    Check action of 'match header fragmentation' in 'policy-map type ipv6'. Remove action
'drop' if fragmentation should be allowed.

 Syslogs:
    325004

----------------------------------------------------------------
Name: ipv6-routing-address-denied
IPv6 routing extension header exceeding configured maximum routing addresses is denied:
routing count is denied by IPv6 extension header configuration:
    This counter is incremented and packet is dropped when the appliance receives a IPv6
packet with too many routing addresses in routing extension header whichis denied by the
user configuration rule.

 Recommendation:
```

```
    Check action of 'match header routing-address count' in 'policy-map type ipv6'. Remove
action 'drop' or increase <count> if <count> routing addresses should be allowed.

 Syslogs:
    325004

----------------------------------------------------------------
Name: ipv6-routing-type-denied
routing type is denied by IPv6 extension header configuration:
    This counter is incremented and packet is dropped when the appliance receives a IPv6
packet with routing type extension header which is denied by the user configuration rule.

 Recommendation:
    Check action of 'match header routing-type' in 'policy-map type ipv6'. Remove action
'drop' if routing-type should be allowed.

 Syslogs:
    325004

----------------------------------------------------------------
Name: ipv6-eh-count-denied
IPv6 extension headers exceeding configured maximum extension headers is denied:
extension header count is denied by IPv6 extension header configuration:
    This counter is incremented and packet is dropped when the appliance receives a IPv6
packet with fragmentation extension header which is denied by the user configuration rule.

 Recommendation:
    Check action of 'match header fragmentation' in 'policy-map type ipv6'. Remove action
'drop' if fragmentation should be allowed.

 Syslogs:
    325004

----------------------------------------------------------------
Name: ipv6-dest-option-denied
destination-option is denied by IPv6 extension header configuration:
    This counter is incremented and packet is dropped when the appliance receives a IPv6
packet with destination-option extension header which is denied by the user configuration
rule.

 Recommendation:
    Check action of 'match header destination-option' in 'policy-map type ipv6'. Remove
action 'drop' if destination-option should be allowed.

 Syslogs:
    325004

----------------------------------------------------------------
Name: ipv6-hop-by-hop-denied
IPv6 hop-by-hp extension header is denied by user configuration:
    This counter is incremented and packet is dropped when the appliance receives a IPv6
packet with hop-by-hop extension header which is denied by the user configuration rule.

 Recommendation:
    Check action of 'match header hop-by-hop' in 'policy-map type ipv6'. Remove action
'drop' if hop-by-hop should be allowed.

 Syslogs:
    325004
```

```
------------------------------------------------------------------
Name: ipv6-esp-denied
ESP is denied by IPv6 extension header configuration:
    This counter is incremented and packet is dropped when the appliance receives a IPv6
packet with ESP extension header which is denied by the user configuration rule.

 Recommendation:
    Check action of 'match header esp' in 'policy-map type ipv6'. Remove action 'drop' if
ESP should be allowed.

 Syslogs:
    325004

------------------------------------------------------------------
Name: ipv6-ah-denied
AH is denied by IPv6 extension header configuration:
    This counter is incremented and packet is dropped when the appliance receives a IPv6
packet with AH extension header which is denied by the user configuration rule.

 Recommendation:
    Check action of 'match header ah' in 'policy-map type ipv6'. Remove action 'drop' if
AH should be allowed.

 Syslogs:
    325004

------------------------------------------------------------------
Name: channel-closed
Data path channel closed:
    This counter is incremented when the data path channel has been closed before the
packet attempts to be sent out through this channel.

Recommendation:
    It is normal in multi-processor system when one processor closes the channel (e.g.,
via CLI), and another processor tries to send a packet through the channel.

 Syslogs:
    None

------------------------------------------------------------------
Name: dispatch-decode-err
Diapatch decode error:
    This counter is incremented when the packet dispatch module finds an error when
decoding the frame.  An example is an unsupported packet frame.
Recommendation:
    Verify the packet format with a capture tool.

 Syslogs:
    None

------------------------------------------------------------------
Name: cp-event-queue-error
CP event queue error:
    This counter is incremented when a CP event queue enqueue attempt has failed due to
queue length exceeded. This queue is used by the data-path to punt packets to the
control-point for additional processing. This condition is only possible in a
multi-processor enviroment. The module that attempted to enqueue the packet may issue its
own packet specific drop in response to this error.
```

```
Recommendation:
    While this error does indicate a failure to completely process a packet, it may not
adversely affect the connection. If the condition persists or connections are adversely
affected contact the Cisco Technical Assistance Center (TAC).

Syslogs:
    None

----------------------------------------------------------------
Name: host-limit
Host limit exceeded:
    This counter is incremented when the licensed host limit is exceeded.

Recommendation:
    None.

Syslogs:
    450001

----------------------------------------------------------------
Name: cp-syslog-event-queue-error
CP syslog event queue error:
    This counter is incremented when a CP syslog event queue enqueue attempt has failed
due to queue length exceeded. This queue is used by the data-path to punt logging events
to the control-point when logging destinations other than to a UDP server are configured.
This condition is only possible in a multi-processor environment.

Recommendation:
    While this error does indicate a failure to completely process a logging event,
logging to UDP servers should not be affected. If the condition persists consider lowering
the logging level and/or removing logging destinations or contact the Cisco Technical
Assistance Center (TAC).

Syslogs:
    None

----------------------------------------------------------------
Name: dispatch-block-alloc
Dispatch block unavailable:
     This counter is incremented and the packet is dropped when the appliance could not
allocate a core local block to process the packet that was received by the interface
driver.

Recommendation:
    This may be due to packets being queued for later processing or a block leak. Core
local blocks may also not be available if they are not replenished on time by the free
resource rebalancing logic. Please use "show blocks core" to further diagnose the problem.

Syslogs:
    None

----------------------------------------------------------------
Name: async-lock-queue-limit
Async lock queue limit exceeded:
    Each async lock working queue has a limit of 1000. When more SIP packets are attempted
to be dispatch to the work queue, packet will be dropped.

Recommendation:
```

```
    Only SIP traffic may be dropped. When SIP packets have the same parent lock and they
can be queued into the same async lock queue, thus may result into blocks depletion,
becasue only single core is handling all the media. If a SIP packet attempts to be queued
when the size of the async lock queue exceeds the limit, the packet will be dropped.

Syslogs:
    None.

----------------------------------------------------------------
Name: loopback-lock-failed
Loopback lock failed
    This counter is incremented and the packet is dropped when packets are sent from one
context of the appliance to another context through a shared intrface and the loopback
queue has failed to acquire a lock.

Recommendations:
    This condition should never be encountered during normal operation and may indicate a
software problem with the appliance. Contact the Cisco Techncial Assistance Center (TAC)
if this error occurs.

Syslogs:
    None

----------------------------------------------------------------
Name: loopback-ifc-not-found
Loopback output interface not found
    This counter is incremented and the packet is dropped when packets are sent from one
context of the appliance to another context through a shared interface, and the output
interface is not found by the loopback queue.

Recommendations:
    This condition should never be encountered during normal operation and may indicate a
software problem with the appliance. Contact the Cisco Techncial Assistance Center (TAC)
if this error occurs.

Syslogs:
    None

----------------------------------------------------------------
Name: loopback-count-exceeded
Loopback count exceeded
    This counter is incremented and the packet is dropped when a packet is sent from one
context of the appliance to another context through a shared intreface, but this packet
has exceeded the number of times it is allowed to queue to the loopback queue.

Recommendations:
    Check the context configuration for each context. The packet is entering a loop in the
context configurations so that it is stuck between contexts, and is repeatedly put into
the loopback queue.

Syslogs:
    None

----------------------------------------------------------------
Name: ips-license-disabled-fail-close
IPS module license disabled
    The IPS module license has been disabled and when the fail-close mode is configured,
all traffic destined for the IPS module will be dropped. The status of the license can be
checked using the "show activation-key" command.

Recommendation:
```

```
    Please apply an activation key using the "activation-key" command that has the IPS
license enabled.

Syslogs:
    420008

------------------------------------------------------------------
Name: backplane-channel-null
Backplane channel null:
The card backplane channel was NULL. This may happen because the channel
was not initialized correctly and had to be closed. ASA will drop the packet.
Recommendation:
    This should not happen. Contact Cisco TAC for assistance.

Syslogs:
    None.

------------------------------------------------------------------

------------------------------------------------------------------
Name: svc-conn-timer-cb-fail
SVC connection timer callback failure:
    This condition occurs when there is a failed attempt to place an event on the async
lock queue for that connection.

 Recommendation:
    None.

 Syslogs:
    None.

------------------------------------------------------------------
Name: svc-udp-conn-timer-cb-fail
SVC UDP connection timer callback failure:
    This condition occurs when there is a failed attempt to place an event on the async
lock queue for that connection.

 Recommendation:
    None.

 Syslogs:
    None.

------------------------------------------------------------------
Name: nat64/46-conversion-fail
IPv6 to IPv4 or vice-versa conversion failure:
    This condition occurs when there is a failure in coversion of IPv6 traffic to IPv4 or
vice-versa.

 Recommendation:
    None.

 Syslogs:
    None.

------------------------------------------------------------------
Name: cluster-cflow-clu-closed
Cluster flow with CLU closed on owner:
```

```
    Director/backup unit received a cluster flow clu delete message from the owner unit
and terminated the flow.

Recommendation:
    This counter should increment for every replicated clu that is torn down on the owner
unit.

Syslogs:
    None.

----------------------------------------------------------------
Name: cluster-cflow-clu-timeout
Cluster flow with CLU removed from due to idle timeout:
    A cluster flow with CLU is considered idle if the director/backup unit no longer
receives periodic updates from the owner, which is supposed to happen at fixed intervals
when the flow is alive.

Recommendation:
    This counter is informational.

Syslogs:
    None.

----------------------------------------------------------------
Name: cluster-redirect
Flow matched a cluster redirect classify rule:
    A stub forwarding flow will thereafter forward packets to the cluster unit that owns
the flow.

Recommendations:
    This counter is informational and the behavior expected. The packet was forwarded to
the owner over the Cluster Control Link.

Syslogs:
    None.

----------------------------------------------------------------
Name: cluster-drop-on-slave
Flow matched a cluster drop-on-slave classify rule:
    This is for cases that the packets from L3 subnet are seen by all units and only
master unit need to process them.

Recommendations:
    This counter is informational and the behavior expected. The packet is processed by
master.

Syslogs:
    None.

----------------------------------------------------------------
Name: cluster-director-change
The flow director changed due to a cluster join event:
    A new unit joined the cluster and is now the director for the flow. The old
director/backup has removed it's flow and the flow owner will update the new director.

Recommendations:
    This counter is informational and the behavior expected.

Syslogs:
    None.
```

```
----------------------------------------------------------------
Name: cluster-mcast-owner-change
The multicast flow owner changed due to a cluster join or leave event:
     This flow gets created on a new owner unit.

Recommendations:
    This counter is informational and the behavior expected.

Syslogs:
    None.

----------------------------------------------------------------
Name: cluster-convert-to-dirbak
Forwarding or redirect flow converted to director or backup flow:
    Forwarding or redirect flow is removed, so that director or  backup flow can be
created.

Recommendations:
    This counter is informational and the behavior expected.

Syslogs:
    None.

----------------------------------------------------------------
Name: inspect-scansafe-server-not-reachable
Scansafe server is not configured or the cloud is down:
    Either the scansafe server IP is not specified in the scansafe general options or the
scansafe server is not reachable.

Recommendations:
    This counter is informational and the behavior expected.

Syslogs:
    None.

----------------------------------------------------------------
Name: inspect-scansafe-public_key_not_configured
Scansafe public key not configured:
    This counter is incremented when the scansafe public key is not configured. The packet
is dropped and the connection isclosed.

Recommendation:
    Verify if the configured scansafe public key is configured on the security appliance.

Syslogs:
    775002.

----------------------------------------------------------------
Name: inspect-scansafe-license-key-not-configured
Scansafe license key not configured:
    This counter is incremented when the scansafe licnese key is not configured. The
packet is dropped and the connection isclosed.

Recommendation:
    Verify if the configured scansafe license key is configured on the security appliance.

Syslogs:
    775002.
```

```
------------------------------------------------------------------
Name: inspect-scansafe-encoding-failed
Inspect  scansafe header encoding failed :
    This counter is incremented when the base64 encoding of user and group name is failed.
The packet is dropped and connection is closed.

Syslogs:
    775002.

------------------------------------------------------------------
Name: inspect-scansafe-hdr-encryption-failed
Inspect  scansafe header encryption failed:
    This counter is incremented when the encryption of scansafe header is failed. The
packet is dropped and connection is closed.

Syslogs:
    775002.

------------------------------------------------------------------
Name: inspect-scansafe-max-conn-reached
Inspect  scansafe max allowed connections reached:
    This counter is incremented when we get a new connection and the maximum allowed
concurrent scansafe connection for the platform is already reached. The packet is dropped
and connection is closed.

Syslogs:
    775002.

------------------------------------------------------------------
Name: inspect-scansafe-duplicate-conn
Inspect scansafe duplicate connection:
     This counter is incremented when duplicate connection with the same source ip address
and port. This packet will be dropped and connection will be closed.

Syslogs:
    775002.

------------------------------------------------------------------
Name: cluster-director-closed
Flow removed due to director flow closed:
    Owner unit received a cluster flow clu delete message from the director unit and
terminated the flow.

Recommendation:
    This counter should increment for every replicated clu that is torn down on the
director unit.

Syslogs:
    None.

------------------------------------------------------------------
Name: cluster-pinhole-master-change
Master only pinhole flow removed at bulk sync due to master change:
    Master only pinhole flow is removed during bulk sync becase cluster master has
changed.

Recommendation:
```

```
    This counter is informational and the behavior expected.

Syslogs:
    302014

------------------------------------------------------------------
Name: np-socket-lock-failure
Dropped pending packets due to a failed attempt to get an internal socket lock:
    This error occurs if an attempt to grab an internal socket lock fails.

Recommendation:
    This condition should never be encountered during normal operation and     may
indicate a software problem with the appliance.  Contact the Cisco     Technical
Assistance Center (TAC) if this error occurs.

Syslogs:
    None.

------------------------------------------------------------------
Name: mp-service-inject-failed
SERVICE Module failed to inject a packet:
    This error occurs if an attempt to inject a packet via the SERVICE     Module fails.

Recommendation:
    None.

Syslogs:
    None.

------------------------------------------------------------------
Name: nat-64-or-46-conversion-fail
IPv6 to IPv4 or vice-versa conversion failure:
    This condition occurs when there is a failure in coversion of     IPv6 traffic to IPv4
or vice-versa.

Recommendation:
    Verify if the NAT64 or NAT46 policies are configured properly.

Syslogs:
    None.

------------------------------------------------------------------
Name: cluster-not-owner
Cluster not owner:
    A Cluster data packet was received without a flow.
Recommendation:
    None.
Syslogs:
    None.

------------------------------------------------------------------
Name: cluster-ccl-cfull-sent
CLU FULL sent:
    A Cluster data packet was received over CCL and full flow is built on a new owner.
This packet is no longer needed.
Recommendation:
    None.
Syslogs:
    None.
```

```
------------------------------------------------------------------
Name: cluster-ccl-backup
Cluster CCL backup:
    A Cluster data packet was received over CCL on a backup unit, when it should have been
received on the owner+director unit.
Recommendation:
    None.
Syslogs:
    None.

------------------------------------------------------------------
Name: cluster-ccl-unknown-stub
Cluster CCL unknown stub:
    A Cluster data packet was received over CCL and a matching stub flow found, but unit
has unknown role.
Recommendation:
    None.
Syslogs:
    None.

------------------------------------------------------------------
Name: cluster-stub-to-full
Cluster stub to full flow:
    A Cluster packet was received on director, stub flow was converted to full flow. Drop
this packet and wait for retransmission.
Recommendation:
    None.
Syslogs:
    None.

------------------------------------------------------------------
Name: cluster-ccl-unknown
Cluster CCL unknown role:
    A Cluster data packet was received over CCL and no matching flow is found, and unit
has unknown role.
Recommendation:
    None.
Syslogs:
    None.

------------------------------------------------------------------
Name: cluster-owner-update
Cluster owner update:
    A Cluster data packet was received updating the flow owner.
Recommendation:
    None.
Syslogs:
    None.

------------------------------------------------------------------
Name: cluster-invalid-pkt
Cluster rcvd invalid packet:
    An invalid cluster packet was received.
Recommendation:
    None.
Syslogs:
    None.
```

```
------------------------------------------------------------------
Name: cluster-no-msgp
Cluster unit is out of message descriptor:
    Cluster unit is out of message descriptor.
Recommendation:
    None.
Syslogs:
    None.

------------------------------------------------------------------
Name: cluster-slave-ignored
Flow matched a cluster drop-on-slave classify rule:
    A multicast routing packet was received on a L3 cluster     interface when the unit
was a slave. Only a master unit     is permitted to process these packets.
Recommendation:
    This counter is informational and the behavior expected. The packet is    processed by
master.
Syslogs:
    None.

------------------------------------------------------------------
Name: cluster-non-owner-ignored
Flow matched a cluster drop-on-non-owner classify rule:
    A multicast data packet was received on a L3 cluster     interface when the unit was
not an elected owner unit.     Only an elected owner unit is permitted to process
these packets.
Recommendation:
    This counter is informational and the behavior expected. The packet is    processed by
one elected owner unit.
Syslogs:
    None.

------------------------------------------------------------------
Name: nat-xlate-failed
NAT failed:
    Failed to create an xlate to translate an IP or transport header.

Recommendation:
    If NAT is not desired, disable "nat-control".  Otherwise, use the "static", "nat" or
"global" command to configure NAT policy for the dropped flow.  For dynamic NAT, ensure
that each "nat" command is paired with at least one "global" command.  Use "show nat" and
"debug pix process" to verify NAT rules.

Syslogs:
    305005, 305006, 305009, 305010, 305011, 305012

------------------------------------------------------------------
Name: nat-rpf-failed
NAT reverse path failed:
    Rejected attempt to connect to a translated host using the translated host's real
address.

Recommendation:
    When not on the same interface as the host undergoing NAT, use the mapped address
instead of the real address to connect to the host. Also, enable the appropriate inspect
command if the application embeds IP address.

Syslogs:
```

```
    305005

------------------------------------------------------------------
Name: nat-cluster-input
NAT invalid input:
    An input value for clustering communication contains an unexpected or invalid value.
Recommendation:
    This could be an internal software error.  Contact Cisco Systems.
Syslogs:
    None.

------------------------------------------------------------------
Name: nat-no-xlate-to-pat-pool
NAT no xlate to pat pool:
    No pre-existing xlate found for a connection with a destination matching a mapped
address in a PAT pool.
Recommendation:
    Configure static PAT is access is desired.
Syslogs:
    None.

------------------------------------------------------------------
Name: nat--xlate-create-failed
NAT xlate creation failed:
    Creation of a PAT xlate failed.
Recommendation:
    Check system memory. Configure at least one backup PAT address. Configure a NAT
address to translate non-overload IP address. Only TCP, UDP, ICMP echo, and PPTP GRE
overloadable.
Syslogs:
    None.

------------------------------------------------------------------
Name: cluster-peer-mcast-ignored
Flow matched a cluster peer mcast data traffic classify rule:
    A multicast data packet was received on a L3 cluster interface when it is from a
cluster peer unit corresponding interface. This is a packet flooded back from L3 subnet.
Recommendation:
    This counter is informational and the behavior expected. The packet has been forwarded
out of the cluster and should be ignored by cluster.
Syslogs:
    None.

------------------------------------------------------------------
Name: cluster-dispatch-queue-fail
Cluster failed to enqueue into global dispatch work queue:
    A forwarded data packet failed to enqueue into global dispatch work queue.
Recommendation:
    This could be an internal software error.  Contact Cisco Systems.
Syslogs:
    None.

------------------------------------------------------------------
Name: cluster-dir-flow-create-fail
Cluster director failed to create director flow:
    Director is trying to create a stub flow but failed due to resource     limitation.
The resource limit may be either:
       1) system memory
```

```
       2) packet block extension memory
       3) system connection limit
    Causes 1 and 2 will occur simultaneously with flow drop reason "No     memory to
complete flow".
Recommendation:
    - Observe if free system memory is low.
    - Observe if flow drop reason "No memory to complete flow" occurs.
    - Observe if connection count reaches the system connection limit with     the command
"show resource usage".
Syslogs:
    None

------------------------------------------------------------------
Name: cluster-early-sec-chk-fail
Cluster early security check has failed:
    Director applied early security check has failed due to ACL, WCCP     redirect,
TCP-intercept or IP option.
Recommendation:
    This counter is informational and the behavior expected. The packet will     be
dropped.
Syslogs:
    None.

------------------------------------------------------------------
Name: cluster-queued-ccl-unknown
Cluster CCL unknown stub:
    A queued cluster data packet received over ccl was processed but unit has     unknown
role.
Recommendation:
    None.
Syslogs:
    None.

------------------------------------------------------------------
Name: cluster-dir-nat-changed
Cluster director NAT action changed:
    Cluster director NAT action has changed due to NAT policy change, update     or
expiration before queued ccl data packet can be processed.Recommendation:
    This counter is informational and the behavior expected. The packet will     be
dropped.
Syslogs:
    None.

------------------------------------------------------------------
Name: cluster-dir-invalid-ifc
Cluster director has packet with invalid ingress/egress interface:
    Cluster director has processed a previously queued packet with invalid     ingress
and/or egress interface. This is a result of interface removal     (through CLI) before
the packet can be processed.
Recommendation:
    This counter is informational and the behavior expected. The packet will     be
dropped.
Syslogs:
    None.

------------------------------------------------------------------
Name: cluster-parent-owner-left
Flow removed at bulk sync becasue parent flow is gone:
    Flow is removed during bulk sync because the parent flow's owner has left the cluster.
```

```
Recommendation:
    This counter is informational and the behavior expected.

Syslogs:
    302014

----------------------------------------------------------------
Name: cluster-ctp-punt-channel-missing
Flow removed at bulk sync becasue CTP punt channel is missing:
    Flow is removed during bulk sync because CTP punt channel is missing in cluster
restored flow.

Recommendation:
    The cluster master may have just left the cluster, and there might be packet drops on
the Cluster Control Link.

Syslogs:
    302014

----------------------------------------------------------------
Name: ike-sa-rate-limit
IKE need SA indication per SA rule rate limit exceeded:
     This counter will increment when the appliance attempts to send a message,indicating
that a new SA is needed for a rate-limited control point service routine and the rate
limit (per/second) is now being exceeded. The current rate is one message every two
seconds.

Recommendation:
     This counter is informational and the behavior expected. The packet will be dropped.

Syslogs:
     None

----------------------------------------------------------------
Name: ike-sa-global-rate-limit
IKE new SA global limit exceeded:
     This counter will increment when the appliance attempts to send a message,indicating
that a new SA is needed for a rate-limited control point service routine and the global
rate limit (per/second) is now being exceeded. The current rate is ten messages per
second.

Recommendation:
     This counter is informational and the behavior expected. The packet will be dropped.

Syslogs:
     None

----------------------------------------------------------------
Name: nat-cluster-invalid-unxlate-redirect
Cluster member dropped an invalid NAT untranslate redirect packet from peer:
    Cluster member received a NAT untranslate packet from peer. However this member does
not own the NAT address pool the packet belongs to.

Recommendation:
    This counter is a temporal condition after a cluster member failure. However, if this
counter is incremented continuously, it could be an internal software error. Contact Cisco
TAC in this case.

Syslogs:
```

```
    None.

----------------------------------------------------------------
Name: nat-cluster-pool-update-fail
Cluster master failed to send NAT pool update to slave:
    Cluster master has failed to send NAT pool update to slave unit. This drop will
increase if system resources is low.

Recommendation:
    - Observe if free system memory is low.
    - Observe if "SEC_NAT_SEND_NO_BUFFER" counter is increasing.

Syslogs:
    None.

----------------------------------------------------------------
```

Flow Drop Reasons

```
----------------------------------------------------------------
Name: tunnel-torn-down
Tunnel has been torn down:
    This counter will increment when the appliance receives a packet associated with an
established flow whose IPSec security association is in the process of being deleted.

Recommendation:
    This is a normal condition when the IPSec tunnel is torn down for any reason.

Syslogs:
    None

----------------------------------------------------------------
Name: no-ipv6-ipsec
IPSec over IPv6 unsupported:
    This counter will increment when the appliance receives an IPSec ESP packet, IPSec
NAT-T ESP packet or an IPSec over UDP ESP packet encapsulated in an IP version 6 header.
The appliance does not currently support any IPSec sessions encapsulated in IP version 6.

Recommendation:
    None

Syslogs:
    None

----------------------------------------------------------------
Name: tunnel-pending
Tunnel being brought up or torn down:
    This counter will increment when the appliance receives a packet matching an entry in
the security policy database (i.e. crypto map) but the security association is in the
process of being negotiated; it’s not complete yet.

    This counter will also increment when the appliance receives a packet matching an
entry in the security policy database but the security association has been or is in the
process of being deleted. The difference between this indication and the 'Tunnel has been
torn down' indication is that the 'Tunnel has been torn down' indication is for
established flows.

Recommendation:
```

```
    This is a normal condition when the IPSec tunnel is in the process of being negotiated
or deleted.

Syslogs:
    None

------------------------------------------------------------------
Name: need-ike
Need to start IKE negotiation:
    This counter will increment when the appliance receives a packet which requires
encryption but has no established IPSec security association. This is generally a normal
condition for LAN-to-LAN IPSec configurations. This indication will cause the appliance to
begin ISAKMP negotiations  with the destination peer.

Recommendation:
    If you have configured IPSec LAN-to-LAN on your appliance, this indication is normal
and does not indicate a problem.  However, if this counter increments rapidly it may
indicate a crypto configuration error or network error preventing the ISAKMP negotiation
from completing.

    Verify that you can communicate with the destination peer and verify your crypto
configuration via the 'show running-config' command.

Syslogs:
    None

------------------------------------------------------------------
Name: vpn-handle-error
VPN handle error:
    This counter is incremented when the appliance is unable to create a VPN handle
because the VPN handle already exists.

Recommendation:
    It is possible to see this counter increment as part of normal operation. However, if
the counter is rapidly incrementing and there is a major malfunction of vpn-based
applications, then this may be caused by a software defect. Use the following command sto
gather more information about this counter and ontact the Cisco TAC to investigate the
issue further.

    capture <name> type asp-drop vpn-handle-error
    show asp table classify crypto
    show asp table vpn-context detail

Syslogs:
    None

------------------------------------------------------------------
Name: vpn-handle-not-found
VPN handle not found:
    This counter is incremented when a datagram hits an encrypt or decrypt rule, and no
VPN handle is found for the flow the datagram is on.

Recommendation:
    It is possible to see this counter increment as part of normal operation. However, if
the counter is rapidly incrementing and there is a major malfunction of vpn-based
applications, then this may be caused by a software defect. Use the following command sto
gather more information about this counter and ontact the Cisco TAC to investigate the
issue further.

    capture <name> type asp-drop vpn-handle-not-found
    show asp table classify crypto
```

```
    show asp table vpn-context detail

Syslogs:
    None

------------------------------------------------------------------
Name: ipsec-spoof-detect
IPSec spoof packet detected:
    This counter will increment when the appliance receives a packet which should have
been encrypted but was not.  The packet matched the inner header security policy check of
a configured and established IPSec connection on the appliance but was received
unencrypted.  This is a security issue.

Recommendation:
    Analyze your network traffic to determine the source of the spoofed IPSec traffic.

Syslogs:
    402117

------------------------------------------------------------------
Name: svc-spoof-detect
SVC spoof packet detected:
    This counter will increment when the security appliance receives a packet which should
have been encrypted but was not. The packet matched the inner header security policy check
of a configured and established SVC connection on the security appliance but was received
unencrypted. This is a security issue.

Recommendation:
    Analyze your network traffic to determine the source of the spoofed SVC traffic.

Syslogs:
    None

------------------------------------------------------------------
Name: svc-failover
An SVC socket connection is being disconnected on the standby unit:
    This counter is incremented for each new SVC socket connection that is disconnected
when the active unit is transitioning into standby state as part of a failover transition.

