to configure the DAP record named user1:

```
hostname(config)# dynamic-access-policy-config user1
hostname(config-dynamic-access-policy-record)#
```

Related Commands

Command	Description
dynamic-access-policy-record	Populates the DAP record with access policy attributes.
show running-config dynamic-access-policy-record	Displays the running configuration for all DAP records, or for the named DAP record.

dynamic-access-policy-record

To create a DAP record and populate it with access policy attributes, use the **dynamic-access-policy-record** command in global configuration mode. To remove an existing DAP record, use the **no** form of this command.

dynamic-access-policy-record *name*

no dynamic-access-policy-record *name*

Syntax Description

name	Specifies the name of the DAP record. The name can be up to 64 characters long and cannot contain spaces.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use the **dynamic-access-policy-record** command in global configuration mode to create one or more DAP records. When you use this command, you enter dynamic-access-policy-record mode, in which you can set attributes for the named DAP record. The commands you can use in dynamic-access-policy-record mode include the following:

- **action** (**continue**, **terminate**, or **quarantine**)
- **description**
- **network-acl**
- **priority**
- **user-message**
- **webvpn**

Examples

The following example shows how to create a DAP record named Finance.

```
hostname(config)# dynamic-access-policy-record Finance
hostname(config-dynamic-access-policy-record)#
```

Related Commands

Command	Description
clear config dynamic-access-policy-record	Removes all DAP records or the named DAP record.
dynamic-access-policy-config url	Configures the DAP Selection Configuration file.
show running-config dynamic-access-policy-record	Displays the running configuration for all DAP records, or for the named DAP record.

dynamic-filter ambiguous-is-black

To treat Botnet Traffic Filter greylisted traffic as blacklisted traffic for dropping purposes, use the **dynamic-filter ambiguous-is-black** command in global configuration mode. To allow greylisted traffic, use the **no** form of this command.

dynamic-filter ambiguous-is-black

no dynamic-filter ambiguous-is-black

Syntax Description

This command has no arguments or keywords.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.2(2)	This command was introduced.

Usage Guidelines

If you configured the **dynamic-filter enable** command and then the **dynamic-filter drop blacklist** command, this command treats greylisted traffic as blacklisted traffic for dropping purposes. If you do not enable this command, greylisted traffic will not be dropped.

Ambiguous addresses are associated with multiple domain names, but not all of these domain names are on the blacklist. These addresses are on the greylist.

Examples

The following example monitors all port 80 traffic on the outside interface, and then drops blacklisted and greylisted traffic at a threat level of moderate or greater:

```
hostname(config)# access-list dynamic-filter_acl extended permit tcp any any eq 80
hostname(config)# dynamic-filter enable interface outside classify-list dynamic-filter_acl
hostname(config)# dynamic-filter drop blacklist interface outside
hostname(config)# dynamic-filter ambiguous-is-black
```

Related Commands

Command	Description
address	Adds an IP address to the blacklist or whitelist.
clear configure dynamic-filter	Clears the running Botnet Traffic Filter configuration.
clear dynamic-filter dns-snoop	Clears Botnet Traffic Filter DNS snooping data.
clear dynamic-filter reports	Clears Botnet Traffic filter report data.
clear dynamic-filter statistics	Clears Botnet Traffic filter statistics.
dns domain-lookup	Enables the ASA to send DNS requests to a DNS server to perform a name lookup for supported commands.
dns server-group	Identifies a DNS server for the ASA.
dynamic-filter blacklist	Edits the Botnet Traffic Filter blacklist.
dynamic-filter database fetch	Manually retrieves the Botnet Traffic Filter dynamic database.
dynamic-filter database find	Searches the dynamic database for a domain name or IP address.
dynamic-filter database purge	Manually deletes the Botnet Traffic Filter dynamic database.
dynamic-filter drop blacklist	Automatically drops blacklisted traffic.
dynamic-filter enable	Enables the Botnet Traffic Filter for a class of traffic or for all traffic if you do not specify an access list.
dynamic-filter updater-client enable	Enables downloading of the dynamic database.
dynamic-filter use-database	Enables use of the dynamic database.
dynamic-filter whitelist	Edits the Botnet Traffic Filter whitelist.
inspect dns dynamic-filter-snoop	Enables DNS inspection with Botnet Traffic Filter snooping.
name	Adds a name to the blacklist or whitelist.
show asp table dynamic-filter	Shows the Botnet Traffic Filter rules that are installed in the accelerated security path.
show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
show dynamic-filter dns-snoop	Shows the Botnet Traffic Filter DNS snooping summary, or with the **detail** keyword, the actual IP addresses and names.
show dynamic-filter reports	Generates reports of the top 10 botnet sites, ports, and infected hosts.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

dynamic-filter blacklist

To edit the Botnet Traffic Filter blacklist, use the **dynamic-filter blacklist** command in global configuration mode. To remove the blacklist, use the **no** form of this command.

dynamic-filter blacklist

no dynamic-filter blacklist

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

After you enter the dynamic-filter blacklist configuration mode, you can manually enter domain names or IP addresses (host or subnet) that you want to tag as bad names in a blacklist using the **address** and **name** commands. You can also enter names or IP addresses in a whitelist (see the **dynamic-filter whitelist** command), so that names or addresses that appear on both the dynamic blacklist and whitelist are identified only as whitelist addresses in syslog messages and reports. Note that you see syslog messages for whitelisted addresses even if the address is not also in the dynamic blacklist.

Static blacklist entries are always designated with a Very High threat level.

When you add a domain name to the static database, the ASA waits 1 minute, and then sends a DNS request for that domain name and adds the domain name/IP address pairing to the *DNS host cache*. (This action is a background process, and does not affect your ability to continue configuring the ASA). We recommend also enabling DNS packet inspection with Botnet Traffic Filter snooping (see the **inspect dns dynamic-filter-snooping** command). The ASA uses Botnet Traffic Filter snooping instead of the regular DNS lookup to resolve static blacklist domain names in the following circumstances:

- The ASA DNS server is unavailable.
- A connection is initiated during the 1-minute waiting period before the ASA sends the regular DNS request.

If DNS snooping is used, when an infected host sends a DNS request for a name on the static database, the ASA looks inside the DNS packets for the domain name and associated IP address and adds the name and IP address to the DNS reverse lookup cache.

The static database lets you augment the dynamic database with domain names or IP addresses that you want to blacklist.

If you do not enable Botnet Traffic Filter snooping, and one of the above circumstances occurs, then that traffic will not be monitored by the Botnet Traffic Filter.

Note This command requires ASA use of a DNS server; see the **dns domain-lookup** and **dns server-group** commands.

Examples

The following example creates entries for the blacklist and whitelist:

```
hostname(config)# dynamic-filter blacklist
hostname(config-llist)# name bad1.example.com
hostname(config-llist)# name bad2.example.com
hostname(config-llist)# address 10.1.1.1 255.255.255.0

hostname(config-llist)# dynamic-filter whitelist
hostname(config-llist)# name good.example.com
hostname(config-llist)# name great.example.com
hostname(config-llist)# name awesome.example.com
hostname(config-llist)# address 10.1.1.2 255.255.255.255
```

Related Commands

Command	Description
address	Adds an IP address to the blacklist or whitelist.
clear configure dynamic-filter	Clears the running Botnet Traffic Filter configuration.
clear dynamic-filter dns-snoop	Clears Botnet Traffic Filter DNS snooping data.
clear dynamic-filter reports	Clears Botnet Traffic filter report data.
clear dynamic-filter statistics	Clears Botnet Traffic filter statistics.
dns domain-lookup	Enables the ASA to send DNS requests to a DNS server to perform a name lookup for supported commands.
dns server-group	Identifies a DNS server for the ASA.
dynamic-filter ambiguous-is-black	Treats greylisted traffic as blacklisted traffic for action purposes.
dynamic-filter database fetch	Manually retrieves the Botnet Traffic Filter dynamic database.
dynamic-filter database find	Searches the dynamic database for a domain name or IP address.
dynamic-filter database purge	Manually deletes the Botnet Traffic Filter dynamic database.
dynamic-filter drop blacklist	Automatically drops blacklisted traffic.
dynamic-filter enable	Enables the Botnet Traffic Filter for a class of traffic or for all traffic if you do not specify an access list.
dynamic-filter updater-client enable	Enables downloading of the dynamic database.
dynamic-filter use-database	Enables use of the dynamic database.
dynamic-filter whitelist	Edits the Botnet Traffic Filter whitelist.

Command	Description
inspect dns dynamic-filter-snoop	Enables DNS inspection with Botnet Traffic Filter snooping.
name	Adds a name to the blacklist or whitelist.
show asp table dynamic-filter	Shows the Botnet Traffic Filter rules that are installed in the accelerated security path.
show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
show dynamic-filter dns-snoop	Shows the Botnet Traffic Filter DNS snooping summary, or with the **detail** keyword, the actual IP addresses and names.
show dynamic-filter reports	Generates reports of the top 10 botnet sites, ports, and infected hosts.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

dynamic-filter database fetch

To test the download of the dynamic database for the Botnet Traffic Filter, use the **dynamic-filter database fetch** command in privileged EXEC mode.

dynamic-filter database fetch

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

The actual database is not stored on the ASA; it is downloaded and then discarded. Use this command for testing purposes only.

Examples

The following example tests the download of the dynamic database:

```
hostname# dynamic-filter database fetch
```

Related Commands

Command	Description
address	Adds an IP address to the blacklist or whitelist.
clear configure dynamic-filter	Clears the running Botnet Traffic Filter configuration.
clear dynamic-filter dns-snoop	Clears Botnet Traffic Filter DNS snooping data.

clear dynamic-filter statistics	Clears Botnet Traffic filter statistics.
dns domain-lookup	Enables the ASA to send DNS requests to a DNS server to perform a name lookup for supported commands.
dns server-group	Identifies a DNS server for the ASA.

Command	Description
dynamic-filter ambiguous-is-black	Treats greylisted traffic as blacklisted traffic for action purposes.
dynamic-filter blacklist	Edits the Botnet Traffic Filter blacklist.
dynamic-filter database find	Searches the dynamic database for a domain name or IP address.
dynamic-filter database purge	Manually deletes the Botnet Traffic Filter dynamic database.
dynamic-filter drop blacklist	Automatically drops blacklisted traffic.
dynamic-filter enable	Enables the Botnet Traffic Filter for a class of traffic or for all traffic if you do not specify an access list.
dynamic-filter updater-client enable	Enables downloading of the dynamic database.
dynamic-filter use-database	Enables use of the dynamic database.
dynamic-filter whitelist	Edits the Botnet Traffic Filter whitelist.
inspect dns dynamic-filter-snoop	Enables DNS inspection with Botnet Traffic Filter snooping.
name	Adds a name to the blacklist or whitelist.
show asp table dynamic-filter	Shows the Botnet Traffic Filter rules that are installed in the accelerated security path.
show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
show dynamic-filter dns-snoop	Shows the Botnet Traffic Filter DNS snooping summary, or with the **detail** keyword, the actual IP addresses and names.
show dynamic-filter reports	Generates reports of the top 10 botnet sites, ports, and infected hosts.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

dynamic-filter database find

To check if a domain name or IP address is included in the dynamic database for the Botnet Traffic Filter, use the **dynamic-filter database find** command in privileged EXEC mode.

dynamic-filter database find *string*

Syntax Description

string	The *string* can be the complete domain name or IP address, or you can enter part of the name or address, with a minimum search string of 3 characters. Regular expressions are not supported for the database search.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

If there are multiple matches, the first two matches are shown. To refine your search for a more specific match, enter a longer string.

Examples

The following example searches on the string “example.com,” and finds one match:

```
hostname# dynamic-filter database find bad.example.com

   bad.example.com
Found 1 matches
```

The following example searches on the string “bad,” and finds more than two matches:

```
hostname# dynamic-filter database find bad

   bad.example.com
   bad.example.net
Found more than 2 matches, enter a more specific string to find an exact
match
```

Related Commands

Command	Description
dynamic-filter ambiguous-is-black	Treats greylisted traffic as blacklisted traffic for action purposes.
dynamic-filter drop blacklist	Automatically drops blacklisted traffic.
address	Adds an IP address to the blacklist or whitelist.
clear configure dynamic-filter	Clears the running Botnet Traffic Filter configuration.
clear dynamic-filter dns-snoop	Clears Botnet Traffic Filter DNS snooping data.
clear dynamic-filter reports	Clears Botnet Traffic filter report data.
clear dynamic-filter statistics	Clears Botnet Traffic filter statistics.
dns domain-lookup	Enables the ASA to send DNS requests to a DNS server to perform a name lookup for supported commands.
dns server-group	Identifies a DNS server for the ASA.
dynamic-filter blacklist	Edits the Botnet Traffic Filter blacklist.
dynamic-filter database fetch	Manually retrieves the Botnet Traffic Filter dynamic database.
dynamic-filter database purge	Manually deletes the Botnet Traffic Filter dynamic database.
dynamic-filter enable	Enables the Botnet Traffic Filter for a class of traffic or for all traffic if you do not specify an access list.
dynamic-filter updater-client enable	Enables downloading of the dynamic database.
dynamic-filter use-database	Enables use of the dynamic database.
dynamic-filter whitelist	Edits the Botnet Traffic Filter whitelist.
inspect dns dynamic-filter-snoop	Enables DNS inspection with Botnet Traffic Filter snooping.
name	Adds a name to the blacklist or whitelist.
show asp table dynamic-filter	Shows the Botnet Traffic Filter rules that are installed in the accelerated security path.
show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
show dynamic-filter dns-snoop	Shows the Botnet Traffic Filter DNS snooping summary, or with the **detail** keyword, the actual IP addresses and names.
show dynamic-filter reports	Generates reports of the top 10 botnet sites, ports, and infected hosts.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

dynamic-filter database purge

To manually delete the Botnet Traffic Filter dynamic database from running memory, use the **dynamic-filter database purge** command in privileged EXEC mode.

dynamic-filter database purge

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

The database files are stored in running memory; they are not stored in flash memory. If you need to delete the database, use the **dynamic-filter database purge** command.

Before you can purge the database files, disable use of the database using the **no dynamic-filter use-database** command.

Examples

The following example disables use of the database, and then purges the database:

```
hostname(config)# no dynamic-filter use-database
hostname(config)# dynamic-filter database purge
```

Related Commands

Command	Description
address	Adds an IP address to the blacklist or whitelist.

dynamic-filter database find	Searches the dynamic database for a domain name or IP address.
dynamic-filter drop blacklist	Automatically drops blacklisted traffic.
dynamic-filter enable	Enables the Botnet Traffic Filter for a class of traffic or for all traffic if you do not specify an access list.
dynamic-filter updater-client enable	Enables downloading of the dynamic database.
dynamic-filter use-database	Enables use of the dynamic database.
dynamic-filter whitelist	Edits the Botnet Traffic Filter whitelist.
inspect dns dynamic-filter-snoop	Enables DNS inspection with Botnet Traffic Filter snooping.
name	Adds a name to the blacklist or whitelist.
show asp table dynamic-filter	Shows the Botnet Traffic Filter rules that are installed in the accelerated security path.
show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
show dynamic-filter dns-snoop	Shows the Botnet Traffic Filter DNS snooping summary, or with the **detail** keyword, the actual IP addresses and names.
show dynamic-filter reports	Generates reports of the top 10 botnet sites, ports, and infected hosts.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

dynamic-filter drop blacklist

To automatically drop blacklisted traffic using the Botnet Traffic Filter, use the **dynamic-filter drop blacklist** command in global configuration mode. To disable the automatic dropping, use the **no** form of this command.

dynamic-filter drop blacklist [**interface** *name*] [**action-classify-list** *subset_access_list*] [**threat-level** {**eq** *level* | **range** *min max*}]

no dynamic-filter drop blacklist [**interface** *name*] [**action-classify-list** *subset_access_list*] [**threat-level** {**eq** *level* | **range** *min max*}]

Syntax Description

action-classify-list *sub_access_list*	(Optional) Identifies a subset of traffic that you want to drop . See the **access-list extended** command to create the access list. The dropped traffic must always be equal to or a subset of the monitored traffic identified by the **dynamic-filter enable** command. For example, if you specify an access list for the **dynamic-filter enable** command, and you specify the **action-classify-list** for this command, then it must be a subset of the **dynamic-filter enable** access list.
interface *name*	(Optional) Limits monitoring to a specific interface. The dropped traffic must always be equal to or a subset of the monitored traffic identified by the **dynamic-filter enable** command. Any interface-specific commands take precedence over the global command.
threat-level {**eq** *level* | **range** *min max*}	(Optional) Limits the traffic dropped by setting the threat level. If you do not explicitly set a threat level, the level used is **threat-level range moderate very-high**. **Note** We highly recommend using the default setting unless you have strong reasons for changing the setting. The *level* and *min* and *max* options are: • **very-low** • **low** • **moderate** • **high** • **very-high** **Note** Static blacklist entries are always designated with a Very High threat level.

Defaults

This command is disabled by default.

The default threat level is **threat-level range moderate very-high**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.2(2)	This command was introduced.

Usage Guidelines

Be sure to first configure a **dynamic-filter enable** command for any traffic you want to drop; the dropped traffic must always be equal to or a subset of the monitored traffic.

You can enter this command multiple times for each interface and global policy. Make sure you do not specify overlapping traffic in multiple commands for a given interface/global policy. Because you cannot control the exact order that commands are matched, overlapping traffic means you do not know which command will be matched. For example, do not specify both a command that matches all traffic (without the **action-classify-list** keyword) as well as a command with the **action-classify-list** keyword for a given interface. In this case, the traffic might never match the command with the **action-classify-list** keyword. Similarly, if you specify multiple commands with the **action-classify-list** keyword, make sure each access list is unique, and that the networks do not overlap.

Examples

The following example monitors all port 80 traffic on the outside interface, and then drops traffic at a threat level of moderate or greater:

```
hostname(config)# access-list dynamic-filter_acl extended permit tcp any any eq 80
hostname(config)# dynamic-filter enable interface outside classify-list dynamic-filter_acl
hostname(config)# dynamic-filter drop blacklist interface outside
```

Related Commands

Command	Description
address	Adds an IP address to the blacklist or whitelist.
clear configure dynamic-filter	Clears the running Botnet Traffic Filter configuration.
clear dynamic-filter dns-snoop	Clears Botnet Traffic Filter DNS snooping data.
clear dynamic-filter reports	Clears Botnet Traffic filter report data.
clear dynamic-filter statistics	Clears Botnet Traffic filter statistics.
dns domain-lookup	Enables the ASA to send DNS requests to a DNS server to perform a name lookup for supported commands.
dns server-group	Identifies a DNS server for the ASA.
dynamic-filter ambiguous-is-black	Treats greylisted traffic as blacklisted traffic for action purposes.
dynamic-filter blacklist	Edits the Botnet Traffic Filter blacklist.
dynamic-filter database fetch	Manually retrieves the Botnet Traffic Filter dynamic database.

Command	Description
dynamic-filter database find	Searches the dynamic database for a domain name or IP address.
dynamic-filter database purge	Manually deletes the Botnet Traffic Filter dynamic database.
dynamic-filter enable	Enables the Botnet Traffic Filter for a class of traffic or for all traffic if you do not specify an access list.
dynamic-filter updater-client enable	Enables downloading of the dynamic database.
dynamic-filter use-database	Enables use of the dynamic database.
dynamic-filter whitelist	Edits the Botnet Traffic Filter whitelist.
inspect dns dynamic-filter-snoop	Enables DNS inspection with Botnet Traffic Filter snooping.
name	Adds a name to the blacklist or whitelist.
show asp table dynamic-filter	Shows the Botnet Traffic Filter rules that are installed in the accelerated security path.
show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
show dynamic-filter dns-snoop	Shows the Botnet Traffic Filter DNS snooping summary, or with the **detail** keyword, the actual IP addresses and names.
show dynamic-filter reports	Generates reports of the top 10 botnet sites, ports, and infected hosts.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

dynamic-filter enable

To enable the Botnet Traffic Filter, use the **dynamic-filter enable** command in global configuration mode. To disable the Botnet Traffic Filter, use the **no** form of this command.

dynamic-filter enable [**interface** *name*] [**classify-list** *access_list*]

no dynamic-filter enable [**interface** *name*] [**classify-list** *access_list*]

Syntax Description

classify-list *access_list*	Identifies the traffic that you want to monitor using an extended access list (see the **access-list extended** command). If you do not create an access list, by default you monitor all traffic.
interface *name*	Limits monitoring to a specific interface.

Defaults

The Botnet Traffic Filter is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

The Botnet Traffic Filter compares the source and destination IP address in each initial connection packet to the IP addresses in the dynamic database, static database, DNS reverse lookup cache, and DNS host cache, and sends a syslog message or drops any matching traffic.

Malware is malicious software that is installed on an unknowing host. Malware that attempts network activity such as sending private data (passwords, credit card numbers, key strokes, or proprietary data) can be detected by the Botnet Traffic Filter when the malware starts a connection to a known bad IP address. The Botnet Traffic Filter checks incoming and outgoing connections against a dynamic database of known bad domain names and IP addresses, and then logs any suspicious activity. You can also supplement the dynamic database with a static database by entering IP addresses or domain names in a local “blacklist” or “whitelist.”