Recommendation:
    None. This is part of a normal cleanup of a SVC connection when the current device is
transitioning from active to standby. Existing SVC connections on the device are no longer
valid and need to be removed.

Syslogs:
    None.

------------------------------------------------------------------
Name: svc-replacement-conn
SVC replacement connection established:
    This counter is incremented when an SVC connection is replaced by a new connection.

Recommendation:
    None. This may indicate that users are having difficulty maintaining connections to
the ASA. Users should evaluate the quality of their home network and Internet connection.

Syslog:
    722032
```

```
-------------------------------------------------------------
Name: ipsec-selector-failure
IPSec VPN inner policy selector mismatch detected:
    This counter is incremented when an IPSec packet is received with an inner IP header
that does not match the configured policy for the tunnel.

 Recommendation:
    Verify that the crypto ACLs for the tunnel are correct and that all acceptable packets
are included in the tunnel identity.  Verify that the box is not under attack if this
message is repeatedly seen.

 Syslogs:
    402116

-------------------------------------------------------------
Name: vpn-context-expired
Expired VPN context:
    This counter will increment when the security appliance receives a packet that
requires encryption or decryption, and the ASP VPN context required to perform the
operation is no longer valid.

 Recommendation:
    This indicates that a software error should be reported to the Cisco TAC.

 Syslogs:
    None

-------------------------------------------------------------
Name: vpn-lock-error
IPSec locking error:
    This counter is incremented when VPN flow cannot be created due to an internal locking
error.

Recommendation:
    This condition should never be encountered during normal operation and may indicate a
software problem with the appliance. Contact the Cisco Technical Assistance Center (TAC)
if this error occurs.

Syslogs:
    None.

-------------------------------------------------------------
Name: out-of-memory
No memory to complete flow:
    This counter is incremented when the appliance is unable to create a flow because of
insufficient memory.

Recommendation:
    Verify that the box is not under attack by checking the current connections. Also
verify if the configured timeout values are too large resulting in idle flows residing in
memory longer. Check the free memory available by issuing 'show memory'.  If free memory
is low, issue the command 'show processes memory' to determine which processes are
utilizing most of the memory.

Syslogs:
    None

-------------------------------------------------------------
Name: parent-closed
Parent flow is closed:
```

```
    When the parent flow of a subordinating flow is closed, the subordinating flow is also
closed.  For example, an FTP data flow (subordinating flow) will be closed with this
specific reason when its control flow (parent flow) is terminated.  This reason is also
given when a secondary flow (pin-hole) is closed by its controlling application.  For
example, when the BYE messaged is received, the SIP inspection engine (controlling
application) will close the corresponding SIP RTP flows (secondary flow).

Recommendation:
    None.

Syslogs:
    None.

----------------------------------------------------------------
Name: closed-by-inspection
Flow closed by inspection:
    This reason is given for closing a flow due to an error detected during application
inspection.  For example, if an error is detected during inspecting an H323 message, the
corresponding H323 flow is closed with this reason.

Recommendation:
    None.

Syslogs:
    None.

----------------------------------------------------------------
Name: fo-primary-closed
Failover primary closed:
    Standby unit received a flow delete message from the active unit and terminated the
flow.

Recommendation:
    If the appliance is running stateful failover, then this counter should increment for
every replicated connection that is torn down on the standby appliance.

Syslogs:
    302014, 302016, 302018

----------------------------------------------------------------
Name: fo-standby
Flow closed by failover standby:
    If a through-the-box packet arrives at an appliance or context is in a Standby state,
and a flow is created, the packet is dropped and the flow removed. This counter will
increment each time a flow is removed in this manner.

Recommendation:
    This counter should never be incrementing on the Active appliance or context. However,
it is normal to see it increment on the Standby appliance or context.

Syslogs:
    302014, 302016, 302018

----------------------------------------------------------------
Name: fo_rep_err
Standby flow replication error:
    Standby unit failed to replicate a flow.

Recommendation:
```

```
    If appliance is processing VPN traffic, then this counter could be constantly
increasing on the standby unit because of the flow could be replicated before the IKE SA
info. No action is required in this case. If the appliance is not processing VPN traffic,
then this indicate a software detect, turn on the debug: "debug fover fail" on the standby
unit, collect the debug output, and report the problem to Cisco TAC.

Syslogs:
    302014, 302016, 302018

----------------------------------------------------------------
Name: loopback
Flow is a loopback:
    This reason is given for closing a flow due to the following conditions: 1) when
U-turn traffic is present on the flow, and, 2) 'same-security-traffic permit
intra-interface' is not configured.

Recommendation:
    To allow U-turn traffic on an interface, configure the interface with
'same-security-traffic permit intra-interface'.

Syslogs:
    None.

----------------------------------------------------------------
Name: acl-drop
Flow is denied by access rule:
     This counter is incremented when a drop rule is hit by the packet and flow creation
is denied. This rule could be a default rule created when the box comes up, when various
features are turned on or off, when an acl is applied to interface or any other feature
etc. Apart from default rule drops, a flow could be denied because of:
     1) ACL configured on an interface
     2) ACL configured for AAA and AAA denied the user
     3) Thru-box traffic arriving at management-only ifc
     4) Unencrypted traffic arriving on a ipsec-enabled interface
     5) Implicity deny 'ip any any' at the end of an ACL

Recommendation:
    Observe if one of syslogs related to packet drop are fired. Flow drop results in the
corresponding packet-drop that would fire requisite syslog.

Syslogs:
    None.

----------------------------------------------------------------
Name: pinhole-timeout
Pinhole timeout:
    This counter is incremented to report that the appliance opened a secondary flow, but
no packets passed through this flow within the timeout interval, and hence it was removed.
An example of a secondary flow is the FTP data channel that is created after successful
negotiation on the FTP control channel.

Recommendation:
    No action required.

Syslogs:
    302014, 302016

----------------------------------------------------------------
Name: host-removed
Host is removed:
```

```
    Flow removed in response to "clear local-host" command.

Recommendation:
    This is an information counter.

Syslogs:
    302014, 302016, 302018, 302021, 305010, 305012, 609002

----------------------------------------------------------------
Name: xlate-removed
Xlate Clear:
    Flow removed in response to "clear xlate" or "clear local-host" command.

Recommendation:
    This is an information counter.

Syslogs:
    302014, 302016, 302018, 302021, 305010, 305012, 609002

----------------------------------------------------------------
Name: connection-timeout
Connection timeout:
    This counter is incremented when a flow is closed because of the expiration of it's
inactivity timer.

Recommendation:
    No action required.

Syslogs:
    302014, 302016, 302018, 302021

----------------------------------------------------------------
Name: conn-limit-exceeded
Connection limit exceeded:
    This reason is given for closing a flow when the connection limit has been exceeded.
The connection limit is configured via the 'set connection conn-max' action command.

Recommendation:
    None.

Syslogs:
    201011

----------------------------------------------------------------
Name: tcp-fins
TCP FINs:
    This reason is given for closing a TCP flow when TCP FIN packets are received.

Recommendations:
    This counter will increment for each TCP connection that is terminated normally with
FINs.

Syslogs:
    302014

----------------------------------------------------------------
Name: syn-timeout
SYN Timeout:
    This reason is given for closing a TCP flow due to expiry of embryonic timer.
```

```
Recommendations:
    If these are valid session which take longer to establish a connection increase the
embryonic timeout.

Syslogs:
    302014

----------------------------------------------------------------
Name: fin-timeout
FIN Timeout:
    This reason is given for closing a TCP flow due to expiry of half-closed timer.

Recommendations:
    If these are valid session which take longer to close a TCP flow, increase the
half-closed timeout.

Syslogs:
    302014

----------------------------------------------------------------
Name: reset-in
TCP Reset-I:
    This reason is given for closing an outbound flow (from a low-security interface to a
same- or high-security interface) when a TCP reset is received on the flow.

Recommendation:
    None.

Syslogs:
    302014

----------------------------------------------------------------
Name: reset-out
TCP Reset-O:
    This reason is given for closing an inbound flow (from a high-security interface to
low-security interface) when a TCP reset is received on the flow.

Recommendation:
    None.

Syslogs:
    302014

----------------------------------------------------------------
Name: reset-appliance
TCP Reset-APPLIANCE:
    This reason is given for closing a flow when a TCP reset is generated by appliance.

Recommendation:
    None.

Syslogs:
    302014

----------------------------------------------------------------
Name: recurse
Close recursive flow:
```

```
    A flow was recursively freed. This reason applies to pair flows, multicast slave
flows, and syslog flows to prevent syslogs being issued for each of these subordinate
flows.

Recommendation:
    No action required.

Syslogs:
    None

----------------------------------------------------------------
Name: tcp-intecept-no-response
TCP intercept, no response from server:
    SYN retransmission timeout after trying three times, once every second. Server
unreachable, tearing down connection.

Recommendation:
    Check if the server is reachable from the ASA.

Syslogs:
    None

----------------------------------------------------------------
Name: tcp-intercept-unexpected
TCP intercept unexpected state:
    Logic error in TCP intercept module, this should never happen.

Recommendation:
    Indicates memory corruption or some other logic error in the TCP intercept module.

Syslogs:
    None

----------------------------------------------------------------
Name: tcpnorm-rexmit-bad
TCP bad retransmission:
    This reason is given for closing a TCP flow when check-retranmission feature is
enabled and the TCP endpoint sent a retranmission with different data from the original
packet.

Recommendations:
    The TCP endpoint maybe attacking by sending different data in TCP retransmits. Please
use the packet capture feature to learn more about the origin of the packet.

Syslogs:
    302014

----------------------------------------------------------------
Name: tcpnorm-win-variation
TCP unexpected window size variation:
    This reason is given for closing a TCP flow when window size advertized by TCP
endpoint is drastically changed without accepting that much data.

Recommendations:
    In order to allow this connection, use the window-variation configuration under
tcp-map.

Syslogs:
    302014
```

```
----------------------------------------------------------------
Name: tcpnorm-invalid-syn
TCP invalid SYN:
    This reason is given for closing a TCP flow when the SYN packet is invalid.

Recommendations:
    SYN packet could be invalid for number of reasons, like invalid checksum, invalid TCP
header. Please use the packet capture feature to understand why the SYN packet is invalid.
If you would like to allow these connection use tcp-map configurations to bypass checks.

Syslogs:
    302014

----------------------------------------------------------------
Name: mcast-intrf-removed
Multicast interface removed:
    An output interface has been removed from the multicast entry.
    - OR -
    All output interfaces have been removed from the multicast entry.

Recommendation:
    No action required.
    - OR -
    Verify that there are no longer any receivers for this group.

Syslogs:
    None

----------------------------------------------------------------
Name: mcast-entry-removed
Multicast entry removed:
    A packet has arrived that matches a multicast flow, but the multicast service is no
longer enabled, or was re-enabled after the flow was built.
    - OR -
    The multicast entry has been deleted so the flow is being cleaned up, but the packet
will be reinjected into the data path.

Recommendation:
    Reenable multicast if it is disabled.
    - OR -
    No action required.

Syslogs:
    None

----------------------------------------------------------------
Name: tcp-intercept-kill
Flow terminated by TCP Intercept:
    TCP intercept would teardown a connection if this is the first SYN, a connection is
created for the SYN, and TCP intercept replied with a SYN cookie, or after seeing a valid
ACK from client, when TCP intercept sends a SYN to server, server replies with a RST.

Recommendation:
    TCP intercept normally does not create a connection for first SYN, except when there
are nailed rules or the packet comes over a VPN tunnel or the next hop gateway address to
reach the client is not resolved. So for the first SYN this indicates that a connection
got created. When TCP intercept receives a RST from server, its likely the corresponding
port is closed on the server.

Syslogs:
```

```
    None

-----------------------------------------------------------------
Name: audit-failure
Audit failure:
    A flow was freed after matching an "ip audit" signature that had reset as the
associated action.

Recommendation:
    If removing the flow is not the desired outcome of matching this signature, then
remove the reset action from the "ip audit" command.

Syslogs:
    None

-----------------------------------------------------------------
Name: cxsc-request
Flow terminated by CXSC:
    This reason is given for terminating a flow as requested by CXSC module.

Recommendations:
    Check syslogs and alerts on CXSC module.

Syslogs:
    429002

-----------------------------------------------------------------
Name: cxsc-fail-close
CXSC fail-close:
    This reason is given for terminating a flow since CXSC card is down and fail-close
option was used with CXSC action.

Recommendations:
    Check and bring up CXSC card.

Syslogs:
    429001

-----------------------------------------------------------------
Name: reset-by-cx
Flow reset by CXSC:
    This reason is given for terminating a TCP flow as requested by the CXSC module.

Recommendations:
    Check syslogs and alerts on CXSC module.

Syslogs:
    429003

-----------------------------------------------------------------
Name: ips-request
Flow terminated by IPS:
    This reason is given for terminating a flow as requested by IPS module.

Recommendations:
    Check syslogs and alerts on IPS module.

Syslogs:
    420002
```

```
------------------------------------------------------------------
Name: cxsc-request
CXSC Module requested drop:
    This counter is incremented and the packet is dropped as requested by the CXSC module
when the packet matches a signature on the CXSC engine.

Recommendations:
    Check syslogs and alerts on the CXSC module.

Syslogs:
    429002

------------------------------------------------------------------
Name: cxsc-bad-tlv-received
CXSC Module requested drop:
    This counter is incremented and the packet is dropped as requested by the CXSC module
when the packet has bad TLVs.

Recommendations:
    Check syslogs and alerts on the CXSC module.
Syslogs:
    None

------------------------------------------------------------------
Name: cxsc-malformed-packet
CXSC Module requested drop:
    This counter is incremented and the packet is dropped as requested by the CXSC module
when the packet is malformed.

Recommendations:
    Check syslogs and alerts on the CXSC module.

Syslogs:
    None

------------------------------------------------------------------
Name: cxsc-fail
CXSC config removed for connection:
    This counter is incremented and the packet is dropped when the CXSC configuration is
not found for a particular connection.

Recommendations:
    Check if any configuration changes have been made for CXSC.

Syslogs:
    None

------------------------------------------------------------------
Name: cxsc-ha-request
CXSC HA replication drop:
    This counter is incremented when the security appliance receives a CXSC HA request
packet, but could not process it and the packet is dropped.

Recommendation:
    This could happen occasionally when CXSC does not have the latest ASA HA state, such
as right after an ASA HA state change. If the counter is constantly increasing however, it
may be because CXSC and ASA are out of sync. If that happens, contact Cisco TAC for
assistance.
```

```
Syslogs:
    None.

-----------------------------------------------------------------
Name: cxsc-invalid-encap
CXSC invalid header drop:
    This counter is incremented when the security appliance receives a CXSC packet with an
invalid messsage header, and the packet is dropped.

Recommendation: This should not happen. Contact Cisco TAC for assistance.

Syslogs:
    None.

-----------------------------------------------------------------
Name: ips-fail-close
IPS fail-close:
    This reason is given for terminating a flow since IPS card is down and fail-close
option was used with IPS inspection.

Recommendations:
    Check and bring up IPS card.

Syslogs:
    420001

-----------------------------------------------------------------
Name: reinject-punt
Flow terminated by punt action:
    This counter is incremented when a packet is punted to the exception-path for
processing by one of the enhanced services such as inspect, aaa etc and the servicing
routine, having detected a violation in the traffic flowing on the flow, requests that the
flow be dropped. The flow is immediately dropped.

Recommendation:
    Please watch for syslogs fired by servicing routine for more information. Flow drop
terminates the corresponding connection.

Syslogs:
    None.

-----------------------------------------------------------------
Name: shunned
Flow shunned:
    This counter will increment when a packet is received which has a source IP address
that matches a host in the shun database.  When a shun command is applied, it will be
incremented for each existing flow that matches the shun command.

Recommendation:
    No action required.

Syslogs:
    401004

-----------------------------------------------------------------
Name: host-limit
host-limit
```

```
---------------------------------------------------------------
Name: nat-failed
NAT failed:
    Failed to create an xlate to translate an IP or transport header.

Recommendation:
    If NAT is not desired, disable "nat-control".  Otherwise, use the "static", "nat" or
"global" command to configure NAT policy for the dropped flow.  For dynamic NAT, ensure
that each "nat" command is paired with at least one "global" command.  Use "show nat" and
"debug pix process" to verify NAT rules.

Syslogs:
    305005, 305006, 305009, 305010, 305011, 305012

---------------------------------------------------------------
Name: nat-rpf-failed
NAT reverse path failed:
    Rejected attempt to connect to a translated host using the translated host's real
address.

Recommendation:
    When not on the same interface as the host undergoing NAT, use the mapped address
instead of the real address to connect to the host. Also, enable the appropriate inspect
command if the application embeds IP address.

Syslogs:
    305005

---------------------------------------------------------------
Name: inspect-fail
Inspection failure:
    This counter will increment when the appliance fails to enable protocol inspection
carried out by the NP for the connection. The cause could be memory allocation failure, or
for ICMP error message, the appliance not being able to find any established connection
related to the frame embedded in the ICMP error message.

Recommendation:
    Check system memory usage.  For ICMP error message, if the cause is an attack, you can
deny the host using the ACLs.

Syslogs:
    313004 for ICMP error.

---------------------------------------------------------------
Name: no-inspect
Failed to allocate inspection:
    This counter will increment when the security appliance fails to allocate a run-time
inspection data structure upon connection creation. The connection will be dropped.

Recommendation:
    This error condition is caused when the security appliance runs out of system memory.
Please check the current available free memory by executing the "show memory" command.

Syslogs:
    None

---------------------------------------------------------------
Name: reset-by-ips
Flow reset by IPS:
    This reason is given for terminating a TCP flow as requested by IPS module.
```

```
Recommendations:
    Check syslogs and alerts on IPS module.

Syslogs:
    420003

------------------------------------------------------------------
Name: flow-reclaimed
Non-tcp/udp flow reclaimed for new request:
    This counter is incremented when a reclaimable flow is removed to make room for a new
flow.  This occurs only when the number of flows through the appliance equals the maximum
number permitted by the software imposed limit, and a new flow request is received. When
this occurs, if the number of reclaimable flows exceeds the number of VPN tunnels
permitted by the appliance, then the oldest reclaimable flow is removed to make room for
the new flow.  All flows except the following are deemed to be reclaimable:
    1. TCP, UDP, GRE and Failover flows
    2. ICMP flows if ICMP stateful inspection is enabled
    3. ESP flows to the appliance

Recommendation:
    No action is required if this counter is incrementing slowly. If this counter is
incrementing rapidly, it could mean that the appliance is under attack and the appliance
is spending more time reclaiming and rebuilding flows.

Syslogs
    302021

------------------------------------------------------------------
Name: non_tcp_syn
non-syn TCP:
    This reason is given for terminating a TCP flow when the first packet is not a SYN
packet.

Recommendations:
    None

Syslogs:
    None

------------------------------------------------------------------
Name: rm-xlate-limit
RM xlate limit reached:
    This counter is incremented when the maximum number of xlates for a context or the
system has been reached and a new connection is attempted.

 Recommendation:
    The device administrator can use the commands 'show resource usage' and 'show resource
usage system' to view context and system resource limits and 'Denied' counts and adjust
resource limits if desired.

 Syslogs:
    321001

------------------------------------------------------------------
Name: rm-host-limit
RM host limit reached:
    This counter is incremented when the maximum number of hosts for a context or the
system has been reached and a new connection is attempted.
```

```
 Recommendation:
    The device administrator can use the commands 'show resource usage' and 'show resource
usage system' to view context and system resource limits and 'Denied' counts and adjust
resource limits if desired.

 Syslogs:
    321001

----------------------------------------------------------------
Name: rm-inspect-rate-limit
RM inspect rate limit reached:
    This counter is incremented when the maximum inspection rate for a context or the
system has been reached and a new connection is attempted.

 Recommendation:
    The device administrator can use the commands 'show resource usage' and 'show resource
usage system' to view context and system resource limits and 'Denied' counts and adjust
resource limits if desired.

 Syslogs:
    321002

----------------------------------------------------------------
Name: tcpmod-connect-clash
A TCP connect socket clashes with an existing listen connection. This is an internal
system error.  Contact TAC.

----------------------------------------------------------------
Name: ssm-app-request
Flow terminated by service module:
    This counter only applies to the ASA 5500 series adaptive security appliance. It is
incremented when the application running on the SSM requests the security appliance to
terminate a connection.

Recommendation:
    You can obtain more information by querying the incident report or system messages
generated by the SSM itself. Please consult the documentation that comes with comes with
the SSM for instructions.

Syslogs:
    None.

----------------------------------------------------------------
Name: ssm-app-fail
Service module failed:
    This counter only applies to the ASA 5500 series adaptive security appliance. It is
incremented when a connection that is being inspected by the SSM is terminated because the
SSM has failed.

Recommendation:
    The card manager process running in the security appliance control plane issued system
messages and CLI warning to inform you of the failure. Please consult the documentation
that comes with the SSM to trouble shoot the SSM failure. Contact Cisco Technical
Assistance Center (TAC) if needed.

Syslog:
    421001.

----------------------------------------------------------------
Name: ssm-app-incompetent
```

```
Service module incompetent:
    This counter only applies to the ASA 5500 series adaptive security appliance. It is
incremented when a connection is supposed to be inspected by the SSM, but the SSM is not
able to inspect it. This counter is reserved for future use. It should always be 0 in the
current release.

Recommendation:
    None.

Syslog:
    None.

----------------------------------------------------------------
Name: ssl-bad-record-detect
SSL bad record detected:
    This counter is incremented for each unknown SSL record type received from the remote
peer. Any unknown record type received from the peer is treated as a fatal error and the
SSL connections that encounter this error must be terminated.

Recommendation:
    It is not normal to see this counter increment at any time. If this counter is
incremented, it usually means that the SSL protocol state is out of sync with the client
software. The most likely cause of this problem is a software defect in the client
software. Contact the Cisco TAC with the client software or web browser version and
provide a network trace of the SSL data exchange to troubleshoot this problem.

Syslogs:
    None.

----------------------------------------------------------------
Name: ssl-handshake-failed
SSL handshake failed:
    This counter is incremented when the TCP connection is dropped because the SSL
handshake failed.

Recommendation:
    This is to indicate that the TCP connection is dropped because the SSL handshake
failed. If the problem cannot be resolved based on the syslog information generated by the
handshake failure condition, please include the related syslog information when contacting
the Cisco TAC.

Syslogs:
    725006.
    725014.

----------------------------------------------------------------
Name: ssl-malloc-error
SSL malloc error:
    This counter is incremented for each malloc failure that occurs in the SSL lib. This
is to indicate that SSL encountered a low memory condition where it can't allocate a
memory buffer or packet block.

Recommendation:
    Check the security appliance memory and packet block condition and contact Cisco the
TAC with this memory information.

Syslogs:
    None.

----------------------------------------------------------------
```

```
Name: ctm-crypto-request-error
CTM crypto request error:
    This counter is incremented each time CTM cannot accept our crypto request. This
usually means the crypto hardware request queue is full.

Recommendation:
    Issue the show crypto protocol statistics ssl command and contact the Cisco TAC with
this information.

Syslogs:
    None.

----------------------------------------------------------------
Name: ssl-record-decrypt-error
SSL record decryption failed:
    This counter is incremented when a decryption error occurs during SSL data receive.
This usually means that there is a bug in the SSL code of the ASA or peer, or an attacker
may be modifying the data stream. The SSL connection has been closed.

Recommendation:
    Investigate the SSL data streams to and from your ASA. If there is no attacker, then
this indicates a software error that should be reported to the Cisco TAC.

Syslogs:
    None.

----------------------------------------------------------------
Name: np-socket-conn-not-accepted
A new socket connection was not accepted:
    This counter is incremented for each new socket connection that is not accepted by the
security appliance.

Recommendation:
    It is possible to see this counter increment as part of normal operation. However, if
the counter is rapidly incrementing and there is a major malfunction of socket-based
applications, then this may be caused by a software defect. Contact the Cisco TAC to
investigate the issue further.

Syslog:
    None.

----------------------------------------------------------------
Name: np-socket-failure
NP socket failure:
    This is a general counter for critical socket processing errors.

Recommendation:
    This indicates that a software error should be reported to the Cisco TAC.

Syslog:
    None.

----------------------------------------------------------------
Name: np-socket-relay-failure
NP socket relay failure:
    This is a general counter for socket relay processing errors.

Recommendation:
```

```
    It is possible to see this counter increment as part of normal operation. However, if
the counter is rapidly incrementing and there is a major malfunction of socket-based
applications, then this may be caused by a software defect. Contact the Cisco TAC to
investigate the issue further.

Syslog:
    None.

----------------------------------------------------------------
Name: np-socket-data-move-failure
NP socket data movement failure:
    This counter is incremented for socket data movement errors.

Recommendation:
    This indicates that a software error should be reported to the Cisco TAC.

Syslog:
    None.

----------------------------------------------------------------
Name: np-socket-new-conn-failure
NP socket new connection failure:
    This counter is incremented for new socket connection failures.

Recommendation:
    This indicates that a software error should be reported to the Cisco TAC.

Syslog:
    None.

----------------------------------------------------------------
Name: np-socket-transport-closed
NP socket transport closed:
    This counter is incremented when the transport attached to the socket is abruptly
closed.

Recommendation:
    It is possible to see this counter increment as part of normal operation. However, if
the counter is rapidly incrementing and there is a major malfunction of socket-based
applications, then this may be caused by a software defect. Contact the Cisco TAC to
investigate the issue further.

Syslog:
    None.

----------------------------------------------------------------
Name: np-socket-block-conv-failure
NP socket block conversion failure:
    This counter is incremented for socket block conversion failures.

Recommendation:
    This indicates that a software error should be reported to the Cisco TAC.

Syslog:
    None.

----------------------------------------------------------------
Name: ssl-received-close-alert
SSL received close alert:
```

```
    This counter is incremented each time the security appliance receives a close alert
from the remote client. This indicates that the client has notified us they are going to
drop the connection. It is part of the normal disconnect process.

Recommendation:
    None.

Syslog:
    725007.

----------------------------------------------------------------
Name: children-limit
Max per-flow children limit exceeded:
    The number of children flows associated with one parent flow exceeds the internal
limit of 200.

Recommendation:
    This message indicates either a misbehaving application or an active attempt to
exhaust the firewall memory. Use "set connection per-client-max" command to further fine
tune the limit. For FTP, additionally enable the "strict" option in "inspect ftp".

Syslogs:
    210005

----------------------------------------------------------------
Name: tracer-flow
packet-tracer traced flow drop:
    This counter is internally used by packet-tracer for flow freed once tracing is
complete.

Recommendation:
    None.

Syslog:
    None.

----------------------------------------------------------------
Name: sp-looping-address
looping-address:
    This counter is incremented when the source and destination addresses in a flow are
the same. SIP flows where address privacy is enabled are excluded, as it is normal for
those flows to have the same source and destination address.

 Recommendation:
    There are two possible conditions when this counter will increment. One is when the
appliance receives a packet with the source address equal to the destination. This
represents a type of DoS attack.  The second is when the NAT configuration of the
appliance NATs a source address to equal that of the destination.  One should examine
syslog message 106017 to determine what IP address is causing the counter to increment,
then enable packet captures to capture the offending packet, and perform additional
analysis.

 Syslogs:
    106017

----------------------------------------------------------------
Name: no-adjacency
No valid adjacency:
```

```
    This counter will increment when the security appliance receives a packet on an
existing flow that no longer has a valid output adjacency. This can occur if the nexthop
is no longer reachable or if a routing change has occurred typically in a dynamic routing
environment.

 Recommendation:
    No action required.

 Syslogs:
    None

------------------------------------------------------------------
Name: np-midpath-service-failure
NP midpath service failure:
    This is a general counter for critical midpath service errors.

Recommendation:
    This indicates that a software error should be reported to the Cisco TAC.

Syslog:
    None.

------------------------------------------------------------------
Name: np-midpath-cp-event-failure
NP midpath CP event failure:
    This is counter for critical midpath events that could not be sent to the CP.

Recommendation:
    This indicates that a software error should be reported to the Cisco TAC.

Syslog:
    None.

------------------------------------------------------------------
Name: np-context-removed
NP virtual context removed:
    This counter is incremented when the virtual context with which the flow is going to
be associated has been removed. This could happen in multi-core environment when one CPU
core is in the process of destroying the virtual context, and another CPU core tries to
create a flow in the context.

Recommendation:
    No action is required.

Syslog:
    None.

------------------------------------------------------------------
Name: fover-idle-timeout
Flow removed from standby unit due to idle timeout:
    A flow is considered idle if standby unit no longer receives periodical update from
active which is supposed to happen to at fixed internal when flow is alive. This counter
is incremented when such flow is removed from standby unit.

Recommendation:
    This counter is informational.

Syslogs:
    None.
```

```
------------------------------------------------------------------
Name: dynamic-filter
Flow matched dynamic-filter blacklist:
    A flow matched a dynamic-filter blacklist or greylist entry with a threat-level higher
than the threat-level threshold configured to drop traffic.

Recommendation:
    Use the internal IP address to trace the infected host. Take remediation steps to
remove the infection.

Syslogs:
    None.

------------------------------------------------------------------

Name: route-change
Flow terminated due to route change:
    When the system adds a lower cost (better metric) route, incoming packets that match
the new route will cause their existing connection to be torn down after the user
configured timeout (floating-conn) value. Subsequent packets will rebuild the connection
out the interface with the better metric.

Recommendation:
    To prevent the addition of lower cost routes from affecting active flows, the
'floating-conn' configuration timeout value can be set to 0:0:0.

Syslogs:
    None.

------------------------------------------------------------------
Name: svc-selector-failure
SVC VPN inner policy selector mismatch detected:
    This counter is incremented when an SVC packet is received with an inner IP header
that does not match the policy for the tunnel.

 Recommendation:
    None. This packet will be discarded automatically.

 Syslogs:
    None.

------------------------------------------------------------------
Name: dtls-hello-close
DTLS hello processed and closed:
     This counter is incremented when the UDP connection is dropped after the DTLS client
hello message processing is finished. This does not indicate an error.

Recommendation:
None.

 Syslogs:
    None.

------------------------------------------------------------------
Name: svc-conn-timer-cb-fail
SVC connection timer callback failure:
    This condition occurs when there is a failed attempt to place an event on the async
lock queue for that connection.
```

```
 Recommendation:
    None.

 Syslogs:
    None.

-----------------------------------------------------------------
Name: svc-udp-conn-timer-cb-fail
SVC UDP connection timer callback failure:
    This condition occurs when there is a failed attempt to place an event on the async
lock queue for that connection.

 Recommendation:
    None.

 Syslogs:
    None.

-----------------------------------------------------------------
Name: nat64/46-conversion-fail
IPv6 to IPv4 or vice-versa conversion failure:
    This condition occurs when there is a failure in coversion of IPv6 traffic to IPv4 or
vice-versa.

 Recommendation:
    None.

 Syslogs:
    None.

-----------------------------------------------------------------
Name: cluster-cflow-clu-closed
Cluster flow with CLU closed on owner:
    Director/backup unit received a cluster flow clu delete message from the owner unit
and terminated the flow.

Recommendation:
    This counter should increment for every replicated clu that is torn down on the owner
unit.

Syslogs:
    None.

-----------------------------------------------------------------
Name: cluster-cflow-clu-timeout
Cluster flow with CLU removed from due to idle timeout:
    A cluster flow with CLU is considered idle if director/backup unit no longer receives
periodical update from owner which is supposed to happen at fixed interval when flow is
alive.

Recommendation:
    This counter is informational.

Syslogs:
    None.

-----------------------------------------------------------------
Name: cluster-redirect
Flow matched a cluster redirect classify rule:
```

```
    A stub forwarding flow will thereafter forward packets to the cluster unit that owns
the flow.

Recommendations:
    This counter is informational and the behavior expected. The packet was forwarded to
the owner over the Cluster Control Link.

Syslogs:
    None.

----------------------------------------------------------------
Name: cluster-drop-on-slave
Flow matched a cluster drop-on-slave classify rule:
    This is for cases that the packets from L3 subnet are seen by all units and only
master unit need to process them.

Recommendations:
    This counter is informational and the behavior expected. The packet is processed by
master.

Syslogs:
    None.

----------------------------------------------------------------
Name: cluster-director-change
The flow director changed due to a cluster join event:
    A new unit joined the cluster and is now the director for the flow. The old
director/backup has removed it's flow and the flow owner will update the new director.

Recommendations:
    This counter is informational and the behavior expected.

Syslogs:
    None.

----------------------------------------------------------------
Name: cluster-mcast-owner-change
The multicast flow owner changed due to a cluster join or leave event:
     This flow gets created on a new owner unit.

Recommendations:
    This counter is informational and the behavior expected.

Syslogs:
    None.

----------------------------------------------------------------
Name: cluster-convert-to-dirbak
Forwarding or redirect flow converted to director or backup flow:
    Forwarding or redirect flow is removed, so that director or backup flow can be
created.

Recommendations:
    This counter is informational and the behavior expected.

Syslogs:
    None.

----------------------------------------------------------------
```

```
Name: inspect-scansafe-server-not-reachable
Scansafe server is not configured or the cloud is down:
    Either the scansafe server IP is not specified in the scansafe general options or the
scansafe server is not reachable.

Recommendations:
    This counter is informational and the behavior expected.

Syslogs:
    None.

----------------------------------------------------------------
Name: cluster-director-closed
Flow removed due to director flow closed:
    Owner unit received a cluster flow clu delete message from the director unit and
terminated the flow.

Recommendation:
    This counter should increment for every replicated clu that is torn down on the
director unit.

Syslogs:
    None.

----------------------------------------------------------------
Name: cluster-pinhole-master-change
Master only pinhole flow removed at bulk sync due to master change:
    Master only pinhole flow is removed during bulk sync because cluster master has
changed.

Recommendation:
    This counter is informational and the behavior expected.

Syslogs:
    302014

----------------------------------------------------------------
Name: cluster-parent-owner-left
Flow removed at bulk sync becasue parent flow is gone:
    Flow is removed during bulk sync becasue the parent flow's owner has left the cluster.

Recommendation:
    This counter is informational and the behavior expected.

Syslogs:
    302014

----------------------------------------------------------------
Name: cluster-ctp-punt-channel-missing
Flow removed at bulk sync becasue CTP punt channel is missing:
    Flow is removed during bulk sync because CTP punt channel is missing in cluster
restored flow.

Recommendation:
    The cluster master may have just left the cluster. And there might be packet drops on
the Cluster Control Link.

Syslogs:
    302014
```

```
------------------------------------------------------------------
Name: vpn-overlap-conflict

VPN Network Overlap Conflict:
When a packet is decrypted, the inner packet is examined against the crypto map
configuration.  If the packet matches a different crypto map entry than the one it was
received on, it will be dropped and this counter will increment.  A common cause for this
is two crypto map entries containing similar/overlapping address spaces.

Recommendation:
    Check your VPN configuration for overlapping networks. Verify the
    order of your crypto maps and use of deny rules in ACLs.

Syslogs:
    None

------------------------------------------------------------------
```

Examples

The following is sample output from the **show asp drop** command, with the timestamp indicating the last time the counters were cleared:

```
hostname# show asp drop

Frame drop:
  Flow is denied by configured rule (acl-drop)                           3
  Dst MAC L2 Lookup Failed (dst-l2_lookup-fail)                       4110
  L2 Src/Dst same LAN port (l2_same-lan-port)                          760
  Expired flow (flow-expired)                                            1

Last clearing: Never

Flow drop:
  Flow is denied by access rule (acl-drop)                              24
  NAT failed (nat-failed)                                            28739
  NAT reverse path failed (nat-rpf-failed)                           22266
  Inspection failure (inspect-fail)                                  19433

Last clearing: 17:02:12 UTC Jan 17 2012 by enable_15
```

Related Commands

Command	Description
capture	Captures packets, including the option to capture packets based on an ASP drop code.
clear asp drop	Clears drop statistics for the accelerated security path.
show conn	Shows information about connections.

show asp event dp-cp

To debug the data path or control path event queues, use the **show asp event dp-cp** command in privileged EXEC mode.

show asp event dp-cp [**cxsc msg**]

Syntax Description

cxsc msg	(Optional) Identifies the CXSC event messages that are sent to the CXSC event queue.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
9.0(1)	This command was introduced.
9.1(3)	A routing event queue entry was added.

Usage Guidelines

The **show asp event dp-cp** command shows the contents of the data path and control path, which might help you troubleshoot a problem. See the CLI configuration guide for more information about the data path and control path. These tables are used for debugging purposes only, and the information output is subject to change. Consult Cisco TAC to help you debug your system with this command.

Examples

The following is sample output from the **show asp event dp-cp** command:

```
hostname# show asp event dp-cp

DP-CP EVENT QUEUE                 QUEUE-LEN  HIGH-WATER
Punt Event Queue                          0        2048
Routing Event Queue                       0           1
Identity-Traffic Event Queue              0          17
General Event Queue                       0           0
Syslog Event Queue                        0        3192
Non-Blocking Event Queue                  0           4
Midpath High Event Queue                  0           0
Midpath Norm Event Queue                  0           0
SRTP Event Queue                          0           0
HA Event Queue                            0           3
Threat-Detection Event Queue              0           3

ha-msg              520          0      520        0      520          0
cxsc-msg            127          0      127        0      127          0
```

show asp load-balance

To display a histogram of the load balancer queue sizes, use the **show asp load-balance** command in privileged EXEC mode.

show asp load-balance [**detail**]

Syntax Description

detail	(Optional) Shows detailed information about hash buckets.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.1(1)	This command was introduced.

Usage Guidelines

The **show asp load-balance** command might help you troubleshoot a problem. Normally a packet will be processed by the same core that pulled it in from the interface receive ring. However, if another core is already processing the same connection as the packet just received, then the packet will be queued to that core. This queuing can cause the load balancer queue to grow while other cores are idle. See the **asp load-balance per-packet** command for more information.

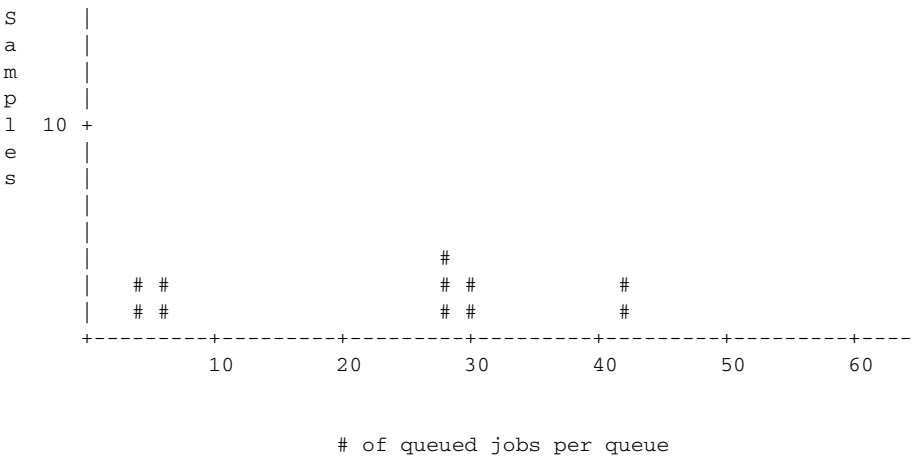
Examples

The following is sample output from the **show asp load-balance** command. The X-axis represents the number of packets queued in different queues. The Y-axis represents the number of load balancer hash buckets (not to be confused with the bucket in the histogram title, which refers to the histogram bucket) that has packets queued. To know the exact number of hash buckets having the queue, use the **detail** keyword.

```
hostname# show asp load-balance

Histogram of 'ASP load balancer queue sizes'
  64 buckets sampling from 1 to 65 (1 per bucket)
  6 samples within range (average=23)
                     ASP load balancer queue sizes

  100 +
      |
      |
      |
```



The following is sample output from the **show asp load-balance detail** command.

```
hostname# show asp load-balance detail

<Same histogram output as before with the addition of the following values for the
histogram>

Data points:
<snip>
  bucket[1-1] = 0 samples
  bucket[2-2] = 0 samples
  bucket[3-3] = 0 samples
  bucket[4-4] = 1 samples
  bucket[5-5] = 0 samples
  bucket[6-6] = 1 samples
<snip>
  bucket[28-28] = 2 samples
  bucket[29-29] = 0 samples
  bucket[30-30] = 1 samples
<snip>
  bucket[41-41] = 0 samples
  bucket[42-42] = 1 samples
```

RelatedCommands

Command	Description
asp load-balance per-packet	Changes the core load balancing method for multi-core ASA models.

show asp table arp

To debug the accelerated security path ARP tables, use the **show asp table arp** command in privileged EXEC mode.

show asp table arp [**interface** *interface_name*] [**address** *ip_address* [**netmask** *mask*]]

Syntax Description

address *ip_address*	(Optional) Identifies an IP address for which you want to view ARP table entries.
interface *interface_name*	(Optional) Identifies a specific interface for which you want to view the ARP table.
netmask *mask*	(Optional) Sets the subnet mask for the IP address.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show arp** command shows the contents of the control plane, while the **show asp table arp** command shows the contents of the accelerated security path, which might help you troubleshoot a problem. See the CLI configuration guide for more information about the accelerated security path. These tables are used for debugging purposes only, and the information output is subject to change. Consult Cisco TAC to help you debug your system with this command.

Examples

The following is sample output from the **show asp table arp** command:

```
hostname# show asp table arp

Context: single_vf, Interface: inside
  10.86.194.50                            Active   000f.66ce.5d46 hits 0
  10.86.194.1                             Active   00b0.64ea.91a2 hits 638
  10.86.194.172                           Active   0001.03cf.9e79 hits 0
  10.86.194.204                           Active   000f.66ce.5d3c hits 0
  10.86.194.188                           Active   000f.904b.80d7 hits 0

Context: single_vf, Interface: identity
```

```
::                                      Active   0000.0000.0000 hits 0
0.0.0.0                                 Active   0000.0000.0000 hits 50208
```

Related Commands

Command	Description
show arp	Shows the ARP table.
show arp statistics	Shows ARP statistics.

show asp table classify

To debug the accelerated security path classifier tables, use the **show asp table classify** command in privileged EXEC mode.

s**how asp table classify** [**interface** *interface_name*] [**crypto** | **domain** *domain_name*] [**hits**] [**match** *regexp*] [**user-statistics**]

Syntax Description

crypto	(Optional) Shows the encrypt, decrypt, and ipsec tunnel flow domains only.
domain *domain_name*	(Optional) Shows entries for a specific classifier domain. See the "Usage Guidelines" section for a list of domains.
hits	(Optional) Shows classifier entries that have non-zero hits values.
interface *interface_name*	(Optional) Identifies a specific interface for which you want to view the classifier table.
match *regexp*	(Optional) Shows classifier entries that match the regular expression. Use quotes when regular expressions include spaces.
user-statistics	(Optional) Specifies user and group information.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(4)	Added the **hits** option and the timestamp to indicate the last time the ASP table counters were cleared.
8.0(2)	A new counter was added to show the number of times a match compilation was aborted. This counter is shown only if the value is greater than 0.
8.2(2)	Added the **match** *regexp* option.
8.4(4.1)	Added the **csxc** and **cxsc-auth-proxy** domains for the ASA CX module.
9.0(1)	The **user-statistics** keyword was added. The output was updated to add security group names and source and destination tags.

Usage Guidelines

The **show asp table classify** command shows the classifier contents of the accelerated security path, which might help you troubleshoot a problem. See the CLI configuration guide for more information about the accelerated security path. The classifier examines properties of incoming packets, such as protocol, and source and destination address, to match each packet to an appropriate classification rule. Each rule is labeled with a classification domain that determines what types of actions are performed, such as dropping a packet or allowing it through. The information shown is used for debugging purposes only, and the output is subject to change. Consult Cisco TAC to help you debug your system with this command.

Classifier domains include the following:

Related Commands

Command	Description
show asp drop	Shows the accelerated security path counters for dropped packets.

show asp table cluster chash-table

To debug the accelerated security path cHash tables for clustering, use the **show asp table cluster chash-table** command in privileged EXEC mode.

show asp table cluster chash-table

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The **show asp table cluster chash-table** command shows the contents of the accelerated security path, which might help you troubleshoot a problem. See the CLI configuration guide for more information about the accelerated security path. These tables are used for debugging purposes only, and the information output is subject to change. Consult Cisco TAC to help you debug your system with this command.

Examples

The following is sample output from the **show asp table cluster chash-table** command:

```
hostname# show asp table cluster chash-table
Cluster current chash table:

Related Commands

Command	Description
show asp cluster counter	Shows cluster datapath counter information.

show asp table cts sgt-map

To show the IP address-security group table mapping from the IP address-security group table database that is maintained in the data path for Cisco TrustSec, use the **show asp table cts sgt-map** command in privileged EXEC mode.

show asp table cts sgt-map [**address** *ipv4* | **address** *ipv6* | **ipv4** | **ipv6** | **sgt** *sgt*]

Syntax Description

address *ipv4*	(Optional) Shows the IP address-security group table mapping for the specified IPv4 addresses.
address *ipv6*	(Optional) Shows the IP address-security group table mapping for the specified IPv6 addresses.
ipv4	(Optional) Shows all of the IP address-security group table mapping for IPv4 addresses.
ipv6	(Optional) Shows all of the IP address-security group table mapping for IPv6 addresses.
sgt *sgt*	(Optional) Shows the IP address-security group table mapping for the specified security group table.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

If the address is not specified, then all the entries in the the IP address-security group table database in the data path appear. The address can be an exact address or a subnet-based address. In addition, the security group names appear when available.

Examples

The following is sample output from the **show asp table cts sgt-map** command:

```
hostname# show asp table cts sgt-map

IP Address                      SGT
================================================
10.10.10.5                      1234:Marketing
```

```
55.67.89.12                         5:Engineering
56.34.0.0                           338:HR
192.4.4.4                           345:Finance

Total number of entries shown = 4
```

The following is sample output from the **show asp table cts sgt-map address** command:

```
hostname# show asp table cts sgt-map address 10.10.10.5

IP Address                          SGT
================================================
10.10.10.5                          1234:Marketing

Total number of entries shown = 1
```

The following is sample output from the **show asp table cts sgt-map ipv6** command:

```
hostname# show asp table cts sgt-map ipv6

IP Address                                SGT
============================================================
FE80::A8BB:CCFF:FE00:110                  17:Marketing-Servers
FE80::A8BB:CCFF:FE00:120                  18:Eng-Servers

Total number of entries shown = 2
```

The following is sample output from the **show asp table cts sgt-map sgt** command:

```
hostname# show asp table cts sgt-map sgt 17

IP Address                                SGT
============================================
FE80::A8BB:CCFF:FE00:110                  17

Total number of entries shown = 1
```

Related Commands

Command	Description
show running-config cts	Shows the SXP connections for the running configuration.
show cts environment	Shows the health and status of the environment data refresh operation.

show asp table dynamic-filter

To debug the accelerated security path Botnet Traffic Filter tables, use the **show asp table dynamic-filter** command in privileged EXEC mode.

show asp table dynamic-filter [**hits**]

Syntax Description

hits	(Optional) Shows classifier entries which have non-zero hits values.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

The **show asp table dynamic-filter** command shows the Botnet Traffic Filter rules in the accelerated security path, which might help you troubleshoot a problem. See the CLI configuration guide for more information about the accelerated security path. These tables are used for debugging purposes only, and the information output is subject to change. Consult Cisco TAC to help you debug your system with this command.

Examples

The following is sample output from the **show asp table dynamic-filter** command:

```
hostname# show asp table dynamic-filter

Context: admin
 Address 10.246.235.42 mask 255.255.255.255 name: example.info
flags: 0x44 hits 0

...
```

Related Commands

Command	Description
address	Adds an IP address to the blacklist or whitelist.
clear configure dynamic-filter	Clears the running Botnet Traffic Filter configuration.
clear dynamic-filter dns-snoop	Clears Botnet Traffic Filter DNS snooping data.
clear dynamic-filter reports	Clears Botnet Traffic filter report data.
clear dynamic-filter statistics	Clears Botnet Traffic filter statistics.
dns domain-lookup	Enables the ASA to send DNS requests to a DNS server to perform a name lookup for supported commands.
dns server-group	Identifies a DNS server for the ASA.
dynamic-filter ambiguous-is-black	Treats greylisted traffic as blacklisted traffic for action purposes.
dynamic-filter blacklist	Edits the Botnet Traffic Filter blacklist.
dynamic-filter database fetch	Manually retrieves the Botnet Traffic Filter dynamic database.
dynamic-filter database find	Searches the dynamic database for a domain name or IP address.
dynamic-filter database purge	Manually deletes the Botnet Traffic Filter dynamic database.
dynamic-filter drop blacklist	Automatically drops blacklisted traffic.
dynamic-filter enable	Enables the Botnet Traffic Filter for a class of traffic or for all traffic if you do not specify an access list.
dynamic-filter updater-client enable	Enables downloading of the dynamic database.
dynamic-filter use-database	Enables use of the dynamic database.
dynamic-filter whitelist	Edits the Botnet Traffic Filter whitelist.
inspect dns dynamic-filter-snoop	Enables DNS inspection with Botnet Traffic Filter snooping.
name	Adds a name to the blacklist or whitelist.
show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
show dynamic-filter dns-snoop	Shows the Botnet Traffic Filter DNS snooping summary, or with the **detail** keyword, the actual IP addresses and names.
show dynamic-filter reports	Generates reports of the top 10 botnet sites, ports, and infected hosts.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

show asp table filter

To debug the accelerated security path filter tables, use the **show asp table filter** command in privileged EXEC mode.

show asp table filter [**access-list** *acl-name*] [**hits**] [**match** *regexp*]

Syntax Description

acl-name	(Optional) Specifies the installed filter for a specified access list.
hits	(Optional) Specifies the filter rules that have non-zero hits values.
match *regexp*	(optional) Shows classifier entries that match the regular expression. Use quotes when regular expressions include spaces.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.2(2)	This command was introduced.

Usage Guidelines

When a filter has been applied to a VPN tunnel, the filter rules are installed into the filter table. If the tunnel has a filter specified, then the filter table is checked before encryption and after decryption to determine whether the inner packet should be permitted or denied.

Examples

The following is sample output from the **show asp table filter** command before a user1 connects. Only the implicit deny rules are installed for IPv4 and IPv6 in both the inbound and outbound directions.

```
hostname# show asp table filter

Global Filter Table:
 in  id=0xd616ef20, priority=11, domain=vpn-user, deny=true
        hits=0, user_data=0xd613ea60, filter_id=0x0(-implicit deny-), protocol=0
        src ip=0.0.0.0, mask=0.0.0.0, port=0
        dst ip=0.0.0.0, mask=0.0.0.0, port=0
 in  id=0xd616f420, priority=11, domain=vpn-user, deny=true
        hits=0, user_data=0xd615ef70, filter_id=0x0(-implicit deny-), protocol=0
        src ip=::/0, port=0
        dst ip=::/0, port=0
 out id=0xd616f1a0, priority=11, domain=vpn-user, deny=true
        hits=0, user_data=0xd614d900, filter_id=0x0(-implicit deny-), protocol=0
```

```
        src ip=0.0.0.0, mask=0.0.0.0, port=0
        dst ip=0.0.0.0, mask=0.0.0.0, port=0
 out id=0xd616f6d0, priority=11, domain=vpn-user, deny=true
        hits=0, user_data=0xd6161638, filter_id=0x0(-implicit deny-), protocol=0
        src ip=::/0, port=0
        dst ip=::/0, port=0
```

The following is sample output from the **show asp table filter** command after a user1 has connected. VPN filter ACLs are defined based on the inbound direction—the source represents the peer and the destination represents inside resources. The outbound rules are derived by swapping the source and destination for the inbound rule.

```
hostname# show asp table filter

Global Filter Table:
 in  id=0xd682f4a0, priority=12, domain=vpn-user, deny=false
        hits=0, user_data=0xd682f460, filter_id=0x2(vpnfilter), protocol=6
        src ip=0.0.0.0, mask=0.0.0.0, port=0
        dst ip=95.1.224.100, mask=255.255.255.255, port=21
 in  id=0xd68366a0, priority=12, domain=vpn-user, deny=false
        hits=0, user_data=0xd6d89050, filter_id=0x2(vpnfilter), protocol=6
        src ip=0.0.0.0, mask=0.0.0.0, port=0
        dst ip=95.1.224.100, mask=255.255.255.255, port=5001
 in  id=0xd45d5b08, priority=12, domain=vpn-user, deny=false
        hits=0, user_data=0xd45d5ac8, filter_id=0x2(vpnfilter), protocol=17
        src ip=0.0.0.0, mask=0.0.0.0, port=0
        dst ip=95.1.224.100, mask=255.255.255.255, port=5002
 in  id=0xd6244f30, priority=12, domain=vpn-user, deny=false
        hits=0, user_data=0xd6244ef0, filter_id=0x2(vpnfilter), protocol=1
        src ip=0.0.0.0, mask=0.0.0.0, port=0

Related Commands

Command	Description
show asp drop	Shows the accelerated security path counters for dropped packets.
show asp table classifier	**S**hows the classifier contents of the accelerated security path.

show asp table interfaces

To debug the accelerated security path interface tables, use the **show asp table interfaces** command in privileged EXEC mode.

show asp table interfaces

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show asp table interfaces** command shows the interface table contents of the accelerated security path, which might help you troubleshoot a problem. See the CLI configuration guide for more information about the accelerated security path. These tables are used for debugging purposes only, and the information output is subject to change. Consult Cisco TAC to help you debug your system with this command.

Examples

The following is sample output from the **show asp table interfaces** command:

```
hostname# show asp table interfaces

** Flags: 0x0001-DHCP, 0x0002-VMAC, 0x0010-Ident Ifc, 0x0020-HDB Initd,
   0x0040-RPF Enabled
Soft-np interface 'dmz' is up
    context single_vf, nicnum 0, mtu 1500
        vlan 300, Not shared, seclvl 50
        0 packets input, 1 packets output
        flags 0x20

Soft-np interface 'foo' is down
    context single_vf, nicnum 2, mtu 1500
        vlan <None>, Not shared, seclvl 0
        0 packets input, 0 packets output
        flags 0x20
```

```
Soft-np interface 'outside' is down
    context single_vf, nicnum 1, mtu 1500
        vlan <None>, Not shared, seclvl 50
        0 packets input, 0 packets output
        flags 0x20

Soft-np interface 'inside' is up
    context single_vf, nicnum 0, mtu 1500
        vlan <None>, Not shared, seclvl 100
        680277 packets input, 92501 packets output
        flags 0x20
...
```

Related Commands

Command	Description
interface	Configures an interface and enters interface configuration mode.
show interface	Displays the runtime status and statistics of interfaces.

show asp table routing

To debug the accelerated security path routing tables, use the **show asp table routing** command in privileged EXEC mode. This command supports IPv4 and IPv6 addresses.

show asp table routing [**input** | **output**] [**address** *ip_address* [**netmask** *mask*] | **interface** *interface_name*]

Syntax Description

address *ip_address*	Sets the IP address for which you want to view routing entries. For IPv6 addresses, you can include the subnet mask as a slash (/) followed by the prefix (0 to 128). For example, enter the following: `fe80::2e0:b6ff:fe01:3b7a/128`
input	Shows the entries from the input route table.
interface *interface_name*	(Optional) Identifies a specific interface for which you want to view the routing table.
netmask *mask*	For IPv4 addresses, specifies the subnet mask.
output	Shows the entries from the output route table.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show asp table routing** command shows the routing table contents of the accelerated security path, which might help you troubleshoot a problem. See the CLI configuration guide for more information about the accelerated security path. These tables are used for debugging purposes only, and the information output is subject to change. Consult Cisco TAC to help you debug your system with this command.

Examples

The following is sample output from the **show asp table routing** command:

```
hostname# show asp table routing

in   255.255.255.255 255.255.255.255 identity

```

Related Commands

Command	Description
show route	Shows the routing table in the control plane.

show asp table socket

To help debug the accelerated security path socket information, use the **show asp table socket** command in privileged EXEC mode.

show asp table socket [**socket handle**] [**stats**]

Syntax Description

socket handle	Specifies the length of the socket.
stats	Shows the statistics from the accelerated security path socket table.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The **show asp table socket** command shows the accelerated security path socket information, which might help in troubleshooting accelerated security path socket problems. See the CLI configuration guide for more information about the accelerated security path. These tables are used for debugging purposes only, and the information output is subject to change. Consult Cisco TAC to help you debug your system with this command.

Examples

The following is sample output from the **show asp table socket** command:

```
TCP Statistics:
  Rcvd:
     total14794
     checksum errors0
     no port0
  Sent:
     total0

UDP Statistics:
  Rcvd:
     total0
     checksum errors0
  Sent:
     total0
```

```
     copied0

NP SSL System Stats:
  Handshake Started:33
  Handshake Complete:33
  SSL Open:4
  SSL Close:117
  SSL Server:58
  SSL Server Verify:0
  SSL Client:0
```

TCP/UDP statistics are packet counters representing the number of packets sent or received that are directed to a service that is running or listening on the ASA, such as Telnet, SSH, or HTTPS. Checksum errors are the number of packets dropped because the calculated packet checksum did not match the checksum value stored in the packet (that is, the packet was corrupted). The NP SSL statistics indicate the number of each type of message received. Most indicate the start and completion of new SSL connections to either the SSL server or SSL client.

Related Commands

Command	Description
show asp table vpn-context	Shows the accelerated security path VPN context tables.

show asp table vpn-context

To debug the accelerated security path VPN context tables, use the **show asp table vpn-context** command in privileged EXEC mode.

show asp table vpn-context [**detail**]

Syntax Description

detail	(Optional) Shows additional detail for the VPN context tables.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0(4)	Added +PRESERVE flag for each context that maintains stateful flows after the tunnel drops.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

The **show asp table vpn-context** command shows the VPN context contents of the accelerated security path, which might help you troubleshoot a problem. See the CLI configuration guide for more information about the accelerated security path. These tables are used for debugging purposes only, and the information output is subject to change. Consult Cisco TAC to help you debug your system with this command.

Examples

The following is sample output from the **show asp table vpn-context** command:

```
hostname# show asp table vpn-context

VPN ID=0058070576, DECR+ESP, UP, pk=0000000000, rk=0000000000, gc=0
VPN ID=0058193920, ENCR+ESP, UP, pk=0000000000, rk=0000000000, gc=0
VPN ID=0058168568, DECR+ESP, UP, pk=0000299627, rk=0000000061, gc=2

Related Commands

Command	Description
show asp drop	Shows the accelerated security path counters for dropped packets.