The DNS snooping is enabled separately (see the **inspect dns dynamic-filter-snoop** command). Typically, for maximum use of the Botnet Traffic Filter, you need to enable DNS snooping, but you can use Botnet Traffic Filter logging independently if desired. Without DNS snooping for the dynamic database, the Botnet Traffic Filter uses only the static database entries, plus any IP addresses in the dynamic database; domain names in the dynamic database are not used.

Botnet Traffic Filter Address Categories

Addresses monitored by the Botnet Traffic Filter include:

- Known malware addresses—These addresses are on the "blacklist."
- Known allowed addresses—These addresses are on the "whitelist."
- Ambiguous addresses—These addresses are associated with multiple domain names, but not all of these domain names are on the blacklist. These addresses are on the "greylist."
- Unlisted addresses—These addresses are unknown, and not included on any list.

Botnet Traffic Filter Actions for Known Addresses

You can configure the Botnet Traffic Filter to log suspicious activity using the **dynamic-filter enable** conmmand, and you can optionally configure it to block suspicious traffic automatically using the **dynamic-filter drop blacklist** command.

Unlisted addresses do not generate any syslog messages, but addresses on the blacklist, whitelist, and greylist generate syslog messages differentiated by type. The Botnet Traffic Filter generates detailed syslog messages numbered 338*nnn*. Messages differentiate between incoming and outgoing connections, blacklist, whitelist, or greylist addresses, and many other variables. (The greylist includes addresses that are associated with multiple domain names, but not all of these domain names are on the blacklist.)

See the syslog messages guide for detailed information about syslog messages.

Examples

The following example monitors all port 80 traffic on the outside interface, and then drops traffic at a threat level of moderate or greater:

```
hostname(config)# access-list dynamic-filter_acl extended permit tcp any any eq 80
hostname(config)# dynamic-filter enable interface outside classify-list dynamic-filter_acl
hostname(config)# dynamic-filter drop blacklist interface outside
```

Related Commands

Command	Description
address	Adds an IP address to the blacklist or whitelist.
clear configure dynamic-filter	Clears the running Botnet Traffic Filter configuration.
clear dynamic-filter dns-snoop	Clears Botnet Traffic Filter DNS snooping data.
clear dynamic-filter reports	Clears Botnet Traffic filter report data.
clear dynamic-filter statistics	Clears Botnet Traffic filter statistics.
dns domain-lookup	Enables the ASA to send DNS requests to a DNS server to perform a name lookup for supported commands.
dns server-group	Identifies a DNS server for the ASA.
dynamic-filter ambiguous-is-black	Treats greylisted traffic as blacklisted traffic for action purposes.
dynamic-filter blacklist	Edits the Botnet Traffic Filter blacklist.
dynamic-filter database fetch	Manually retrieves the Botnet Traffic Filter dynamic database.
dynamic-filter database find	Searches the dynamic database for a domain name or IP address.
dynamic-filter database purge	Manually deletes the Botnet Traffic Filter dynamic database.
dynamic-filter drop blacklist	Automatically drops blacklisted traffic.

Command	Description
dynamic-filter updater-client enable	Enables downloading of the dynamic database.
dynamic-filter use-database	Enables use of the dynamic database.
dynamic-filter whitelist	Edits the Botnet Traffic Filter whitelist.
inspect dns dynamic-filter-snoop	Enables DNS inspection with Botnet Traffic Filter snooping.
name	Adds a name to the blacklist or whitelist.
show asp table dynamic-filter	Shows the Botnet Traffic Filter rules that are installed in the accelerated security path.
show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
show dynamic-filter dns-snoop	Shows the Botnet Traffic Filter DNS snooping summary, or with the **detail** keyword, the actual IP addresses and names.
show dynamic-filter reports	Generates reports of the top 10 botnet sites, ports, and infected hosts.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

dynamic-filter updater-client enable

To enable downloading of the dynamic database from the Cisco update server for the Botnet Traffic Filter, use the **dynamic-filter updater-client enable** command in global configuration mode. To disable downloading of the dynamic database, use the **no** form of this command.

dynamic-filter updater-client enable

no dynamic-filter updater-client enable

Syntax Description

This command has no arguments or keywords.

Defaults

Downloading is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

If you do not have a database already installed on the ASA, it downloads the database after approximately 2 minutes. The update server determines how often the ASA polls the server for future updates, typically every hour.

The Botnet Traffic Filter can receive periodic updates for the dynamic database from the Cisco update server.

This database lists thousands of known bad domain names and IP addresses. When the domain name in a DNS reply matches a name in the dynamic database, the Botnet Traffic Filter adds the name and IP address to the *DNS reverse lookup cache*. When the infected host starts a connection to the IP address of the malware site, then the ASA sends a syslog message informing you of the suspicious activity.

To use the database, be sure to configure a domain name server for the ASA so that it can access the URL. To use the domain names in the dynamic database, you need to enable DNS packet inspection with Botnet Traffic Filter snooping; the ASA looks inside the DNS packets for the domain name and associated IP address.

In some cases, the IP address itself is supplied in the dynamic database, and the Botnet Traffic Filter logs any traffic to that IP address without having to inspect DNS requests.

The database files are stored in running memory; they are not stored in flash memory. If you need to delete the database, use the **dynamic-filter database purge** command.

Note This command requires ASA use of a DNS server; see the **dns domain-lookup** and **dns server-group** commands.

Examples

The following multiple mode example enables downloading of the dynamic database, and enables use of the database in context1 and context2:

```
hostname(config)# dynamic-filter updater-client enable
hostname(config)# changeto context context1
hostname/context1(config)# dynamic-filter use-database
hostname/context1(config)# changeto context context2
hostname/context2(config)# dynamic-filter use-database
```

The following single mode example enables downloading of the dynamic database, and enables use of the database:

```
hostname(config)# dynamic-filter updater-client enable
hostname(config)# dynamic-filter use-database
```

Related Commands

Command	Description
address	Adds an IP address to the blacklist or whitelist.
clear configure dynamic-filter	Clears the running Botnet Traffic Filter configuration.
clear dynamic-filter dns-snoop	Clears Botnet Traffic Filter DNS snooping data.

clear dynamic-filter statistics	Clears Botnet Traffic filter statistics.
dns domain-lookup	Enables the ASA to send DNS requests to a DNS server to perform a name lookup for supported commands.
dns name-server	Identifies a DNS server for the ASA.
dynamic-filter ambiguous-is-black	Treats greylisted traffic as blacklisted traffic for action purposes.
dynamic-filter blacklist	Edits the Botnet Traffic Filter blacklist.
dynamic-filter database fetch	Manually retrieves the Botnet Traffic Filter dynamic database.
dynamic-filter database find	Searches the dynamic database for a domain name or IP address.
dynamic-filter database purge	Manually deletes the Botnet Traffic Filter dynamic database.
dynamic-filter drop blacklist	Automatically drops blacklisted traffic.
dynamic-filter enable	Enables the Botnet Traffic Filter for a class of traffic or for all traffic if you do not specify an access list.
dynamic-filter use-database	Enables use of the dynamic database.
dynamic-filter whitelist	Edits the Botnet Traffic Filter whitelist.
inspect dns dynamic-filter-snoop	Enables DNS inspection with Botnet Traffic Filter snooping.
name	Adds a name to the blacklist or whitelist.

Command	Description
show asp table dynamic-filter	Shows the Botnet Traffic Filter rules that are installed in the accelerated security path.
show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
show dynamic-filter dns-snoop	Shows the Botnet Traffic Filter DNS snooping summary, or with the **detail** keyword, the actual IP addresses and names.
show dynamic-filter reports	Generates reports of the top 10 botnet sites, ports, and infected hosts.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

dynamic-filter use-database

To enable use of the dynamic database for the Botnet Traffic Filter, use the **dynamic-filter use-database** command in global configuration mode. To disable use of the dynamic database, use the **no** form of this command.

dynamic-filter use-database

no dynamic-filter use-database

Syntax Description

This command has no arguments or keywords.

Defaults

Use of the database is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

Disabling use of the downloaded database is useful in multiple context mode, so you can configure use of the database on a per-context basis. To enable downloading of the dynamic database, see the **dynamic-filter updater-client enable** command.

Examples

The following multiple mode example enables downloading of the dynamic database, and enables use of the database in context1 and context2:

```
hostname(config)# dynamic-filter updater-client enable
hostname(config)# changeto context context1
hostname/context1(config)# dynamic-filter use-database
hostname/context1(config)# changeto context context2
hostname/context2(config)# dynamic-filter use-database
```

The following single mode example enables downloading of the dynamic database, and enables use of the database:

```
hostname(config)# dynamic-filter updater-client enable
hostname(config)# dynamic-filter use-database
```

Related Commands

Command	Description
address	Adds an IP address to the blacklist or whitelist.
clear configure dynamic-filter	Clears the running Botnet Traffic Filter configuration.

inspect dns dynamic-filter-snoop	Enables DNS inspection with Botnet Traffic Filter snooping.
name	Adds a name to the blacklist or whitelist.
show asp table dynamic-filter	Shows the Botnet Traffic Filter rules that are installed in the accelerated security path.
show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
show dynamic-filter dns-snoop	Shows the Botnet Traffic Filter DNS snooping summary, or with the **detail** keyword, the actual IP addresses and names.
show dynamic-filter reports	Generates reports of the top 10 botnet sites, ports, and infected hosts.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

dynamic-filter whitelist

To edit the Botnet Traffic Filter whitelist, use the **dynamic-filter whitelist** command in global configuration mode. To remove the whitelist, use the **no** form of this command.

dynamic-filter whitelist

no dynamic-filter whitelist

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

The static database lets you augment the dynamic database with domain names or IP addresses that you want to whitelist. After you enter the dynamic-filter whitelist configuration mode, you can manually enter domain names or IP addresses (host or subnet) that you want to tag as good names in a whitelist using the **address** and **name** commands. Names or addresses that appear on both the dynamic blacklist and static whitelist are identified only as whitelist addresses in syslog messages and reports. Note that you see syslog messages for whitelisted addresses even if the address is not also in the dynamic blacklist. You can enter names or IP addresses in the static blacklist using the **dynamic-filter blacklist** command.

When you add a domain name to the static database, the ASA waits 1 minute, and then sends a DNS request for that domain name and adds the domain name/IP address pairing to the *DNS host cache*. (This action is a background process, and does not affect your ability to continue configuring the ASA). We recommend also enabling DNS packet inspection with Botnet Traffic Filter snooping (see the **inspect dns dynamic-filter-snooping** command). The ASA uses Botnet Traffic Filter snooping instead of the regular DNS lookup to resolve static blacklist domain names in the following circumstances:

- The ASA DNS server is unavailable.
- A connection is initiated during the 1 minute waiting period before the ASA sends the regular DNS request.

If DNS snooping is used, when an infected host sends a DNS request for a name on the static database, the ASA looks inside the DNS packets for the domain name and associated IP address and adds the name and IP address to the DNS reverse lookup cache.

If you do not enable Botnet Traffic Filter snooping, and one of the above circumstances occurs, then that traffic will not be monitored by the Botnet Traffic Filter.

Note This command requires ASA use of a DNS server; see the **dns domain-lookup** and **dns server-group** commands.

Examples

The following example creates entries for the blacklist and whitelist:

```
hostname(config)# dynamic-filter blacklist
hostname(config-llist)# name bad1.example.com
hostname(config-llist)# name bad2.example.com
hostname(config-llist)# address 10.1.1.1 255.255.255.0

hostname(config-llist)# dynamic-filter whitelist
hostname(config-llist)# name good.example.com
hostname(config-llist)# name great.example.com
hostname(config-llist)# name awesome.example.com
hostname(config-llist)# address 10.1.1.2 255.255.255.255
```

clear dynamic-filter statistics	Clears Botnet Traffic filter statistics.
dns domain-lookup	Enables the ASA to send DNS requests to a DNS server to perform a name lookup for supported commands.
dns server-group	Identifies a DNS server for the ASA.
dynamic-filter ambiguous-is-black	Treats greylisted traffic as blacklisted traffic for action purposes.
dynamic-filter blacklist	Edits the Botnet Traffic Filter blacklist.
dynamic-filter database fetch	Manually retrieves the Botnet Traffic Filter dynamic database.
dynamic-filter database find	Searches the dynamic database for a domain name or IP address.
dynamic-filter database purge	Manually deletes the Botnet Traffic Filter dynamic database.
dynamic-filter drop blacklist	Automatically drops blacklisted traffic.
dynamic-filter enable	Enables the Botnet Traffic Filter for a class of traffic or for all traffic if you do not specify an access list.
dynamic-filter updater-client enable	Enables downloading of the dynamic database.
dynamic-filter use-database	Enables use of the dynamic database.
inspect dns dynamic-filter-snoop	Enables DNS inspection with Botnet Traffic Filter snooping.
name	Adds a name to the blacklist or whitelist.
show asp table dynamic-filter	Shows the Botnet Traffic Filter rules that are installed in the accelerated security path.

Command	Description
show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
show dynamic-filter dns-snoop	Shows the Botnet Traffic Filter DNS snooping summary, or with the **detail** keyword, the actual IP addresses and names.
show dynamic-filter reports	Generates reports of the top 10 botnet sites, ports, and infected hosts.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

CHAPTER 20

eigrp log-neighbor-changes through export webvpn webcontent Commands

eigrp log-neighbor-changes

To enable the logging of EIGRP neighbor adjacency changes, use the **eigrp log-neighbor-changes** command in router configuration mode. To turn off this function, use the **no** form of this command.

eigrp log-neighbor-changes

no eigrp log-neighbor-changes

Syntax Description

This command has no arguments or keywords.

Defaults

This command is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The **eigrp log-neighbor-changes** command is enabled by default; only the **no** form of the command appears in the running configuration.

Examples

The following example disables the logging of EIGRP neighbor changes:

```
hostname(config)# router eigrp 100
hostname(config-router)# no eigrp log-neighbor-changes
```

Related Commands

Command	Description
eigrp log-neighbor-warnings	Enables logging of neighbor warning messages.
router eigrp	Enters router configuration mode for the EIGRP routing process.
show running-config router	Displays the commands in the global router configuration.

eigrp log-neighbor-warnings

To enable the logging of EIGRP neighbor warning messages, use the **eigrp log-neighbor-warnings** command in router configuration mode. To turn off this function, use the **no** form of this command.

eigrp log-neighbor-warnings [*seconds*]

no eigrp log-neighbor-warnings

Syntax Description

seconds	(Optional) The time interval (in seconds) between repeated neighbor warning messages. Valid values are from 1 to 65535. Repeated warnings are not logged if they occur during this interval.

Defaults

This command is enabled by default. All neighbor warning messages are logged.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The **eigrp log-neighbor-warnings** command is enabled by default; only the **no** form of the command appears in the running configuration.

Examples

The following example disables the logging of EIGRP neighbor warning messages:

```
hostname(config)# router eigrp 100
hostname(config-router)# no eigrp log-neighbor-warnings
```

The following example logs EIGRP neighbor warning messages and repeats the warning messages in 5-minute (300 seconds) intervals:

```
hostname(config)# router eigrp 100
hostname(config-router)# eigrp log-neighbor-warnings 300
```

Related Commands

Command	Description
eigrp log-neighbor-messages	Enables the logging of changes in EIGRP neighbor adjacencies.
router eigrp	Enters router configuration mode for the EIGRP routing process.
show running-config router	Displays the commands in the global router configuration.

eigrp router-id

To specify router ID used by the EIGRP routing process, use the **eigrp router-id** command in router configuration mode. To restore the default value, use the **no** form of this command.

eigrp router-id *ip-addr*

no eigrp router-id [*ip-addr*]

Syntax Description

ip-addr	Router ID in IP address (dotted-decimal) format. You cannot use 0.0.0.0 or 255.255.255.255 as the router ID.

Defaults

If not specified, the highest-level IP address on the ASA is used as the router ID.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

If the **eigrp router-id** command is not configured, EIGRP automatically selects the highest IP address on the ASA to use as the router ID when an EIGRP process is started. The router ID is not changed unless the EIGRP process is removed using the **no router eigrp** command or unless the router ID is manually configured with the **eigrp router-id** command.

The router ID is used to identify the originating router for external routes. If an external route is received with the local router ID, the route is discarded. To prevent this, use the **eigrp router-id** command to specify a global address for the router ID.

A unique value should be configured for each EIGRP router.

Examples

The following example configures 172.16.1.3 as a fixed router ID for the EIGRP routing process:

```
hostname(config)# router eigrp 100
hostname(config-router)# eigrp router-id 172.16.1.3
```

Related Commands

Command	Description
router eigrp	Enters router configuration mode for the EIGRP routing process.
show running-config router	Displays the commands in the global router configuration.

eigrp stub

To configure the EIGRP routing process as a stub routing process, use the **eigrp stub** command in router configuration mode. To remove EIGRP stub routing, use the **no** form of this command.

eigrp stub [**receive-only**] | {[**connected**] [**redistributed**] [**static**] [**summary**]}

no eigrp stub [**receive-only**] | {[**connected**] [**redistributed**] [**static**] [**summary**]}

Syntax Description

connected	(Optional) Advertises connected routes.
receive-only	(Optional) Sets the ASA as a received-only neighbor.
redistributed	(Optional) Advertises routes redistributed from other routing protocols.
static	(Optional) Advertises static routes.
summary	(Optional) Advertises summary routes.

Defaults

Stub routing is not enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

Use the **eigrp stub** command to configure the ASA as a stub where the ASA directs all IP traffic to a distribution router.

Using the **receive-only** keyword restricts the ASA from sharing any of its routes with any other router in the autonomous system; the ASA only receives updates from the EIGRP neighbor. You cannot use any other keyword with the **receive-only** keyword.

You can specify one or more of the **connected**, **static**, **summary**, and **redistributed** keywords. If any of these keywords is used with the **eigrp stub** command, only the route types specified by the particular keyword are sent.

The **connected** keyword permits the EIGRP stub routing process to send connected routes. If the connected routes are not covered by a **network** statement, it may be necessary to redistribute connected routes with the **redistribute** command under the EIGRP process.

The **static** keyword permits the EIGRP stub routing process to send static routes. Without the configuration of this option, EIGRP will not send any static routes, including internal static routes that normally would be automatically redistributed. You must still redistribute static routes using the **redistribute static** command.

The **summary** keyword permits the EIGRP stub routing process to send summary routes. You can create summary routes manually with the **summary-address eigrp** command or automatically with the **auto-summary** command enabled (this command is enabled by default).

The **redistributed** keyword permits the EIGRP stub routing process to send routes redistributed into the EIGRP routing process from other routing protocols. If you do you configure this option, EIGRP does not advertise redistributed routes.

Examples

The following example uses the **eigrp stub** command to configure the ASA as an EIGRP stub that advertises connected and summary routes:

```
hostname(config)# router eigrp 100
hostname(config-router)# network 10.0.0.0
hostname(config-router)# eigrp stub connected summary
```

The following example uses the **eigrp stub** command to configure the ASA as an EIGRP stub that advertises connected and static routes. Sending summary routes is not permitted.

```
hostname(config)# router eigrp 100
hostname(config-router)# network 10.0.0.0
hostname(config-router)# eigrp stub connected static
```

The following example uses the **eigrp stub** command to configure the ASA as an EIGRP stub that only receives EIGRP updates. Connected, summary, and static route information is not sent.

```
hostname(config)# router eigrp 100
hostname(config-router)# network 10.0.0.0 eigrp
hostname(config-router)# eigrp stub receive-only
```

The following example uses the **eigrp stub** command to configure the ASA as an EIGRP stub that advertises routes redistributed into EIGRP from other routing protocols:

```
hostname(config)# router eigrp 100
hostname(config-router)# network 10.0.0.0
hostname(config-router)# eigrp stub redistributed
```

The following example uses the **eigrp stub** command without any of the optional arguments. When used without arugments, the **eigrp stub** commands advertises connected and static routes by default.

```
hostname(config)# router eigrp 100
hostname(config-router)# network 10.0.0.0
hostname(config-router)# eigrp stub
```

Related Commands

Command	Description
router eigrp	Clears the EIGRP router configuration mode commands from the running configuration.
show running-config router eigrp	Displays the EIGRP router configuration mode commands in the running configuration.

eject

To support the removal of an ASA external compact flash device, use the **eject** command in user EXEC mode.

eject [**/noconfirm**] *disk1:*

Syntax Description

disk1:	Specifies the device to eject.
/noconfirm	Specifies that you do not need to confirm device removal before physically removing the external flash device from the ASA.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC	•	•	•	•	•

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The **eject** command allows you to safely remove a compact flash device from an ASA 5500 series.

The following example shows how to use the **eject** command to shut down *disk1* gracefully before the device is physically removed from the ASA:

```
hostname# eject /noconfig disk1:
It is now safe to remove disk1:
hostname# show version
Cisco Adaptive Security Appliance Software Version 8.0(2)34

Compiled on Fri 18-May-07 10:28 by juser System image file is "disk0:/cdisk.asa"
Config file at boot was "startup-config"

wef5520 up 5 hours 36 mins

Hardware:   ASA5520, 512 MB RAM, CPU Pentium 4 Celeron 2000 MHz
Internal ATA Compact Flash, 256MB
Slot 1: Compact Flash has been ejected!
It may be removed and a new device installed.
BIOS Flash M50FW016 @ 0xffe00000, 2048KB
<---More--->
```

Related Commands

Command	Description
show version	Displays information about the operating system software.

email

To include the indicated e-mail address in the Subject Alternative Name extension of the certificate during enrollment, use the **email** command in crypto ca-trustpoint configuration mode. To restore the default setting, use the **no** form of this command.

email *address*

no email

Syntax Description

address	Specifies the e-mail address. The maximum length is 64 characters.

Defaults

The default setting is not set.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca-trustpoint configuration	•	•	•		

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example enters crypto ca-trustpoint configuration mode for the trustpoint central, and includes the e-mail address user1@user.net in the enrollment request for the trustpoint central:

```
hostname(config)# crypto ca-trustpoint central
hostname(ca-trustpoint)# email user1@user.net
hostname(ca-trustpoint)#
```

Related Commands

Command	Description
crypto ca-trustpoint	Enters crypto ca-trustpoint configuration mode.

enable

To enter privileged EXEC mode, use the **enable** command in user EXEC mode.

enable [*level*]

Syntax Description

level	(Optional) The privilege level between 0 and 15. Not used with enable authentication (the **aaa authentication enable console** command).

Defaults

Enters privilege level 15 unless you are using enable authentication (using the **aaa authentication enable console** command), in which case the default level depends on the level configured for your username.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The default enable password is blank. See the **enable password** command to set the password.

Without enable authentication, when you enter the **enable** command, your username changes to enable_*level*, where the default level is 15. With enable authentication (using the **aaa authentication enable console** command), the username and associated level are preserved. Preserving the username is important for command authorization (the **aaa authorization command** command, using either local or TACACS+).

Levels 2 and above enter privileged EXEC mode. Levels 0 and 1 enter user EXEC mode. To use levels in between, enable local command authorization (the **aaa authorization command LOCAL** command) and set the commands to different privilege levels using the **privilege** command. TACACS+ command authorization does not use the privilege levels configured on the ASA.

See the **show curpriv** command to view your current privilege level.

Enter the **disable** command to exit privileged EXEC mode.

Examples

The following example enters privileged EXEC mode:

```
hostname> enable
Password: Pa$$w0rd
hostname#
```

The following example enters privileged EXEC mode for level 10:

```
hostname> enable 10
Password: Pa$$w0rd10
hostname#
```

Related Commands

Command	Description
enable password	Sets the enable password.
disable	Exits privileged EXEC mode.
aaa authorization command	Configures command authorization.
privilege	Sets the command privilege levels for local command authorization.
show curpriv	Shows the currently logged in username and the user privilege level.

enable (webvpn)

To enable WebVPN or e-mail proxy access on a previously configured interface, use the **enable** command. For WebVPN, use this command in webvpn configuration mode. For e-mail proxies (IMAP4S. POP3S, and SMTPS), use this command in the applicable e-mail proxy configuration mode. To disable WebVPN on an interface, use the **no** form of the command.

enable *ifname*

no enable

Syntax Description

ifname	Identifies the previously configured interface. Use the **nameif** command to configure interfaces.

Defaults

WebVPN is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Imap4s configuration	•	—	•	—	—
Pop3s configuration	•	—	•	—	—
Smtps configuration	•	—	•	—	—
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to enable WebVPN on the interface named Outside:

```
hostname(config)# webvpn
hostname(config-webvpn)# enable Outside
```

The following example shows how to configure POP3S e-mail proxy on the interface named Outside:

```
hostname(config)# pop3s
hostname(config-pop3s)# enable Outside
```

enable (cluster group)

To enable clustering, use the **enable** command in cluster group configuration mode. To disable clustering, use the **no** form of this command.

enable [**as-slave** | **noconfirm**]

no enable

Syntax Description

as-slave	(Optional) Enables clustering without checking the running configuration for incompatible commands and ensures that the slave joins the cluster with no possibility of becoming the master in any current election. Its configuration is overwritten with the one synced from the master unit.
noconfirm	(Optional) When you enter the **enable** command, the ASA scans the running configuration for incompatible commands for features that are not supported with clustering, including commands that may be present in the default configuration. You are prompted to delete the incompatible commands. If you respond **No**, then clustering is not enabled. Use the **noconfirm** keyword to bypass the confirmation and delete incompatible commands automatically.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Cluster group configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

For the first unit enabled, a master unit election occurs. Because the first unit should be the only member of the cluster so far, it will become the master unit. Do not perform any configuration changes during this period.

If you already have a master unit, and are adding slave units to the cluster, you can avoid any configuration incompatibilities (primarily the existence of any interfaces not yet configured for clustering) by using the **enable as-slave** command.

To disable clustering, enter the **no enable** command.

Note If you disable clustering, all data interfaces are shut down, and only the management interface is active. If you want to remove the unit from the cluster entirely (and thus want to have active data interfaces), you need to remove the entire cluster group configuration.

Examples

The following example enables clustering and removes incopatible configuration:

```
hostname(config)# cluster group cluster1
hostname(cfg-cluster)# enable
INFO: Clustering is not compatible with following commands:
policy-map global_policy
 class inspection_default
 inspect skinny
policy-map global_policy
 class inspection_default
  inspect sip
 Would you like to remove these commands? [Y]es/[N]o:Y

INFO: Removing incompatible commands from running configuration...
Cryptochecksum (changed): f16b7fc2 a742727e e40bc0b0 cd169999
INFO: Done
```

Related Commands

Command	Description
clacp system-mac	When using spanned EtherChannels, the ASA uses cLACP to negotiate the EtherChannel with the neighbor switch.
cluster group	Names the cluster and enters cluster configuration mode.
cluster-interface	Specifies the cluster control link interface.
cluster interface-mode	Sets the cluster interface mode.
conn-rebalance	Enables connection rebalancing.
console-replicate	Enables console replication from slave units to the master unit.
health-check	Enables the cluster health check feature, which includes unit health monitoring and interface health monitoring.
key	Sets an authentication key for control traffic on the cluster control link.
local-unit	Names the cluster member.
mtu cluster-interface	Specifies the maximum transmission unit for the cluster control link interface.
priority (cluster group)	Sets the priority of this unit for master unit elections.

enable gprs

To enable GPRS with RADIUS accounting, use the **enable gprs** command in radius-accounting parameter configuration mode. To disable this command, use the **no** form of this command.

enable gprs

no enable gprs

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Radius-accounting parameter configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command is accessed by using the **inspect radius-accounting** command. The ASA checks for the 3GPP VSA 26-10415 in the Accounting-Request Stop messages to correctly handle secondary PDP contexts. This option is disabled by default. A GTP license is required to enable this feature.

Examples

The following example shows how to enable GPRS with RADIUS accounting:

```
hostname(config)# policy-map type inspect radius-accounting ra
hostname(config-pmap)# parameters
hostname(config-pmap-p)# enable gprs
```

Related Commands

Commands	Description
inspect radius-accounting	Sets inspection for RADIUS accounting.
parameters	Sets parameters for an inspection policy map.

enable password

To set the enable password for privileged EXEC mode, use the **enable password** command in global configuration mode. To remove the password for a level other than 15, use the **no** form of this command.

enable password *password* [**level** *level*] [**encrypted**]

no enable password level *level*

Syntax Description

encrypted	(Optional) Specifies that the password is in encrypted form. The password is saved in the configuration in encrypted form, so you cannot view the original password after you enter it. If for some reason you need to copy the password to another ASA but do not know the original password, you can enter the **enable password** command with the encrypted password and this keyword. Normally, you only see this keyword when you enter the **show running-config enable** command.
level *level*	(Optional) Sets a password for a privilege level between 0 and 15.
password	Sets the password as a case-sensitive string of 3 to 32 alphanumeric and special characters. You can use any character in the password except a question mark or a space.

Defaults

The default password is blank. The default level is 15.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The default password for enable level 15 (the default level) is blank. To reset the password to be blank, do not enter any text for the *password* argument.You cannot remove the level 15 password.

For multiple context mode, you can create an enable password for the system configuration as well as for each context.

To use privilege levels other than the default of 15, configure local command authorization (see the **aaa authorization command** command and specify the **LOCAL** keyword), and set the commands to different privilege levels using the **privilege** command. If you do not configure local command authorization, the enable levels are ignored, and you have access to level 15 regardless of the level you set. See the **show curpriv** command to view your current privilege level.

Levels 2 and above enter privileged EXEC mode. Levels 0 and 1 enter user EXEC mode.

Examples

The following example sets the enable password to Pa$$w0rd:

```
hostname(config)# enable password Pa$$w0rd
```

The following example sets the enable password to Pa$$w0rd10 for level 10:

```
hostname(config)# enable password Pa$$w0rd10 level 10
```

The following example sets the enable password to an encrypted password that you copied from another ASA:

```
hostname(config)# enable password jMorNbK0514fadBh encrypted
```

Related Commands

Command	Description
aaa authorization command	Configures command authorization.
enable	Enters privileged EXEC mode.
privilege	Sets the command privilege levels for local command authorization.
show curpriv	Shows the currently logged in username and the user privilege level.
show running-config enable	Shows the enable passwords in encrypted form.

encryption

To specify the encryption algorithm in an IKEv2 security association (SA) for AnyConnect IPsec connections, use the **encryption** command in ikev2 policy configuration mode. To remove the command and use the default setting, use the **no** form of this command:

encryption [**des** | **3des** | **aes** | **aes-192** | **aes-256** | **aes-gcm** | **aes-gcm-192** | **aes-gcm-256** | **null**]

no encryption [**des** | **3des** | **aes** | **aes-192** | **aes-256** | **aes-gcm** | **aes-gcm-192** | **aes-gcm-256** | **null**]

Syntax Description

des	Specifies 56-bit DES-CBC encryption for ESP.
3des	(Default) Specifies the triple DES encryption algorithm for ESP.
aes	Specifies AES with a 128-bit key encryption for ESP.
aes-192	Specifies AES with a 192-bit key encryption for ESP.
aes-256	Specifies AES with a 256-bit key encryption for ESP.
aes-gcm	Specifies AES-GCM algorithm for IKEv2 encryption.
aes-gcm-192	Specifies AES-GCM algorithm for IKEv2 encryption.
aes-gcm-256	Specifies AES-GCM algorithm for IKEv2 encryption.
null	Choose null integrity algorithm if AES-GCM/GMAC is configured as the encryption algorithm.

Defaults

The default is 3DES.

Usage Guidelines

An IKEv2 SA is a key used in Phase 1 to enable IKEv2 peers to communicate securely in Phase 2. After entering the **crypto ikev2 policy** command, you can use the **encryption** command to set the SA encryption algorithm.

When OSPFv3 encryption is enabled on an interface, a delay may occur when you establish adjacencies while the IPsec tunnel is configured. Use the **show crypto sockets**, **show ipsec policy**, and **show ipsec sa** commands to determine the underlying IPsec tunnel status and to confirm that processing is occurring.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ikev2-policy configuration	•	—	•	—	—

Command History

Release	Modification
8.4(1)	This command was added.
9.0(1)	Added the AES-GCM algorithm to use for IKEv2 encryption.

Examples

The following example enters ikev2-policy configuration mode and sets the encryption to AES-256:

```
hostname(config)# crypto ikev2 policy 1
hostname(config-ikev2-policy)# encryption aes-256
```

Related Commands

Command	Description
group	Specifies the Diffie-Hellman group in an IKEv2 SA for AnyConnect IPsec connections.
integrity	Specifies the ESP integrity algorithm in an IKEv2 SA for AnyConnect IPsec connections.
prf	Specifies the pseudo-random function in an IKEv2 SA for AnyConnect IPsec connections.
lifetime	Specifies the SA lifetime for the IKEv2 SA for AnyConnect IPsec connections.

endpoint

To add an endpoint to an HSI group for H.323 protocol inspection, use the **endpoint** command in hsi group configuration mode. To disable this feature, use the **no** form of this command.

endpoint *ip_address if_name*

no endpoint *ip_address if_name*

Syntax Description

if_name	The interface through which the endpoint is connected to the ASA.
ip_address	The IP address of the endpoint to add. A maximum of ten endpoints per HSI group is allowed.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Hsi-group configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to add endpoints to an HSI group in an H.323 inspection policy map:

```
hostname(config-pmap-p)# hsi-group 10
hostname(config-h225-map-hsi-grp)# endpoint 10.3.6.1 inside
hostname(config-h225-map-hsi-grp)# endpoint 10.10.25.5 outside
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
hsi-group	Creates an HSI group.
hsi	Adds an HSI to the HSI group.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

endpoint-mapper

To configure endpoint mapper options for DCERPC inspection, use the **endpoint-mapper** command in parameters configuration mode. To disable this feature, use the **no** form of this command.

endpoint-mapper [**epm-service-only**] [**lookup-operation** [**timeout** *value*]]

no endpoint-mapper [**epm-service-only**] [**lookup-operation** [**timeout** *value*]]

Syntax Description

epm-service-only	Specifies to enforce endoint mapper service during binding.
lookup-operation	Specifies to enable lookup operation of the endpoint mapper service.
timeout *value*	Specifies the timeout for pinholes from the lookup operation. The range is from 0:0:1 to 1193:0:0.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to configure the endpoint mapper in a DCERPC policy map:

```
hostname(config)# policy-map type inspect dcerpc dcerpc_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# endpoint-mapper epm-service-only
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

enforcenextupdate

To specify how to handle the NextUpdate CRL field, use the **enforcenextupdate** command in ca-crl configuration mode. To permit a lapsed or missing NextUpdate field, use the **no** form of this command.

enforcenextupdate

no enforcenextupdate

Syntax Description

This command has no arguments or keywords.

Defaults

The default setting is enforced (on).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca-crl configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If set, this command requires CRLs to have a NextUpdate field that has not yet lapsed. If not used, the ASA allows a missing or lapsed NextUpdate field in a CRL.

Examples

The following example enters crypto ca-crl configuration mode and requires CRLs to have a NextUpdate field that has not expired for the trustpoint central:

```
hostname(config)# crypto ca trustpoint central
hostname(ca-trustpoint)# crl configure
hostname(ca-crl)# enforcenextupdate
hostname(ca-crl)#
```

Related Commands

Command	Description
cache-time	Specifies a cache refresh time in minutes.
crl configure	Enters ca-crl configuration mode.
crypto ca trustpoint	Enters crypto ca-trustpoint configuration mode.

enrollment-retrieval

To specify the time in hours that an enrolled user can retrieve a PKCS12 enrollment file, use the **enrollment-retrieval** command in local crypto ca-server configuration mode. To reset the time to the default number of hours (24), use the **no** form of this command.

enrollment-retrieval *timeout*

no enrollment-retrieval

Syntax Description

timeout	Specifies the number of hours users have to retrieve an issued certificate from the local CA enrollment web page. Valid timeout values range from 1 to 720 hours.

Defaults

By default, the PKCS12 enrollment file is stored and retrievable for 24 hours.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca-server configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

A PKCS12 enrollment file contains an issued certificate and key pair. The file is stored on the local CA server and is available for retrieval from the enrollment web page for the time period specified with the **enrollment-retrieval** command.

When a user is marked as allowed to enroll, that user has the amount of time to enroll with that password specified in the **otp expiration** command. Once the user enrolls successfully, a PKCS12 file is generated, stored, and a copy is returned through the enrollment web page. The user can return for another copy of the file for any reason (such as when a download fails while trying enrollment) for the command time period specified in the **enrollment-retrieval** command.

Note This time is independent from the OTP expiration period.

Examples

The following example specifies that a PKCS12 enrollment file is available for retrieval from the local CA server for 48 hours after the certificate is issued:

```
hostname(config)# crypto ca server
```

```
hostname(config-ca-server)# enrollment-retrieval 48
hostname(config-ca-server)#
```

The following example resets the retrieval time back to the default of 24 hours:

```
hostname(config)# crypto ca server
hostname(config-ca-server)# no enrollment-retrieval
hostname(config-ca-server)#
```

Related Commands

Command	Description
crypto ca server	Provides access to ca-server configuration mode commands, which allow you to configure and manage the local CA.
OTP expiration	Specifies the duration in hours that an issued one-time password for the CA enrollment page is valid.
smtp from-address	Specifies the e-mail address to use in the E-mail From: field for all e-mails generated by the CA server.
smtp subject	Specifies the text appearing in the subject field of all e-mails generated by the local CA server.
subject-name-default	Specifies a generic subject-name DN to be used along with the username in all user certificates issued by a CA server.

enrollment retry count

To specify a retry count, use the **enrollment retry count** command in crypto ca-trustpoint configuration mode. To restore the default setting of the retry count, use the **no** form of the command.

enrollment retry count *number*

no enrollment retry count

Syntax Description

number	The maximum number of attempts to send an enrollment request. The valid values are 0, and 1-100 retries.

Defaults

The default setting for the *number* argument is 0 (unlimited).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca-trustpoint configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

After requesting a certificate, the ASA waits to receive a certificate from the CA. If the ASA does not receive a certificate within the configured retry period, it sends another certificate request. The ASA repeats the request until either it receives a response or reaches the end of the configured retry period. This command is optional and applies only when automatic enrollment is configured.

Examples

The following example enters crypto ca-trustpoint configuration mode for the trustpoint central, and configures an enrollment retry count of 20 retries within the trustpoint central:

```
hostname(config)# crypto ca trustpoint central
hostname(ca-trustpoint)# enrollment retry count 20
hostname(ca-trustpoint)#
```

Related Commands

Command	Description
crypto ca trustpoint	Enters crypto ca-trustpoint configuration mode.

Command	Description
default enrollment	Returns enrollment parameters to their defaults.
enrollment retry period	Specifies the number of minutes to wait before resending an enrollment request.

enrollment retry period

To specify a retry period, use the **enrollment retry period** command in crypto ca trustpoint configuration mode. To restore the default setting of the retry period, use the **no** form of the command.

enrollment retry period *minutes*

no enrollment retry period

Syntax Description

minutes	The number of minutes between attempts to send an enrollment request. The valid range is 1- 60 minutes.

Defaults

The default setting is 1 minute.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca-trustpoint configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

After requesting a certificate, the ASA waits to receive a certificate from the CA. If the ASA does not receive a certificate within the specified retry period, it sends another certificate request. This command is optional and applies only when automatic enrollment is configured.

Examples

The following example enters crypto ca-trustpoint configuration mode for the trustpoint central, and configures an enrollment retry period of 10 minutes within the trustpoint central:

```
hostname(config)# crypto ca trustpoint central
hostname(ca-trustpoint)# enrollment retry period 10
hostname(ca-trustpoint)#
```

Related Commands

Command	Description
crypto ca trustpoint	Enters crypto ca-trustpoint configuration mode.
default enrollment	Returns all enrollment parameters to their system default values.
enrollment retry count	Defines the number of retries to requesting an enrollment.

enrollment terminal

To specify cut and paste enrollment with this trustpoint (also known as manual enrollment), use the **enrollment terminal** command in crypto ca-trustpoint configuration mode. To restore the default setting of the command, use the **no** form of the command.

enrollment terminal

no enrollment terminal

Syntax Description

This command has no arguments or keywords.

Defaults

The default setting is off.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca-trustpoint configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example enters crypto ca-trustpoint configuration mode forthe trustpoint central, and specifies the cut-and-paste method of CA enrollment for the trustpoint central:

```
hostname(config)# crypto ca trustpoint central
hostname(ca-trustpoint)# enrollment terminal
hostname(ca-trustpoint)#
```

Related Commands

Command	Description
crypto ca trustpoint	Enters crypto ca-trustpoint configuration mode.
default enrollment	Returns enrollment parameters to their defaults.
enrollment retry count	Specifies the number of retries to attempt to send an enrollment request.
enrollment retry period	Specifies the number of minutes to wait before resending an enrollment request.
enrollment url	Specifies automatic enrollment (SCEP) with this trustpoint and configures the URL.

enrollment url

To specify automatic enrollment (SCEP) to enroll with this trustpoint and to configure the enrollment URL, use the **enrollment url** command in crypto ca-trustpoint configuration mode. To restore the default setting of the command, use the **no** form of the command.

enrollment url *url*

no enrollment url

Syntax Description

url	Specifies the name of the URL for automatic enrollment. The maximum length is 1K characters (effectively unbounded).