CHAPTER 46

show blocks through show cpu Commands

show blocks

To show the packet buffer utilization, use the **show blocks** command in privileged EXEC mode.

show blocks [{**address** *hex* | **all** | **assigned** | **free** | **old** | **pool** *size* [**summary**]} [**diagnostics** | **dump** | **header** | **packet**] | **queue history** [**detail**]]

Syntax Description

address *hex*	(Optional) Shows a block corresponding to this address, in hexadecimal.
all	(Optional) Shows all blocks.
assigned	(Optional) Shows blocks that are assigned and in use by an application.
detail	(Optional) Shows a portion (128 bytes) of the first block for each unique queue type.
dump	(Optional) Shows the entire block contents, including the header and packet information. The difference between dump and packet is that dump includes additional information between the header and the packet.
diagnostics	(Optional) Shows block diagnostics.
free	(Optional) Shows blocks that are available for use.
header	(Optional) Shows the header of the block.
old	(Optional) Shows blocks that were assigned more than a minute ago.
packet	(Optional) Shows the header of the block as well as the packet contents.
pool *size*	(Optional) Shows blocks of a specific size.
queue history	(Optional) Shows where blocks are assigned when the ASA runs out of blocks. Sometimes, a block is allocated from the pool but never assigned to a queue. In that case, the location is the code address that allocated the block.
summary	(Optional) Shows detailed information about block usage sorted by the program addresses of applications that allocated blocks in this class, program addresses of applications that released blocks in this class, and the queues to which valid blocks in this class belong.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	The **pool summary** option was added.
8.0(2)	The dupb block uses 0 length blocks now instead of 4 byte blocks. An additional line was added for 0 byte blocks.

Usage Guidelines

The **show blocks** command helps you determine if the ASA is overloaded. This command lists preallocated system buffer utilization. A full memory condition is not a problem as long as traffic is moving through the ASA. You can use the **show conn** command to see if traffic is moving. If traffic is not moving and the memory is full, there may be a problem.

You can also view this information using SNMP.

The information shown in a security context includes the system-wide information as well as context-specific information about the blocks in use and the high water mark for block usage.

See the "Examples" section for a description of the display output.

Examples

The following is sample output from the **show blocks** command in single mode:

```
hostname# show blocks
  SIZE    MAX    LOW    CNT
     0    100     99    100
     4   1600   1598   1599
    80    400    398    399
   256   3600   3540   3542
  1550   4716   3177   3184
 16384     10     10     10
  2048   1000   1000   1000
```

Table 46-1 shows each field description.

Table 46-1 show blocks Fields

Field	Description
SIZE	Size, in bytes, of the block pool. Each size represents a particular type. Examples are shown below.
0	Used by dupb blocks.
4	Duplicates existing blocks in applications such as DNS, ISAKMP, URL filtering, uauth, TFTP, and TCP modules. Also, this sized block can be used normally by code to send packets to drivers, etc.
80	Used in TCP intercept to generate acknowledgment packets and for failover hello messages.

Table 46-1 show blocks Fields (continued)

Field	Description
256	Used for Stateful Failover updates, syslogging, and other TCP functions. These blocks are mainly used for Stateful Failover messages. The active ASA generates and sends packets to the standby ASA to update the translation and connection table. In bursty traffic, where high rates of connections are created or torn down, the number of available blocks might drop to 0. This situation indicates that one or more connections were not updated to the standby ASA. The Stateful Failover protocol catches the missing translation or connection the next time. If the CNT column for 256-byte blocks stays at or near 0 for extended periods of time, then the ASA is having trouble keeping the translation and connection tables synchronized because of the number of connections per second that the ASA is processing. Syslog messages sent out from the ASA also use the 256-byte blocks, but they are generally not released in such quantity to cause a depletion of the 256-byte block pool. If the CNT column shows that the number of 256-byte blocks is near 0, ensure that you are not logging at Debugging (level 7) to the syslog server. This is indicated by the logging trap line in the ASA configuration. We recommend that you set logging at Notification (level 5) or lower, unless you require additional information for debugging purposes.
1550	Used to store Ethernet packets for processing through the ASA. When a packet enters an ASA interface, it is placed on the input interface queue, passed up to the operating system, and placed in a block. The ASA determines whether the packet should be permitted or denied based on the security policy and processes the packet through to the output queue on the outbound interface. If the ASA is having trouble keeping up with the traffic load, the number of available blocks will hover close to 0 (as shown in the CNT column of the command output). When the CNT column is zero, the ASA attempts to allocate more blocks, up to a maximum of 8192. If no more blocks are available, the ASA drops the packet.
16384	Only used for the 64-bit, 66-MHz Gigabit Ethernet cards (i82543). See the description for 1550 for more information about Ethernet packets.
2048	Control or guided frames used for control updates.
MAX	Maximum number of blocks available for the specified byte block pool. The maximum number of blocks are carved out of memory at bootup. Typically, the maximum number of blocks does not change. The exception is for the 256- and 1550-byte blocks, where the ASA can dynamically create more when needed, up to a maximum of 8192.
LOW	Low-water mark. This number indicates the lowest number of this size blocks available since the ASA was powered up, or since the last clearing of the blocks (with the **clear blocks** command). A zero in the LOW column indicates a previous event where memory was full.
CNT	Current number of blocks available for that specific size block pool. A zero in the CNT column means memory is full now.

The following is sample output from the **show blocks all** command:

```
hostname# show blocks all
Class 0, size 4
     Block   allocd_by    freed_by  data size    alloccnt     dup_cnt  oper location
0x01799940  0x00000000  0x00101603          0           0           0 alloc not_specified
0x01798e80  0x00000000  0x00101603          0           0           0 alloc not_specified
0x017983c0  0x00000000  0x00101603          0           0           0 alloc not_specified
```

```
...

```

Table 46-2 shows each field description.

Table 46-2 show blocks all Fields

Field	Description
Block	The block address.
allocd_by	The program address of the application that last used the block (0 if not used).
freed_by	The program address of the application that last released the block.
data size	The size of the application buffer/packet data that is inside the block.
alloccnt	The number of times this block has been used since the block came into existence.
dup_cnt	The current number of references to this block if used: 0 means 1 reference, 1 means 2 references.
oper	One of the four operations that was last performed on the block: alloc, get, put, or free.
location	The application that uses the block, or the program address of the application that last allocated the block (same as the allocd_by field).

The following is sample output from the **show blocks** command in a context:

```
hostname/contexta# show blocks
  SIZE    MAX    LOW    CNT  INUSE   HIGH
     4   1600   1599   1599      0      0
    80    400    400    400      0      0
   256   3600   3538   3540      0      1
  1550   4616   3077   3085      0      0
```

The following is sample output from the **show blocks queue history** command:

```
hostname# show blocks queue history
Each Summary for User and Queue_type is followed its top 5 individual queues
Block Size: 4
Summary for User "http", Queue "tcp_unp_c_in", Blocks 1595, Queues 1396
Blk_cnt Q_cnt Last_Op Queue_Type        User      Context
    186     1 put                               contexta
     15     1 put                               contexta

Table 46-3 shows each field description.

Table 46-3 show blocks pool summary Fields

Field	Description
total_count	The number of blocks for a given class.
miss_count	The number of blocks not reported in the specified category due to technical reasons.
Freed_pc	The program addresses of applications that released blocks in this class.
Alloc_pc	The program addresses of applications that allocated blocks in this class.
Queue	The queues to which valid blocks in this class belong.
valid_cnt	The number of blocks that are currently allocated.
invalid_cnt	The number of blocks that are not currently allocated.
Invalid Bad qtype	Either this queue has been freed and the contents are invalid or this queue was never initialized.
Valid tcp_usr_conn_inp	The queue is valid.

Related Commands

Command	Description
blocks	Increases the memory assigned to block diagnostics
clear blocks	Clears the system buffer statistics.
show conn	Shows active connections.

show boot device (IOS)

To view the default boot partition, use the **show boot device** command.

show boot device [*mod_num*]

Syntax Description

mod_num	(Optional) Specifies the module number. Use the **show module** command to view installed modules and their numbers.

Defaults

The default boot partition is cf:4.

Command Modes

Privileged EXEC.

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show boot device** command that shows the boot partitions for each installed ASA on Cisco IOS software:

```
Router# show boot device
[mod:1 ]:
[mod:2 ]:
[mod:3 ]:
[mod:4 ]: cf:4
[mod:5 ]: cf:4
[mod:6 ]:
[mod:7 ]: cf:4
[mod:8 ]:
[mod:9 ]:
```

Related Commands

Command	Description
boot device (IOS)	Sets the default boot partition.
show module (IOS)	Shows all installed modules.

show bootvar

To show the boot file and configuration properties, use the **show bootvar** command in privileged EXEC mode.

show bootvar

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The BOOT variable specifies a list of bootable images on various devices. The CONFIG_FILE variable specifies the configuration file used during system initialization. Set these variables with the **boot system** command and **boot config** command, respectively.

Examples

The BOOT variable contains disk0:/f1_image, which is the image booted when the system reloads. The current value of BOOT is disk0:/f1_image; disk0:/f1_backupimage. This value means that the BOOT variable has been modified with the **boot system** command, but the running configuration has not been saved with the **write memory** command. When the running configuration is saved, the BOOT variable and current BOOT variable will both be disk0:/f1_image; disk0:/f1_backupimage. Assuming that the running configuration is saved, the boot loader will try to load the contents of the BOOT variable, starting with disk0:/f1image, but if that is not present or invalid, the boot loader will try to boot disk0:1/f1_backupimage.

The CONFIG_FILE variable points to the system startup configuration. In this example it is not set, so the startup configuration file is the default specified with the **boot config** command. The current CONFIG_FILE variable may be modified with the **boot config** command and saved with the **write memory** command.

The following is sample output from the **show bootvar** command:

```
hostname# show bootvar
BOOT variable = disk0:/f1_image
Current BOOT variable = disk0:/f1_image; disk0:/f1_backupimage
```

```
CONFIG_FILE variable =
Current CONFIG_FILE variable =
hostname#
```

Related Commands

Command	Description
boot	Specifies the configuration file or image file used at startup.

show bridge-group

To show bridge group information such as interfaces assigned, MAC addresses, and IP addresses, use the **show bridge-group** command in privileged EXEC mode.

show bridge-group *bridge-group-number*

Syntax Description

bridge-group-number	Specifies the bridge group number as an integer between 1 and 100.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	—	•	•	•	—

Command History

Release	Modification
8.4(1)	We introduced this command.

Examples

The following is sample output from the **show bridge-group** command with IPv4 addresses:

```
hostname# show bridge-group 1
 Interfaces: GigabitEthernet0/0.101, GigabitEthernet0/0.201
 Management System IP Address: 10.0.1.1 255.255.255.0
 Management Current IP Address: 10.0.1.1 255.255.255.0
 Management IPv6 Global Unicast Address(es):
    N/A
 Static mac-address entries: 0
 Dynamic mac-address entries: 2
```

The following is sample output from the **show bridge-group** command with IPv4 and IPv6 addresses:

```
hostname# show bridge-group 1
 Interfaces: GigabitEthernet0/0.101, GigabitEthernet0/0.201
 Management System IP Address: 10.0.1.1 255.255.255.0
 Management Current IP Address: 10.0.1.1 255.255.255.0
 Management IPv6 Global Unicast Address(es):
    2000:100::1, subnet is 2000:100::/64
    2000:101::1, subnet is 2000:101::/64
    2000:102::1, subnet is 2000:102::/64
 Static mac-address entries: 0
 Dynamic mac-address entries: 2
```

Related Commands

Command	Description
bridge-group	Groups transparent firewall interfaces into a bridge group.
clear configure interface bvi	Clears the bridge group interface configuration.
interface	Configures an interface.
interface bvi	Creates a bridge virtual interface.
ip address	Sets the management IP address for a bridge group.
show running-config interface bvi	Shows the bridge group interface configuration.

show call-home

To display the configured Call Home information, use the **show call-home** command in privileged EXEC mode.

[**cluster exec**] **show call-home** [**alert-group** | **detail** | **events** | **mail-server status** | **profile** {*profile _name* | **all**} | **statistics**]

Syntax Description

alert-group	(Optional) Displays the available alert group.
cluster exec	(Optional) In a clustering environment, enables you to issue the **show call-home** command in one unit and run the command in all the other units at the same time.
detail	(Optional) Displays the Call Home configuration in detail.
events	(Optional) Displays current detected events.
mail-server status	(Optional) Displays the Call Home mail server status information.
profile *profile _name* **all**	(Optional) Displays configuration information for all existing profiles.
statistics	(Optional) Displays the Call Home statistics.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.2(2)	This command was introduced.
9.1(3)	A new type of Smart Call Home message has been added to include the output of the **show cluster history** command and **show cluster info** command.

Examples

The following is sample output from the **show call-home** command and displays the configured Call Home settings:

```
hostname# show call-home
Current Smart Call-Home settings:
Smart Call-Home feature : enable
Smart Call-Home message's from address: from@example.com
Smart Call-Home message's reply-to address: reply-to@example.com

The following is sample output from the **show call-home statistics** command and displays the call-home statistics:

```
hostname# show call-home statistics
Description: Show smart call-home statistics.
Supported Modes: single mode and system context in multi mode, routed/transparent.
Output:
Message Types Total Email HTTP
-------------------- ---------------- ---------------- ----------------
Total Success 0 0 0
Total In-Queue 0 0 0
Total Dropped 5 4 1
Tx Failed 5 4 1
inventory 3 2 1
configuration 2 2 0
Event Types Total
-------------------- ----------------
Total Detected 2
inventory 1
configuration 1
Total In-Queue 0
Total Dropped 0
Last call-home message sent time: 2009-06-17 14:22:09 GMT-07:00
```

The following is sample output from the **show call-home status** command and displays the call-home status:

```
hostname# show call-home mail-server status
Description: Show smart call-home configuration, status, and statistics.
Supported Modes: single mode and system context in multi mode, routed/transparent.
Output:
Mail-server[1]: Address: kafan-lnx-01.cisco.com Priority: 1 [Available]
Mail-server[2]: Address: kafan-lnx-02.cisco.com Priority: 10 [Not Available]

37. ciscoasa# show call-home events
Description: Show current detected events.
Supported Modes: single mode and system context in multi mode, routed/transparent.
Output:
Active event list:
Event client alert-group severity active (sec)
-------------------------------------------------------------------
Configuration Client configuration none 5
Inventory inventory none 15
```

The following is sample output from the **cluster exec show call-home statistics** command and displays call-home statistics for a cluster:

```
hostname(config)# cluster exec show call-home statistics

```

Related Commands

Command	Description
call-home	Enters call home configuration mode.
call-home send alert-group	Sends a specific alert group message.
service call-home	Enables or disables Call Home.

show call-home registered-module status

To display the registered module status, use the **show call-home registered-module status** command in privileged EXEC mode.

show call-home registered-module status [**all**]

Note The [**all**] option is only valid in system context mode.

Syntax Description

all	Displays module status based on the device, not per context. In multiple context mode, if a module is enabled in at least one context, it is displayed as enabled if the "**all**" option is included.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.2(2)	This command was introduced.

Examples

The following example displays the **show call-home registered-module status all** output:

```
Output:
Module Name Status
---------------------------------------- --------------------
Smart Call-Home enabled
Failover Standby/Active
```

Related Commands

Command	Description
call-home	Enters call-home configuration mode.
call-home send alert-group	Sends a specific alert group message.
service call-home	Enables or disables Call Home.

show capture

To display the capture configuration when no options are specified, use the **show capture** command in privileged EXEC mode.

[**cluster exec**] **show capture** [*capture_name*] [**access-list** *access_list_name*] [**count** *number*] [**decode**] [**detail**] [**dump**] [**packet-number** *number*]

Syntax Description

access-list *access_list_name*	(Optional) Displays information for packets that are based on IP or higher fields for the specific access list identification.
capture_name	(Optional) Specifies the name of the packet capture.
cluster exec	(Optional) In a clustering environment, enables you to issue the **show capture** command in one unit and run the command in all the other units at the same time.
count *number*	(Optional) Displays the number of packets specified data.
decode	This option is useful when a capture of type isakmp is applied to an interface. All ISAKMP data flowing through that interface will be captured after decryption and shown with more information after decoding the fields.
detail	(Optional) Displays additional protocol information for each packet.
dump	(Optional) Displays a hexadecimal dump of the packets that are transported over the data link.
packet-number *number*	Starts the display at the specified packet number.

Defaults

This command has no default settings.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
8.4(2)	Added detailed information in the output for IDS.
9.0(1)	The **cluster exec** option was added.

Usage Guidelines

If you specify the *capture_name*, then the capture buffer contents for that capture are displayed.

The **dump** keyword does not display MAC information in the hexadecimal dump.

The decoded output of the packets depend on the protocol of the packet. In Table 46-4, the bracketed output is displayed when you specify the **detail** keyword.

Table 46-4 Packet Capture Output Formats

Packet Type	Capture Output Format
802.1Q	*HH:MM:SS.ms* [ether-hdr] *VLAN-info encap-ether-packet*
ARP	*HH:MM:SS.ms* [ether-hdr] *arp-type arp-info*
IP/ICMP	*HH:MM:SS.ms* [ether-hdr] *ip-source* > *ip-destination:* icmp: *icmp-type icmp-code* [checksum-failure]
IP/UDP	*HH:MM:SS.ms* [ether-hdr] *src-addr.src-port dest-addr.dst-port*: [checksum-info] udp *payload-len*
IP/TCP	*HH:MM:SS.ms* [ether-hdr] *src-addr.src-port* d*est-addr.dst-port*: *tcp-flags* [header-check] [checksum-info] *sequence-number ack-number tcp-window urgent-info tcp-options*
IP/Other	*HH:MM:SS.ms* [ether-hdr] *src-addr dest-addr*: *ip-protocol ip-length*
Other	*HH:MM:SS.ms ether-hdr*: *hex-dump*

Examples

This example shows how to display the capture configuration:

```
hostname(config)# show capture
capture arp ethernet-type arp interface outside
capture http access-list http packet-length 74 interface inside
```

This example shows how to display the packets that are captured by an ARP capture:

```
hostname(config)# show capture arp
2 packets captured
19:12:23.478429 arp who-has 171.69.38.89 tell 171.69.38.10
19:12:26.784294 arp who-has 171.69.38.89 tell 171.69.38.10
2 packets shown
```

The following example shows how to display the packets that are captured on a single unit in a clustering environment:

```
hostname(config)# show capture
capture 1 cluster type raw-data interface primary interface cluster [Buffer Full - 524187
bytes]
capture 2 type raw-data interface cluster [Capturing - 232354 bytes]
```

The following example shows how to display the packets that are captured on all units in a clustering environment:

```
hostname(config)# cluster exec show capture
mycapture (LOCAL):-------------------------------------------------------------

capture 1 type raw-data interface primary [Buffer Full - 524187 bytes]
capture 2 type raw-data interface cluster [Capturing - 232354 bytes]

yourcapture:-------------------------------------------------------------------
capture 1 type raw-data interface primary [Capturing - 191484 bytes]
capture 2 type raw-data interface cluster [Capturing - 532354 bytes]
```

The following example shows the packets that are captured on the cluster control link in a clustering environment after the following commands are entered:

```
hostname (config)# capture a interface cluster
hostname (config)# capture cp interface cluster match udp any eq 49495 any
hostname (config)# capture cp interface cluster match udp any any eq 49495
hostname (config)# access-list cc1 extended permit udp any any eq 4193
hostname (config)# access-list cc1 extended permit udp any eq 4193 any
hostname (config)# capture dp interface cluster access-list cc1
hostname (config)# capture lacp type lacp interface gigabitEthernet 0/0

hostname(config)# show capture
capture a type raw-data interface cluster [Capturing - 970 bytes]
capture cp type raw-data interface cluster [Capturing - 26236 bytes]
  match udp any eq 49495 any
capture dp type raw-data access-list cc1 interface cluster [Capturing - 4545230 bytes]
capture lacp type lacp interface gigabitEthernet0/0 [Capturing - 140 bytes]
```

Related Commands

Command	Description
capture	Enables packet capture capabilities for packet sniffing and network fault isolation.
clear capture	Clears the capture buffer.
copy capture	Copies a capture file to a server.

show chardrop

To display the count of characters dropped from the serial console, use the **show chardrop** command in privileged EXEC mode.

show chardrop

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
9.0(1)	This command was introduced.

Examples

The following is sample output from the **show chardrop** command:

```
hostname# show chardrop
Chars dropped pre-TxTimeouts: 0, post-TxTimeouts: 0
```

Related Commands

Command	Description
show running-config	Shows the current operating configuration.

show checkheaps

To show the checkheaps statistics, use the **show checkheaps** command in privileged EXEC mode. Checkheaps is a periodic process that verifies the sanity of the heap memory buffers (dynamic memory is allocated from the system heap memory region) and the integrity of the code region.

show checkheaps

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show checkheaps** command:

```
hostname# show checkheaps

Checkheaps stats from buffer validation runs
--------------------------------------------
Time elapsed since last run     : 42 secs
Duration of last run            : 0 millisecs
Number of buffers created       : 8082
Number of buffers allocated     : 7808
Number of buffers free          : 274
Total memory in use             : 43570344 bytes
Total memory in free buffers    : 87000 bytes
Total number of runs            : 310
```

Related Commands

Command	Description
checkheaps	Sets the checkheap verification intervals.

show checksum

To display the configuration checksum, use the **show checksum** command in privileged EXEC mode.

show checksum

Syntax Description

This command has no arguments or keywords.

Defaults

This command has no default settings.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

The **show checksum** command allows you to display four groups of hexadecimal numbers that act as a digital summary of the configuration contents. This checksum is calculated only when you store the configuration in flash memory.

If a dot (“.”) appears before the checksum in the **show config** or **show checksum** command output, the output indicates a normal configuration load or write mode indicator (when loading from or writing to the ASA flash partition). The “.” shows that the ASA is preoccupied with the operation but is not “hung up.” This message is similar to a “system processing, please wait” message.

Examples

This example shows how to display the configuration or the checksum:

```
hostname(config)# show checksum
Cryptochecksum: 1a2833c0 129ac70b 1a88df85 650dbb81
```

show chunkstat

To display the chunk statistics, use the **show chunkstat** command in privileged EXEC mode.

show chunkstat

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

This example shows how to display the chunk statistics:

```
hostname# show chunkstat
Global chunk statistics: created 181, destroyed 34, siblings created 94, siblings
destroyed 34

Per-chunk statistics: siblings created 0, siblings trimmed 0
Dump of chunk at 01edb4cc, name "Managed Chunk Queue Elements", data start @ 01edbd24, end
@ 01eddc54
next: 01eddc8c, next_sibling: 00000000, prev_sibling: 00000000
flags 00000001
maximum chunk elt's: 499, elt size: 16, index first free 498
# chunks in use: 1, HWM of total used: 1, alignment: 0
Per-chunk statistics: siblings created 0, siblings trimmed 0
Dump of chunk at 01eddc8c, name "Registry Function List", data start @ 01eddea4, end @
01ede348
next: 01ede37c, next_sibling: 00000000, prev_sibling: 00000000
flags 00000001
maximum chunk elt's: 99, elt size: 12, index first free 42
# chunks in use: 57, HWM of total used: 57, alignment: 0
```

Related Commands

Command	Description
show counters	Displays the protocol stack counters.
show cpu	Displays the CPU utilization information.

show class

To show the contexts assigned to a class, use the **show class** command in privileged EXEC mode.

show class *name*

Syntax Description

name	Specifies the name as a string up to 20 characters long. To show the default class, enter **default** for the name.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	—	•

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following is sample output from the **show class default** command:

```
hostname# show class default

Class Name           Members    ID   Flags
default                All       1    0001
```

Related Commands

Command	Description
class	Configures a resource class.
clear configure class	Clears the class configuration.
context	Configures a security context.
limit-resource	Sets the resource limit for a class.
member	Assigns a context to a resource class.

show clock

To view the time on the ASA, use the **show clock** command in user EXEC mode.

show clock [**detail**]

Syntax Description

detail	(Optional) Indicates the clock source (NTP or user configuration) and the current summer-time setting (if any).

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show clock** command:

```
hostname> show clock
12:35:45.205 EDT Tue Jul 27 2004
```

The following is sample output from the **show clock detail** command:

```
hostname> show clock detail
12:35:45.205 EDT Tue Jul 27 2004
Time source is user configuration
Summer time starts 02:00:00 EST Sun Apr 4 2004
Summer time ends 02:00:00 EDT Sun Oct 31 2004
```

Related Commands

Command	Description
clock set	Manually sets the clock on the ASA.
clock summer-time	Sets the date range to show daylight saving time.
clock timezone	Sets the time zone.
ntp server	Identifies an NTP server.
show ntp status	Shows the status of the NTP association.

show cluster

To view aggregated data for the entire cluster or other information, use the **show cluster** command in privileged EXEC mode.

show cluster {**access-list** [*acl_name*] | **conn** [**count**] | **cpu** [**usage**] | **history** | **interface-mode** | **memory** | **resource usage** | **traffic** | **xlate count**}

Syntax Description

access-list [*acl_name*]	Shows hit counters for access policies. To see the counters for a specific ACL, enter the *acl_name*.
conn [**count**]	Shows the aggregated count of in-use connections for all units. If you enter the **count** keyword, only the connection count is shown.
cpu [**usage**]	Shows CPU usage information.
history	Shows cluster switching history.
interface-mode	Shows the cluster interface mode, either spanned or individual.
memory	Shows system memory utilization and other information.
resource usage	Shows system resources and usage.
traffic	Shows traffic statistics.
xlate count	Shows current translation information.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

See also the **show cluster info** and **show cluster user-identity** commands.