Defaults

The default setting is off.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca-trustpoint configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example enters crypto ca-trustpoint configuration mode for the trustpoint central, and specifies SCEP enrollment at the URL https://enrollsite for trustpoint central:

```
hostname(config)# crypto ca trustpoint central
hostname(ca-trustpoint)# enrollment url https://enrollsite
hostname(ca-trustpoint)#
```

Related Commands

Command	Description
crypto ca trustpoint	Enters crypto ca-trustpoint configuration mode.
default enrollment	Returns enrollment parameters to their defaults.
enrollment retry count	Specifies the number of retries to attempt to send an enrollment request.
enrollment retry period	Specifies the number of minutes to wait before resending an enrollment request.
enrollment terminal	Specifies cut-and-paste enrollment with this trustpoint.

enrollment-retrieval

To specify the time in hours that an enrolled user can retrieve a PKCS12 enrollment file, use the **enrollment-retrieval** command in local ca-server configuration mode. To reset the time to the default number of hours (24), use the **no** form of this command.

enrollment-retrieval *timeout*

no enrollment-retrieval

Syntax Description

timeout	Specifies the number of hours users have to retrieve an issued certificate from the local CA enrollment web page. Valid timeout values range from 1 to 720 hours.

Defaults

By default, the PKCS12 enrollment file is stored and retrievable for 24 hours.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca-server configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

A PKCS12 enrollment file contains an issued certificate and key pair. The file is stored on the local CA server and is available for retrieval from the enrollment web page for the time period specified with the **enrollment-retrieval** command.

When a user is marked as allowed to enroll, that user has the amount of time to enroll with that password specified by the **otp expiration** command. Once the user enrolls successfully, a PKCS12 file is generated, stored, and a copy is returned through the enrollment web page. The user can return for another copy of the file for any reason (such as when a download fails while trying enrollment) for the time period specified in the **enrollment-retrieval** command.

Note This time is independent from the OTP expiration period.

Examples

The following example specifies that a PKCS12 enrollment file is available for retrieval from the local CA server for 48 hours after the certificate is issued:

```
hostname(config)# crypto ca server
```

```
hostname(config-ca-server)# enrollment-retrieval 48
hostname(config-ca-server)#
```

The following example resets the retrieval time back to the default of 24 hours:

```
hostname(config)# crypto ca server
hostname(config-ca-server)# no enrollment-retrieval
hostname(config-ca-server)#
```

Related Commands

Command	Description
crypto ca server	Provides access to ca-server configuration mode commands, which allow you to configure and manage the local CA.
OTP expiration	Specifies the duration in hours that an issued one-time password for the CA enrollment page is valid.
smtp from-address	Specifies the e-mail address to use in the E-mail From: field for all e-mails generated by the CA server.
smtp subject	Specifies the text appearing in the subject field of all e-mails generated by the local CA server.
subject-name-default	Specifies a generic subject-name DN to be used along with the username in all user certificates issued by a CA server.

eool

To define an action when the End of Options List (EOOL) option occurs in a packet with IP Options inspection, use the **eool** command in parameters configuration mode. To disable this feature, use the **no** form of this command.

eool action {allow | clear}

no eool action {allow | clear}

Syntax Description

allow	Instructs the ASA to allow a packet containing the End of Options List IP option to pass.
clear	Instructs the ASA to clear the End of Options List IP option from a packet and then allow the packet to pass.

Defaults

By default, IP Options inspection, drops packets containing the End of Options List IP option.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
8.2(2)	This command was introduced.

Usage Guidelines

This command can be configured in an IP Options inspection policy map.

You can configure IP Options inspection to control which IP packets with specific IP options are allowed through the ASA. Configuring this inspection instructs the ASA to allow a packet to pass or to clear the specified IP options and then allow the packet to pass.

The End of Options List option, which contains just a single zero byte, appears at the end of all options to mark the end of a list of options. This might not coincide with the end of the header according to the header length.

Examples

The following example shows how to set up an action for IP Options inspection in a policy map:

```
hostname(config)# policy-map type inspect ip-options ip-options_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# eool action allow
hostname(config-pmap-p)# nop action allow
hostname(config-pmap-p)# router-alert action allow
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

eou allow

To enable clientless authentication in a NAC Framework configuration, use the **eou allow** command in global configuration mode. To remove the command from the configuration, use the **no** form of this command.

eou allow {**audit** | **clientless** | **none**}

no eou allow {**audit** | **clientless** | **none**}

Syntax Description

audit	Performs clientless authentication.
clientless	Performs clientless authentication.
none	Disables clientless authentication.

Defaults

The default configuration contains the **eou allow clientless** configuration.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.
8.0(2)	Added the **audit** option.

Usage Guidelines

The ASA uses this command only if both of the following are true:

- The group policy is configured to use a NAC Framework NAC policy type.
- A host on the session does not respond to EAPoUDP requests.

Examples

The following example enables the use of an ACS to perform clientless authentication:

```
hostname(config)# eou allow clientless
hostname(config)#
```

The following example shows how to configure the ASA to use an audit server to perform clientless authentication:

```
hostname(config)# eou allow audit
hostname(config)#
```

The following example shows how to disable the use of an audit server:

```
hostname(config)# no eou allow clientless
hostname(config)#
```

Related Commands

Command	Description
debug eou	Enables logging of EAP over UDP events to debug NAC Framework messaging.
eou clientless	Changes the username and password to be sent to the ACS for clientless authentication in a NAC Framework configuration.
show vpn-session.db	Displays information about VPN sessions, including NAC results.

eou clientless

To change the username and password to be sent to the Access Control Server for clientless authentication in a NAC Framework configuration, use the **eou clientless** command in global configuration mode. To use the default value, use the **no** form of this command.

eou clientless username *username* **password** *password*

no eou clientless username *username* **password** *password*

Syntax Description

password	Enter to change the password sent to the Access Control Server to obtain clientless authentication for a remote host that does not respond to EAPoUDP requests.
password	Enter the password configured on the Access Control Server to support clientless hosts. Enter 4-32 ASCII characters.
username	Enter to change the username sent to the Access Control Server to obtain clientless authentication for a remote host that does not respond to EAPoUDP requests.
username	Enter the username configured on the Access Control Server to support clientless hosts. Enter 1-64 ASCII characters, excluding leading and trailing spaces, pound signs (#), question marks (?), quotation marks ("), asterisks (*), and angle brackets (< and >).

Defaults

The default value for both the username and password attributes is clientless.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command is effective only if all of the following are true:

- An Access Control Server is configured on the network to support clientless authentication.
- Clientless authentication is enabled on the ASA.
- NAC is configured on the ASA.

This command applies only to the Framework implementation of Cisco NAC.

Examples

The following example changes the username for clientless authentication to sherlock:

```
hostname(config)# eou clientless username sherlock
```

```
hostname(config)#
```

The following example changes the username for clientless authentication to the default value, clientless:

```
hostname(config)# no eou clientless username
hostname(config)#
```

The following example changes the password for clientless authentication to secret:

```
hostname(config)# eou clientless password secret
hostname(config)#
```

The following example changes the password for clientless authentication to the default value, clientless:

```
hostname(config)# no eou clientless password
hostname(config)#
```

Related Commands

Command	Description
eou allow	Enables clientless authentication in a NAC Framework configuration.
debug eou	Enables logging of EAP over UDP events to debug NAC Framework messaging.
debug nac	Enables logging of NAC Framework events.

eou initialize

To clear the resources assigned to one or more NAC Framework sessions and initiate a new, unconditional posture validation for each of the sessions, use the **eou initialize** command in privileged EXEC mode.

eou initialize {**all** | **group** *tunnel-group* | **ip** *ip-address*}

Syntax Description

all	Revalidates all NAC Framework sessions on this ASA
group	Revalidates all NAC Framework sessions assigned to a tunnel group.
ip	Revalidates a single NAC Framework session.
ip-address	IP address of the remote peer end of the tunnel.
tunnel-group	Name of the tunnel group used to negotiate parameters to set up the tunnel.

Defaults

No default behavior or values.

Command Modes

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Use this command if a change occurs in the posture of the remote peers or if the assigned access policies (that is, the downloaded ACLs) change, and you want to clear the resources assigned to the sessions. Entering this command purges the EAPoUDP associations and access policies used for posture validation. The NAC default ACL is effective during the revalidations, so the session initializations can disrupt user traffic. This command does not affect peers that are exempt from posture validation.

This command applies only to the Framework implementation of Cisco NAC.

Examples

The following example initializes all NAC Framework sessions:

```
hostname# eou initialize all
hostname
```

The following example initializes all NAC Framework sessions assigned to the tunnel group named tg1:

```
hostname# eou initialize group tg1
hostname
```

The following example initializes the NAC Framework session for the endpoint with the IP address 209.165. 200.225:

```
hostname# eou initialize 209.165.200.225
hostname
```

Related Commands

Command	Description
eou revalidate	Forces immediate posture revalidation of one or more NAC Framework sessions.
reval-period	Specifies the interval between each successful posture validation in a NAC Framework session.
sq-period	Specifies the interval between each successful posture validation in a NAC Framework session and the next query for changes in the host posture.
show vpn-session.db	Displays information about VPN sessions, including NAC results.
debug nac	Enables logging of NAC Framework events.

eou max-retry

To change the number of times the ASA resends an EAP over UDP message to the remote computer, use the **eou max-retry** command in global configuration mode. To use the default value, use the **no** form of this command.

eou max-retry *retries*

no eou max-retry

Syntax Description

retries	Limits the number of consecutive retries sent in response to retransmission timer expirations. Enter a value in the range of 1 to 3.

Defaults

The default value is 3.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command is effective only if all of the following are true:

- An Access Control Server is configured on the network to support clientless authentication.
- Clientless authentication is enabled on the ASA.
- NAC is configured on the ASA.

This command applies only to the Framework implementation of Cisco NAC.

Examples

The following example limits the number of EAP over UDP retransmissions to 1:

```
hostname(config)# eou max-retry 1
hostname(config)#
```

The following example changes the number of EAP over UDP retransmissions to its default value, 3:

```
hostname(config)# no eou max-retry
hostname(config)#
```

Related Commands

eou timeout	Changes the number of seconds to wait after sending an EAP over UDP message to the remote host in a NAC Framework configuration.
sq-period	Specifies the interval between each successful posture validation in a NAC Framework session and the next query for changes in the host posture.
debug eou	Enables logging of EAP over UDP events to debug NAC Framework messaging.
debug nac	Enables logging of NAC Framework events.
show vpn-session.db	Displays information about VPN sessions, including NAC results.

eou port

To change the port number for EAP over UDP communication with the Cisco Trust Agent in a NAC Framework configuration, use the **eou port** command in global configuration mode. To use the default value, use the **no** form of this command.

eou port *port_number*

no eou port

Syntax Description

port_number	Port number on the client endpoint to be designated for EAP over UDP communications. This number is the port number configured on the Cisco Trust Agent. Enter a value in the range of 1024 to 65535.

Defaults

The default value is 21862.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command applies only to the Framework implementation of Cisco NAC.

Examples

The following example changes the port number for EAP over UDP communication to 62445:

```
hostname(config)# eou port 62445
hostname(config)#
```

The following example changes the port number for EAP over UDP communication to its default value:

```
hostname(config)# no eou port
hostname(config)#
```

Related Commands

debug eou	Enables logging of EAP over UDP events to debug NAC Framework messaging.
eou initialize	Clears the resources assigned to one or more NAC Framework sessions and initiates a new, unconditional posture validation for each of the sessions.
eou revalidate	Forces immediate posture revalidation of one or more NAC Framework sessions.
show vpn-session.db	Displays information about VPN sessions, including VLAN mapping and NAC results.
show vpn-session_summary.db	Displays the number IPsec, Cisco AnyConnect, and NAC sessions, including VLAN mapping session data.

eou revalidate

To force immediate posture revalidation of one or more NAC Framework sessions, use the **eou revalidate** command in privileged EXEC mode.

eou revalidate {**all** | **group** *tunnel-group* | **ip** *ip-address*}

Syntax Description

all	Revalidates all NAC Framework sessions on this ASA
group	Revalidates all NAC Framework sessions assigned to a tunnel group.
ip	Revalidates a single NAC Framework session.
ip-address	IP address of the remote peer end of the tunnel.
tunnel-group	Name of the tunnel group used to negotiate parameters to set up the tunnel.

Defaults

No default behavior or values.

Command Modes

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Use this command if the posture of the peer or the assigned access policy (that is, the downloaded ACL, if any) has changed. The command initiates a new, unconditional posture validation. The posture validation and assigned access policy that were in effect before you entered the command remain in effect until the new posture validation succeeds or fails. This command does not affect peers that are exempt from posture validation.

This command applies only to the Framework implementation of Cisco NAC.

Examples

The following example revalidates all NAC Framework sessions:

```
hostname# eou revalidate all
hostname
```

The following example revalidates all NAC Framework sessions assigned to the tunnel group named tg-1:

```
hostname# eou revalidate group tg-1
hostname
```

The following example revalidates the NAC Framework session for the endpoint with the IP address 209.165. 200.225:

```
hostname# eou revalidate ip 209.165.200.225
hostname
```

Related Commands

Command	Description
debug eou	Enables logging of EAP over UDP events to debug NAC Framework messaging.
eou initialize	Clears the resources assigned to one or more NAC Framework sessions and initiates a new, unconditional posture validation for each of the sessions.
eou timeout	Changes the number of seconds to wait after sending an EAP over UDP message to the remote host in a NAC Framework configuration.
reval-period	Specifies the interval between each successful posture validation in a NAC Framework session.
sq-period	Specifies the interval between each successful posture validation in a NAC Framework session and the next query for changes in the host posture.

eou timeout

To change the number of seconds to wait after sending an EAP over UDP message to the remote host in a NAC Framework configuration, use the **eou timeout** command in global configuration mode. To use the default value, use the **no** form of this command.

eou timeout {**hold-period** | **retransmit**} *seconds*

no eou timeout {**hold-period** | **retransmit**}

Syntax Description

hold-period	Maximum time to wait after sending EAPoUDP messages equal to the number of EAPoUDP retries. The **eou initialize** or **eou revalidate** command also clears this timer. If this timer expires, the ASA initiates a new EAP over UDP association with the remote host.
retransmit	Maximum time to wait after sending an EAPoUDP message. A response from the remote host clears this timer. The **eou initialize** or **eou revalidate** command also clears this timer. If the timer expires, the ASA retransmits the EAPoUDP message to the remote host.
seconds	Number of seconds for the ASA to wait. Enter a value in the range of 60 to 86400 for the hold-period attribute, or the range of 1 to 60 for the retransmit attribute.

Defaults

The default value of the **hold-period** option is 180.

The default value of the **retransmit** option is 3.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command applies only to the Framework implementation of Cisco NAC.

Examples

The following example changes the wait period before initiating a new EAP over UDP association to 120 seconds:

```
hostname(config)# eou timeout hold-period 120
hostname(config)#
```

The following example changes the wait period before initiating a new EAP over UDP association to its default value:

```
hostname(config)# no eou timeout hold-period
hostname(config)#
```

The following example changes the retransmission timer to 6 seconds:

```
hostname(config)# eou timeout retransmit 6
hostname(config)#
```

The following example changes the retransmission timer to its default value:

```
hostname(config)# no eou timeout retransmit
hostname(config)#
```

Related Commands

Command	Description
debug eou	Enables logging of EAP over UDP events to debug NAC Framework messaging.
eou max-retry	Changes the number of times the ASA resends an EAP over UDP message to the remote computer.

erase

To erase and reformat the file system, use the **erase** command in privileged EXEC mode. This command overwrites all files and erases the file system, including hidden system files, then reinstalls the file system.

erase [**disk0: | disk1: | flash:**]

Syntax Description

disk0:	(Optional) Specifies the f, followed by a colon.
disk1:	(Optional) Specifies the external, compact Flash memory card, followed by a colon.
flash:	(Optional) Specifies the internal Flash memory, followed by a colon. **Caution** Erasing the flash memory also removes the licensing information, which is stored in flash memory. Save the licensing information before erasing the flash memory. On the ASA 5500 series, the **flash** keyword is aliased to **disk0:**.

Defaults

No default beahviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **erase** command erases all data in the flash memory using the OxFF pattern and then rewrites an empty file system allocation table to the device.

To delete all visible files (excluding hidden system files), enter the **delete /recursive** command, instead of the **erase** command.

Note On the Cisco ASA 5500 series, the **erase** command destroys all user data on the disk with the 0xFF pattern. In contrast, the **format** command only resets the file system control structures. If you used a raw disk read tool, you could still see the information.

Examples

The following example erases and reformats the file system:

```
hostname# erase flash:
```

Related Commands

Command	Description
delete	Removes all visible files, excluding hidden system files.
format	Erases all files (including hidden system files) and formats the file system.

esp

To specify parameters for ESP and AH tunnels for IPsec Pass-Through inspection, use the **esp** command in parameters configuration mode. To disable this feature, use the **no** form of this command.

{**esp** | **ah**} [**per-client-max** *num*] [**timeout** *time*]

no {**esp** | **ah**} [**per-client-max** *num*] [**timeout** *time*]

Syntax Description

esp	Specifies parameters for the ESP tunnel.
ah	Specifies parameters for the AH tunnel.
per-client-max *num*	Specifies the maximum number of tunnels from one client.
timeout *time*	Specifies the idle timeout for the ESP tunnel.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to permit UDP 500 traffic:

```
hostname(config)# access-list test-udp-acl extended permit udp any any eq 500
hostname(config)# class-map test-udp-class
hostname(config-pmap-c)# match access-list test-udp-acl

hostname(config)# policy-map type inspect ipsec-pass-thru ipsec-map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# esp per-client-max 32 timeout 00:06:00
hostname(config-pmap-p)# ah per-client-max 16 timeout 00:05:00

hostname(config)# policy-map test-udp-policy
hostname(config-pmap)# class test-udp-class
hostname(config-pmap-c)# inspect ipsec-pass-thru ipsec-map
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

established

To permit return connections on ports that are based on an established connection, use the **established** command in global configuration mode. To disable the **established** feature, use the **no** form of this command.

established *est_protocol dest_port* [*source_port*] [**permitto** *protocol port* [*-port*]] [**permitfrom** *protocol port*[*-port*]]

no established *est_protocol dest_port* [*source_port*] [**permitto** *protocol port* [*-port*]] [**permitfrom** *protocol port*[*-port*]]

Syntax Description

est_protocol	Specifies the IP protocol (UDP or TCP) to use for the established connection lookup.
dest_port	Specifies the destination port to use for the established connection lookup.
permitfrom	(Optional) Allows the return protocol connection(s) originating from the specified port.
permitto	(Optional) Allows the return protocol connections destined to the specified port.
port [*-port*]	(Optional) Specifies the (UDP or TCP) destination port(s) of the return connection.
protocol	(Optional) IP protocol (UDP or TCP) used by the return connection.
source_port	(Optional) Specifies the source port to use for the established connection lookup.

Defaults

The defaults are as follows:

- *dest_port*—0 (wildcard)
- *source_port*—0 (wildcard)

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	The keywords **to** and **from** were removed from the CLI. Use the keywords **permitto** and **permitfrom** instead.

Usage Guidelines

The **established** command lets you permit return access for outbound connections through the ASA. This command works with an original connection that is outbound from a network and protected by the ASA and a return connection that is inbound between the same two devices on an external host. The **established** command lets you specify the destination port that is used for connection lookups. This

addition allows more control over the command and provides support for protocols where the destination port is known, but the source port is unknown. The **permitto** and **permitfrom** keywords define the return inbound connection.

Caution We recommend that you always specify the **established** command with the **permitto** and **permitfrom** keywords. Using the **established** command without these keywords is a security risk because when connections are made to external systems, those system can make unrestricted connections to the internal host involved in the connection. This situation can be exploited for an attack of your internal systems.

Examples

The following set of examples shows potential security violations could occur if you do not use the **established** command correctly.

This example shows that if an internal system makes a TCP connection to an external host on port 4000, then the external host could come back in on any port using any protocol:

```
hostname(config)# established tcp 4000 0
```

You can specify the source and destination ports as **0** if the protocol does not specify which ports are used. Use wildcard ports (0) only when necessary.

```
hostname(config)# established tcp 0 0
```

Note To allow the **established** command to work correctly, the client must listen on the port that is specified with the **permitto** keyword.

You can use the **established** command with the **nat 0** command (where there are no **global** commands).

Note You cannot use the **established** command with PAT.

The ASA supports XDMCP with assistance from the **established** command.

Caution Using XWindows system applications through the ASA may cause security risks.

XDMCP is on by default, but it does not complete the session unless you enter the **established** command as follows:

```
hostname(config)# established tcp 6000 0 permitto tcp 6000 permitfrom tcp 1024-65535
```

Entering the **established** command enables the internal XDMCP-equipped (UNIX or ReflectionX) hosts to access external XDMCP-equipped XWindows servers. UDP/177-based XDMCP negotiates a TCP-based XWindows session, and subsequent TCP back connections are permitted. Because the source port(s) of the return traffic is unknown, specify the *source_port* field as 0 (wildcard). The *dest_port* should be 6000 + *n*, where *n* represents the local display number. Use this UNIX command to change this value:

```
hostname(config)# setenv DISPLAY hostname:displaynumber.screennumber
```

The **established** command is needed because many TCP connections are generated (based on user interaction) and the source port for these connections is unknown. Only the destination port is static. The ASA performs XDMCP fixups transparently. No configuration is required, but you must enter the **established** command to accommodate the TCP session.

The following example shows a connection between two hosts using protocol A destined for port B from source port C. To permit return connections through the ASA and protocol D (protocol D can be different from protocol A), the source port(s) must correspond to port F and the destination port(s) must correspond to port E.

```
hostname(config)# established A B C permitto D E permitfrom D F
```

The following example shows how a connection is started by an internal host to an external host using TCP destination port 6060 and any source port. The ASA permits return traffic between the hosts through TCP destination port 6061 and any TCP source port.

```
hostname(config)# established tcp 6060 0 permitto tcp 6061 permitfrom tcp 0
```

The following example shows how a connection is started by an internal host to an external host using UDP destination port 6060 and any source port. The ASA permits return traffic between the hosts through TCP destination port 6061 and TCP source port 1024-65535.

```
hostname(config)# established udp 6060 0 permitto tcp 6061 permitfrom tcp 1024-65535
```

The following example shows how a local host starts a TCP connection on port 9999 to a foreign host. The example allows packets from the foreign host on port 4242 back to local host on port 5454.

```
hostname(config)# established tcp 9999 permitto tcp 5454 permitfrom tcp 4242
```

Related Commands

Command	Description
clear configure established	Removes all established commands.
show running-config established	Displays the allowed inbound connections that are based on established connections.

exceed-mss

To allow or drop packets whose data length exceeds the TCP maximum segment size (MSS) set by the peer during a three-way handshake, use the **exceed-mss** command in tcp-map configuration mode. To remove this specification, use the **no** form of this command.

exceed-mss {**allow** | **drop**}

no exceed-mss {**allow** | **drop**}

Syntax Description

allow	Allows packets that exceed the MSS. This setting is the default.
drop	Drops packets that exceed the MSS.

Defaults

Packets are allowed by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tcp-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(4)/8.0(4)	The default was changed from **drop** to **allow**.

Usage Guidelines

The **tcp-map** command is used along with the Modular Policy Framework infrastructure. Define the class of traffic using the **class-map** command and customize the TCP inspection with **tcp-map** commands. Apply the new TCP map using the **policy-map** command. Activate TCP inspection with **service-policy** commands.

Use the **tcp-map** command to enter tcp-map configuration mode. Use the **exceed-mss** command in tcp-map configuration mode to drop TCP packets whose data length exceed the TCP maximum segment size set by the peer during a three-way handshake.

Examples

The following example drops flows on port 21 if they are in excess of MSS:

```
hostname(config)# tcp-map tmap
hostname(config-tcp-map)# exceed-mss drop
hostname(config)# class-map cmap
hostname(config-cmap)# match port tcp eq ftp
hostname(config)# policy-map pmap
hostname(config-pmap)# class cmap
```

```
hostname(config-pmap)# set connection advanced-options tmap
hostname(config)# service-policy pmap global
```

Related Commands

Command	Description
class	Specifies a class map to use for traffic classification.
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
set connection advanced-options	Configures advanced connection features, including TCP normalization.
tcp-map	Creates a TCP map and allows access to tcp-map configuration mode.

exempt-list

To add an entry to the list of remote computer types that are exempt from posture validation, use the **exempt-list** command in nac-policy-nac-framework configuration mode. To remove an entry from the exemption list, use the **no** form of this command and name the operating system and ACL in the entry to be removed.

exempt-list os "*os-name*" [**disable | filter** *acl-name* [**disable**]]

no exempt-list os "*os-name*" [**disable | filter** *acl-name* [**disable**]]

Syntax Description

acl-name	Name of the ACL present in the ASA configuration. When specified, it must follow the **filter** keyword.
disable	Performs one of two functions, as follows: • If you enter it after the "os-name," the ASA ignores the exemption, and applies NAC posture validation to the remote hosts that are running that operating system. • If you enter it after the *acl-name*, ASA exempts the operating system, but does not assign the ACL to the associated traffic.
filter	Applies an ACL to filter the traffic if the computer's operating system matches the *os name*. The **filter**/*acl-name* pair is optional.
os	Exempts an operating system from posture validation.
os name	Operating system name. Quotation marks are required only if the name includes a space (for example, "Windows XP").

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Nac-policy-nac-framework configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.
8.0(2)	Command name changed from **vpn-nac-exempt** to **exempt-list**. Command moved from group-policy configuration mode to nac-policy-nac-framework configuration mode.

Usage Guidelines

When the command specifies an operating system, it does not overwrite the previously added entry to the exception list; enter the command once for each operating system and ACL that you want to exempt.

The **no exempt-list** command removes all exemptions from the NAC Framework policy. Specifying an entry when issuing the **no** form of the command removes the entry from the exemption list.

To remove all entries from the exemption list associated with this NAC policy, use the **no** form of this command without specifying additional keywords.

Examples

The following example adds all hosts running Windows XP to the list of computers that are exempt from posture validation:

```
hostname(config-group-policy)# exempt-list os "Windows XP"
hostname(config-group-policy)
```

The following example exempts all hosts running Windows XP and applies the ACL acl-1 to traffic from those hosts:

```
hostname(config-nac-policy-nac-framework)# exempt-list os "Windows XP" filter acl-1
hostname(config-nac-policy-nac-framework)
```

The following example removes the same entry from the exemption list:

```
hostname(config-nac-policy-nac-framework)# no exempt-list os "Windows XP" filter acl-1
hostname(config-nac-policy-nac-framework)
```

The following example removes all entries from the exemption list:

```
hostname(config-nac-policy-nac-framework)# no exempt-list
hostname(config-nac-policy-nac-framework)
```

Related Commands

Command	Description
debug nac	Enables logging of NAC Framework events.
nac-policy	Creates and accesses a Cisco NAC policy, and specifies its type.
nac-settings	Assigns a NAC policy to a group policy.
show vpn-session.db	Displays information about VPN sessions, including NAC results.
show vpn-session_summary.db	Displays the number of IPsec, Cisco AnyConnect, and NAC sessions.

exit

To exit the current configuration mode, or to logout from privileged or user EXEC modes, use the **exit** command.

exit

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can also use the key sequence **Ctrl+Z** to exit global configuration (and higher) modes. This key sequence does not work with privileged or user EXEC modes.

When you enter the **exit** command in privileged or user EXEC modes, you log out from the ASA. Use the **disable** command to return to user EXEC mode from privileged EXEC mode.

Examples

The following example shows how to use the **exit** command to exit global configuration mode, then log out from the session:

```
hostname(config)# exit
hostname# exit

Logoff
```

The following example shows how to use the **exit** command to exit global configuration mode, then use the **disable** command to exit privileged EXEC mode:

```
hostname(config)# exit
hostname# disable
hostname#
```

Related Commands

Command	Description
quit	Exits a configuration mode or logs out of the privileged or user EXEC modes.

expiry-time

To configure an expiration time for caching objects without revalidating them, use the **expiry-time** command in cache configuration mode. To remove the expiration time from the configuration and reset it to the default value, use the **no** form of this command.

expiry-time *time*

no expiry-time

Syntax Description

time	The amount of time in minutes that the ASA caches objects without revalidating them.

Defaults

The default is 1 minute.

Command Modes

The following table shows the modes in which you enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Cache configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The expiration time is the amount of time in minutes that the ASA caches an object without revalidating it. Revalidation consists of rechecking the content.

Examples

The following example shows how to set an expiration time with a value of 13 minutes:

```
hostname(config)# webvpn
hostname(config-webvpn)# cache
hostname(config-webvpn-cache)#expiry-time 13
hostname(config-webvpn-cache)#
```

Related Commands

Command	Description
cache	Enters webvpn cache configuration mode.
cache-compressed	Configures WebVPN cache compression.
disable	Disables caching.

Command	Description
lmfactor	Sets a revalidation policy for caching objects that have only the last-modified timestamp.
max-object-size	Defines the maximum size of an object to cache.
min-object-size	Defines the minimum sizze of an object to cache.

export

To specify the certificate to be exported to the client, use the **export** command in ctl-provider configuration mode. To remove the configuration, use the **no** form of this command.

export certificate *trustpoint_name*

no export certificate [*trustpoint_name*]

Syntax Description

certificate *trustpoint_name*	Specifies the certificate to be exported to the client.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ctl-provider configuration	•	•	•		—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use the **export** command in ctl-provider configuration mode to specify the certificate to be exported to the client. The trustpoint name is defined by the **crypto ca trustpoint** command. The certificate will be added to the CTL file composed by the CTL client.

Examples

The following example shows how to create a CTL provider instance:

```
hostname(config)# ctl-provider my_ctl
hostname(config-ctl-provider)# client interface inside 172.23.45.1
hostname(config-ctl-provider)# client username CCMAdministrator password XXXXXX encrypted
hostname(config-ctl-provider)# export certificate ccm_proxy
hostname(config-ctl-provider)# ctl install
```

Related Commands

Commands	Description
ctl	Parses the CTL file from the CTL client and install trustpoints.
ctl-provider	Configures a CTL provider instance in ctl-provider configuration mode.
client	Specifies clients allowed to connect to the CTL provider and the username and password for client authentication.

Commands	Description
service	Specifies the port to which the CTL provider listens.
tls-proxy	Defines a TLS proxy instance and sets the maximum sessions.

export webvpn AnyConnect-customization

To export a customization object that customizes the AnyConnect client GUI, use the **export webvpn AnyConnect-customization** command in privileged EXEC mode:

export webvpn AnyConnect-customization type *type* **platform** *platform* **name** *name*

Syntax Description

name	The name that identifies the customization object. The maximum number is 64 characters.
type	The type of customization: • binary—An executable that replaces the AnyConnect GUI. • transform—A transform that customizes the MSI.
url	Remote path and filename to export the XML customization object, in the form *URL/filename* (the maximum number is 255 characters).

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

An AnyConnect customization object is an XML file that resides in cache memory, and customizes the GUI screens for AnyConnect client users. When you export a customization object, an XML file containing XML tags is created at the URL you specify.

The XML file created by the customization object named *Template* contains empty XML tags, and provides the basis for creating new customization objects. This object cannot be changed or deleted from cache memory, but can be exported, edited, and imported back into the ASA as a new customization object.

The content of *Template* is the same as the initial DfltCustomization object state.

For a complete list of resource files used the AnyConnect GUI and their filenames, see the *AnyConnect VPN Client Administrator Guide*.

Examples

The following example exports the Cisco logo used on the AnyConnect GUI:

```
hostname# export webvpn AnyConnect-customization type resource company_logo.bmp
tftp://209.165.200.225/dflt_custom
!!!!!!!!!!!!!!!!INFO: Customization object 'DfltCustomization' was exported to
tftp://10.86.240.197/dflt_custom
hostname#
```

Related Commands

Command	Description
import webvpn customization	Imports an XML file to cache memory as a customization object .
revert webvpn customization	Removes a customization object from cache memory.
show import webvpn customization	Displays information about customization objects resident in cache memory.

export webvpn customization

To export a customization object that customizes screens visible to Clientless SSL VPN users, use the **export webvpn customization** command in privileged EXEC mode.

export webvpn customization *name url*

Syntax Description

name	The name that identifies the customization object. The maximum number is 64 characters.
url	Remote path and filename to export the XML customization object, in the form *URL/filename* (the maximum number is 255 characters).

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

A customization object is an XML file that resides in cache memory, and customizes the screens visible to Clientless SSL VPN users, including login and logout screens, the portal page, and available languages. When you export a customization object, an XML file containing XML tags is created at the URL that you specify.

The XML file created by the customization object named *Template* contains empty XML tags, and provides the basis for creating new customization objects. This object cannot be changed or deleted from cache memory, but can be exported, edited, and imported back into the ASA as a new customization object.

The content of *Template* is the same as the initial DfltCustomization object state.

You can export a customization object using the **export webvpn customization** command, make changes to the XML tags, and import the file as a new object using the **import webvpn customization** command.

Examples

The following example exports the default customization object (DfltCustomization) and creates the resulting XML file named dflt_custom:

```
hostname# export webvpn customization DfltCustomization tftp://209.165.200.225/dflt_custom
```

```
!!!!!!!!!!!!!!!!INFO: Customization object 'DfltCustomization' was exported to
tftp://10.86.240.197/dflt_custom
hostname#
```

Related Commands

Command	Description
import webvpn customization	Imports an XML file to cache memory as a customization object .
revert webvpn customization	Removes a customization object from cache memory.
show import webvpn customization	Displays information about customization objects resident in cache memory.

export webvpn plug-in

To export a plug-in from the flash device of the ASA, enter the **export webvpn plug-in** command in privileged EXEC mode.

import webvpn plug-in protocol *protocol URL*

Syntax Description

protocol	• **rdp** The Remote Desktop Protocol plug-in lets the remote user connect to a computer running Microsoft Terminal Services. Cisco redistributes this plug-in without any changes. The web site containing the original is http://properjavardp.sourceforge.net/. • **ssh,telnet** The Secure Shell plug-in lets the remote user establish a secure channel to a remote computer, or lets the remote user use Telnet to connect to a remote computer. Cisco redistributes this plug-in without any changes. The web site containing the original is http://javassh.org/. **Caution** The **export webvpn plug-in protocol ssh,telnet** *URL* command exports *both* the SSH and Telnet plug-ins. Do *not* enter this command once for SSH and once for Telnet. When typing the **ssh,telnet** string, do *not* insert a space. • **vnc** The Virtual Network Computing plug-in lets the remote user use a monitor, keyboard, and mouse to view and control a computer with remote desktop sharing turned on. Cisco redistributes this plug-in without any changes. The web site containing the original is http://www.tightvnc.com/.
URL	Path to the remote device.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Exporting a plug-in does not remove it from flash. Exporting creates a copy of the plug-in at the specified URL.

Examples

The following command exports the RDP plugin:

```
hostname# export webvpn plug-in protocol rdp tftp://209.165.201.22/plugins/rdp-plugin.jar
```

Related Commands

Command	Description
import webvpn plugin	Imports a specified plug-in from a local device to the ASA flash.
revert webvpn plug-in protocol	Removes the specified plug-in from the flash device of the ASA.
show import webvpn plug-in	Lists the plug-ins present on the flash device of the ASA.

export webvpn mst-translation

To export a Microsoft transform (MST) that translates the AnyConnect installer program, use the **export webvpn mst-translation** command in privileged EXEC mode:

export webvpn mst-translation *component* **language** *language URL*

Syntax Description

component	The component to which this MST applies. The only valid choice is AnyConnect.
language	The language code of the MST exported. Use the code in the same format that the browser requires.
URL	The remote path and filename to export the transform to, in the form *URL/filename* (the maximum number is 255 characters).

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

As with the AnyConnect client GUI, you can translate messages displayed by the client installer program. The ASA uses transforms to translate the messages displayed by the installer. The transform alters the installation, but leaves the original security-signed MSI intact. These transforms only translate the installer screens and do not translate the client GUI screens.

Each language has its own transform. You can edit a transform with a transform editor such as Orca, and make changes to the message strings. Then you import the transform to the ASA. When the user downloads the client, the client detects the preferred language of the computer (the locale specified during installation of the operating system) and applies the appropriate transform.

We currently offer transforms for 30 languages. These transforms are available in the following .zip file on the AnyConnect client software download page at cisco.com:

anyconnect-win-<VERSION>-web-deploy-k9-lang.zip

In this file, <VERSION> is the version of AnyConnect release (for exmaple, 2.2.103).

Examples

The following example exports the English language transform as AnyConnect_Installer_English:

```
hostname# export webvpn mst-translation AnyConnect language es
tftp://209.165.200.225/AnyConnect_Installer_English
```

Related Commands

Command	Description
import webvpn customization	Imports an XML file to cache memory as a customization object .
revert webvpn customization	Removes a customization object from cache memory.
show import webvpn customization	Displays information about customization objects resident in cache memory.

export webvpn translation-table

To export a translation table used to translate terms displayed to remote users establishing SSL VPN connections, use the **export webvpn translation-table** command in privileged EXEC mode.

export webvpn translation-table *translation_domain* {**language** *language* | **template**} *url*

Syntax Description

language	Specifies the name of a previously imported translation table. Enter the value in the manner expressed by your browser language options.
translation_domain	The functional area and associated messages. Table 20-1 lists available translation domains.
url	Specifies the URL of the object.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
rivileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The ASA provides language translation for the portal and screens displayed to users that initiate browser-based, clientless SSL VPN connections, as well as the user interface displayed to AnyConnect VPN Client users.

Each functional area and its messages that are visible to remote users has its own translation domain, which are specified by the *translation_domain* argument. Table 20-1 shows the translation domains and the functional areas translated.

Table 20-1 Translation Domains and Functional Areas Affected

Translation Domain	Functional Areas Translated
AnyConnect	Messages displayed on the user interface of the Cisco AnyConnect VPN Client.
banners	Banners displayed to remote users and messages when VPN access is denied.
CSD	Messages for the Cisco Secure Desktop (CSD).

Translation Domain	Functional Areas Translated
customization	Messages on the login and logout pages, portal page, and all the messages customizable by the user.
plugin-ica	Messages for the Citrix plug-in.
plugin-rdp	Messages for the Remote Desktop Protocol plug-in.
plugin-telnet,ssh	Messages for the Telnet and SSH plug-in.
plugin-vnc	Messages for the VNC plug-in.
PortForwarder	Messages displayed to Port Forwarding users.
url-list	Text that user specifies for URL bookmarks on the portal page.
webvpn	All the layer 7, AAA, and portal messages that are not customizable.

A translation template is an XML file in the same format as the translation table, but has all the translations empty. The software image package for the ASA includes a template for each domain that is part of the standard functionality. Templates for plug-ins are included with the plug-ins and define their own translation domains. Because you can customize the login and logout pages, portal page, and URL bookmarks for clientless users, the ASA generates the customization and url-list translation domain templates dynamically, and the template automatically reflects your changes to these functional areas.

Exporting a previously-imported translation table creates an XML file of the table at the URL location. You can view a list of available templates and previously-imported tables using the **show import webvpn translation-table** command.

Download a template or translation table using the **export webvpn translation-table** command, make changes to the messages, and import the translation table using the **import webvpn translation-table** command.

Examples

The following example exports a template for the translation domain *customization*, which is used to translate the login and logout pages, portal page, and all the messages customizable and visible to remote users establishing clientless SSL VPN connections. The ASA creates the XML file with the name *Sales*:

```
hostname# export webvpn translation-table customization template
tftp://209.165.200.225/Sales
hostname# !!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
```

The following example exports a previously imported translation table for the Chinese language named *zh*, an abbreviation compatible with the abbreviation specified for Chinese in the Internet Options of the Microsoft Internet Explorer browser. The ASA creates the XML file with the name *Chinese*:

```
hostname# export webvpn translation-table customization language zh
tftp://209.165.200.225/Chinese
hostname# !!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
```

Related Commands

Command	Description
import webvpn translation-table	Imports a translation table.

revert	Removes translation tables from cache memory.
show import webvpn translation-table	Displays information about imported translation tables.

export webvpn url-list

To export a URL list to a remote location, use the **export webvpn url-list** command in privileged EXEC mode.

export webvpn url-list *name url*

Syntax Description

name	The name that identifies the URL list. The maximum inumber is 64 characters.
url	The remote path to the source of the URL list. The maximum number is 255 characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•		—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

No URL lists are present in WebVPN by default.

An object, Template, is available for downloading with the **export webvpn url-list** command. The Template object cannot be changed or deleted. The contents of the Template object can be edited and saved as a custom URL list, and imported with the **import webvpn url-list** command to add a custom URL list.

Exporting a previously imported URL list creates an XML file of the list at the URL location. You can view a list of available templates and previously imported tables using the **show import webvpn url-list** command.

Examples

The following example exports a URL list, *servers*:

```
hostname# export webvpn url-list servers2 tftp://209.165.200.225
hostname#
```

Related Commands

Command	Description
import webvpn url-list	Imports a URL list.
revert webvpn url-list	Removes URL lists from cache memory.
show import webvpn url-list	Displays information about imported URL lists.

export webvpn webcontent

To export previously imported content in flash memory that is visible to remote Clientless SSL VPN users, use the **export webvpn webcontent** command in privileged EXEC mode.

export webvpn webcontent *source url destination url*

Syntax Description

destination url	The URL to export to. The maximum number is 255 characters.
source url	The URL in the ASA flash memory in which the content resides. The maximum number is 64 characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•		—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Content exported with the **webcontent** option is content visible to remote clientless users. This includes previously imported help content visible on the clientless portal and logos used by customization objects.