Examples

The following is sample output from the **show cluster access-list** command:

```
hostname#  show cluster access-list
hitcnt display order: cluster-wide aggregated result, unit-A, unit-B,  unit-C, unit-D
access-list cached ACL log flows: total 0, denied 0 (deny-flow-max 4096) alert-interval
300
access-list 101; 122 elements; name hash: 0xe7d586b5
```

```
access-list 101 line 1 extended permit tcp 192.168.143.0 255.255.255.0 any eq www

```

To display the aggregated count of in-use connections for all units, enter:

```
hostname# show cluster conn count
Usage Summary In Cluster:*********************************************
  200 in use (cluster-wide aggregated)
     cl2(LOCAL):*************************************************************
  100 in use, 100 most used

  cl1:*************************************************************
  100 in use, 100 most used
```

Related Commands

Command	Description
show cluster info	Shows cluster information.
show cluster user-identity	Shows cluster user identity information and statistics.

show cluster info

To view cluster information, use the **show cluster info** command in privileged EXEC mode.

show cluster info [**clients | conn-distribution | goid** [*options*] **| health | incompatible-config | loadbalance | old-members | packet-distribution | trace** [*options*] **| transport {asp | cp}**]

Syntax Description

clients	(Optional) Shows the version of register clients.
conn-distribution	(Optional) Shows the connection distribution in the cluster.
goid [*options*]	(Optional) Shows the global object ID database. Options include: • **classmap** • **conn-set** • **hwidb** • **idfw-domain** • **idfw-group** • **interface** • **policymap** • **virtual-context**
health	(Optional) Shows health monitoring information.
incompatible-config	(Optional) Shows commands that are incompatible with clustering in the current running configuration. This command is useful before you enable clustering.
loadbalance	(Optional) Shows load balancing information.
old-members	(Optional) Shows former members of the cluster.
packet-distribution	(Optional) Shows packet distribution in the cluster.
trace [*options*]	(Optional) Shows the clustering control module event trace. Options include: • **latest** [*number*]—Displays the latest *number* events, where the number is from 1 to 2147483647. The default is to show all. • **level** *level*—Filters events by level where the *level* is one of the following: **all**, **critical**, **debug**, **informational**, or **warning**. • **module** *module*—Filters events by module where the *module* is one of the following: **ccp**, **datapath**, **fsm**, **general**, **hc**, **license**, **rpc**, **or transport**. • **time** {[*month day*] [*hh*:*mm*:*ss*]}—Shows events before the specified time or date.
transport {asp | cp}	(Optional) Show transport related statistics for the following: • **asp**—Data plane transport statistics. • **cp**—Control plane transport statistics.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
	Routed	Transparent	Single	Multiple Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

If you do not specify any options, the **show cluster info** command shows general cluster information including the cluster name and status, the cluster members, the member states, and so on.

Clear statistics using the **clear cluster info** command.

See also the **show cluster** and **show cluster user-identity** commands.

Examples

The following is sample output from the **show cluster info** command:

```
hostname# show cluster info
Cluster stbu: On
  This is "C" in state SLAVE
      ID        : 0
      Version   : 100.8(0.52)
      Serial No.: P3000000025
      CCL IP    : 10.0.0.3
      CCL MAC   : 000b.fcf8.c192
      Last join : 17:08:59 UTC Sep 26 2011
      Last leave: N/A
Other members in the cluster:
  Unit "D" in state SLAVE
      ID        : 1
      Version   : 100.8(0.52)
      Serial No.: P3000000001
      CCL IP    : 10.0.0.4
      CCL MAC   : 000b.fcf8.c162
      Last join : 19:13:11 UTC Sep 23 2011
      Last leave: N/A
  Unit "A" in state MASTER
      ID        : 2
      Version   : 100.8(0.52)
      Serial No.: JAB0815R0JY
      CCL IP    : 10.0.0.1
      CCL MAC   : 000f.f775.541e
      Last join : 19:13:20 UTC Sep 23 2011
      Last leave: N/A
  Unit "B" in state SLAVE
      ID        : 3
      Version   : 100.8(0.52)
      Serial No.: P3000000191
      CCL IP    : 10.0.0.2
      CCL MAC   : 000b.fcf8.c61e
      Last join : 19:13:50 UTC Sep 23 2011
      Last leave: 19:13:36 UTC Sep 23 2011
```

The following is sample output from the **show cluster info incompatible-config** command:

```
hostname(cfg-cluster)# show cluster info incompatible-config
INFO: Clustering is not compatible with following commands which given a user's
confirmation upon enabling clustering, can be removed automatically from running-config.
policy-map global_policy
 class scansafe-http
  inspect scansafe http-map fail-close
policy-map global_policy
 class scansafe-https
  inspect scansafe https-map fail-close

INFO: No manually-correctable incompatible configuration is found.
```

The following is sample output from the **show cluster info trace** command:

```
hostname# show cluster info trace
 Feb 02 14:19:47.456 [DBUG]Receive CCP message: CCP_MSG_LOAD_BALANCE
 Feb 02 14:19:47.456 [DBUG]Receive CCP message: CCP_MSG_LOAD_BALANCE
 Feb 02 14:19:47.456 [DBUG]Send CCP message to all: CCP_MSG_KEEPALIVE from 80-1 at MASTER
```

Related Commands

Command	Description
show cluster	Displays aggregated data for the entire cluster.
show cluster user-identity	Shows cluster user identity information and statistics.

show cluster user-identity

To view cluster-wide user identity information and statistics, use the **show cluster user-identity** command in privileged EXEC mode.

show cluster user-identity {**statistics** [**user** *name* | **user-group** *group_name*] | **user** [**active** [**domain** *name*] | **user** *name* | **user-group** *group_name*] [**list** [*detail*] | **all** [**list** [*detail*] | **inactive** {**domain** *name* | **user-group** *group_name*] [**list** [*detail*]]}

Syntax Description

active	Shows users with active IP-user mappings.
all	Shows all users in the user database.
domain *name*	Shows user info for a domain.
inactive	Shows users with inactive IP-user mappings.
list [*detail*]	Shows a list of users.
statistics	Shows cluster user identity statistics.
user	Shows the user database.
user *name*	Show information for a specific user.
user-group *group_name*	Shows information for each user of a specific group.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

See also the **show cluster info** and **show cluster** commands.

Related Commands

Command	Description
show cluster	Displays aggregated data for the entire cluster.
show cluster info	Shows cluster information.

show compression svc

To view compression statistics for SVC connections on the ASA, use the **show compression svc** command from privileged EXEC mode.

show compression svc

Defaults

There is no default behavior for this command.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•		—

Command History

Release	Modification
7.1(1)	This command was introduced.

Examples

The following example shows the output of the **show compression svc** command:

```
hostname# show compression svc
Compression SVC Sessions                        1
Compressed Frames                          249756
Compressed Data In (bytes)                0048042
Compressed Data Out (bytes)               4859704
Expanded Frames                                 1
Compression Errors                              0
Compression Resets                              0
Compression Output Buf Too Small                0
Compression Ratio                            2.06
Decompressed Frames                        876687
Decompressed Data In                     279300233
```

Related Commands

Command	Description
compression	Enables compression for all SVC and WebVPN connections.
svc compression	Enables compression of http data over an SVC connection for a specific group or user.

show configuration

To display the configuration that is saved in flash memory on the ASA, use the **show configuration** command in privileged EXEC mode.

show configuration

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was modified.

Usage Guidelines

The **show configuration** command displays the saved configuration in flash memory on the ASA. Unlike the **show running-config** command, the **show configuration** command does not use many CPU resources to run.

To display the active configuration in memory (including saved configuration changes) on the ASA, use the **show running-config** command.

Examples

The following is sample output from the **show configuration** command:

```
hostname# show configuration

Related Commands

Command	Description
configure	Configures the ASA from the terminal.

show conn

To display the connection state for the designated connection type, use the **show conn** command in privileged EXEC mode. This command supports IPv4 and IPv6 addresses.

show conn [**count** | [**all**] [**detail**] [**long**] [**state** *state_type*] [**protocol** {**tcp** | **udp**}] [**scansafe**] [**address** *src_ip*[**-***src_ip*] [**netmask** *mask*]] [**port** *src_port*[**-***src_port*]] [**address** *dest_ip*[**-***dest_ip*] [**netmask** *mask*]] [**port** *dest_port*[**-***dest_port*]] [**user-identity** | **user** [*domain_nickname*\]*user_name* | **user-group** [*domain_nickname*\\]*user_group_name*] | **security-group**]

Syntax Description

address	(Optional) Displays connections with the specified source or destination IP address.
all	(Optional) Displays connections that are to the device or from the device, in addition to through-traffic connections.
count	(Optional) Displays the number of active connections.
dest_ip	(Optional) Specifies the destination IP address (IPv4 or IPv6). To specify a range, separate the IP addresses with a dash (-). For example: `10.1.1.1-10.1.1.5`
dest_port	(Optional) Specifies the destination port number. To specify a range, separate the port numbers with a dash (-). For example: `1000-2000`
detail	(Optional) Displays connections in detail, including translation type and interface information.
long	(Optional) Displays connections in long format.
netmask *mask*	(Optional) Specifies a subnet mask for use with the given IP address.
port	(Optional) Displays connections with the specified source or destination port.
protocol {**tcp** | **udp**}	(Optional) Specifies the connection protocol, which can be **tcp** or **udp**.
scansafe	(Optional) Shows connections being forwarded to the Cloud Web Security server.
security-group	(Optional) Specifies that all connections displayed belong to the specified security group.
src_ip	(Optional) Specifies the source IP address (IPv4 or IPv6). To specify a range, separate the IP addresses with a dash (-). For example: `10.1.1.1-10.1.1.5`
src_port	(Optional) Specifies the source port number. To specify a range, separate the port numbers with a dash (-). For example: `1000-2000`
state *state_type*	(Optional) Specifies the connection state type. See Table 46-5 for a list of the keywords available for connection state types.
user [*domain_nickname*\] *user_name*	(Optional) Specifies that all connections displayed belong to the specified user. When you do not include the *domain_nickname* argument, the ASA displays information for the user in the default domain.

user-group [*domain_nickname*\\] *user_group_name*	(Optional) Specifies that all connections displayed belong to the specified user group. When you do not include the *domain_nickname* argument, the ASA displays information for the user group in the default domain.
user-identity	(Optional) Specifies that the ASA display all connections for the Identity Firewall feature. When displaying the connections, the ASA displays the user name and IP address when it identifies a matching user. Similarly, the ASA displays the host name and an IP address when it identifies a matching host.

Defaults

All through connections are shown by default. You need to use the **all** keyword to also view management connections to the device.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(8)/7.2(4)/8.0(4)	The syntax was simplified to use source and destination concepts instead of “local” and “foreign.” In the new syntax, the source address is the first address entered and the destination is the second address. The old syntax used keywords like **foreign** and **fport** to determine the destination address and port.
7.2(5)/8.0(5)/8.1(2)/8.2(4)/ 8.3(2)	The **tcp_embryonic** state type was added. This type shows all TCP connections with the i flag (incomplete connections); i flag connections for UDP are not shown.
8.2(1)	The b flag was added for TCP state bypass.
8.4(2)	Added the **user-identity**, **user**, and **user-group** keywords to support the Identity Firewall.
9.0(1)	Support for clustering was added. We added the **scansafe** and **security-group** keywords.

Usage Guidelines

The **show conn** command displays the number of active TCP and UDP connections, and provides information about connections of various types. Use the **show conn all** command to see the entire table of connections.

Note When the ASA creates a pinhole to allow secondary connections, this is shown as an incomplete conn by the **show conn** command. To clear this incomplete conn use the **clear conn** command.

The connection types that you can specify using the **show conn state** command are defined in Table 46-5. When specifying multiple connection types, use commas without spaces to separate the keywords.

Table 46-5 Connection State Types

Keyword	Connection Type Displayed
up	Connections in the up state.
conn_inbound	Inbound connections.
ctiqbe	CTIQBE connections
data_in	Inbound data connections.
data_out	Outbound data connections.
finin	FIN inbound connections.
finout	FIN outbound connections.
h225	H.225 connections
h323	H.323 connections
http_get	HTTP get connections.
mgcp	MGCP connections.
nojava	Connections that deny access to Java applets.
rpc	RPC connections.
service_module	Connections being scanned by an SSM.
sip	SIP connections.
skinny	SCCP connections.
smtp_data	SMTP mail data connections.
sqlnet_fixup_data	SQL*Net data inspection engine connections.
tcp_embryonic	TCP embryonic connections.
vpn_orphan	Orphaned VPN tunneled flows.

When you use the **detail** option, the system displays information about the translation type and interface information using the connection flags defined in Table 46-6.

Table 46-6 Connection Flags

Flag	Description
a	awaiting outside ACK to SYN
A	awaiting inside ACK to SYN
b	TCP state bypass
B	initial SYN from outside
C	Computer Telephony Interface Quick Buffer Encoding (CTIQBE) media connection
d	dump
D	DNS

Table 46-6 Connection Flags (continued)

Flag	Description
E	outside back connection. This is a secondary data connection that must be initiated from the inside host. For example, using FTP, after the inside client issues the PASV command and the outside server accepts, the ASA preallocates an outside back connection with this flag set. If the inside client attempts to connect back to the server, then the ASA denies this connection attempt. Only the outside server can use the preallocated secondary connection.
f	inside FIN
F	outside FIN
g	Media Gateway Control Protocol (MGCP) connection
G	connection is part of a group[1]
h	H.225
H	H.323
i	incomplete TCP or UDP connection
I	inbound data
k	Skinny Client Control Protocol (SCCP) media connection
K	GTP t3-response
m	SIP media connection
M	SMTP data
O	outbound data
p	replicated (unused)
P	inside back connection. This is a secondary data connection that must be initiated from the inside host. For example, using FTP, after the inside client issues the PORT command and the outside server accepts, the ASA preallocates an inside back connection with this flag set. If the outside server attempts to connect back to the client, then the ASA denies this connection attempt. Only the inside client can use the preallocated secondary connection.
q	SQL*Net data
r	inside acknowledged FIN
R	outside acknowledged FIN for TCP connection
R	UDP RPC[2]
s	awaiting outside SYN
S	awaiting inside SYN
t	SIP transient connection[3]
T	SIP connection[4]
U	up
V	VPN orphan
W	WAAS
X	Inspected by the service module, such as a CSC SSM.
y	For clustering, identifies a backup owner flow.
Y	For clustering, identifies a director flow.

Table 46-6 Connection Flags (continued)

Flag	Description
z	For clustering, identifies a forwarder flow.
Z	Cloud Web Security

1. The G flag indicates the connection is part of a group. It is set by the GRE and FTP Strict fixups to designate the control connection and all its associated secondary connections. If the control connection terminates, then all associated secondary connections are also terminated.
2. Because each row of **show conn** command output represents one connection (TCP or UDP), there will be only one R flag per row.
3. For UDP connections, the value t indicates that it will timeout after one minute.
4. For UDP connections, the value T indicates that the connection will timeout according to the value specified using the **timeout sip** command.

Note For connections using a DNS server, the source port of the connection may be replaced by the *IP address of DNS server* in the **show conn** command output.

A single connection is created for multiple DNS sessions, as long as they are between the same two hosts, and the sessions have the same 5-tuple (source/destination IP address, source/destination port, and protocol). DNS identification is tracked by *app_id*, and the idle timer for each app_id runs independently.

Because the app_id expires independently, a legitimate DNS response can only pass through the ASA within a limited period of time and there is no resource build-up. However, when you enter the **show conn** command, you will see the idle timer of a DNS connection being reset by a new DNS session. This is due to the nature of the shared DNS connection and is by design.

Note When there is no TCP traffic for the period of inactivity defined by the **timeout conn** command (by default, 1:00:00), the connection is closed and the corresponding conn flag entries are no longer displayed.

If a LAN-to-LAN/Network-Extension Mode tunnel drops and does not come back, there might be a number of orphaned tunnel flows. These flows are not torn down as a result of the tunnel going down, but all the data attempting to flow through them is dropped. The **show conn** command output shows these orphaned flows with the **V** flag.

When the following TCP connection directionality flags are applied to connections between same-security interfaces (see the **same-security permit** command), the direction in the flag is not relevant because for same-security interfaces, there is no “inside” or “outside.” Because the ASA has to use these flags for same-security connections, the ASA may choose one flag over another (for example, f vs. F) based on other connection characteristics, but you should ignore the directionality chosen.

- B—Initial SYN from outside
- a—Awaiting outside ACK to SYN
- A—Awaiting inside ACK to SYN
- f—Inside FIN
- F—Outside FIN
- s—Awaiting outside SYN
- S—Awaiting inside SYN

To display information for a specific connection, include the **security-group** keyword and specify a security group table value or security group name for both the source and destination of the connection. The ASA displays the connection matching the specific security group table values or security group names.

When you specify the **security-group** keyword without specifying a source and destination security group table value or a source and destination security group name, the ASA displays data for all SXP connections.

The ASA displays the connection data in the format *security_group_name* (*SGT_value*) or just as the *SGT_value* when the security group name is unknown.

Note Security group data is not available for stub connections because stub connection do not go through the slow path. Stub connections maintain only the information necessary to forward packets to the owner of the connection.

You can specify a single security group name to display all connections in a cluster; for example, the following example displays connections matching security-group mktg in all units of the cluster:

```
hostname# show cluster conn security-group name mktg
```

Examples

When specifying multiple connection types, use commas without spaces to separate the keywords. The following example displays information about RPC, H.323, and SIP connections in the Up state:

```
hostname# show conn state up,rpc,h323,sip
```

The following is sample output from the **show conn count** command:

```
hostname# show conn count
54 in use, 123 most used
```

The following is sample output from the **show conn** command. This example shows a TCP session connection from inside host 10.1.1.15 to the outside Telnet server at 10.10.49.10. Because there is no B flag, the connection is initiated from the inside. The “U”, “I”, and “O” flags denote that the connection is active and has received inbound and outbound data.

```
hostname# show conn
54 in use, 123 most used
TCP out 10.10.49.10:23 in 10.1.1.15:1026 idle 0:00:22, bytes 1774, flags UIO

TCP outside:10.132.64.167/50250 inside:192.168.1.35/2000,
    flags UIOB, idle 26s, uptime 1D21h, timeout 1h0m, bytes 375617
```

The following is sample output from the **show conn** command when an orphan flow exists, as indicated by the **V** flag:

```
hostname# show conn
16 in use, 19 most used
TCP out 192.168.110.251:7393 in 192.168.150.252:21 idle 0:00:00, bytes 1048, flags UOVB
TCP out 192.168.110.251:21137 in 192.168.150.252:21 idle 0:00:00, bytes 1048, flags UIOB
```

To limit the report to those connections that have orphan flows, add the **vpn_orphan** option to the **show conn state** command, as in the following example:

```
hostname# show conn state vpn_orphan
14 in use, 19 most used
TCP out 192.168.110.251:7393 in 192.168.150.252:5013, idle 0:00:00, bytes 2841019, flags
UOVB
```

For clustering, to troubleshoot the connection flow, first see connections on all units by entering the **cluster exec show conn** command on the master unit. Look for flows that have the following flags: director (Y), backup (y), and forwarder (z). The following example shows an SSH connection from 172.18.124.187:22 to 192.168.103.131:44727 on all three ASAs; ASA 1 has the z flag showing it is a forwarder for the connection, ASA3 has the Y flag showing it is the director for the connection, and ASA2 has no special flags showing it is the owner. In the outbound direction, the packets for this connection enter the inside interface on ASA2 and exit the outside interface. In the inbound direction, the packets for this connection enter the outside interface on ASA 1 and ASA3, are forwarded over the cluster control link to ASA2, and then exit the inside interface on ASA2.

```
hostname/ASA1/master# cluster exec show conn
ASA1(LOCAL):**********************************************************
18 in use, 22 most used
Cluster stub connections: 0 in use, 5 most used
TCP outside  172.18.124.187:22 inside  192.168.103.131:44727, idle 0:00:00, bytes
37240828, flags z

ASA2:**********************************************************************
12 in use, 13 most used
Cluster stub connections: 0 in use, 46 most used
TCP outside  172.18.124.187:22 inside  192.168.103.131:44727, idle 0:00:00, bytes
37240828, flags UIO

ASA3:**********************************************************************
10 in use, 12 most used
Cluster stub connections: 2 in use, 29 most used
TCP outside  172.18.124.187:22 inside  192.168.103.131:44727, idle 0:00:03, bytes 0, flags
Y
```

The output of **show conn detail** on ASA2 shows that the most recent forwarder was ASA1:

```
hostname/ASA2/slave# show conn detail
12 in use, 13 most used
Cluster stub connections: 0 in use, 46 most used
Flags: A - awaiting inside ACK to SYN, a - awaiting outside ACK to SYN,
       B - initial SYN from outside, b - TCP state-bypass or nailed, C - CTIQBE media,
       D - DNS, d - dump, E - outside back connection, F - outside FIN, f - inside FIN,
       G - group, g - MGCP, H - H.323, h - H.225.0, I - inbound data,
       i - incomplete, J - GTP, j - GTP data, K - GTP t3-response
       k - Skinny media, M - SMTP data, m - SIP media, n - GUP
       O - outbound data, P - inside back connection, p - Phone-proxy TFTP connection,
       q - SQL*Net data, R - outside acknowledged FIN,
       R - UDP SUNRPC, r - inside acknowledged FIN, S - awaiting inside SYN,
       s - awaiting outside SYN, T - SIP, t - SIP transient, U - up,
       V - VPN orphan, W - WAAS, Z - Scansafe redirection,
       X - inspected by service module
       Y - director stub flow
       y - backup stub flow
       z - forwarder stub flow
TCP outside: 172.18.124.187/22 inside: 192.168.103.131/44727,
```

```
    flags UIO , idle 0s, uptime 25s, timeout 1h0m, bytes 1036044, cluster sent/rcvd bytes
0/1032983, cluster sent/rcvd total bytes 0/1080779, owners (1,255)
Traffic received at interface outside
        Locally received: 0 (0 byte/s)
        From most recent forwarder ASA1: 1032983 (41319 byte/s)
Traffic received at interface inside
        Locally received: 3061 (122 byte/s)
```

The following examples show how to display connections for the Identity Firewall feature:

```
hostname# show conn user-identity ?
exec mode commands/options:
  all       Enter this keyword to show conns including to-the-box and from-the-box
  detail    Enter this keyword to show conn in detail
  long      Enter this keyword to show conn in long format
  port      Enter this keyword to specify port
  protocol  Enter this keyword to specify conn protocol
  state     Enter this keyword to specify conn state
  |         Output modifiers

```

Related Commands

Commands	Description
clear conn	Clears connections.
inspect ctiqbe	Enables CTIQBE application inspection.
inspect h323	Enables H.323 application inspection.
inspect mgcp	Enables MGCP application inspection.
inspect sip	Removes Java applets from HTTP traffic.
inspect skinny	Enables SCCP application inspection.

show console-output

To display the currently captured console output, use the **show console-output** command in privileged EXEC mode.

show console-output

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show console-output** command, which displays the following message when there is no console output:

```
hostname# show console-output
Sorry, there are no messages to display
```

Related Commands

Command	Description
clear configure console	Restores the default console connection settings.
clear configure timeout	Restores the default idle time durations in the configuration.
console timeout	Sets the idle timeout for a console connection to the ASA.
show running-config console timeout	Displays the idle timeout for a console connection to the ASA.

show context

To show context information including allocated interfaces and the configuration file URL, the number of contexts configured, or from the system execution space, a list of all contexts, use the **show context** command in privileged EXEC mode.

show context [*name* | **detail** | **count**]

Syntax Description

count	(Optional) Shows the number of contexts configured.
detail	(Optional) Shows additional detail about the context(s) including the running state and information for internal use.
name	(Optional) Sets the context name. If you do not specify a name, the ASA displays all contexts. Within a context, you can only enter the current context name.

Defaults

In the system execution space, the ASA displays all contexts if you do not specify a name.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	—	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0(2)	Information about assigned IPS virtual sensors was added.

Usage Guidelines

See the “Examples” section for a description of the display output.

Examples

The following is sample output from the **show context** command. The following sample display shows three contexts:

```
hostname# show context

Context Name      Interfaces                    URL
*admin            GigabitEthernet0/1.100        flash:/admin.cfg
                  GigabitEthernet0/1.101
contexta          GigabitEthernet0/1.200        flash:/contexta.cfg
                  GigabitEthernet0/1.201
contextb          GigabitEthernet0/1.300        flash:/contextb.cfg
                  GigabitEthernet0/1.301
Total active Security Contexts: 3
```

Table 46-7 shows each field description.

Table 46-7 show context Fields

Field	Description
Context Name	Lists all context names. The context name with the asterisk (*) is the admin context.
Interfaces	The interfaces assigned to the context.
URL	The URL from which the ASA loads the context configuration.

The following is sample output from the **show context detail** command in the system execution space:

```
hostname# show context detail

Context "admin", has been created, but initial ACL rules not complete
  Config URL: flash:/admin.cfg
  Real Interfaces: Management0/0
  Mapped Interfaces: Management0/0
  Real IPS Sensors: ips1, ips2
  Mapped IPS Sensors: highsec, lowsec
  Flags: 0x00000013, ID: 1

Context "ctx", has been created, but initial ACL rules not complete
  Config URL: ctx.cfg
  Real Interfaces: GigabitEthernet0/0.10, GigabitEthernet0/1.20,
     GigabitEthernet0/2.30
  Mapped Interfaces: int1, int2, int3
  Real IPS Sensors: ips1, ips3
  Mapped IPS Sensors: highsec, lowsec
  Flags: 0x00000011, ID: 2

Context "system", is a system resource
  Config URL: startup-config
  Real Interfaces:
  Mapped Interfaces: Control0/0, GigabitEthernet0/0,
     GigabitEthernet0/0.10, GigabitEthernet0/1, GigabitEthernet0/1.10,
     GigabitEthernet0/1.20, GigabitEthernet0/2, GigabitEthernet0/2.30,
     GigabitEthernet0/3, Management0/0, Management0/0.1
  Flags: 0x00000019, ID: 257

Context "null", is a system resource
  Config URL: ... null ...
  Real Interfaces:
  Mapped Interfaces:
  Flags: 0x00000009, ID: 258
```

Table 46-8 shows each field description.

Table 46-8 Context States

Field	Description
Context	The context name. The null context information is for internal use only. The system context represents the system execution space.
State Message:	The context state. See the possible messages below.
Has been created, but initial ACL rules not complete	The ASA parsed the configuration but has not yet downloaded the default ACLs to establish the default security policy. The default security policy applies to all contexts initially, and includes disallowing traffic from lower security levels to higher security levels, enabling application inspection, and other parameters. This security policy ensures that no traffic can pass through the ASA after the configuration is parsed but before the configuration ACLs are compiled. You are unlikely to see this state because the configuration ACLs are compiled very quickly.
Has been created, but not initialized	You entered the **context** *name* command, but have not yet entered the **config-url** command.
Has been created, but the config hasn't been parsed	The default ACLs were downloaded, but the ASA has not parsed the configuration. This state might exist because the configuration download might have failed because of network connectivity issues, or you have not yet entered the **config-url** command. To reload the configuration, from within the context, enter **copy startup-config running-config**. From the system, reenter the **config-url** command. Alternatively, you can start configuring the blank running configuration.
Is a system resource	This state applies only to the system execution space and to the null context. The null context is used by the system, and the information is for internal use only.
Is a zombie	You deleted the context using the **no context** or **clear context** command, but the context information persists in memory until the ASA reuses the context ID for a new context, or you restart.
Is active	This context is currently running and can pass traffic according to the context configuration security policy.
Is ADMIN and active	This context is the admin context and is currently running.
Was a former ADMIN, but is now a zombie	You deleted the admin context using the **clear configure context** command, but the context information persists in memory until the ASA reuses the context ID for a new context, or you restart.
Real Interfaces	The interfaces assigned to the context. If you mapped the interface IDs in the **allocate-interface** command, this display shows the real name of the interface.
Mapped Interfaces	If you mapped the interface IDs in the **allocate-interface** command, this display shows the mapped names. If you did not map the interfaces, the display lists the real names again.
Real IPS Sensors	The IPS virtual sensors assigned to the context if you have an AIP SSM installed. If you mapped the sensor names in the **allocate-ips** command, this display shows the real name of the sensor.

Table 46-8 Context States (continued)

Field	Description
Mapped IPS Sensors	If you mapped the sensor names in the **allocate-ips** command, this display shows the mapped names. If you did not map the sensor names, the display lists the real names again.
Flag	For internal use only.
ID	An internal ID for this context.

The following is sample output from the **show context count** command:

```
hostname# show context count
Total active contexts: 2
```

Related Commands

Command	Description
admin-context	Sets the admin context.
allocate-interface	Assigns interfaces to a context.
changeto	Changes between contexts or the system execution space.
config-url	Specifies the location of the context configuration.
context	Creates a security context in the system configuration and enters context configuration mode.

show controller

To view controller-specific information of all interfaces present, use the **show controller** command in privileged EXEC mode.

show controller [**slot**] [*physical_interface*] [**pci** [**bridge** [*bridge-id* [*port-num*]]]] [**detail**]

Syntax Description

bridge	(Optional) Displays PCI bridge-specific information for the ASA 5585-X.
bridge-id	(Optional) Displays each unique PCI bridge identifier for the ASA 5585-X.
detail	(Optional) Shows additional detail about the controller.
pci	(Optional) Displays a summary of PCI devices along with their first 256 bytes of PCI configuration space for the ASA 5585-X.
physical_interface	(Optional) Identifies the interface ID.
port-num	(Optional) Displays the unique port number within each PCI bridge for the ASA 5585-X adaptive ASA.
slot	(Optional) Displays PCI-e bus and slot information for the ASA 5580 only.

Defaults

If you do not identify an interface, this command shows information for all interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.2(1)	This command was introduced.
8.0(2)	This command now applies to all platforms, and not just the ASA 5505. The **detail** keyword was added.
8.1(1)	The **slot** keyword was added for the ASA 5580.
8.2(5)	The **pci**, **bridge**, *bridge-id,* and *port-num* options were added for the ASA 5585-X with an IPS SSP installed. In addition, support for sending pause frames to enable flow control on 1 GigabitEthernet interfaces has been added for all ASA models.
8.6(1)	Support was added for the **detail** keyword for the ASA 5512-X through ASA 5555-X Internal-Control0/0 interface, used for control traffic between the ASA and the software module, and for the Internal-Data0/1 interface used for data traffic to the ASA and the software module.

Usage Guidelines

This command helps Cisco TAC gather useful debug information about the controller when investigating internal and customer found defects. The actual output depends on the model and Ethernet controller. The command also displays information about all the PCI bridges of interest in the ASA 5585-X with an IPS SSP installed. For the ASA Services Module, the **show controller** command output does not show any PCIe slot information.

Examples

The following is sample output from the **show controller** command:

```
hostname# show controller

Related Commands

Command	Description
show interface	Shows the interface statistics.
show tech-support	Shows information so Cisco TAC can diagnose problems.

show coredump filesystem

To show the contents of the coredump filesystem, enter the **show coredump filesystem** command.

show coredump filesystem

Syntax Descriptionn

This command has no arguments or keywords.

Defaults

By default, coredumps are not enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

This command shows the contents of the coredump filesystem.

Examples

To show the contents of any recent coredumps generated, enter the **show coredump filesystem** command.

```
hostname(config)# show coredump filesystem
Coredump Filesystem Size is 100 MB
Filesystem type is FAT for disk0
Filesystem 1k-blocks Used Available Use% Mounted on
/dev/loop0 102182 75240 26942 74% /mnt/disk0/coredumpfsys
Directory of disk0:/coredumpfsys/
246 -rwx 20205386 19:14:53 Nov 26 2008 core_lina.2008Nov26_191244.203.11.gz
247 -rwx 36707919 19:17:27 Nov 26 2008 core_lina.2008Nov26_191456.203.6.gz
```

Related Commands

Command	Description
coredump enable	Enables the coredump feature.
clear configure coredump	Removes any coredumps currently stored on the coredump filesystem and clears the coredump log. Does not touch the coredump filesystem itself and does not change or affect the coredump configuration.

Command	Description
clear coredump	Removes any coredumps currently stored on the coredump filesystem and clears the coredump log. Does not touch the coredump filesystem itself and does not change/effect the coredump configuration.
show coredump log	Shows the coredump log.

show coredump log

To show the contents of the coredump log, newest first, enter the **show coredump log** command. To show the contents of the coredump log, oldest first, enter the **show coredump log reverse** command.

show coredump log

show coredump log [**reverse**]

Syntax Description

reverse	Shows the oldest coredump log.

Defaults

By default, coredumps are not enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

This command displays the contents of the coredump log. The logs should reflect what is currently on the disk.

Examples

The following example shows the output from these commands:

```
hostname(config)# show coredump log
[ 1 ] Wed Feb 18 22:12:09 2009: Coredump completed for module 'lina', coredump file
'core_lina.2009Feb18_221032.203.6.gz', size 971722752 bytes, compressed size 21293688
[ 2 ] Wed Feb 18 22:11:01 2009: Filesystem full on 'disk0', removing module coredump
record 'core_lina.2009Feb18_213558.203.11.gz'
[ 3 ] Wed Feb 18 22:10:32 2009: Coredump started for module 'lina', generating coredump
file 'core_lina.2009Feb18_221032.203.6.gz' on 'disk0'
[ 4 ] Wed Feb 18 21:37:35 2009: Coredump completed for module 'lina', coredump file
'core_lina.2009Feb18_213558.203.11.gz', size 971722752 bytes, compressed size 21286383
[ 5 ] Wed Feb 18 21:35:58 2009: Coredump started for module 'lina', generating coredump
file 'core_lina.2009Feb18_213558.203.11.gz' on 'disk0'
```

Note The older coredump file is deleted to make room for the new coredump. This is done automatically by the ASA in the event the coredump filesystem fills and room is needed for the current coredump. This is why it is imperative to archive coredumps as soon as possible, to insure they don't get overwritten in the event of a crash.

```
hostname(config)# show coredump log reverse
[ 1 ] Wed Feb 18 21:35:58 2009: Coredump started for module 'lina', generating coredump
file 'core_lina.2009Feb18_213558.203.11.gz' on 'disk0''
[ 2 ] Wed Feb 18 21:37:35 2009: Coredump completed for module 'lina', coredump file
'core_lina.2009Feb18_213558.203.11.gz', size 971722752 bytes, compressed size 21286383
[ 3 ] Wed Feb 18 22:10:32 2009: Coredump started for module 'lina', generating coredump
file 'core_lina.2009Feb18_221032.203.6.gz' on 'disk0'
[ 4 ] Wed Feb 18 22:11:01 2009: Filesystem full on 'disk0', removing module coredump
record 'core_lina.2009Feb18_213558.203.11.gz'
[ 5 ] Wed Feb 18 22:12:09 2009: Coredump completed for module 'lina', coredump file
'core_lina.2009Feb18_221032.203.6.gz', size 971722752 bytes, compressed size 21293688
```

show counters

To display the protocol stack counters, use the **show counters** command in privileged EXEC mode.

show counters [all | context *context-name* **| summary | top** *N* **] [detail] [protocol** *protocol_name* **[:***counter_name***]] [threshold** *N***]**

Syntax Description

all	Displays the filter details.
context *context-name*	Specifies the context name.
:*counter_name*	Specifies a counter by name.
detail	Displays additional counters information.
protocol *protocol_name*	Displays the counters for the specified protocol.
summary	Displays a counter summary.
threshold *N*	Displays only those counters at or above the specified threshold. The range is 1 through 4294967295.
top *N*	Displays the counters at or above the specified threshold. The range is 1 through 4294967295.

Defaults

show counters summary detail threshold 1

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
9.0(1)	This command was introduced.

Examples

The following example shows how to display all counters:

```
hostname# show counters all
Protocol     Counter           Value   Context
IOS_IPC      IN_PKTS               2   single_vf
IOS_IPC      OUT_PKTS              2   single_vf

hostname# show counters
Protocol     Counter           Value   Context
NPCP         IN_PKTS            7195   Summary
NPCP         OUT_PKTS           7603   Summary
IOS_IPC      IN_PKTS             869   Summary
IOS_IPC      OUT_PKTS            865   Summary
IP           IN_PKTS             380   Summary
IP           OUT_PKTS            411   Summary
IP           TO_ARP              105   Summary
IP           TO_UDP                9   Summary
UDP          IN_PKTS               9   Summary
UDP          DROP_NO_APP           9   Summary
FIXUP        IN_PKTS             202   Summary
UAUTH        IPV6_UNSUPPORTED     27   Summary
IDFW         HIT_USER_LIMIT        2   Summary
```

The following example shows how to display a summary of counters:

```
hostname# show counters summary
Protocol     Counter           Value   Context
IOS_IPC      IN_PKTS               2   Summary
IOS_IPC      OUT_PKTS              2   Summary
```

The following example shows how to display counters for a context:

```
hostname# show counters context single_vf
Protocol     Counter           Value   Context
IOS_IPC      IN_PKTS               4   single_vf
IOS_IPC      OUT_PKTS              4   single_vf
```

Related Commands

Command	Description
clear counters	Clears the protocol stack counters.

show cpu

To display the CPU utilization information, use the **show cpu** command in privileged EXEC mode.

[**cluster exec**] **show cpu** [**usage** *core-id* | **profile** | **dump** | **detailed**]

From the system configuration in multiple context mode:

[**cluster exec**] **show cpu** [**usage**] [**context** {**all** | *context_name*}]

Syntax Description

all	Specifies that the display show all contexts.
cluster exec	(Optional) In a clustering environment, enables you to issue the **show cpu** command in one unit and run the command in all the other units at the same time.
context	Specifies that the display show a context.
context_name	Specifies the name of the context to display.
core-id	Specifies the number of the processor core.
detailed	(Optional) Displays the CPU usage internal details.
dump	(Optional) Displays the dump profiling data to the TTY.
profile	(Optional) Displays the CPU profiling data.
usage	(Optional) Displays the CPU usage.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
8.6(1)	The *core-id* option was added to support the ASA 5512-X, 5515-X, 5525-X, 5545-X, and 5555-X.
9.1(2)	The output was updated for the **show cpu profile** and **show cpu profile dump** commands.

Usage Guidelines

The CPU usage is computed using an approximation of the load every five seconds, and by further feeding this approximation into two, following moving averages.

You can use the **show cpu** command to find process related loads (that is, activity on behalf of items listed by the output of the **show process** command in both single mode and from the system configuration in multiple context mode).

Further, you can request, when in multiple context mode, a breakdown of the process related load to CPU consumed by any configured contexts by changing to each context and entering the **show cpu** command or by entering the **show cpu context** command.

While process related load is rounded to the nearest whole number, context related loads include one additional decimal digit of precision. For example, entering the **show cpu** command from the system context produces a different number than from entering the **show cpu context system** command. The former is an approximate summary of everything that appears in the **show cpu context all** command, and the latter is only a portion of that summary.

You can use the **show cpu profile dump** command in conjunction with the **cpu profile activate** command to collect information for TAC use in troubleshooting CPU issues. The **show cpu profile dump** command output is in hexadecimal format.

If the CPU profiler is waiting for a starting condition to occur, the **show cpu profile** command displays the following output:

```
CPU profiling started: 12:45:57.209 UTC Wed Nov 14 2012
CPU Profiling waiting on starting condition.
Core 0: 0 out of 10 samples collected.
Core 1: 0 out of 10 samples collected.
Core 2: 0 out of 10 samples collected.
Core 3: 0 out of 10 samples collected.
CP
0 out of 10 samples collected.
```

Examples

The following example shows how to display the CPU utilization:

```
hostname# show cpu usage
CPU utilization for 5 seconds = 18%; 1 minute: 18%; 5 minutes: 18%
```

The following example shows how to display detailed CPU utilization information:

```
hostname# show cpu detailed
Break down of per-core data path versus control point cpu usage:
Core         5 sec            1 min            5 min
Core 0       0.0 (0.0 + 0.0)  3.3 (0.0 + 3.3)  2.4 (0.0 + 2.4)

Current control point elapsed versus the maximum control point elapsed for:
      5 seconds = 99.0%; 1 minute: 99.8%; 5 minutes: 95.9%

CPU utilization of external processes for:
      5 seconds = 0.2%; 1 minute: 0.0%; 5 minutes: 0.0%

Total CPU utilization for:
      5 seconds = 0.2%; 1 minute: 3.3%; 5 minutes: 2.5%
```

Note The "Current control point elapsed versus the maximum control point elapsed for" statement means that the current control point load is compared to the maximum load seen within the defined time period. This is a ratio instead of an absolute number. The figure of 99% for the 5-second interval means that the current control point load is at 99% of the maximum load that is visible over this 5-second interval. If the load continues to increase all the time, then it will always remain at 100%. However, the actual CPU may still have a lot of free capacity because the maximum absolute value has not been defined.

The following example shows how to display the CPU utilization for the system context in multiple mode:

```
hostname# show cpu context system
CPU utilization for 5 seconds = 9.1%; 1 minute: 9.2%; 5 minutes: 9.1%
```

The following example shows how to display the CPU utilization for all contexts:

```
hostname# show cpu usage context all
5 sec  1 min  5 min  Context Name
9.1%   9.2%   9.1%  system
0.0%   0.0%   0.0%  admin
5.0%   5.0%   5.0%  one
4.2%   4.3%   4.2%  two
```

The following example shows how to display the CPU utilization for a context named “one”:

```
hostname/one# show cpu usage
CPU utilization for 5 seconds = 5.0%; 1 minute: 5.0%; 5 minutes: 5.0%
```

The following example activates the profiler and instructs it to store 1000 samples.

```
hostname# cpu profile activate
Activated CPU profiling for 1000 samples.
Use "show cpu profile" to display the progress or "show cpu profile dump" to interrupt
profiling and display the incomplete results.
```

The following examples show the status of the profiing (in-progress and completed):

```
hostname# show cpu profile
CPU profiling started: 13:45:10.400 PST Fri Nov 16 2012
CPU profiling currently in progress:
Core 0: 209 out of 1000 samples collected.
Use "show cpu profile dump" to see the results after it is complete or to interrupt
profiling and display the incomplete results.

hostname# show cpu profile dump
Cisco Adaptive Security Appliance Software Version 9.1(2)
Hardware:   ASA5555
CPU profiling started: 09:13:32.079 UTC Wed Jan 30 2013
No CPU profiling process specified.
No CPU profiling trigger specified.
cores: 2

Process virtual address map:
---------------------------
…
---------------------------
End of process map
Samples for core 0 - stopped
{0x00000000007eadb6,0x000000000211ee7e} ...
```

Copy this information and provide it to the TAC for decoding.

Related Commands

Command	Description
show counters	Displays the protocol stack counters.
cpu profile activate	Activates CPU profiling.

CHAPTER 47

show crashinfo through show curpriv Commands

show crashinfo

To display the contents of the crash file stored in Flash memory, enter the **show crashinfo** command in privileged EXEC mode.

show crashinfo [**save**]

Syntax Description

save	(Optional) Displays if the ASA is configured to save crash information to Flash memory or not.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If the crash file is from a test crash (generated from the **crashinfo test** command), the first string of the crash file is "`: Saved_Test_Crash`" and the last string is "`: End_Test_Crash`". If the crash file is from a real crash, the first string of the crash file is "`: Saved_Crash`" and the last string is "`: End_Crash`". (This includes crashes from use of the **crashinfo force page-fault** or **crashinfo force watchdog** commands).

If there is no crash data saved in flash, or if the crash data has been cleared by entering the **clear crashinfo** command, the **show crashinfo** command displays an error message.

Examples

The following example shows how to display the current crash information configuration:

```
hostname# show crashinfo save
crashinfo save enable
```

The following example shows the output for a crash file test. (However, this test does not actually crash the ASA. It provides a simulated example file.)

```
hostname(config)# crashinfo test
hostname(config)# exit
hostname# show crashinfo
: Saved_Test_Crash

Related Commands

Command	Description
clear crashinfo	Deletes the contents of the crash file.
crashinfo force	Forces a crash of the ASA.
crashinfo save disable	Disables crash information from writing to flash memory.
crashinfo test	Tests the ability of the ASA to save crash information to a file in flash memory.

show crashinfo console

To display the configuration setting of the **crashinfo console** command, enter the **show crashinfo console** command.

show crashinfo console

Syntax Description

This command has no arguments or keywords.

Defaults

This command has no default settings.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(4)	This command was introduced.

Usage Guidelines

Compliance with FIPS 140-2 prohibits the distribution of Critical Secu rity Parameters (keys, passwords, etc.) outside of the crypto boundary (chassis). When the device crashes, due to an assert or checkheaps failure, it is possible that the stack or memory regions dumped to the console contain sensitive data. This output must be suppressed in FIPS-mode.

Examples

```
sw8-5520(config)# show crashinfo console
crashinfo console enable
```

Related Commands

Command	Description
clear configure fips	Clears the system or module FIPS configuration information stored in NVRAM.
crashinfo console disable	Disables the reading, writing and configuration of crash write info to flash.
fips enable	Enables or disablea policy-checking to enforce FIPS compliance on the system or module.
show running-config fips	Displays the FIPS configuration that is running on the ASA.

show crypto accelerator statistics

To display the global and accelerator-specific statistics from the hardware crypto accelerator MIB, use the **show crypto accelerator statistics** command in global configuration or privileged EXEC mode.

show crypto accelerator statistics

Syntax Description

This command has no keywords or variables.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—
Privileged EXEC	•	•	•	• —	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The output statistics are defined as follows:

Accelerator 0 shows statistics for the software-based crypto engine.

Accelerator 1 shows statistics for the hardware-based crypto engine.

RSA statistics show RSA operations for 2048-bit keys, which are executed in software by default. This means that when you have a 2048-bit key, IKE/SSL VPN performs RSA operations in software during the IPsec/SSL negotiation phase. Actual IPsec/SSL traffic is still processed using hardware. This may cause high CPU if there are many simultaneous sessions starting at the same time, which may result in multiple RSA key operations and high CPU. If you run into a high CPU condition because of this, then you should use a 1024-bit key to process RSA key operations in hardware. To do so, you must reenroll the identity certificate. In releases 8.3(2) or later, you can also use the crypto engine large-mod-accel command on the 5510-5550 platforms to perform these operations in hardware.

If you are using a 2048-bit RSA key and the RSA processing is performed in software, you can use CPU profiling to determine which functions are causing high CPU usage. Generally, the bn_* and BN_* functions are math operations on the large data sets used for RSA, and are the most useful when examining CPU usage during an RSA operation in software. For example:

```
@@@@@@@@@@@@@@@@@@@@............................. 36.50% : _bn_mul_add_words
@@@@@@@@@@.....................................  19.75% : _bn_sqr_comba8
```

Diffie-Hellman statistics show that any crypto operation with a modulus size greater than 1024 is performed in software (for example, DH5 (Diffie-Hellman group 5 uses 1536)). If so, a 2048-bit key certificate will be processed in software, which can result in high CPU usage when a lot of sessions are running.

Note The ASA 5505 (with a Cavium CN505 processor) only supports Diffie-Hellman Groups 1 and 2 for hardware-accelerated, 768-bit and 1024-bit key generation. Diffie-Hellman Group 5 (1536-bit key generation) is performed in software.

A single crypto engine in the adaptive security appliance performs the IPsec and SSL operations. To display the versions of crypto (Cavium) microcode that are loaded into the hardware crypto accelerator at boot time, enter the **show version** command. For example:

```
hostname(config) show version

Cisco Adaptive Security Appliance Software Version 8.0(4)8
Device Manager Version 6.1(5)
Compiled on Wed 15-Oct-09 17:27 by builders
System image file is "disk0:/interim/asa804-8-k8.bin"
Config file at boot was "startup-config"
asa up 5 days 17 hours
Hardware:   ASA5505, 512 MB RAM, CPU Geode 500 MHz
Internal ATA Compact Flash, 512MB
BIOS Flash M50FW080 @ 0xffe00000, 1024KB
Encryption hardware device : Cisco ASA-5505 on-board accelerator (revision 0x0)
                             Boot microcode   : CN1000-MC-BOOT-2.00
                             SSL/IKE microcode: CNLite-MC-SSLm-PLUS-2.03
                             IPsec microcode  : CNlite-MC-IPSECm-MAIN-2.05
```

DSA statistics show key generation in two phases. The first phase is a choice of algorithm parameters, which may be shared between different users of the system. The second phase computes private and public keys for a single user.

SSL statistics show records for the processor-intensive public key encryption algorithms involved in SSL transactions to the hardware crypto accelerator.

RNG statistics show records for a sender and receiver, which can generate the same set of random numbers automatically to use as keys.

Examples

The following example, entered in global configuration mode, shows global crypto accelerator statistics:

```
hostname # show crypto accelerator statistics

Crypto Accelerator Status
-------------------------
[Capacity]
   Supports hardware crypto: True
   Supports modular hardware crypto: False
   Max accelerators: 1
   Max crypto throughput: 100 Mbps
   Max crypto connections: 750
[Global Statistics]
   Number of active accelerators: 1
   Number of non-operational accelerators: 0
   Input packets: 700
   Input bytes: 753488
   Output packets: 700
   Output error packets: 0
```

```
   Output bytes: 767496
[Accelerator 0]
   Status: Active
   Software crypto engine
   Slot: 0
   Active time: 167 seconds
   Total crypto transforms: 7
   Total dropped packets: 0
   [Input statistics]
      Input packets: 0
      Input bytes: 0
      Input hashed packets: 0
      Input hashed bytes: 0
      Decrypted packets: 0
      Decrypted bytes: 0
   [Output statistics]
      Output packets: 0
      Output bad packets: 0
      Output bytes: 0
      Output hashed packets: 0
      Output hashed bytes: 0
      Encrypted packets: 0
      Encrypted bytes: 0
   [Diffie-Hellman statistics]
      Keys generated: 0
      Secret keys derived: 0
   [RSA statistics]
      Keys generated: 0
      Signatures: 0
      Verifications: 0
      Encrypted packets: 0
      Encrypted bytes: 0
      Decrypted packets: 0
      Decrypted bytes: 0
   [DSA statistics]
      Keys generated: 0
      Signatures: 0
      Verifications: 0
   [SSL statistics]
      Outbound records: 0
      Inbound records: 0
   [RNG statistics]
      Random number requests: 98
      Random number request failures: 0
[Accelerator 1]
   Status: Active
   Encryption hardware device : Cisco ASA-55x0 on-board accelerator
(revision 0x0)

   Encrypted bytes: 0
   Decrypted packets: 0
   Decrypted bytes: 0
[DSA statistics]
   Keys generated: 0
   Signatures: 0
   Verifications: 0
[SSL statistics]
   Outbound records: 0
   Inbound records: 0
[RNG statistics]
   Random number requests: 1
   Random number request failures: 0
```

The following table describes what the output entries indicates.

Output	Decription
Capacity	This section pertains to the crypto acceleration that the ASA can support.
Supports hardware crypto	(True/False) The ASA can support hardware crypto acceleration.
Supports modular hardware crypto	(True/False) Any supported hardware crypto accelerator can be inserted as a separate plug-in card or module.
Max accelerators	The maximum number of hardware crypto accelerators that the ASA supports.
Mac crypto throughput	The maximum rated VPN throughput for the ASA.
Max crypto connections	The maximum number of supported VPN tunnels for the ASA.
Global Statistics	This section pertains to the combined hardware crypto accelerators in the ASA.
Number of active accelerators	The number of active hardware accelerators. An active hardware accelerator has been initialized and is avaialble to process crypto commands.
Number of non-operational accelerators	The number of inactive hardware accelerators. An inactive hardware accelerator has been detected, but either has not completed initialization or has failed and is no longer usable.
Input packets	The number of inbound packets processed by all hardware crypto accelerators.
Input bytes	The number of bytes of data in the processed inbound packets.

Output (continued)	Decription (continued)
Output packets	The number of outbound packets processed by all hardware crypto accelerators.
Output error packets	The number of outbound packets processed processed by all hardware crypto accelerators in which an error has been detected.
Output bytes	The number of bytes of data in the processed outbound packets.
Accelerator 0	Each of these sections pertains to a crypto accelerator. The first one (Accelerator 0) is always the software crypto engine. Although not a hardware accelerator, the ASA uses it to perform specific crypto tasks, and its statistics appear here. Accelerators 1 and higher are always hardware crypto accelerators.
Status	The status of the accelerator, which indicates whether the accelerator is being initialized, is active, or has failed.
Software crypto engine	The type of accelerator and firmware version (if applicable).
Slot	The slot number of the accelerator (if applicable).
Active time	The length of time that the accelerator has been in the active state.
Total crypto transforms	The total number of crypto commands that were performed by the accelerator.
Total dropped packets	The total number of packets that were dropped by the accelerator because of errors.
Input statistics	This section pertains to input traffic that was processed by the accelerator. Input traffic is considered to be ciphertext that must be decrypted and/or authenticated.
Input packets	The number of input packets that have been processed by the accelerator.
Input bytes	The number of input bytes that have been processed by the accelerator
Input hashed packets	The number of packets for which the accelerator has performed hash operations.
Input hashed bytes	The number of bytes over which the accelerator has performed hash operations.
Decrypted packets	The number of packets for which the accelerator has performed symmetric decryption operations.
Decrypted bytes	The number of bytes over which the accelerator has performed symmetric decryption operations.
Output statistics	This section pertains to output traffic that has been processed by the accelerator. Input traffic is considered clear text that must be encrypted and/or hashed.
Output packets	The number of output packets that have been processed by the accelerator.

Output (continued)	Decription (continued)
Output bad packets	The number of output packets that have been processed by the accelerator in which an error has been detected.
Output bytes	The number of output bytes that have been processed by the accelerator.
Output hashed packets	The number of packets for which the accelerator has performed outbound hash operations.
Output hashed bytes	The number of bytes over which the accelerator has performed outbound hash operations.
Encyrpted packets	The number of packets for which the accelerator has performed symmetric encryption operations.
Encyrpted bytes	The number of bytes over which the accelerator has performed symmetric encryption operations.
Diffie-Hellman statistics	This section pertains to Diffie-Hellman key exchange operations.
Keys generated	The number of Diffie-Hellman key sets that have been generated by the accelerator.
Secret keys derived	The number of Diffie-Hellman shared secrets that have been derived by the accelerator.
RSA statistics	This section pertains to RSA crypto operations.
Keys generated	The number of RSA key sets that have been generated by the accelerator.
Signatures	The number of RSA signature operations that have been performed by the accelerator.
Verifications	The number of RSA signature verifications that have been performed by the accelerator.
Encrypted packets	The number of packets for which the accelerator has performed RSA encryption operations.
Decrypted packets	The number of packets for which the accelerator has performed RSA decryption operations.
Decrypted bytes	The number of bytes of data over which the accelerator has performed RSA decryption operations.
DSA statistics	This section pertains to DSA operations. Note that DSA is not supported as of Version 8.2, so these statistics are no longer displayed.
Keys generated	The number of DSA key sets that have been generated by the accelerator.
Signatures	The number of DSA signature operations that have been performed by the accelerator.
Verifications	The number of DSA signature verifications that have been performed by the accelerator.
SSL statistics	This section pertains to SSL record processing operations.
Outbound records	The number of SSL records that have been encrypted and authenticated by the accelerator.

Output (continued)	Decription (continued)
Inbound records	The number of SSL records that have been decrypted and authenticated by the accelerator.
RNG statistics	This section pertains to random number generation.
Random number requests	The number of requests to the accelerator for a random number.
Random number request failures	The number of randum number requests to the accelerator that did not succeed.

Related Commands

Command	Description
clear crypto accelerator statistics	Clears the global and accelerator-specific statistics in the crypto accelerator MIB.
clear crypto protocol statistics	Clears the protocol-specific statistics in the crypto accelerator MIB.
show crypto protocol statistics	Displays the protocol-specific statistics from the crypto accelerator MIB.

show crypto ca certificates

To display the certificates associated with a specific trustpoint or to display all the certificates installed on the system, use the **show crypto ca certificates** command in global configuration or privileged EXEC mode.

show crypto ca certificates [*trustpointname*]

Syntax Description

trustpointname	(Optional) The name of a trustpoint. If you do not specify a name, this command displays all certificates installed on the ASA.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Examples

The following is sample output from the **show crypto ca certificates** command:

```
hostname(config)# show crypto ca certificates tp1
CA Certificate
    Status: Available
    Certificate Serial Number 2957A3FF296EF854FD0D6732FE25B45
    Certificate Usage: Signature
    Issuer:
        CN = ms-root-sha-06-2004
        OU = rootou
        O = cisco
        L = franklin
        ST - massachusetts
        C = US
        EA = a@b.con
    Subject:
        CN = ms-root-sha-06-2004
        OU = rootou
        O = cisco
        L = franklin
        ST = massachusetts
        C = US
        EA = example.com
    CRL Distribution Point
```

```
        ldap://w2kadvancedsrv/CertEnroll/ms-root-sha-06-2004.crl
    Validity Date:
        start date: 14:11:40 UTC Jun 26 2004
        end date: 14:01:30 UTC Jun 4 2022
    Associated Trustpoints: tp2 tp1
hostname(config)#
```

Related Commands

Command	Description
crypto ca authenticate	Obtains a CA certificate for a specified trustpoint.
crypto ca crl request	Requests a CRL based on the configuration parameters of a specified trustpoint.
crypto ca enroll	Initiates the enrollment process with a CA.
crypto ca import	Imports a certificate to a specified trustpoint.
crypto ca trustpoint	Enters trustpoint configuration mode for a specified trustpoint.

show crypto ca crl

To display all cached CRLs or to display all CRLs cached for a specified trustpoint, use the **show crypto ca crl** command in global configuration or privileged EXEC mode.

show crypto ca crl [trustpool | trustpoint <*trustpointname*>]

Syntax Description

trustpointname	(Optional) The name of a trustpoint. If you do not specify a name, this command displays all CRLs cached on the ASA.
trustpool	tbd?

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•

Release	Modification
8.0(2)	This command was introduced.

Examples

The following is sample output from the **show crypto ca server** command:

```
hostname# show crypto ca server
#Certificate Server LOCAL-CA-SERVER:
    Status: disabled
    State: disabled
    Server's configuration is unlocked (enter "no shutdown" to lock it)
    Issuer name: CN=asa1.cisco.com
    CA cert fingerprint: -Not found-
    Last certificate issued serial number: 0x0
    CA certificate expiration timer: 00:00:00 UTC Jan 1 2009
    CRL not present.
    Current primary storage dir: nvram:
hostname#
```

Related Commands

Command	Description
crypto ca server	Provides access to the ca server configuration mode CLI command set, which allows you to configure and manage the local CA.
debug crypto ca server	Shows debugging messages when you configure the local CA server.

Command	Description
show crypto ca server certificate	Displays the certificate of the local CA in base64 format.
show crypto ca server crl	Displays the lifetime of the local CA CRL.

show crypto ca server cert-db

To display all or a subset of local CA server certificates, including those issued to a specific user, use the **show crypto ca server cert-db** command in ca server configuration, global configuration, or privileged EXEC mode.

show crypto ca server cert-db [**username** *username* | **allowed** | **enrolled** | **expired** | **on-hold**] [**serial** *certificate-serial-number*]

Syntax Description

allowed	Specifies that users who are allowed to enroll appear, regardless of the status of their certificate.
enrolled	Specifies that users with valid certificates appear.
expired	Specifies that users holding expired certificates appear.
on-hold	Specifies that users who have not yet enrolled appear.
serial *certificate-serial-number*	Specifies the serial number of a specific certificate that displays. The serial number must be in hexadecimal format.
username *username*	Specifies the certificate owner. The username may be a username or an e-mail address. For e-mail addresses, it is the e-mail address used to contact and deliver the one-time password (OTP) to the end user. An e-mail address is required to enable e-mail notifications for the end user.

Defaults

By default, if no username or certificate serial number is specified, the entire database of issued certificates appears.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Ca server configuration	•	—	•	—	—
Global configuration	•	—	•	—	—
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The **show crypto ca server cert-db** command displays a list of the user certificates that are issued by the local CA server. You can display a subset of the certificate database by specifying a specific username with one or more of the optional certificate-type keywords, and/or with an optional certificate serial number.

If you specify a username without a keyword or a serial number, all of the certificates issued for that user appear. For each user, the output shows the username, e-mail address, domain name, the time period for which enrollment is allowed, and the number of times that the user has been notified with an enrollment invitation.

In addition, the following information appears in the output:

- The NOTIFIED field is required to support multiple reminders. It tracks when a user needs to be notified of the OTP for enrollment and the reminder notification attempts. This field is set to 0 initially. It is incremented to 1 when the user entry is marked as being allowed to enroll. At this time, the initial OTP notification is generated.
- The NOTIFY field is incremented each time a reminder is sent. Three notifications are sent before the OTP is due to expire. A notification is sent when the user is allowed to enroll, at the mid-point of the expiration, and when ¾ of the expiration time has passed. This field is used only for administrator-initiated enrollments. For automatic certificate renewals, the NOTIFYfield in the certificate database is used.

Each certificate displays the certificate serial number, the issued and expired dates, and the certificate status (Revoked/Not Revoked).

Examples

The following example requests the display of all of the certificates issued for asa by the CA server:

```
hostname# show crypto ca server cert-db username asa
Username: asa
Renewal allowed until: Not Allowed
Number of times user notified: 0
PKCS12 file stored until: 10:28:05 UTC Wed Sep 25 2013
Certificates Issued:
serial:   0x2
issued:   10:28:04 UTC Tue Sep 24 2013
expired:  10:28:04 UTC Thu Sep 26 2013
status:   Not Revoked
```

The following example requests the display of all the certificates issued by the local CA server with a serial number of 0x2:

```
hostname# show crypto ca server cert-db serial 2

Username:asa
Renewal allowed until: Not Allowed
Number of times user notified: 0
PKCS12 file stored until: 10:28:05 UTC Wed Sep 25 2013
Certificates Issued:
serial:   0x2
issued:   10:28:04 UTC Tue Sep 24 2013
expired:  10:28:04 UTC Thu Sep 26 2013
status:   Not Revoked
```

The following example requests the display of all of the certificates issued by the local CA server:

```
hostname# show crypto ca server cert-db
Username: asa
Renewal allowed until: Not Allowed
Number of times user notified: 0
PKCS12 file stored until: 10:28:05 UTC Wed Sep 25 2013
Certificates Issued:
serial:   0x2
issued:   10:28:04 UTC Tue Sep 24 2013
expired:  10:28:04 UTC Thu Sep 26 2013
status:   Not Revoked
```

Related Commands

Command	Description
crypto ca server	Provides access to the ca server configuration mode CLI command set, which allows you to configure and manage the local CA.
crypto ca server revoke	Marks a certificate issued by the local CA server as revoked in both the certificate database and CRL.
lifetime crl	Specifies the lifetime of the CRL.

show crypto ca server certificate

To display the certificate for the local CA server in base64 format, use the **show crypto ca server certificate** command in ca server configuration, global configuration, or privileged EXEC mode.

show crypto ca server certificate

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca server configuration	•	—	•	—	—
Global configuration	•	—	•	—	—
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The **show crypto ca server certificate** command displays the local CA server certificate in base64 format. This display allows you to cut and paste a certificate while exporting it to other devices that need to trust the local CA server.

Examples

The following is sample output from the **show crypto ca server certificate** command:

```
hostname# show crypto ca server certificate

The base64 encoded local CA certificate follows:

MIIXlwIBAzCCF1EGCSqGSIb3DQEHAaCCF0IEghc+MIIXOjCCFzYGCSqGSIb3DQEHBqCCFycwghcjAgEAMIIXHAYJKo

hostname#
```

Related Commands

Command	Description
crypto ca server	Provides access to the ca server configuration mode CLI command set, which allows you to configure and manage a local CA.
issuer-name	Specifies the subject-name DN of the certificate authority certificate.
keysize	Specifies the size of the public and private keys generated at user certificate enrollment.
lifetime	Specifies the lifetime of the CA certificate and issued certificates.
show crypto ca server	Displays the local CA configuration in ASCII text format.

show crypto ca server crl

To display the current CRL of the local CA, use the **show crypto ca server crl** command in ca server configuration, global configuration, or privileged EXEC mode.

show crypto ca server crl

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca server configuration	•	—	•	—	—
Global configuration	•	—	•	—	—
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Examples

The following is sample output from the **show crypto ca server crl** command:

```
hostname# show crypto ca server crl
asa5540(config)# sh cry ca ser crl
Certificate Revocation List:
    Issuer: cn=asa5540.frqa.cisco.com
    This Update: 07:32:27 UTC Oct 16 2006
    Next Update: 13:32:27 UTC Oct 16 2006
    Number of CRL entries: 0
    CRL size: 232 bytes
asa5540(config)#
hostname#
```

Related Commands

Command	Description
cdp-url	Specifies the CRL distribution point (CDP) to be included in the certificates issued by the CA.
crypto ca server	Provides access to the ca server configuration mode CLI command set, which allows you to configure and manage the local CA.
crypto ca server revoke	Marks a certificate issued by the local CA server as revoked in the certificate database and CRL.

Command	Description
lifetime crl	Specifies the lifetime of the CRL.
show crypto ca server	Displays the status of the CA configuration.

show crypto ca server user-db

To display users included in the local CA server user database, use the **show crypto ca server user-db** command in ca server configuration, global configuration, or privileged EXEC mode.

show crypto ca server user-db [**expired** | **allowed** | **on-hold** | **enrolled**]

Syntax Description

allowed	(Optional) Specifies that users who are allowed to enroll display, regardless of the status of their certificate.
enrolled	(Optional) Specifies that users with valid certificates display.
expired	(Optional) Specifies that users holding expired certificates display.
on-hold	(Optional) Specifies that users who have not enrolled yet display.

Defaults

By default, all users in the database display if no keywords are entered.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca server configuration	•	—	•	—	—
Global configuration	•	—	•	—	—
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Examples

The following example displays currently enrolled users:

```
hostname# show crypto ca server user-db enrolled
Username   DN                Certificate issued    Certificate expiration
exampleusercn=Example User,o=...5/31/2009           5/31/2010

hostname#
```

Related Commands

Command	Description
crypto ca server user-db add	Adds a user to the CA server user database.
crypto ca server user-db allow	Allows a specific user or a subset of users in the CA server database to enroll with the local CA.
crypto ca server user-db remove	Removes a user from the CA server user database.

Command	Description
crypto ca server user-db write	Writes user information configured in the local CA database to storage.
show crypto ca server cert-db	Displays all certificates issued by the local CA.

show crypto ca trustpool

To display the certificates that constitute the trustpool, use the **show crypto ca trustpool** command in privileged EXEC mode.

show crypto ca trustpool [detail]

Syntax Description

This command has no arguments or keywords.

Defaults

This command shows an abbreviated display of all the trustpool certificates. When the "detail" option is specified, more information is included.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The output of the show crypto ca trustpool command includes the fingerprint value of each certificate. These values are required for removal operation.

Examples

```
hostname# show crypto ca trustpool

CA Certificate

Related Commands

Command	Description
clear crypto ca trustpool	Removes all certificates from the trustpool.
crypto ca trustpool import	Imports certificates that constitute the PKI trustpool.
crypto ca trustpool remove	Removes a single specified certificate from the trustpool.

show crypto ca trustpool policy

To display the configured trustpool policy and process any applied certificate maps to show how those impact the policy, use the **show crypto ca trustpool policy** command in privileged EXEC mode.

show crypto ca trustpool policy

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Examples

```
hostname(config)# sh run cry ca cert map
crypto ca certificate map map1 1
issuer-name eq cn = mycompany manufacturing ca
issuer-name eq cn = mycompany ca
crypto ca certificate map map 2 1
issuer-name eq cn = mycompany manufacturing ca
issuer-name eq cn = mycompany ca2
ciscoasa(config)#

hostname(config)# sh run crypto ca trustpool policy
crypto ca trustpool policy
revocation-check none
match certificate map2 allow expired-certificate
match certificate map1 skip revocation-check
crl cache-time 123
ciscoasa(config)#

hostname# show crypto ca trustpool policy
800 trustpool certificates installed
Trustpool Policy
Trustpool revocation checking is disabled
CRL cache time: 123 seconds
CRL next update field: required and forced
Policy overrides:
map: map1
match:issuer-name eq cn=Mycompany Manufacturing CA
match:issuer-name eq cn=Mycompany CA
```

```
action:skip revocation-check

map: map2
match: issuer-name eq cn=mycompany Manufacturing CA
match: issuer-name eq cn=mycompany CA2
action: allowed expired certificates

hostname(config)#
```

Related Commands

Command	Description
crypto ca trustpool policy	Enters a submode that provides the commands that define the trustpool policy.

show crypto debug-condition

To display the currently configured filters, the unmatched states, and the error states for IPsec and ISAKMP debugging messages, use the **show crypto debug-condition** command in global configuration mode.

show crypto debug-condition

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Examples

The following example shows the filtering conditions:

```
hostname(config)# show crypto debug-condition
Crypto conditional debug is turned ON
IKE debug context unmatched flag:  OFF
IPsec debug context unmatched flag:  ON

IKE peer IP address filters:
1.1.1.0/24   2.2.2.2

IKE user name filters:
my_user
```

Related Commands

Command	Description
debug crypto condition	Sets filtering conditions for IPsec and ISAKMP debugging messages.
debug crypto condition error	Shows debugging messages whether or not filtering conditions have been specified.
debug crypto condition unmatched	Shows debugging messages for IPsec and ISAKMP that do not include sufficient context information for filtering.

show crypto ikev1 sa

To display the IKEv1 runtime SA database, use the **show crypto ikev1 sa** command in global configuration mode or privileged EXEC mode.

show crypto ikev1 sa [**detail**]

Syntax Description

detail	Displays detailed output about the SA database.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	•	—
Privileged EXEC	•	—	•	• —	—

Command History

Release	Modification
8.4(1)	This command command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

The output from this command includes the following fields:

Detail not specified.

IKE Peer	Type	Dir	Rky	State
209.165.200.225	L2L	Init	No	MM_Active

Detail specified.

IKE Peer	Type	Dir	Rky	State	Encrypt	Hash	Auth	Lifetime
209.165.200.225	L2L	Init	No	MM_Active	3des	md5	preshrd	86400

Examples

The following example, entered in global configuration mode, displays detailed information about the SA database:

```
hostname(config)# show crypto ikev1 sa detail

IKE Peer  Type  Dir   Rky  State      Encrypt Hash  Auth    Lifetime
1 209.165.200.225 User  Resp  No   AM_Active  3des    SHA   preshrd 86400

IKE Peer  Type  Dir   Rky  State      Encrypt Hash  Auth    Lifetime
2 209.165.200.226 User  Resp  No   AM_ACTIVE  3des    SHA   preshrd 86400

IKE Peer  Type  Dir   Rky  State      Encrypt Hash  Auth    Lifetime
3 209.165.200.227 User  Resp  No   AM_ACTIVE  3des    SHA   preshrd 86400

IKE Peer  Type  Dir   Rky  State      Encrypt Hash  Auth    Lifetime
4 209.165.200.228 User  Resp  No   AM_ACTIVE  3des    SHA   preshrd 86400

hostname(config)#
```

Related Commands

Command	Description
show crypto ikev2 sa	Displays the IKEv2 runtime SA database.
show running-config crypto isakmp	Displays all the active ISAKMP configuration.

show crypto ikev2 sa

To display the IKEv2 runtime SA database, use the **show crypto ikev2 sa** command in global configuration mode or privileged EXEC mode.

show crypto ikev2 sa [**detail**]

Syntax Description

detail	Displays detailed output about the SA database.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context

show crypto ipsec df-bit

To display the IPsec DF-bit policy for IPsec packets for a specified interface, use the **show crypto ipsec df-bit** command in global configuration mode and privileged EXEC mode.

show crypto ipsec df-bit *interface*

Syntax Description

interface	Specifies an interface name.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	• —	—
Privileged EXEC	•	•	•	• —	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Examples

The following example displays the IPsec DF-bit policy for interface named inside:

```
hostname(config)# show crypto ipsec df-bit inside
df-bit inside copy
hostname(config)#
```

Related Commands

Command	Description
crypto ipsec df-bit	Configures the IPsec DF-bit policy for IPsec packets.
crypto ipsec fragmentation	Configures the fragmentation policy for IPsec packets.
show crypto ipsec fragmentation	Displays the fragmentation policy for IPsec packets.

show crypto ipsec fragmentation

To display the fragmentation policy for IPsec packets, use the **show crypto ipsec fragmentation** command in global configuration or privileged EXEC mode.

show crypto ipsec fragmentation *interface*

Syntax Description

interface	Specifies an interface name.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	• —	—
Privileged EXEC	•	•	•	• —	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Examples

The following example, entered in global configuration mode, displays the IPsec fragmentation policy for an interface named inside:

```
hostname(config)# show crypto ipsec fragmentation inside
fragmentation inside before-encryption
hostname(config)#
```

Related Commands

Command	Description
crypto ipsec fragmentation	Configures the fragmentation policy for IPsec packets.
crypto ipsec df-bit	Configures the DF-bit policy for IPsec packets.
show crypto ipsec df-bit	Displays the DF-bit policy for a specified interface.

show crypto ipsec policy

To display IPsec secure socket API (SS API) security policy information provided by OSPFv3, use the **show crypto ipsec policy** command in global configuration or privileged EXEC mode. You can also use the alternate form of this command: **show ipsec policy**.

show crypto ipsec policy [name]

Syntax Description

name	Specifies a policy name.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	• —	—
Privileged EXEC	•	•	•	• —	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Examples

The following example, entered in global configuration mode, displays the crypto secure socket API installed policy information for a policy named CSSU-UTF:

```
hostname(config)# show crypto ipsec policy
Crypto IPsec client security policy data

       Policy name:      CSSU-UTF
       Policy refcount:  0
       Inbound  ESP SPI:        1031 (0x407)
       Outbound ESP SPI:        1031 (0x407)
       Inbound  ESP Auth Key:   0123456789abcdef
       Outbound ESP Auth Key:   0123456789abcdef
       Inbound  ESP Cipher Key:
       Outbound ESP Cipher Key:
       Transform set:    esp-sha-hmac
```

Related Commands

Command	Description
show crypto ipsec fragmentation	Displays the fragmentation policy for IPsec packets.
show crypto ipsec sa	Displays a list of IPsec SA.
show crypto ipsec df-bit	Displays the DF-bit policy for a specified interface.
show crypto sockets	Displays crypto secure sockets and the socket state.

show crypto ipsec sa

To display a list of IPsec SAs, use the **show crypto ipsec sa** command in global configuration mode or privileged EXEC mode. You can also use the alternate form of this command: **show ipsec sa**.

show crypto ipsec sa [**entry** | **identity** | **map** *map-name* | **peer** *peer-addr*] [**detail**]

Syntax Description

detail	(Optional) Displays detailed error information on what is displayed.
entry	(Optional) Displays IPsec SAs sorted by peer address
identity	(Optional) Displays IPsec SAs for sorted by identity, not including ESPs. This is a condensed form.
map *map-name*	(Optional) Displays IPsec SAs for the specified crypto map.
peer *peer-addr*	(Optional) Displays IPsec SAs for specified peer IP addresses.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	• —	—
Privileged EXEC	•	•	•	• —	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Added support for OSPFv3, multipe context mode, Suite B algorithm in the transform and IV size portion, and ESPV3 IPsec output.

Examples

The following example, entered in global configuration mode, displays IPsec SAs that include a tunnel identified as OSPFv3.

```
hostname(config)# show crypto ipsec sa
interface: outside2
    Crypto map tag: def, local addr: 10.132.0.17

      local ident (addr/mask/prot/port): (0.0.0.0/0.0.0.0/0/0)
      remote ident (addr/mask/prot/port): (172.20.0.21/255.255.255.255/0/0)
      current_peer: 172.20.0.21
      dynamic allocated peer ip: 10.135.1.5

      #pkts encaps: 0, #pkts encrypt: 0, #pkts digest: 0
      #pkts decaps: 1145, #pkts decrypt: 1145, #pkts verify: 1145
      #pkts compressed: 0, #pkts decompressed: 0
      #pkts not compressed: 0, #pkts comp failed: 0, #pkts decomp failed: 0
```

```
      #pre-frag successes: 2, #pre-frag failures: 1, #fragments created: 10
      #PMTUs sent: 5, #PMTUs rcvd: 2, #decapstulated frags needing reassembly: 1
      #send errors: 0, #recv errors: 0

      local crypto endpt.: 10.132.0.17, remote crypto endpt.: 172.20.0.21

      path mtu 1500, ipsec overhead 60, media mtu 1500
      current outbound spi: DC15BF68

    inbound esp sas:
      spi: 0x1E8246FC (511854332)
         transform: esp-3des esp-md5-hmac
         in use settings ={L2L, Transport, Manual key, (OSPFv3), }
         slot: 0, conn_id: 3, crypto-map: def
         sa timing: remaining key lifetime (sec): 548
         IV size: 8 bytes
         replay detection support: Y
    outbound esp sas:
      spi: 0xDC15BF68 (3692412776)
         transform: esp-3des esp-md5-hmac
         in use settings ={L2L, Transport, Manual key, (OSPFv3), }
         slot: 0, conn_id: 3, crypto-map: def
         sa timing: remaining key lifetime (sec): 548
         IV size: 8 bytes
         replay detection support: Y

    Crypto map tag: def, local addr: 10.132.0.17

      local ident (addr/mask/prot/port): (0.0.0.0/0.0.0.0/0/0)
hostname(config)#
```

Note Fragmentation statistics are pre-fragmentation statistics if the IPsec SA policy states that fragmentation occurs before IPsec processing. Post-fragmentation statistics appear if the SA policy states that fragmentation occurs after IPsec processing.

The following example, entered in global configuration mode, displays IPsec SAs for a crypto map named def.

```
hostname(config)# show crypto ipsec sa map def
cryptomap: def
    Crypto map tag: def, local addr: 172.20.0.17

      local ident (addr/mask/prot/port): (0.0.0.0/0.0.0.0/0/0)
      remote ident (addr/mask/prot/port): (10.132.0.21/255.255.255.255/0/0)
      current_peer: 10.132.0.21
      dynamic allocated peer ip: 90.135.1.5

      #pkts encaps: 0, #pkts encrypt: 0, #pkts digest: 0

```

Related Commands

Command	Description
clear configure isakmp	Clears all the ISAKMP configuration.
clear configure isakmp policy	Clears all ISAKMP policy configuration.
clear isakmp sa	Clears the IKE runtime SA database.

Command	Description
isakmp enable	Enables ISAKMP negotiation on the interface on which the IPsec peer communicates with the ASA.
show running-config isakmp	Displays all the active ISAKMP configuration.

show crypto ipsec stats

To display a list of IPsec statistics, use the **show crypto ipsec stats** command in global configuration mode or privileged EXEC mode.

show crypto ipsec stats

Syntax Description

This command has no keywords or variables.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	• —	—
Privileged EXEC	•	•	•	• —	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Examples

The following example, entered in global configuration mode, displays IPsec statistics:

```
hostname(config)# show crypto ipsec stats

IPsec Global Statistics
-----------------------
Active tunnels: 2
Previous tunnels: 9
Inbound
    Bytes: 4933013
    Decompressed bytes: 4933013
    Packets: 80348
    Dropped packets: 0
    Replay failures: 0
    Authentications: 80348
    Authentication failures: 0
    Decryptions: 80348
    Decryption failures: 0
    Decapsulated fragments needing reassembly: 0
Outbound
    Bytes: 4441740
    Uncompressed bytes: 4441740
    Packets: 74029
    Dropped packets: 0
    Authentications: 74029
    Authentication failures: 0
    Encryptions: 74029
```

```
    Encryption failures: 0
    Fragmentation successes: 3
        Pre-fragmentation successes:2
        Post-fragmentation successes: 1

```

Related Commands

Command	Description
clear configure crypto isakmp	Clears all the ISAKMP configuration.
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.
clear crypto isakmp sa	Clears the IKE runtime SA database.
crypto isakmp enable	Enables ISAKMP negotiation on the interface on which the IPsec peer communicates with the ASA.
show running-config crypto isakmp	Displays all the active ISAKMP configuration.

show crypto isakmp sa

To display the IKE runtime SA database, use the **show crypto isakmp sa** command in global configuration mode or privileged EXEC mode.

show crypto isakmp sa [**detail**]

Syntax Description

detail	Displays detailed output about the SA database.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	• —	—
Privileged EXEC	•	—	•	• —	—

Command History

Release	Modification
7.0(1)	The **show isakmp sa** command was introduced.
7.2(1)	This command was deprecated. The **show crypto isakmp sa** command replaces it.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

The output from this command includes the following fields:

Detail not specified.

IKE Peer	Type	Dir	Rky	State
209.165.200.225	L2L	Init	No	MM_Active

Detail specified.