You can see a list of content available for export by entering a question mark (**?**) after the **export webvpn webcontent** command. For example:

```
hostname# export webvpn webcontent ?

Select webcontent to export:
  /+CSCOE+/help/en/app-access-hlp.inc
  /+CSCOU+/cisco_logo.gif
```

Examples

The following example exports the file *logo.gif*, using TFTP, to 209.165.200.225, as the filename *logo_copy.gif*:

```
hostname# export webvpn webcontent /+CSCOU+/logo.gif tftp://209.165.200.225/logo_copy.gif
!!!!* Web resource `/+CSCOU+/logo.gif' was successfully initialized
```

Related Commands

Command	Description
import webvpn webcontent	Imports content visible to Clientless SSL VPN users.
revert webvpn webcontent	Removes content from flash memory.
show import webvpn webcontent	Displays information about imported content.

failover through fallback Commands

failover

To enable failover, use the **failover** command in global configuration mode. To disable failover, use the **no** form of this command.

failover

no failover

Syntax Description

This command has no arguments or keywords.

Defaults

Failover is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was limited to enable or disable failover in the configuration (see the **failover active** command).

Usage Guidelines

Use the **no** form of this command to disable failover.

Caution All information sent over the failover and Stateful Failover links is sent in clear text unless you secure the communication with a failover key. If the ASA is used to terminate VPN tunnels, this information includes any usernames, passwords and preshared keys used for establishing the tunnels. Transmitting this sensitive data in clear text could pose a significant security risk. We recommend securing the failover communication with a failover key if you are using the ASA to terminate VPN tunnels.

The ASA 5505 device allows only Stateless Failover, and only while not acting as an Easy VPN hardware client.

Examples

The following example disables failover:

```
hostname(config)# no failover
hostname(config)#
```

Related Commands

Command	Description
clear configure failover	Clears **failover** commands from the running configuration and restores failover default values.
failover active	Switches the standby unit to active.
show failover	Displays information about the failover status of the unit.
show running-config failover	Displays the **failover** commands in the running configuration.

failover active

To switch a standby ASA or failover group to the active state, use the **failover active** command in privileged EXEC mode. To switch an active ASA or failover group to standby, use the **no** form of this command.

failover active [**group** *group_id*]

no failover active [**group** *group_id*]

Syntax Description

group *group_id*	(Optional) Specifies the failover group to make active.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was modified to include failover groups.

Usage Guidelines

Use the **failover active** command to initiate a failover switch from the standby unit, or use the **no failover active** command from the active unit to initiate a failover switch. You can use this feature to return a failed unit to service, or to force an active unit offline for maintenance. If you are not using Stateful Failover, all active connections are dropped and must be reestablished by the clients after the failover occurs.

Switching for a failover group is available only for Active/Active failover. If you enter the **failover active** command on an Active/Active failover unit without specifying a failover group, all groups on the unit become active.

Examples

The following example switches the standby group 1 to active:

```
hostname# failover active group 1
```

Related Commands

Command	Description
failover reset	Moves an ASA from a failed state to standby.

failover exec

To execute a command on a specific unit in a failover pair, use the **failover exec** command in privileged EXEC or global configuration mode.

failover exec {**active** | **standby** | **mate**} *cmd_string*

Syntax Description

active	Specifies that the command is executed on the active unit or failover group in the failover pair. Configuration commands entered on the active unit or failover group are replicated to the standby unit or failover group.
cmd_string	The command to be executed. **Show**, configuration, and EXEC commands are supported.
mate	Specifies that the command is executed on the failover peer.
standby	Specifies that the command is executed on the standby unit or failover group in the failover pair. Configuration commands executed on the standby unit or failover group are not replicated to the active unit or failover group.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

You can use the **failover exec** command to send commands to a specific unit in a failover pair.

Because configuration commands are replicated from the active unit or context to the standby unit or context, you can use the **failover exec** command to enter configuration commands on the correct unit, no matter which unit you are logged in to. For example, if you are logged in to the standby unit, you can use the **failover exec active** command to send configuration changes to the active unit. Those changes are then replicated to the standby unit. Do not use the **failover exec** command to send configuration commands to the standby unit or context; those configuration changes are not replicated to the active unit and the two configurations will no longer be synchronized.

Output from configuration, exec, and **show** commands is displayed in the current terminal session, so you can use the **failover exec** command to issue **show** commands on a peer unit and view the results in the current terminal.

You must have sufficient privileges to execute a command on the local unit to execute the command on the peer unit.

Command Modes

The **failover exec** command maintains a command mode state that is separate from the command mode of your terminal session. By default, the **failover exec** command mode is global configuration mode for the specified device. You can change that command mode by sending the appropriate command (such as the **interface** command) using the **failover exec** command.

Changing **failover exec** command modes for the specified device does not change the command mode for the session that you are using to access the device. For example, if you are logged in to the active unit of a failover pair, and you issue the following command in global configuration mode, you will remain in global configuration mode, but any commands sent using the **failover exec** command will be executed in interface configuration mode:

```
hostname(config)# failover exec interface GigabitEthernet0/1
hostname(config)#
```

Changing commands modes for your current session to the device does not affect the command mode used by the **failover exec** command. For example, if you are in interface configuration mode on the active unit, and you have not changed the **failover exec** command mode, the following command would be executed in global configuration mode:

```
hostname(config-if)# failover exec active router ospf 100
hostname(config-if)#
```

Use the **show failover exec** command to display the command mode on the specified device in which commands sent with the **failover exec** command are executed.

Security Considerations

The **failover exec** command uses the failover link to send commands to and receive the output of the command execution from the peer unit. You should use the **failover key** command to encrypt the failover link to prevent eavesdropping or man-in-the-middle attacks.

Limitations

- If you upgrade one unit using the zero-downtime upgrade procedure and not the other, both units must be running software that supports the **failover exec** command for the command to work.
- Command completion and context help are not available for the commands in the *cmd_string* argument.
- In multiple context mode, you can only send commands to the peer context on the peer unit. To send commands to a different context, you must first change to that context on the unit you are logged in to.
- You cannot use the following commands with the **failover exec** command:
  - **changeto**
  - **debug** (**undebug**)
- If the standby unit is in the failed state, it can still receive commands from the **failover exe**c command if the failure is due to a service card failure; otherwise, the remote command execution will fail.
- You cannot use the **failover exec** command to switch from privileged EXEC mode to global configuration mode on the failover peer. For example, if the current unit is in privileged EXEC mode, and you enter the **failover exec mate configure terminal** command, the **show failover exec**

mate command output will show that the failover exec session is in global configuration mode. However, entering configuration commands for the peer unit using the **failover exec** command will fail until you enter global configuration mode on the current unit.

- You cannot enter recursive **failover exec** commands, such as the **failover exec mate failover exec mate** *command.*
- Commands that require user input or confirmation must use the **/nonconfirm** option.

Examples

The following example shows how to use the **failover exec** command to display failover information on the active unit. The unit on which the command is executed is the active unit, so the command is executed locally.

```
hostname(config)# failover exec active show failover

Failover On
Failover unit Primary

        Xmit Q:         0       1       344
```

The following example uses the **failover exec** command to display the failover configuration of the failover peer. The command is executed on the primary unit, which is the active unit, so the information displayed is from the secondary, standby unit.

```
hostname(config)# failover exec mate show running-config failover

failover
failover lan interface failover GigabitEthernet0/3
failover polltime unit 1 holdtime 3
failover polltime interface 3 holdtime 15
failover link failover GigabitEthernet0/3
failover interface ip failover 10.0.5.1 255.255.255.0 standby 10.0.5.2
ciscoasa(config)#
```

The following example uses the **failover exec** command to create a context on the active unit from the standby unit. The command is replicated from the active unit back to the standby unit. Note the two "Creating context…" messages. One is from the **failover exec** command output from the peer unit when the context is created, and the other is from the local unit when the replicated command creates the context locally.

```
hostname(config)# show context

Context Name      Class      Interfaces           URL
*admin            default    GigabitEthernet0/0,  disk0:/admin.cfg
                             GigabitEthernet0/1

Total active Security Contexts: 1

! The following is executed in the system execution space on the standby unit.

hostname(config)# failover exec active context text

Creating context 'text'... Done. (2)
Creating context 'text'... Done. (3)

hostname(config)# show context
Context Name      Class      Interfaces           URL
*admin            default    GigabitEthernet0/0,  disk0:/admin.cfg
                             GigabitEthernet0/1
 text             default                         (not entered)

Total active Security Contexts: 2
```

The following example shows the warning that is returned when you use the **failover exec** command to send configuration commands to a failover peer in the standby state:

```
hostname# failover exec mate static (inside,outside) 192.168.5.241 192.168.0.241

       **** WARNING ****
        Configuration Replication is NOT performed from Standby unit to Active unit.
        Configurations are no longer synchronized.
hostname(config)#
```

The following example uses the **failover exec** command to send the **show interface** command to the standby unit:

```
hostname(config)# failover exec standby show interface

```

The following example shows the error message returned when issuing an illegal command to the peer unit:

```
hostname# failover exec mate bad command

bad command
  ^
ERROR: % Invalid input detected at '^' marker.
```

The following example shows the error message that is returned when you use the **failover exec** command when failover is disabled:

```
hostname(config)# failover exec mate show failover

ERROR: Cannot execute command on mate because failover is disabled
```

Related Commands

Command	Description
debug fover	Displays failover-related debugging messages.
debug xml	Displays debugging messages for the XML parser used by the **failover exec** command.
show failover exec	Displays the **failover exec** command mode.

failover group

To configure an Active/Active failover group, use the **failover group** command in global configuration mode. To remove a failover group, use the **no** form of this command.

failover group *num*

no failover group *num*

Syntax Description

num	Failover group number. Valid values are 1 or 2.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Global configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can define a maximum of two failover groups. The **failover group** command can only be added to the system context of devices configured for multiple context mode. You can create and remove failover groups only when failover is disabled.

Entering this command puts you in the failover group command mode. The **primary**, **secondary**, **preempt**, **replication http**, **interface-policy**, **mac address**, and **polltime interface** commands are available in the failover group configuration mode. Use the **exit** command to return to global configuration mode.

Note The **failover polltime interface**, **failover interface-policy**, **failover replication http**, and **failover mac address** commands have no affect in Active/Active failover configurations. They are overridden by the following failover group configuration mode commands: **polltime interface**, **interface-policy**, **replication http**, and **mac address**.

When removing failover groups, you must remove failover group 1 last. Failover group 1 always contains the admin context. Any context not assigned to a failover group defaults to failover group 1. You cannot remove a failover group that has contexts explicitly assigned to it.

Note If you have more than one Active/Active failover pair on the same network, it is possible to have the same default virtual MAC addresses assigned to the interfaces on one pair as are assigned to the interfaces of the other pairs because of the way the default virtual MAC addresses are determined. To avoid having duplicate MAC addresses on your network, make sure you assign each physical interface a virtual active and standby MAC address using the **mac address** command.

Examples

The following partial example shows a possible configuration for two failover groups:

```
hostname(config)# failover group 1
hostname(config-fover-group)# primary
hostname(config-fover-group)# preempt 100
hostname(config-fover-group)# exit
hostname(config)# failover group 2
hostname(config-fover-group)# secondary
hostname(config-fover-group)# preempt 100
hostname(config-fover-group)# exit
hostname(config)#
```

Related Commands

Command	Description
asr-group	Specifies an asymmetrical routing interface group ID.
interface-policy	Specifies the failover policy when monitoring detects interface failures.
join-failover-group	Assigns a context to a failover group.
mac address	Defines virtual mac addresses for the contexts within a failover group.
polltime interface	Specifies the amount of time between hello messages sent to monitored interfaces.
preempt	Specifies that a unit with a higher priority becomes the active unit after a reboot.
primary	Gives the primary unit higher priority for a failover group.
replication http	Specifies HTTP session replication for the selected failover group.
secondary	Gives the secondary unit higher priority for a failover group.

failover interface ip

To specify the IPv4 address and mask or IPv6 address and prefixfor the failover interface and the Stateful Failover interface, use the **failover interface ip** command in global configuration mode. To remove the IP address, use the **no** form of this command.

failover interface ip *if_name* [*ip_address mask* **standby** *ip_address* | *ipv6_address*/*prefix* **standby***ipv6_address*]

no failover interface ip *if_name* [*ip_address mask* **standby** *ip_address* | *ipv6_address*/*prefix* **standby***ipv6_address*]

Syntax Description

if_name	Interface name for the failover or Stateful Failover interface.
ip_address mask	Specifies the IP address and mask for the failover or Stateful Failover interface on the primary device.
ipv6_address	Specifies the IPv6 address fore the failover or Stateful Failover interface on the primary device.
prefix	Indicates how many of the high-order, contiguous bits of the address comprise the IPv6 prefix (the network portion of the IPv6 address).
standby *ip_address*	Specifies the IP address used by the secondary device to communicate with the primary device.
standby*ipv6_address*	Specifies the IPv6 address used by the secondary device to communicate with the primary device.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.
8.2(2)	IPv6 address support was added to the command.

Usage Guidelines

The standby address must be in the same subnet as the primary address.

You can only have one **failvover interface ip** command in the configuration. Therefore, your failover interface can have either an IPv6 or an IPv4 address; you cannot assign both an IPv6 and an IPv4 address to the interface.

Failover and Stateful Failover interfaces are functions of Layer 3, even when the ASA is operating in transparent firewall mode, and are global to the system.

In multiple context mode, you configure failover in the system context (except for the **monitor-interface** command).

This command must be part of the configuration when bootstrapping an ASA for LAN failover.

Examples

The following example shows how to specify an IPv4 address and mask for the failover interface:

```
hostname(config)# failover interface ip lanlink 172.27.48.1 255.255.255.0 standby
172.27.48.2
```

The following example shows how to specify an IPv6 address and prefix for the failover interface:

```
hostname(config)# failover interface ip lanlink 2001:a0a:b00::a0a:b70/64 standby
2001:a0a:b00::a0a:b71
```

Related Commands

Command	Description
clear configure failover	Clears **failover** commands from the running configuration and restores failover default values.
failover lan interface	Specifies the interface used for failover communication.
failover link	Specifies the interface used for Stateful Failover.
monitor-interface	Monitors the health of the specified interface.
show running-config failover	Displays the **failover** commands in the running configuration.

failover interface-policy

To specify the policy for failover when monitoring detects an interface failure, use the **failover interface-policy** command in global configuration mode. To restore the default, use the **no** form of this command.

failover interface-policy *num*[**%**]

no failover interface-policy *num*[**%**]

Syntax Description

num	Specifies a number from 1 to 100 when used as a percentage, or 1 to the maximum number of interfaces when used as a number.
%	(Optional) Specifies that the number *num* is a percentage of the monitored interfaces.

Defaults

The defaults are as follows:

- *num* is 1.
- Monitoring of physical interfaces is enabled by default; monitoring of logical interfaces is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

There is no space between the *num* argument and the optional **%** keyword.

If the number of failed interfaces meets the configured policy and the other ASA is functioning correctly, the ASA marks itself as failed and a failover might occur (if the active ASA is the one that fails). Only interfaces that are designated as monitored by the **monitor-interface** command count towards the policy.

Note This command applies to Active/Standby failover only. In Active/Active failover, you configure the interface policy for each failover group with the **interface-policy** command in failover group configuration mode.

Examples

The following examples show two ways to specify the failover policy:

```
hostname(config)# failover interface-policy 20%

hostname(config)# failover interface-policy 5
```

Related Commands

Command	Description
failover polltime	Specifies the unit and interface poll times.
failover reset	Restores a failed unit to an unfailed state.
monitor-interface	Specifies the interfaces being monitored for failover.
show failover	Displays information about the failover state of the unit.

failover ipsec pre-shared-key

To establish IPsec LAN-to-LAN tunnels on the failover and state links between the units to encrypt all failover communications, use the **failover ipsec pre-shared-key** command in global configuration mode To remove the key, use the **no** form of this command.

failover ipsec pre-shared-key *key*

no failover ipsec pre-shared-key

Syntax Description

0	Specifies an unencrypted password. This is the default.
8	Specifies an encrypted password. If you use a master passphrase (see the **password encryption aes** and **key config-key password-encryption** commands), then the key is encrypted in the configuration. If you are copying from the configuration (for example, from **more system:running-config** output), specify that the key is encrypted by using the **8** keyword. **Note** The **failover ipsec pre-shared-key** shows as ***** in **show running-config** output; this obscured key is not copyable.
key	A *key* that you specify on both units that is used by IKEv2 to establish the tunnels, up to 128 characters in length.

Command Default

0 (unencrypted) is the default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	—	•

Command History

Release	Modification
9.1(2)	We introduced this command.

Usage Guidelines

Unless you secure the failover communications, all information sent over the failover and Stateful Failover links is sent in clear text. If the ASA is used to terminate VPN tunnels, this information includes any usernames, passwords and preshared keys used for establishing the tunnels. Transmitting this sensitive data in clear text could pose a significant security risk. We recommend securing the failover communication if you are using the ASA to terminate VPN tunnels.

We recommend using the **failover ipsec pre-shared-key** method of encryption over the legacy **failover key** method.

You cannot use both IPsec encryption and the legacy **failover key** encryption. If you configure both methods, IPsec is used. However, if you use the master passphrase (see the **password encryption aes** and **key config-key password-encryption** commands), you must first remove the failover key using the **no failover key** command before you configure IPsec encryption.

Note Failover LAN-to-LAN tunnels do not count against the IPsec (Other VPN) license.

Examples

The following example configures an IPsec pre-shared key:

```
hostname(config)# failover ipsec pre-shared-key a3rynsun
```

Related Commands

Command	Description
show running-config failover	Displays the failover commands in the running configuration.
show vpn-sessiondb	Shows information about VPN tunnels, including the failover IPsec tunnels.

failover key

To specify the key for encrypted and authenticated communication between units in a failover pair (over the failover and state links), use the **failover key** command in global configuration mode. To remove the key, use the **no** form of this command.

failover key [**0** | **8**] {**hex** *key* | *shared_secret*}

no failover key

Syntax Description

0	Specifies an unencrypted password. This is the default.
8	Specifies an encrypted password. If you use a master passphrase (see the **password encryption aes** and **key config-key password-encryption** commands), then the shared secret is encrypted in the configuration. If you are copying from the configuration (for example, from **more system:running-config** output), specify that the shared secret is encrypted by using the **8** keyword. **Note** The **failover key** shared secret shows as ***** in **show running-config** output; this obscured key is not copyable.
hex *key*	Specifies a hexadecimal value for the encryption key. The key must be 32 hexadecimal characters (0-9, a-f).
shared_secret	Specifies an alphanumeric shared secret. The secret can be from 1 to 63 characters. Valid character are any combination of numbers, letters, or punctuation. The shared secret is used to generate the encryption key.

Defaults

0 (unencrypted) is the default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was modified from **failover lan key** to **failover key**.
7.0(4)	This command was modified to include the **hex** *key* keyword and argument.
8.3(1)	This command was modified to support the master passphrase with the **0** and **8** keywords.

Usage Guidelines

Unless you secure the failover communications, all information sent over the failover and Stateful Failover links is sent in clear text. If the ASA is used to terminate VPN tunnels, this information includes any usernames, passwords and preshared keys used for establishing the tunnels. Transmitting this sensitive data in clear text could pose a significant security risk. We recommend securing the failover communication if you are using the ASA to terminate VPN tunnels.

We recommend using the **failover ipsec pre-shared-key** method of encryption over the legacy **failover key** method.

You cannot use both IPsec encryption (the **failover ipsec pre-shared-key** command) and the legacy **failover key** encryption. If you configure both methods, IPsec is used. However, if you use the master passphrase (see the **password encryption aes** and **key config-key password-encryption** commands), you must first remove the failover key using the **no failover key** command before you configure IPsec encryption.

Examples

The following example shows how to specify a shared secret for securing failover communication between units in a failover pair:

```
hostname(config)# failover key abcdefg
```

The following example shows how to specify a hexadecimal key for securing failover communication between two units in a failover pair:

```
hostname(config)# failover key hex 6a1ed228381cf5c68557cb0c32e614dc
```

The following example shows an encrypted password copied and pasted from **more system:running-config** output:

```
hostname(config)# failover key 8 TPZCVNgdegLhWMa
```

Related Commands

Command	Description
show running-config failover	Displays the failover commands in the running configuration.

failover lan interface

To specify the interface used for failover communication, use the **failover lan interface** command in global configuration mode. To remove the failover interface, use the **no** form of this command.

failover lan interface *if_name* {*phy_if*[.*sub_if*] | *vlan_if*]}

no failover lan interface [*if_name* {*phy_if*[.*sub_if*] | *vlan_if*]}]

Syntax Description

if_name	Specifies the name of the ASA interface dedicated to failover.
phy_if	Specifies the physical interface.
sub_if	(Optional) Specifies a subinterface number.
vlan_if	Used on the ASA 5505 to specify a VLAN interface as the failover link.

Defaults

Not configured.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was modified to include the *phy_if* argument.
7.2(1)	This command was modified to include the *vlan_if* argument.

Usage Guidelines

LAN failover requires a dedicated interface for passing failover traffic. However you can also use the LAN failover interface for the Stateful Failover link.

Note If you use the same interface for both LAN failover and Stateful Failover, the interface needs enough capacity to handle both the LAN-based failover and Stateful Failover traffic.

You can use any unused Ethernet interface on the device as the failover interface. You cannot specify an interface that is currently configured with a name. The failover interface is not configured as a normal networking interface; it exists only for failover communications. This interface should only be used for the failover link (and optionally for the state link). You can connect the LAN-based failover link by using a dedicated switch with no hosts or routers on the link or by using a crossover Ethernet cable to link the units directly.

Note When using VLANs, use a dedicated VLAN for the failover link. Sharing the failover link VLAN with any other VLANs can cause intermittent traffic problems and ping and ARP failures. If you use a switch to connect the failover link, use dedicated interfaces on the switch and ASA for the failover link; do not share the interface with subinterfaces carrying regular network traffic.

On systems running in multiple context mode, the failover link resides in the system context. This interface and the state link, if used, are the only interfaces that you can configure in the system context. All other interfaces are allocated to and configured from within security contexts.

Note The IP address and MAC address for the failover link do not change at failover.

The **no** form of this command also clears the failover interface IP address configuration.

This command must be part of the configuration when bootstrapping an ASA for LAN failover.

Caution All information sent over the failover and Stateful Failover links is sent in clear text unless you secure the communication with a failover key. If the ASA is used to terminate VPN tunnels, this information includes any user names, passwords and preshared keys used for establishing the tunnels. Transmitting this sensitive data in clear text could pose a significant security risk. We recommend securing the failover communication with a failover key if you are using the ASA to terminate VPN tunnels.

Examples

The following example configures the failover LAN interface using a subinterface on an ASA 5500 series (except for the ASA 5505):

```
hostname(config)# failover lan interface folink GigabitEthernet0/3.1
```

The following example configures the failover LAN interface on the ASA 5505:

```
hostname(config)# failover lan interface folink Vlan6
```

Related Commands

Command	Description
failover lan unit	Specifies the LAN-based failover primary or secondary unit.
failover link	Specifies the Stateful Failover interface.

failover lan unit

To configure the ASA as either the primary or secondary unit in a LAN failover configuration, use the **failover lan unit** command in global configuration mode. To restore the default setting, use the **no** form of this command.

failover lan unit {**primary** | **secondary**}

no failover lan unit {**primary** | **secondary**}

Syntax Description

primary	Specifies the ASA as a primary unit.
secondary	Specifies the ASA as a secondary unit.

Defaults

Secondary.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

For Active/Standby failover, the primary and secondary designation for the failover unit refers to which unit becomes active at boot time. The primary unit becomes the active unit at boot time when the following occurs:

- The primary and secondary unit both complete their boot sequence within the first failover poll check.
- The primary unit boots before the secondary unit.

If the secondary unit is already active when the primary unit boots, the primary unit does not take control; it becomes the standby unit. In this case, you need to enter the **no failover active** command on the secondary (active) unit to force the primary unit back to active status.

For Active/Active failover, each failover group is assigned a primary or secondary unit preference. This preference determines on which unit in the failover pair the contexts in the failover group become active at startup when both units start simultaneously (within the failover polling period).

This command must be part of the configuration when bootstrapping an ASA for LAN failover.

Examples

The following example sets the ASA as the primary unit in LAN-based failover:

```
hostname(config)# failover lan unit primary
```

Related Commands

Command	Description
failover lan interface	Specifies the interface used for failover communication.

failover link

To specify the Stateful Failover interface, use the **failover link** command in global configuration mode. To remove the Stateful Failover interface, use the **no** form of this command.

failover link *if_name* [*phy_if*]

no failover link

Syntax Description

if_name	Specifies the name of the ASA interface dedicated to Stateful Failover.
phy_if	(Optional) Specifies the physical or logical interface port. If the Stateful Failover interface is sharing the interface assigned for failover communication or sharing a standard firewall interface, then this argument is not required.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was modified to include the *phy_if* argument.
7.0(4)	This command was modified to accept standard firewall interfaces.

Usage Guidelines

This command is not available on the ASA 5505, which does not support Stateful Failover.

The physical or logical interface argument is required when not sharing the failover communication or a standard firewall interface.

The **failover link** command enables Stateful Failover. Enter the **no failover link** command to disable Stateful Failover. If you are using a dedicated Stateful Failover interface, the **no failover link** command also clears the Stateful Failover interface IP address configuration.

To use Stateful Failover, you must configure a Stateful Failover link to pass all state information. You have three options for configuring a Stateful Failover link:

- You can use a dedicated Ethernet interface for the Stateful Failover link.
- If you are using LAN-based failover, you can share the failover link.
- You can share a regular data interface, such as the inside interface. However, this option is not recommended.

If you are using a dedicated Ethernet interface for the Stateful Failover link, you can use either a switch or a crossover cable to directly connect the units. If you use a switch, no other hosts or routers should be on this link.

Note Enable the PortFast option on Cisco switch ports that connect directly to the ASA.

If you are using the failover link as the Stateful Failover link, you should use the fastest Ethernet interface available. If you experience performance problems on that interface, consider dedicating a separate interface for the Stateful Failover interface.

If you use a data interface as the Stateful Failover link, you will receive the following warning when you specify that interface as the Stateful Failover link:

```
******* WARNING ***** WARNING ******* WARNING ****** WARNING  *********
  Sharing Stateful failover interface with regular data interface is not
  a recommended configuration due to performance and security concerns.
******* WARNING ***** WARNING ******* WARNING ****** WARNING  *********
```

Sharing a data interface with the Stateful Failover interface can leave you vulnerable to replay attacks. Additionally, large amounts of Stateful Failover traffic may be sent on the interface, causing performance problems on that network segment.

Note Using a data interface as the Stateful Failover interface is only supported in single context, routed mode.

In multiple context mode, the Stateful Failover link resides in the system context. This interface and the failover interface are the only interfaces in the system context. All other interfaces are allocated to and configured from within security contexts.

Note The IP address and MAC address for the Stateful Failover link does not change at failover unless the Stateful Failover link is configured on a regular data interface.

Caution All information sent over the failover and Stateful Failover links is sent in clear text unless you secure the communication with a failover key. If the ASA is used to terminate VPN tunnels, this information includes any user names, passwords and preshared keys used for establishing the tunnels. Transmitting this sensitive data in clear text could pose a significant security risk. We recommend securing the failover communication with a failover key if you are using the ASA to terminate VPN tunnels.

Examples

The following example shows how to specify a dedicated interface as the Stateful Failover interface. The interface in the example does not have an existing configuration.

```
hostname(config)# failover link stateful_if e4
INFO: Non-failover interface config is cleared on Ethernet4 and its sub-interfaces
```

Related Commands

Command	Description
failover interface ip	Configures the IP address of the **failover** command and Stateful Failover interface.
failover lan interface	Specifies the interface used for failover communication.

failover mac address

To specify the failover virtual MAC address for a physical interface, use the **failover mac address** command in global configuration mode. To remove the virtual MAC address, use the **no** form of this command.

failover mac address *phy_if active_mac standby_mac*

no failover mac address *phy_if active_mac standby_mac*

Syntax Description

active_mac	The MAC address assigned to the specified interface the active ASA. The MAC address must be entered in h.h.h format, where h is a 16-bit hexadecimal number.
phy_if	The physical name of the interface to set the MAC address.
standby_mac	The MAC address assigned to the specified interface of the standby ASA. The MAC address must be entered in h.h.h format, where h is a 16-bit hexadecimal number.

Defaults

Not configured.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **failover mac address** command lets you configure virtual MAC addresses for an Active/Standby failover pair. If virtual MAC addresses are not defined, then when each failover unit boots it uses the burned-in MAC addresses for its interfaces and exchanges those addresses with its failover peer. The MAC addresses for the interfaces on the primary unit are used for the interfaces on the active unit.

However, if both units are not brought online at the same time and the secondary unit boots first and becomes active, it uses the burned-in MAC addresses for its own interfaces. When the primary unit comes online, the secondary unit will obtain the MAC addresses from the primary unit. This change can disrupt network traffic. Configuring virtual MAC addresses for the interfaces ensures that the secondary unit uses the correct MAC address when it is the active unit, even if it comes online before the primary unit.

The **failover mac address** command is unnecessary (and therefore cannot be used) on an interface configured for LAN-based failover because the **failover lan interface** command does not change the IP and MAC addresses when failover occurs. This command has no affect when the ASA is configured for Active/Active failover.

When adding the **failover mac address** command to your configuration, it is best to configure the virtual MAC address, save the configuration to flash memory, and then reload the failover pair. If the virtual MAC address is added when there are active connections, then those connections stop. Also, you must write the complete configuration, including the **failover mac address** command, to the flash memory of the secondary ASA for the virtual MAC addressing to take effect.

If the **failover mac address** is specified in the configuration of the primary unit, it should also be specified in the bootstrap configuration of the secondary unit.

Note This command applies to Active/Standby failover only. In Active/Active failover, you configure the virtual MAC address for each interface in a failover group with the **mac address** command in failover group configuration mode.

You can also set the MAC address using other commands or methods, but we recommend using only one method. If you set the MAC address using multiple methods, the MAC address used depends on many variables, and might not be predictable.

Examples

The following example configures the active and standby MAC addresses for the interface named intf2:

```
hostname(config)# failover mac address Ethernet0/2 00a0.c969.87c8 00a0.c918.95d8
```

Related Commands

Command	Description
show interface	Displays interface status, configuration, and statistics.

failover polltime

To specify the failover unit poll and hold times, use the **failover polltime** command in global configuration mode. To restore the default poll and hold times, use the **no** form of this command.

failover polltime [**unit**] [**msec**] *poll_time* [**holdtime** [**msec**] *time*]

no failover polltime [**unit**] [**msec**] *poll_time* [**holdtime** [**msec**] *time*]

Syntax Description

holdtime *time*	(Optional) Sets the time during which a unit must receive a hello message on the failover link, after which the peer unit is declared failed. Valid values are from 3 to 45 seconds or from 800 to 999 milliseconds if the optional **msec** keyword is used.
msec	(Optional) Specifies that the given time is in milliseconds.
poll_time	Sets the amount of time between hello messages. Valid values are from 1 to 15 seconds or from 200 to 999 milliseconds if the optional **msec** keyword is used.
unit	(Optional) Indicates that the command is used for unit poll and hold times. Adding this keyword to the command does not have any affect on the command, but it can make it easier to differentiate this command from the **failover polltime interface** commands in the configuration.

Defaults

The default values on the ASA are as follows:

- The *poll_time* is 1 second.
- The **holdtime** *time* is 15 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was changed from the **failover poll** command to the **failover polltime** command and now includes **unit** and **holdtime** keywords.
7.2(1)	The **msec** keyword was added to the **holdtime** keyword. The **polltime** minimum value was reduced to 200 milliseconds from 500 milliseconds. The **holdtime** minimum value was reduced to 800 milliseconds from 3 seconds.

Usage Guidelines

You cannot enter a **holdtime** value that is less than three times the unit poll time. With a faster poll time, the ASA can detect failure and trigger failover faster. However, faster detection can cause unnecessary switch overs when the network is temporarily congested.

If a unit does not hear hello packet on the failover communication interface or cable for one polling period, additional testing occurs through the remaining interfaces. If there is still no response from the peer unit during the hold time, the unit is considered failed and, if the failed unit is the active unit, the standby unit takes over as the active unit.

You can include both **failover polltime** [**unit**] and **failover polltime interface** commands in the configuration.

Note When CTIQBE traffic is passed through an ASA in a failover configuration, you should decrease the failover hold time on the ASA to below 30 seconds. The CTIQBE keepalive timeout is 30 seconds and may time out before failover occurs in a failover situation. If CTIQBE times out, Cisco IP SoftPhone connections to Cisco CallManager are dropped, and the IP SoftPhone clients need to reregister with the CallManager.

Examples

The following example changes the unit poll time frequency to 3 seconds:

```
hostname(config)# failover polltime 3
```

The following example configures the ASA to send a hello packet every 200 milliseconds and to fail over in 800 milliseconds if no hello packets are received on the failover interface within that time. The optional **unit** keyword is included in the command.

```
hostname(config)# failover polltime unit msec 200 holdtime msec 800
```

Related Commands

Command	Description
failover polltime interface	Specifies the interface poll and hold times for Active/Standby failover configurations.
polltime interface	Specifies the interface poll and hold times for Active/Active failover configurations.
show failover	Displays failover configuration information.

failover polltime interface

To specify the data interface poll and hold times in an Active/Standby failover configuration, use the **failover polltime interface** command in global configuration mode. To restore the default poll and hold times, use the **no** form of this command.

failover polltime interface [**msec**] *time* [**holdtime** *time*]

no failover polltime interface [**msec**] *time* [**holdtime** *time*]

Syntax Description

holdtime *time*	(Optional) Sets the time during which a data interface must receive a hello message on the data interface, after which the peer is declared failed. Valid values are from 5 to 75 seconds.
interface *time*	Specifies the poll time for interface monitoring. Valid values range from 1 to 15 seconds. If the optional **msec** keyword is used, the valid values are from 500 to 999 milliseconds.
msec	(Optional) Specifies that the given time is in milliseconds.

Defaults

The default values are as follows:

- The poll *time* is 5 seconds.
- The **holdtime** *time* is 5 times the poll *time*.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was changed from the **failover poll** command to the **failover polltime** command and includes **unit**, **interface**, and **holdtime** keywords.
7.2(1)	The optional **holdtime** *time* and the ability to specify the poll time in milliseconds was added.

Usage Guidelines

Use the **failover polltime interface** command to change the frequency that hello packets are sent out on data interfaces. This command is available for Active/Standby failover only. For Active/Active failover, use the **polltime interface** command in failover group configuration mode instead of the **failover polltime interface** command.

You cannot enter a **holdtime** value that is less than five times the unit poll time. With a faster poll time, the ASA can detect failure and trigger failover faster. However, faster detection can cause unnecessary switchovers when the network is temporarily congested. Interface testing begins when a hello packet is not heard on the interface for over half the hold time.

You can include both **failover polltime unit** and **failover polltime interface** commands in the configuration.

Note When CTIQBE traffic is passed through an ASA in a failover configuration, you should decrease the failover hold time on the ASA to below 30 seconds. The CTIQBE keepalive timeout is 30 seconds and may time out before failover occurs in a failover situation. If CTIQBE times out, Cisco IP SoftPhone connections to Cisco CallManager are dropped, and the IP SoftPhone clients need to reregister with the CallManager.

Examples

The following example sets the interface poll time frequency to 15 seconds:

```
hostname(config)# failover polltime interface 15
```

The following example sets the interface poll time frequency to 500 milliseconds and the hold time to 5 seconds:

```
hostname(config)# failover polltime interface msec 500 holdtime 5
```

Related Commands

Command	Description
failover polltime	Specifies the unit failover poll and hold times.
polltime interface	Specifies the interface polltime for Active/Active failover configurations.
show failover	Displays failover configuration information.

failover reload-standby

To force the standby unit to reboot, use the **failover reload-standby** command in privileged EXEC mode.

failover reload-standby

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use this command when your failover units do not synchronize. The standby unit restarts and resynchronizes to the active unit after it finishes booting.

Examples

The following example shows how to use the **failover reload-standby** command on the active unit to force the standby unit to reboot:

```
hostname# failover reload-standby
```

Related Commands

Command	Description
write standby	Writes the running configuration to the memory on the standby unit.

failover replication http

To enable HTTP (port 80) connection replication, use the **failover replication http** command in global configuration mode. To disable HTTP connection replication, use the **no** form of this command.

failover replication http

no failover replication http

Syntax Description

This command has no arguments or keywords.

Defaults

Disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was changed from **failover replicate http** to **failover replication http**.

Usage Guidelines

By default, the ASA does not replicate HTTP session information when Stateful Failover is enabled. Because HTTP sessions are typically short-lived, and because HTTP clients typically retry failed connection attempts, not replicating HTTP sessions increases system performance without causing serious data or connection loss. The **failover replication http** command enables the stateful replication of HTTP sessions in a Stateful Failover environment, but could have a negative affect on system performance.

In Active/Active failover configurations, you control HTTP session replication per failover group using the **replication http** command in failover group configuration mode.

Examples

The following example shows how to enable HTTP connection replication:

```
hostname(config)# failover replication http
```

Related Commands

Command	Description
replication http	Enables HTTP session replication for a specific failover group.
show running-config failover	Displays the **failover** commands in the running configuration.

failover replication rate

To configure the bulk-sync connection replication rate, use the **failover replication rate** command in global configuration mode. To restore the default setting, use the **no** form of this command.

failover replication rate *rate*

no failover replication rate

Syntax Description

rate	Sets the number of connections per second. Values and the default setting depend on your model's maximum connections per second.

Command Default

Varies depending on your model.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
8.4(4.1)/8.5(1.7)	We introduced this command.

Usage Guidelines

You can configure the rate at which the ASA replicates connections to the standby unit when using Stateful Failover. By default, connections are replicated to the standby unit during a 15 second period. However, when a bulk sync occurs (for example, when you first enable failover), 15 seconds may not be long enough to sync large numbers of connections due to a limit on the maximum connections per second. For example, the maximum connections on the ASASM is 8 million; replicating 8 million connections in 15 seconds means creating 533 K connections per second. However, the maximum connections allowed per second is 300 K. You can now specify the rate of replication to be less than or equal to the maximum connections per second, and the sync period will be adjusted until all the connections are synced.

Examples

The following example sets the failover replication rate to 20000 connections per second:

```
hostname(config)# failover replication rate 20000
```

Related Commands

Command	Description
failover rate http	Enables HTTP connection replication.

failover reset

To restore a failed ASA to an unfailed state, use the **failover reset** command in privileged EXEC mode.

failover reset [**group** *group_id*]

Syntax Description

group	(Optional) Specifies a failover group. The **group** keyword applies to Active/Active failover only.
group_id	Failover group number.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was modified to add the optional failover group ID.

Usage Guidelines

The **failover reset** command allows you to change the failed unit or group to an unfailed state. The **failover reset** command can be entered on either unit, but we recommend that you always enter the command on the active unit. Entering the **failover reset** command at the active unit will "unfail" the standby unit.

You can display the failover status of the unit with the **show failover** or **show failover state** commands.

There is no **no** form of this command.

In Active/Active failover, entering **failover reset** resets the whole unit. Specifying a failover group with the command resets only the specified group.

Examples

The following example shows how to change a failed unit to an unfailed state:

```
hostname# failover reset
```

Related Commands

Command	Description
failover interface-policy	Specifies the policy for failover when monitoring detects interface failures.
show failover	Displays information about the failover status of the unit.

failover timeout

To specify the failover reconnect timeout value for asymmetrically routed sessions, use the **failover timeout** command in global configuration mode. To restore the default timeout value, use the **no** form of this command.

failover timeout *hh*[**:***mm*:[**:***ss*]

no failover timeout [*hh*[**:***mm*:[**:***ss*]]

Syntax Description

hh	Specifies the number of hours in the timeout value. Valid values range from -1 to 1193. By default, this value is set to 0. Setting this value to -1 disables the timeout, allowing connections to reconnect after any amount of time. Setting this value to 0, without specifying any of the other timeout values, sets the command back to the default value, which prevents connections from reconnecting. Entering **no failover timeout** command also sets this value to the default (0). **Note** When set to the default value, this command does not appear in the running configuration.
mm	(Optional) Specifies the number of minutes in the timeout value. Valid values range from 0 to 59. By default, this value is set to 0.
ss	(Optional) Specifies the number of seconds in the timeout value. Valid values range from 0 to 59. By default, this value is set to 0.

Defaults

By default, *hh*, *mm*, and *ss* are 0, which prevents connections from reconnecting.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was modified to appear in the command listing.

Usage Guidelines

This command is used in conjunction with the **static** command with the **nailed** option. The **nailed** option allows connections to be reestablished in a specified amount of time after bootup or a system goes active. The **failover timeout** command specifies that amount of time. If not configured, the connections cannot be reestablished. The **failover timeout** command does not affect the **asr-group** command.

Note Adding the **nailed** option to the **static** command causes TCP state tracking and sequence checking to be skipped for the connection.

Entering the **no** form of this command restores the default value. Entering **failover timeout 0** also restores the default value. When set to the default value, this command does not appear in the running configuration.

Examples

The following example switches the standby group 1 to active:

```
hostname(config)# failover timeout 12:30
hostname(config)# show running-config failover
no failover
failover timeout 12:30:00
```

Related Commands

Command	Description
static	Configures a persistent one-to-one address translation rule by mapping a local IP address to a global IP address.

fallback

To configure the fallback timers that the Cisco Intercompany Media Engine uses to fallback from VoIP to PSTN when connection integrity degrades, use the **fallback** command in uc-ime configuration mode. To remove the fallback settings, use the **no** form of this command.

fallback {**sensitivity-file** *filename* | **monitoring timer** *timer_millisec* **hold-down timer** *timer_sec*}

no fallback fallback {**sensitivity-file** *filename* | **monitoring timer** *timer_millisec* **hold-down timer** *timer_sec*}

Syntax Description

filename	Specifies the filename of the sensitivity file. Enter the name of a file on disk that includes the .fbs file extension. To specify the filename, you can include the path on the local disk, for example `disk0:/file001.fbs`.
hold-down timer	Sets the amount of time that ASA waits before notifying Cisco UCM whether to fall back to PSTN.
monitoring timer	Sets the time between which the ASA samples the RTP packets received from the Internet. The ASA uses the data sample to determine if fallback to the PSTN is needed for a call.
sensitivity-file	Specifies the file to use for mid-call PSTN fallback. The sensitivity file is parsed by the ASA and entered in the RMA library.
timer_millisec	Specifies the length of the monitoring timer in milliseconds. Enter an integer within the range 10-600. By default, the length of the monitoring timer is 100 milliseconds.
timer_sec	Secifies the length of the hold-down timer in seconds. Enter an integer within the range 10-360. By default, the length of the hold-down timer is 20 seconds.

Defaults

By default, the length of the monitoring timer is 100 milliseconds.

By default, the length of the hold-down timer is 20 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Uc-ime configuration	•	—	•	—	—

Command History

Release	Modification
8.3(1)	The command was introduced.

Usage Guidelines

Specifies the fallback timer for the Cisco Intercompany Media Engine.

Internet connections can vary wildly in their quality and vary over time. Therefore, even if a call is sent over VoIP because the quality of the connection was good, the connection quality might worsen mid-call. To ensure an overall good experience for the end user, Cisco Intercompany Media Engine attempts to perform a mid-call fallback.

Performing a mid-call fallback requires the ASA to monitor the RTP packets coming from the Internet and send information into an RTP Monitoring Algorithm (RMA) API, which will indicates to the ASA whether fallback is required. If fallback is required, the ASA sends a REFER message to Cisco UCM to tell it that it needs to fallback the call to PSTN.

Note You cannot change the fallback timer when the Cisco Intercompany Media Engine proxy is enabled for SIP inspection. Remove the Cisco Intercompany Media Engine proxy from SIP inspection before changing the fallback timer.

Examples

The following example shows how to configure the Cisco Intercompany Media Engine while specifying the fallback timers:

```
hostname(config)# uc-ime local_uc-ime_proxy
hostname(config-uc-ime)# media-termination ime-media-term
hostname(config-uc-ime)# ucm address 192.168.10.30 trunk-security-mode non-secure
hostname(config-uc-ime)# ticket epoch 1 password password1234
hostname(config-uc-ime)# fallback monitoring timer 120
hostname(config-uc-ime)# fallback hold-down timer 30
```

The following example shows how to configure the Cisco Intercompany Media Engine while specifying a sensitivity file:

```
hostname(config)# uc-ime local_uc-ime_proxy
hostname(config-uc-ime)# media-termination ime-media-term
hostname(config-uc-ime)# ucm address 192.168.10.30 trunk-security-mode non-secure
hostname(config-uc-ime)# ticket epoch 1 password password1234
hostname(config-uc-ime)# fallback sensitivity-file local_uc-ime_fallback_policy
```

Related Commands

Command	Description
show running-config uc-ime	Shows the running configuration of the Cisco Intercompany Media Engine proxy.
show uc-ime	Displays statistical or detailed information about fallback notifications, mapping service sessions, and signaling sessions.
uc-ime	Creates the Cisco Intercompany Media Engine proxy instance on the ASA.

CHAPTER 22

file-bookmarks through functions Commands

file-bookmarks

To customize the File Bookmarks title or the File Bookmarks links on the WebVPN Home page that is displayed to authenticated WebVPN users, use the **file-bookmarks** command from webvpn customization configuration mode. To remove the command from the configuration and cause the value to be inherited, use the **no** form of this command.

file-bookmarks {**link** {**style** *value*} | **title** {**style** *value* | **text** *value*}}

no file-bookmarks {**link** {**style** *value*} | **title** {**style** *value* | **text** *value*}}

Syntax Description

link	Specifies a change to the links.
title	Specifies a change to the title.
style	Specifies a change to the HTML style.
text	Specifies a change to the text.
value	The actual text or CSS parameters to display (the maximum number is 256 characters).

Defaults

The default link style is color:#669999;border-bottom: 1px solid #669999;text-decoration:none.

The default title style is color:#669999;background-color:#99CCCC;font-weight:bold.

The default title text is “File Folder Bookmarks”.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Webvpn customization configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The **style** option is expressed as any valid CSS parameters. Describing these parameters is beyond the scope of this document. For more information about CSS parameters, consult CSS specifications at the W3C website at www.w3.org. Appendix F of the CSS 2.1 Specification contains a convenient list of CSS parameters, and is available at www.w3.org/TR/CSS21/propidx.html.

Here are some tips for making the most common changes to the WebVPN pages—the page colors:

- You can use a comma-separated RGB value, an HTML color value, or the name of the color if recognized in HTML.

- RGB format is 0,0,0, a range of decimal numbers from 0 to 255 for each color (red, green, blue); the comma-separated entry indicates the level of intensity of each color to combine with the others.
- HTML format is #000000, six digits in hexadecimal format; the first and second represent red, the third and fourth green, and the fifth and sixth represent blue.

Note To easily customize the WebVPN pages, we recommend that you use ASDM, which has convenient features for configuring style elements, including color swatches and preview capabilities.

Examples

The following example customizes the File Bookmarks title to "Corporate File Bookmarks":

```
F1-asa1(config)# webvpn
F1-asa1(config-webvpn)# customization cisco
F1-asa1(config-webvpn-custom)# file-bookmarks title text Corporate File Bookmarks
```

Related Commands

Command	Description
application-access	Customizes the Application Access box of the WebVPN Home page.
browse-networks	Customizes the Browse Networks box of the WebVPN Home page.
web-applications	Customizes the Web Application box of the WebVPN Home page.
web-bookmarks	Customizes the Web Bookmarks title or links on the WebVPN Home page.

file-browsing

To enable or disable CIFS/FTP file browsing for file servers or shares, use the **file-browsing** command in dap webvpn configuration mode.

file-browsing enable | disable

Syntax Description

enable | disable	Enables or disables the ability to browse for file servers or shares.

Defaults

No default value or behaviors.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Dap webvpn configuration	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The following usage notes apply to file browsing:

- File browsing does not support internationalization.
- Browsing requires NBNS (Master Browser or WINS). If that fails or is not configured, use DNS.

The ASA can apply attribute values from a variety of sources. It applies them according to the following hierarchy:

1. DAP record
2. Username
3. Group policy
4. Group policy for the tunnel group
5. Default group policy

It follows that DAP values for an attribute have a higher priority than those configured for a user, group policy, or tunnel group.

When you enable or disable an attribute for a DAP record, the ASA applies that value and enforces it. For example, when you disable file browsing in dap webvpn configuration mode, the ASA looks no further for a value. When you instead set no value for the **file-browsing** command, the attribute is not present in the DAP record, so the ASA moves down to the AAA attribute in the username, and if necessary, the group policy to find a value to apply.

Examples

The following example shows how to enable file browsing for the DAP record called Finance:

```
hostname (config)# config-dynamic-access-policy-record Finance
hostname(config-dynamic-access-policy-record)# webvpn
hostname(config-dap-webvpn)# file-browsing enable
hostname(config-dap-webvpn)#
```

Related Commands

Command	Description
dynamic-access-policy-record	Creates a DAP record.
file-entry	Enables or disables the ability to enter file server names to access.

file-encoding

To specify the character encoding for pages from Common Internet File System servers, use the **file-encoding** command in webvpn configuration mode. To remove the values of the file-encoding attribute use the **no** form of this command.

file-encoding {**server-name** | **server-ip-addr**} *charset*

no file-encoding {**server-name** | **server-ip-addr**}

Syntax Description

charset	String consisting of up to 40 characters, and equal to one of the valid character sets identified in http://www.iana.org/assignments/character-sets. You can use either the name or the alias of a character set listed on that page. Examples include iso-8859-1, shift_jis, and ibm850. The string is case-insensitive. The command interpreter converts upper case to lower case in the ASA configuration.
server-ip-addr	IP address, in dotted-decimal notation, of the CIFS server for which you want to specify character encoding.
server-name	Name of the CIFS server for which you want to specify character encoding. The ASA retains the case that you specify, although it ignores the case when matching the name to a server.

Defaults

Pages from all CIFS servers that do not have explicit file encoding entries in the WebVPN configuration inherit the character encoding value from the character encoding attribute.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Enter file encoding entries for all CIFS servers that require character encoding entries that differ from the value of the webvpn character encoding attribute.

The WebVPN portal pages downloaded from the CIFS server to the WebVPN user encode the value of the WebVPN file encoding attribute identifying the server, or if one does not, they inherit the value of the character encoding attribute. The remote user's browser maps this value to an entry in its character encoding set to determine the correct character set to use. The WebVPN portal pages do not specify a

value if WebVPN configuration does not specify a file encoding entry for the CIFS server and the character encoding attribute is not set. The remote browser uses its own default encoding if the WebVPN portal page does not specify the character encoding, or if it specifies a character encoding value that the browser does not support.

The mapping of CIFS servers to their appropriate character encoding, globally with the WebVPN character encoding attribute, and individually with file encoding overrides, provides for the accurate handling and display of CIFS pages when the correct rendering of file names or directory paths, as well as pages, are an issue.

Note The character encoding and file encoding values do not exclude the font family to be used by the browser. You need to complement the setting of one of these values with the **page style** command in webvpn customization command mode to replace the font family if you are using Japanese Shift_JIS character encoding, as shown in the following example, or enter the **no page style** command in webvpn customization command mode to remove the font family.

Examples

The following example sets the file encoding attribute of the CIFS server named "CISCO-server-jp" to support Japanese Shift_JIS characters, removes the font family, and retains the default background color:

```
hostname(config)# webvpn
hostname(config-webvpn)# file-encoding CISCO-server-jp shift_jis
F1-asa1(config-webvpn)# customization DfltCustomization
F1-asa1(config-webvpn-custom)# page style background-color:white
F1-asa1(config-webvpn-custom)#
```

The following example sets the file encoding attribute of the CIFS server 10.86.5.174 to support IBM860 (alias "CP860") characters:

```
hostname(config)# webvpn
hostname(config-webvpn)# file-encoding 10.86.5.174 cp860
hostname(config-webvpn)
```

Related Commands

Command	Description
character-encoding	Specifies the global character encoding used in all WebVPN portal pages except for pages from servers specified in file encoding entries in the WebVPN configuration.
show running-config webvpn	Displays the running configuration for WebVPN. Use the **all** keyword to include the default configuration.
debug webvpn cifs	Displays debugging messages about the Common Internet File System.

file-entry

To enable or disable the ability of a user to enter file server names to access, use the **file-entry** command in dap webvpn configuration mode.

file-entry enable | disable

Syntax Description

enable | disable	Enables or disables the ability to enter file server names to access.

Defaults

No default value or behaviors.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Dap webvpn configuration	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The ASA can apply attribute values from a variety of sources according to the following hierarchy:

1. DAP record
2. Username
3. Group policy
4. Group policy for the Connection Profile (tunnel group)
5. Default group policy

It follows that DAP values for an attribute have a higher priority than those configured for a user, group policy, or Connection Profile.

When you enable or disable an attribute for a DAP record, the ASA applies that value and enforces it. For example, when you disable file entry in dap webvpn configuration mode, the ASA looks no further for a value. When you instead set no value for the **file-entry** command, the attribute is not present in the DAP record, so the ASA moves down to the AAA attribute in the username, and if necessary, the group policy to find a value to apply.

Examples

The following example shows how to enable file entry for the DAP record called Finance:

```
hostname (config)# config-dynamic-access-policy-record Finance
hostname(config-dynamic-access-policy-record)# webvpn
hostname(config-dap-webvpn)# file-entry enable
```

```
hostname(config-dap-webvpn)#
```

Related Commands

Command	Description
dynamic-access-policy-record	Creates a DAP record.
file-browsing	Enables or disables the ability to browse for file servers or shares.

filter

To specify the name of the access list to use for WebVPN connections for this group policy or username, use the **filter** command in webvpn configuration mode. To remove the access list, use the **no** form of this command.

filter {**value** *ACLname* | **none**}

no filter

Syntax Description

none	Indicates that there is no WebVPN type access list. Sets a null value, thereby disallowing an access list. Prevents inheriting an access list from another group policy.
value *ACLname*	Provides the name of the previously configured access list.

Defaults

WebVPN access lists do not apply until you use the **filter** command to specify them.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **no** option allows inheritance of a value from another group policy. To prevent inheriting filter values, use the **filter value none** command.

You configure ACLs to permit or deny various types of traffic for this user or group policy. You then use the **filter** command to apply those ACLs for WebVPN traffic.

WebVPN does not use ACLs defined in the **vpn-filter** command.

Examples

The following example shows how to set a filter that invokes an access list named *acl_in* for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# filter acl_in
```

Related Commands

Command	Description
access-list	Creates an access list, or uses a downloadable access list.
webvpn	Use in group-policy configuration mode or in username configuration mode. Lets you enter webvpn configuration mode to configure parameters that apply to group policies or usernames.

filter activex

To remove ActiveX objects in HTTP traffic passing through the ASA, use the **filter activex** command in global configuration mode. To remove the configuration, use the **no** form of this command.

filter activex *port* [**-***port*] | **except** *local_ip mask foreign_ip foreign_mask*

no filter activex *port* [**-***port*] | **except** *local_ip mask foreign_ip foreign_mask*

Syntax Description

except	Creates an exception to a previous filter condition.
foreign_ip	The IP address of the lowest security level interface to which access is sought. You can use 0.0.0.0 (or in shortened form, 0) to specify all hosts.
foreign_mask	Network mask of the *foreign_ip* argument. Always specify a specific mask value. You can use 0.0.0.0 (or in shortened form, 0) to specify all hosts.
local_ip	The IP address of the highest security level interface from which access is requested. You can set this address to 0.0.0.0 (or in shortened form, 0) to specify all hosts.
mask	Network mask of the *local_ip* argument. You can use 0.0.0.0 (or in shortened form, 0) to specify all hosts.
port	The TCP port to which filtering is applied. Typically, this is port 21, but other values are accepted. The http or url literal can be used for port 21. The range of values permitted is 0 to 65535.
-*port*	(Optional) Specifies a port range.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

ActiveX objects may pose security risks because they can contain code intended to attack hosts and servers on a protected network. You can disable ActiveX objects with the **filter activex** command.

ActiveX controls, formerly known as OLE or OCX controls, are components that you can insert in a web page or other application. These controls include custom forms, calendars, or any of the extensive third-party forms for gathering or displaying information. As a technology, ActiveX creates many potential problems for network clients including causing workstations to fail, introducing network security problems, or being used to attack servers.

The **filter activex** command blocks the HTML **object** commands by commenting them out within the HTML web page. ActiveX filtering of HTML files is performed by selectively replacing the <applet> and </applet> and <object classid> and </object> tags with comments. Filtering of nested tags is supported by converting top-level tags to comments.

Caution The <object> tag is also used for Java applets, image files, and multimedia objects, which will also be blocked by this command.

If the <object> or </object> HTML tags split across network packets or if the code in the tags is longer than the number of bytes in the MTU, the ASA cannot block the tag.

ActiveX blocking does not occur when users access an IP address referenced by the **alias** command or for WebVPN traffic.

Examples

The following example specifies that ActiveX objects are blocked on all outbound connections:

```
hostname(config)# filter activex 80 0 0 0 0
```

This command specifies that the ActiveX object blocking applies to web traffic on port 80 from any local host and for connections to any foreign host.

Related Commands\

Commands	Description
filter url	Directs traffic to a URL filtering server.
filter java	Removes Java applets from HTTP traffic passing through the ASA.
show running-config filter	Displays filtering configuration.
url-block	Manages the URL buffers used for web server responses while waiting for a filtering decision from the filtering server.
url-server	Identifies anN2H2 or Websense server for use with the **filter** command.

filter ftp

To identify the FTP traffic to be filtered by a Websense or N2H2 server, use the **filter ftp** command in global configuration mode. To remove the configuration, use the **no** form of this command.

filter ftp *port* [**-***port*] | **except** *local_ip mask foreign_ip foreign_mask* [**allow**] [**interact-block**]

no filter ftp *port* [**-***port*] | **except** *local_ip mask foreign_ip foreign_mask* [**allow**] [**interact-block**]

Syntax Description

allow	(Optional) When the server is unavailable, let outbound connections pass through the ASA without filtering. If you omit this option, and if the N2H2 or Websense server goes off line, the ASA stops outbound port 80 (Web) traffic until the N2H2 or Websense server is back on line.
except	Creates an exception to a previous filter condition.
foreign_ip	The IP address of the lowest security level interface to which access is requested. You can use 0.0.0.0 (or in shortened form, 0) to specify all hosts.
foreign_mask	Network mask of the *foreign_ip* argument. Always specify a specific mask value. You can use 0.0.0.0 (or in shortened form, 0) to specify all hosts.
interact-block	(Optional) Prevents users from connecting to the FTP server through an interactive FTP program.
local_ip	The IP address of the highest security level interface from which access is sought. You can set this address to 0.0.0.0 (or in shortened form, 0) to specify all hosts.
mask	Network mask of the *local_ip* argument. You can use 0.0.0.0 (or in shortened form, 0) to specify all hosts.
port	The TCP port to which filtering is applied. Typically, this is port 21, but other values are accepted. The ftp literal can be used for port 80.
-*port*	(Optional) Specifies a port range.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **filter ftp** command lets you identify the FTP traffic to be filtered by a Websense or N2H2 server.

After enabling this feature, when a user issues an FTP GET request to a server, the ASA sends the request to the FTP server and to the Websense or N2H2 server at the same time. If the Websense or N2H2 server permits the connection, the ASA allows the successful FTP return code to reach the user unchanged. For example, a successful return code is "250: CWD command successful."

If the Websense or N2H2 server denies the connection, the ASA alters the FTP return code to show that the connection was denied. For example, the ASA would change code 250 to "550 Requested file is prohibited by URL filtering policy." Websense only filters FTP GET commands and not PUT commands.

Use the **interactive-block** option to prevent interactive FTP sessions that do not provide the entire directory path. An interactive FTP client allows the user to change directories without typing the entire path. For example, the user might enter **cd ./files** instead of **cd /public/files**. You must identify and enable the URL filtering server before using these commands.

Examples

The following example shows how to enable FTP filtering:

```
hostname(config)# url-server (perimeter) host 10.0.1.1
hostname(config)# filter ftp 21 0 0 0 0
hostname(config)# filter ftp except 10.0.2.54 255.255.255.255 0 0
```

Related Commands

Commands	Description
filter https	Identifies the HTTPS traffic to be filtered by a Websense sor N2H2 erver.
filter java	Removes Java applets from HTTP traffic passing through the ASA.
filter url	Directs traffic to a URL filtering server.
show running-config filter	Displays filtering configuration.
url-block	Manages the URL buffers used for web server responses while waiting for a filtering decision from the filtering server.
url-server	Identifies an N2H2 or Websense server for use with the **filter** command.

filter https

To identify the HTTPS traffic to be filtered by a N2H2 or Websense server, use the **filter https** command in global configuration mode. To remove the configuration, use the **no** form of this command.

filter https *port* [**-***port*] | **except** *local_ip mask foreign_ip foreign_mask* [**allow**]

no filter https *port* [**-***port*] | **except** *local_ip mask foreign_ip foreign_mask* [**allow**]

Syntax Description

allow	(Optional) When the server is unavailable, let outbound connections pass through the ASA without filtering. If you omit this option, and if the N2H2 or Websense server goes offline, the ASA stops outbound port 443 traffic until the N2H2 or Websense server is back online.
except	(Optional) Creates an exception to a previous filter condition.
foreign_ip	The IP address of the lowest security level interface to which access is sought. You can use 0.0.0.0 (or in shortened form, 0) to specify all hosts.
foreign_mask	Network mask of the *foreign_ip* argument. Always specify a specific mask value. You can use 0.0.0.0 (or in shortened form, 0) to specify all hosts.
local_ip	The IP address of the highest security level interface from which access is sought. You can set this address to 0.0.0.0 (or in shortened form, 0) to specify all hosts.
mask	Network mask of the *local_ip* argument. You can use 0.0.0.0 (or in shortened form, 0) to specify all hosts.
port	The TCP port to which filtering is applied. Typically, this is port 443, but other values are accepted. The https literal can be used for port 443.
-*port*	(Optional) Specifies a port range.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The ASA supports filtering of HTTPS and FTP sites using an external Websense or N2H2 filtering server.

HTTPS filtering works by preventing the completion of SSL connection negotiation if the site is not allowed. The browser displays an error message such as "The Page or the content cannot be displayed."

Because HTTPS content is encrypted, the ASA sends the URL lookup without directory and filename information.

Examples

The following example filters all outbound HTTPS connections except those from the 10.0.2.54 host:

```
hostname(config)# url-server (perimeter) host 10.0.1.1
hostname(config)# filter https 443 0 0 0 0
hostname(config)# filter https except 10.0.2.54 255.255.255.255 0 0
```