IKE Peer	Type	Dir	Rky	State	Encrypt	Hash	Auth	Lifetime
209.165.200.225	L2L	Init	No	MM_Active	3des	md5	preshrd	86400

Examples

The following example, entered in global configuration mode, displays detailed information about the SA database:

```
hostname(config)# show crypto isakmp sa detail

IKE Peer  Type  Dir   Rky  State      Encrypt Hash  Auth    Lifetime
1 209.165.200.225 User  Resp  No   AM_Active  3des    SHA   preshrd 86400

IKE Peer  Type  Dir   Rky  State      Encrypt Hash  Auth    Lifetime
2 209.165.200.226 User  Resp  No   AM_ACTIVE  3des    SHA   preshrd 86400

IKE Peer  Type  Dir   Rky  State      Encrypt Hash  Auth    Lifetime
3 209.165.200.227 User  Resp  No   AM_ACTIVE  3des    SHA   preshrd 86400

IKE Peer  Type  Dir   Rky  State      Encrypt Hash  Auth    Lifetime
4 209.165.200.228 User  Resp  No   AM_ACTIVE  3des    SHA   preshrd 86400

hostname(config)#
```

show crypto key mypubkey

To display the key name, usage, and elliptic curve size for ECDSA keys, use the **show crypto key mypubkey** command in global configuration mode or privileged EXEC mode.

show crypto key mypubkey dsa | rsa

Syntax Description

dsa	Specifies the key name.
rsa	Specifies the key name.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	—	—
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
9.0(1)	The **show crypto key mypubkey** command was introduced.

show crypto protocol statistics

To display the protocol-specific statistics in the crypto accelerator MIB, use the **show crypto protocol statistics** command in global configuration or privileged EXEC mode.

show crypto protocol statistics *protocol*

Syntax Description

protocol	Specifies the name of the protocol for which to display statistics. Protocol choices are as follows: **ikev1**—Internet Key Exchange version 1. **ipsec**—IP Security Phase-2 protocols. **ssl**—Secure Sockets Layer. **other**—Reserved for new protocols. **all**—All protocols currently supported.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	• —	—
Privileged EXEC	•	•	•	• —	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Examples

The following examples entered in global configuration mode, display crypto accelerator statistics for specified protocols:

```
hostname # show crypto protocol statistics ikev1
[IKEv1 statistics]
   Encrypt packet requests: 39
   Encapsulate packet requests: 39
   Decrypt packet requests: 35
   Decapsulate packet requests: 35
   HMAC calculation requests: 84
   SA creation requests: 1
   SA rekey requests: 3
    SA deletion requests: 2
```

```
   Next phase key allocation requests: 2
   Random number generation requests: 0
    Failed requests: 0

hostname # show crypto protocol statistics ipsec
[IPsec statistics]
   Encrypt packet requests: 700
   Encapsulate packet requests: 700
   Decrypt packet requests: 700
   Decapsulate packet requests: 700
   HMAC calculation requests: 1400
   SA creation requests: 2
   SA rekey requests: 0
   SA deletion requests: 0
   Next phase key allocation requests: 0
   Random number generation requests: 0
   Failed requests: 0

hostname # show crypto protocol statistics ssl
[SSL statistics]
   Encrypt packet requests: 0
   Encapsulate packet requests: 0
   Decrypt packet requests: 0
   Decapsulate packet requests: 0
   HMAC calculation requests: 0
   SA creation requests: 0
   SA rekey requests: 0
   SA deletion requests: 0
   Next phase key allocation requests: 0
   Random number generation requests: 0
   Failed requests: 0

hostname # show crypto protocol statistics other
[Other statistics]
   Encrypt packet requests: 0
   Encapsulate packet requests: 0
   Decrypt packet requests: 0
   Decapsulate packet requests: 0
   HMAC calculation requests: 0
   SA creation requests: 0
   SA rekey requests: 0
   SA deletion requests: 0
   Next phase key allocation requests: 0
   Random number generation requests: 99
   Failed requests: 0

hostname # show crypto protocol statistics all
[IKEv1 statistics]
   Encrypt packet requests: 46
   Encapsulate packet requests: 46
   Decrypt packet requests: 40
   Decapsulate packet requests: 40
   HMAC calculation requests: 91
    SA creation requests: 1
   SA rekey requests: 3
   SA deletion requests: 3
   Next phase key allocation requests: 2
   Random number generation requests: 0
   Failed requests: 0
[IKEv2 statistics]
   Encrypt packet requests: 0
   Encapsulate packet requests: 0
    Decrypt packet requests: 0
   Decapsulate packet requests: 0
```

```
   HMAC calculation requests: 0
   SA creation requests: 0
   SA rekey requests: 0
   SA deletion requests: 0
   Next phase key allocation requests: 0
   Random number generation requests: 0
   Failed requests: 0
[IPsec statistics]
   Encrypt packet requests: 700
   Encapsulate packet requests: 700
    Decrypt packet requests: 700
   Decapsulate packet requests: 700
   HMAC calculation requests: 1400
   SA creation requests: 2
   SA rekey requests: 0
   SA deletion requests: 0
   Next phase key allocation requests: 0
   Random number generation requests: 0
   Failed requests: 0
[SSL statistics]
   Encrypt packet requests: 0
   Encapsulate packet requests: 0
   Decrypt packet requests: 0
   Decapsulate packet requests: 0
   HMAC calculation requests: 0
   SA creation requests: 0
   SA rekey requests: 0
   SA deletion requests: 0
   Next phase key allocation requests: 0
   Random number generation requests: 0
   Failed requests: 0
[SSH statistics are not supported]
[SRTP statistics are not supported]
[Other statistics]
   Encrypt packet requests: 0
   Encapsulate packet requests: 0
   Decrypt packet requests: 0
   Decapsulate packet requests: 0
    HMAC calculation requests: 0
   SA creation requests: 0
   SA rekey requests: 0
   SA deletion requests: 0
   Next phase key allocation requests: 0
   Random number generation requests: 99
   Failed requests: 0
hostname #
```

Related Commands

Command	Description
clear crypto accelerator statistics	Clears the global and accelerator-specific statistics in the crypto accelerator MIB.
clear crypto protocol statistics	Clears the protocol-specific statistics in the crypto accelerator MIB.
show crypto accelerator statistics	Displays the global and accelerator-specific statistics from the crypto accelerator MIB.

show crypto sockets

To display crypto secure socket information, use the **show crypto sockets** command in global configuration mode or privileged EXEC mode.

show crypto sockets

Syntax Description

This command has no keywords or variables.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Examples

The following example, entered in global configuration mode, displays crypto secure socket information:

```
hostname(config)# show crypto sockets

Number of Crypto Socket connections 1

       Gi0/1  Peers: (local): 2001:1::1
                     (remote): ::
              Local Ident (addr/plen/port/prot): (2001:1::1/64/0/89)
              Remote Ident (addr/plen/port/prot): (::/0/0/89)
              IPsec Profile: "CSSU-UTF"
              Socket State: Open
              Client: "CSSU_App(UTF)" (Client State: Active)

       Crypto Sockets in Listen state:
```

The following table describes the fields in the **show crypto sockets** command output.

Field	Description
Number of Crypto Socket connections	Number of crypto sockets in the system.

Socket State	This state can be Open, which means that active IPsec security associations (SAs) exist, or it can be Closed, which means that no active IPsec SAs exist.
Client	Application name and its state.
Flags	If this field says “shared,” the socket is shared with more than one tunnel interface.
Crypto Sockets in Listen state	Name of the crypto IPsec profile.

Related Commands

Command	Description
show crypto ipsec policy	Displays the crypto secure socket API installed policy information.

show csc node-count

To display the number of nodes for which the CSC SSM scanned traffic, use the **show csc node-count** command in privileged EXEC mode:

show csc node-count [**yesterday**]

Syntax Description

yesterday	(Optional) Shows the number of nodes for which the CSC SSM scanned traffic in the preceding 24-hour period, from midnight to midnight.

Defaults

By default, the node count displayed is the number of nodes scanned since midnight.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

A node is any distinct source IP address or the address of a device that is on a network protected by the ASA. The ASA keeps track of a daily node count and communicates this to the CSC SSM for user license enforcement.

Examples

The following is sample output of the **show csc node-count** command, which displays the number of nodes for which the CSC SSM has scanned traffic since midnight:

```
hostname# show csc node-count
Current node count is 1
```

The following is sample output of the **show csc node-count** command, which displays the number of nodes for which the CSC SSM scanned traffic in the preceding 24-hour period, from midnight to midnight:

```
hostname(config)# show csc node-count yesterday
Yesterday's node count is 2
```

Related Commands

csc	Sends network traffic to the CSC SSM for scanning of FTP, HTTP, POP3, and SMTP, as configured on the CSC SSM.
show running-config class-map	Shows current class map configuration.
show running-config policy-map	Shows the current policy map configuration.
show running-config service-policy	Shows the current service policy configuration.

show ctiqbe

To display information about CTIQBE sessions established across the ASA, use the **show ctiqbe** command in privileged EXEC mode.

show ctiqbe

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show ctiqbe** command displays information of CTIQBE sessions established across the ASA. Along with **debug ctiqbe** and **show local-host**, this command is used for troubleshooting CTIQBE inspection engine issues.

Note We recommend that you have the **pager** command configured before using the **show ctiqbe** command. If there are a lot of CTIQBE sessions and the **pager** command is not configured, it can take a while for the **show ctiqbe** command output to reach the end.

Examples

The following is sample output from the **show ctiqbe** command under the following conditions. There is only one active CTIQBE session setup across the ASA. It is established between an internal CTI device (for example, a Cisco IP SoftPhone) at local address 10.0.0.99 and an external Cisco Call Manager at 172.29.1.77, where TCP port 2748 is the Cisco CallManager. The heartbeat interval for the session is 120 seconds.

```
hostname# show ctiqbe

Total: 1
  LOCAL  FOREIGN  STATE  HEARTBEAT
-----------------------------------------------------------
1  10.0.0.99/1117   172.29.1.77/2748  1  120
  RTP/RTCP: PAT xlates: mapped to 172.29.1.99(1028  1029)
```

```
|MEDIA: Device ID 27|Call ID 0
|Foreign 172.29.1.99|(1028|1029)
|Local|172.29.1.88|(26822|26823)
|------------------------------------------
```

The CTI device has already registered with the CallManager. The device internal address and RTP listening port is PATed to 172.29.1.99 UDP port 1028. Its RTCP listening port is PATed to UDP 1029.

The line beginning with `RTP/RTCP: PAT xlates:` appears only if an internal CTI device has registered with an external CallManager and the CTI device address and ports are PATed to that external interface. This line does not appear if the CallManager is located on an internal interface, or if the internal CTI device address and ports are NATed to the same external interface that is used by the CallManager.

The output indicates a call has been established between this CTI device and another phone at 172.29.1.88. The RTP and RTCP listening ports of the other phone are UDP 26822 and 26823. The other phone locates on the same interface as the CallManager because the ASA does not maintain a CTIQBE session record associated with the second phone and CallManager. The active call leg on the CTI device side can be identified with Device ID 27 and Call ID 0.

The following is the xlate information for these CTIBQE connections:

```
hostname# show xlate debug
3 in use, 3 most used
Flags: D|DNS, d|dump, I|identity, i|inside, n|no random,
|o|outside, r|portmap, s|static
TCP PAT from inside:10.0.0.99/1117 to outside:172.29.1.99/1025 flags ri idle 0:00:22
timeout 0:00:30
UDP PAT from inside:10.0.0.99/16908 to outside:172.29.1.99/1028 flags ri idle 0:00:00
timeout 0:04:10
UDP PAT from inside:10.0.0.99/16909 to outside:172.29.1.99/1029 flags ri idle 0:00:23
timeout 0:04:10
hostname#
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
inspect ctiqbe	Enables CTIQBE application inspection.
service-policy	Applies a policy map to one or more interfaces.
show conn	Displays the connection state for different connection types.
timeout	Sets the maximum idle time duration for different protocols and session types.

show ctl-file

To show the contents of the CTL file used by the phone proxy, use the **show ctl-file** command in global configuration mode.

show ctl-file *filename* [**parsed**]

Syntax Description

filename	Displays the phones capable of secure mode stored in the database.
parsed	(Optional) Displays detailed information from the CTL file specified.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.2(1)	The command was introduced.

Usage Guidelines

When specifying the filename of the CTL file stored in Flash memory, specify the disk number, filename, and extension; for example: `disk0:/testctl.tlv`. Using the **show ctl-file** command is useful for debugging when configuring the phone proxy instance.

Examples

The following example shows the use of the **show ctl-file** command to show general information about the CTL file:

```
hostname# show ctl-file disk0:/ctlfile.tlv
Total Number of Records: 1
CTL Record Number 1
  Subject Name:
     serialNumber=JMX1215L2TX+hostname=ciscoasa
  Issuer Name:
     serialNumber=JMX1215L2TX+hostname=ciscoasa
  Function:
     cucm
  IP Address:
     192.168.52.102
  Associated Trustpoint:
     cucm_primary
```

The following example shows the use of the **show ctl-file** command to show detailed information about the CTL file:

```
hostname# show ctl-file disk0:/ctlfile.tlv parsed

Related Commands

Command	Description
ctl-file (global)	Specifies the CTL instance to create for the phone proxy or parses the CTL file stored in Flash memory.
ctl-file (phone-proxy)	Specifies the CTL instance to use when configuring the phone proxy.
phone proxy	Configures the Phone Proxy instance.

show cts environment-data

To show the health and status of the environment data refresh operation on the ASA for Cisco TrustSec, use the **show cts environment-data** command in privileged EXEC mode.

show cts environment-data

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

This command is not supported on a standby device in a failover configuration. If you enter this command on a standby device, the following error message appears:

```
ERROR: This command is only permitted on the active device.
```

This command is only supported on the master unit in a clustering configuration. If you enter this command on a slave unit, the following error message appears:

```
This command is only permitted on the master device.
```

Examples

The following is sample output from the **show cts environment-data** command

```
hostname# show cts environment-data

CTS Environment Data
====================
Status:                    Active
Last download attempt:     Successful
Environment Data Lifetime: 1200 secs
Last update time:          18:12:07 EST Feb 27 2012
Env-data expires in:       0:00:12:24 (dd:hr:mm:sec)
Env-data refreshes in:     0:00:02:24 (dd:hr:mm:sec)
```

Related Commands

show running-config cts	Shows the SXP connections for the running configuration.
show cts pac	Shows the components on the PAC.

show cts environment-data sg-table

To show the resident security group table on the ASA for Cisco TrustSec, use the **show cts environment-data sg-table** command in privileged EXEC mode.

show cts environment-data sg-table

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

This command is not supported on a standby device in a failover configuration. If you enter this command on a standby device, the following error message appears:

```
ERROR: This command is only permitted on the active device.
```

This command is only supported on the master unit in a clustering configuration. If you enter this command on a slave unit, the following error message appears:

```
This command is only permitted on the master device.
```

Examples

The following is sample output from the **show cts environment-data sg-table** command

```
hostname# show cts environment-data sg-table

Related Commands

Commands	Description
show running-config cts	Shows the SXP connections for the running configuration.
show cts pac	Shows the components on the PAC.

show cts pac

To show the components of the Protected Access Credential (PAC) on the ASA for Cisco TrustSec, use the **show cts pac** command in privileged EXEC mode.

show cts pac

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The **show cts pac** command displays PAC information, including the expiration time. The expiration time is important because the ASA cannot retrieve security group table updates after the PAC lifetime lapses. The administrator must request and install a new PAC before the old one expires to maintain synchronization with the security group table on the Identity Services Engine.

This command is not supported on a standby device in a failover configuration. If you enter this command on a standby device, the following error message appears:

```
ERROR: This command is only permitted on the active device.
```

This command is only supported on the master unit in a clustering configuration. If you enter this command on a slave unit, the following error message appears:

```
This command is only permitted on the master device.
```

Examples

The following is sample output from the **show cts pac** command

```
hostname# show cts pac

Related Commands

Commands	Description
show running-config cts	Shows the SXP connections for the running configuration.
show cts environment	Shows the health and status of the environment data refresh operation.

show cts sgt-map

To show the IP address-security group table manager entries in the control path, use the **show cts sgt-map** command in privileged EXEC mode.

show cts sgt-map [**sgt** *sgt*] [**address** *ipv4* **| address** *ipv6* [*/prefix*] **| ipv4 | ipv6**] [**name**] [**brief | detail**]

Syntax Description

address i*pv4*/*ipv6* */prefix*	Shows only IP address-security group table mapping for the specific IPv4 or IPv6 address or subnet.
brief	Shows the IP address-security group table mapping summary.
detail	Shows the IP address-security group table mapping.
ipv4	Shows the IPv4 address-security group table mapping. By default, only the IPv4 address-security group table mapping is displayed.
ipv6	Shows the IPv6 address-security group table mapping.
name	Shows IP address-security group table mapping with the matched security group name.
sgt *sgt*	Shows only IP address-security group table mapping with the matched security group table.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
9.01)	The command was introduced.

Usage Guidelines

This command displays the IP address-security group table manager entries in the control path.

Examples

The following is sample output from the **show cts sgt-map ipv6** command:

```
hostname# show cts sgt-map ipv6
Active IP-SGT Bindings Information

IP Address                                SGT     Source
============================================================
```

```
3330::1                                 17      SXP
FE80::A8BB:CCFF:FE00:110                17      SXP

IP-SGT Active Bindings Summary
============================================
Total number of SXP    bindings = 2
Total number of active   bindings = 2
```

The following is sample output from the **show cts sgt-map ipv6 detail** command:

```
hostname# show cts sgt-map ipv6 detail
Active IP-SGT Bindings Information

IP Address                  Security Group                          Source
================================================================================
3330::1                      2345                                    SXP
1280::A8BB:CCFF:FE00:110    Security Tech Business Unit(12345)      SXP

IP-SGT Active Bindings Summary
==================================
Total number of SXP bindings    = 2
Total number of active bindings = 2
```

The following is sample output from the **show cts sgt-map ipv6 brief** command:

```
hostname# show cts sgt-map ipv6 brief
Active IP-SGT Bindings Information

IP-SGT Active Bindings Summary
==================================
Total number of SXP bindings    = 2
Total number of active bindings = 2
```

The following is sample output from the **show cts sgt-map address** command:

```
hostname# show cts sgt-map address 10.10.10.5 mask 255.255.255.255

Active IP-SGT Bindings Information

IP Address              SGT     Source
============================================================
10.10.10.5              1234    SXP

IP-SGT Active Bindings Summary
============================================
Total number of SXP    bindings = 1
Total number of active   bindings = 1
```

Related Commands

Command	Description
show running-config cts	Shows the SXP connections for the running configuration.
show cts environment	Shows the health and status of the environment data refresh operation.

show cts sxp connections

To show the Security eXchange Protocol (SXP) connections on the ASA, use the **show cts sxp connections** command in privileged EXEC mode.

show cts sxp connections [**peer** *peer addr*] [**local** *local addr*] [**ipv4 | ipv6**] [**status** {**on | off | delete-hold-down | pending-on**}] [**mode** {**speaker | listener**}] [**brief**]

Syntax Description

brief	(Optional) Shows the SXP connection summary.
delete-hold-down	(Optional) The TCP connection was terminated (TCP is down) when it was in the ON state. Only an ASA configured in listener mode can be in this state.
ipv4	(Optional) Shows SXP connections with IPv4 addresses.
ipv6	(Optional) Shows SXP connections with IPv6 addresses.
listener	(Optional) Shows the ASA configured in listener mode.
local *local addr*	(Optional) Shows SXP connections with the matched local IP addresses.
mode	(Optional) Shows SXP connections with the matched mode.
off	(Optional) The TCP connection has not been initiated. The ASA retries the TCP connection only in this state.
on	(Optional) An SXP OPEN or SXP OPEN RESP message has been received. The SXP connection has been successfully established. The ASA only exchanges SXP messages in this state.
peer *peer addr*	(Optional) Shows SXP connections with the matched peer IP addresses.
pending-on	(Optional) An SXP OPEN message has been sent to the peer; the response from the peer is being awaited.
speaker	(Optional) Shows the ASA configured in speaker mode.
status	(Optional) Shows SXP connections with the matched status.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Provileged EXEC	•	•	•	•	—

Command History

Release	Modification
9.0(1)	The command was introduced.

Usage Guidelines

The SXP states change under the following conditions:

- If the SXP listener drops its SXP connection because its peer unconfigures SXP or disables SXP, then the SXP listener moves to the OFF state.
- If the SXP listener drops its SXP connection because its peer crashes or has the interface shut down, then the SXP listener moves to the DELETE_HOLD_DOWN state.
- The SXP speaker moves to the OFF state when either of the first two conditions occurs.

This command is not supported on a standby device in a failover configuration. If you enter this command on a standby device, the following error message appears:

```
ERROR: This command is only permitted on the active device.
```

This command is only supported on the master unit in a clustering configuration. If you enter this command on a slave unit, the following error message appears:

```
This command is only permitted on the master device.
```

Examples

The following is sample output from the **show cts sxp connections** command:

```

```

Related Commands

Command	Description
show running-config cts	Shows the SXP connections for the running configuration.
show cts environment	Shows the health and status of the environment data refresh operation.

show cts sxp sgt-map

To show the current IP address-security group table mapping database entries in the Security eXchange Protocol (SXP) module on the ASA for Cisco TrustSec, use the **show cts sxp sgt-map** command in privileged EXEC mode.

show cts sxp sgt-map [**peer** *peer_addr*] [**sgt** *sgt*] [**address** *ipv4* | **address** *ipv6* [*/prefix*] | **ipv4** | **ipv6**] [**name**] [**brief** | **detail**] [**status**]

Syntax Description

address i*pv4*/*ipv6* */prefix*	Shows only IP address-security group table mapping for the specific IPv4 or IPv6 address or subnet.
brief	Shows the IP address-security group table mapping summary.
detail	Shows the security group table information. If a security group name is not available, only the security group table value is displayed without the bracket.
ipv4	Shows the IP address-security group table mapping with IPv4 addresses. By default, only the IP address-security group table mapping with IPv4 addresses is displayed.
ipv6	Shows the IP address-security group table mapping with IPv6 addresses.
name	Shows IP address-security group table mapping with the matched security group name.
peer *peer addr*	Shows only IP address-security group table mapping with the matched peer IP address.
sgt *sgt*	Shows only IP address-security group table mapping with the matched security group table.
status	Shows active or inactive mapped entries.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
9.01)	The command was introduced.

Usage Guidelines

This command displays the active IP address-security group table mapped entries consolidated from SXP.

This command is not supported on a standby device in a failover configuration. If you enter this command on a standby device, the following error message appears:

```
ERROR: This command is only permitted on the active device.
```

This command is only supported on the master unit in a clustering configuration. If you enter this command on a slave unit, the following error message appears:

```
This command is only permitted on the master device.
```

Examples

The following is sample output from the **show cts sxp sgt-map** command:

```
hostname# show cts sxp sgt-map
Total number of IP-SGT mappings : 3

SGT        : 7
IPv4       : 2.2.2.1
Peer IP    : 2.2.2.1
Ins Num    : 1

SGT        : 7
IPv4       : 2.2.2.0
Peer IP    : 3.3.3.1
Ins Num    : 1

SGT        : 7

7.0(1)	Modified to conform to CLI guidelines.

Usage Guidelines

The **show curpriv** command displays the current privilege level. Lower privilege level numbers indicate lower privilege levels.

Examples

These examples show output from the **show curpriv** command when a user named enable_15 is at different privilege levels. The username indicates the name that the user entered when the user logged in. P_PRIV indicates that the user has entered the **enable** command. P_CONF indicates that the user has entered the **config terminal** command.

```
hostname(config)# show curpriv
Username : enable_15
Current privilege level : 15
Current Mode/s : P_PRIV P_CONF
hostname(config)# exit

hostname(config)# show curpriv
Username : enable_15
Current privilege level : 15
Current Mode/s : P_PRIV
hostname(config)# exit

hostname(config)# show curpriv
Username : enable_1
```

```
Current privilege level : 1
Current Mode/s : P_UNPR
hostname(config)#
```

The following example shows a known behavior. When you are in enable mode, then enter disable mode, the initial logged-in username is replaced with enable_1:

```
hostname(config)# show curpriv
Username : enable_15
Current privilege level : 15
Current Mode/s : P_PRIV P_CONF
hostname(config)# exit
hostname# show curpriv
Username : enable_15
Current privilege level : 15
Current Mode/s : P_PRIV
hostname# exit

Logoff

Type help or '?' for a list of available commands.
hostname# show curpriv
Username : enable_1
Current privilege level : 1
Current Mode/s : P_UNPR
hostname#
```

Related Commands

Command	Description
clear configure privilege	Remove privilege command statements from the configuration.
show running-config privilege	Display privilege levels for commands.

CHAPTER 48

show ddns update interface through show environment Commands

show ddns update interface

To display the DDNS methods assigned to ASA interfaces, use the **show ddns update interface** command in privileged EXEC mode.

show ddns update interface [*interface-name*]

Syntax Description

interface-name	(Optional) The name of a network interface.

Defaults

Omitting the *interface-name* string displays the DDNS method assigned to each interface.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example displays the DDNS method assigned to the inside interface:

```
hostname# show ddns update interface inside
Dynamic DNS Update on inside:
  Update Method Name            Update Destination
  ddns-2                        not available
hostname#
```

Related Commands

Command	Description
ddns (DDNS-update-method mode)	Specifies a DDNS update method type for a created DDNS method.
ddns update (interface config mode)	Associates an ASA interface with a DDNS update method or a DDNS update hostname.
ddns update method (global config mode)	Creates a method for dynamically updating DNS resource records.
show ddns update method	Displays the type and interval for each configured DDNS method. a DHCP server to perform DDNS updates.
show running-config ddns	Displays the type and interval of all configured DDNS methods in the running configuration.

show ddns update method

To display the DDNS update methods in the running configuration, use the **show ddns update method** command in privileged EXEC mode.

show ddns update method [*method-name*]

Syntax Description

method-name	(Optional) The name of a configured DDNS update method.

Defaults

Omitting the *method-name* string displays all configured DDNS update methods.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example displays the DDNS method named ddns-2:

```
hostname(config)# show ddns update method ddns-2

Dynamic DNS Update Method: ddns-2
  IETF standardized Dynamic DNS 'A' and 'PTR' records update
  Maximum update interval: 0 days 0 hours 10 minutes 0 seconds
hostname(config)#
```

Related Commands

Command	Description
ddns (DDNS-update-method mode)	Specifies a DDNS update method type for a created DDNS method.
ddns update (interface config mode)	Associates a ASA interface with a Dynamic DNS (DDNS) update method or a DDNS update hostname.
ddns update method (global config mode)	Creates a method for dynamically updating DNS resource records.
show ddns update interface	Displays the interfaces associated with each configured DDNS method.
show running-config ddns	Displays the type and interval of all configured DDNS methods in the running configuration.

show debug

To show the current debugging configuration, use the **show debug** command.

show debug [*command* [*keywords*]]

Syntax Description

command	(Optional) Specifies the **debug** command whose current configuration you want to view.
keywords	(Optional) For each *command*, the *keywords* following the *command* are identical to the *keywords* supported by the associated **debug** command.

Defaults

This command has no default settings.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0(2)	The **eigrp** keyword was added to the list of possible command values.
8.4(1)	The **route** keyword was added to the list of possible command values.

Usage Guidelines

For each *command*, the *keywords* following the *command* are identical to the *keywords* supported by the associated **debug** command. For information about the supported syntax, see the associated **debug** command.

Note The availability of each *command* depends on the command modes that support the applicable **debug** command.

The valid *command* values are as follows:

- **aaa**
- **appfw**
- **arp**
- **asdm**
- **context**
- **crypto**

- **ctiqbe**
- **ctm**
- **dhcpc**
- **dhcpd**
- **dhcprelay**
- **disk**
- **dns**
- **eigrp**
- **email**
- **entity**
- **fixup**
- **fover**
- **fsm**
- **ftp**
- **generic**
- **gtp**
- **h323**
- **http**
- **http-map**
- **icmp**
- **igmp**
- **ils**
- **imagemgr**
- **ipsec-over-tcp**
- **ipv6**
- **iua-proxy**
- **kerberos**
- **ldap**
- **mfib**
- **mgcp**
- **mrib**
- **ntdomain**
- **ntp**
- **ospf**
- **parser**
- **pim**
- **pix**
- **pptp**

- **radius**
- **rip**
- **route**
- **rtsp**
- **sdi**
- **sequence**
- **sip**
- **skinny**
- **smtp**
- **sqlnet**
- **ssh**
- **ssl**
- **sunrpc**
- **tacacs**
- **timestamps**
- **vpn-sessiondb**
- **webvpn**
- **xdmcp**
- **xml**

Examples

You can use the **show debug** command to view all debugging configurations, a debugging configuration for a specific feature, and a debugging configuration for a portion of a feature.

The following commands enable debugging for authentication, accounting, and flash memory:

```
hostname# debug aaa authentication
debug aaa authentication enabled at level 1
hostname# debug aaa accounting
debug aaa accounting enabled at level 1
hostname# debug disk filesystem
debug disk filesystem enabled at level 1
hostname# show debug
debug aaa authentication enabled at level 1
debug aaa accounting enabled at level 1
debug disk filesystem enabled at level 1
hostname# show debug aaa
debug aaa authentication enabled at level 1
debug aaa authorization is disabled.
debug aaa accounting enabled at level 1
debug aaa internal is disabled.
debug aaa vpn is disabled.
hostname# show debug aaa accounting
debug aaa accounting enabled at level 1
hostname#
```

Related Commands

Command	Description
debug	Displays all **debug** commands.

show debug mmp

To display current debug settings for the MMP inspection module, use the **show debug mmp** command in privileged EXEC mode.

show debug mmp

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Examples

The following example shows the use of the **show debug mmp** command to displaythe current debug settings for the MMP inspection module:

```
hostname# show debug mmp
debug mmp  enabled at level 1
```

Related Commands

Command	Description
debug mmp	Display inspect MMP events.
inspect mmp	Configures the MMP inspection engine.

show dhcpd

To view DHCP binding, state, and statistical information, use the **show dhcpd** command in privileged EXEC or global configuration mode.

show dhcpd {**binding** [*IP_address*] | **state** | **statistics**}

Syntax Description

binding	Displays binding information for a given server IP address and its associated client hardware address and lease length.
IP_address	Shows the binding information for the specified IP address.
state	Displays the state of the DHCP server, such as whether it is enabled in the current context and whether it is enabled on each of the interfaces.
statistics	Displays statistical information, such as the number of address pools, bindings, expired bindings, malformed messages, sent messages, and received messages.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If you include the optional IP address in the **show dhcpd binding** command, only the binding for that IP address is shown.

The **show dhcpd binding | state | statistics** commands are also available in global configuration mode.

Examples

The following is sample output from the **show dhcpd binding** command:

```
hostname# show dhcpd binding
IP Address Client-id       Lease Expiration Type
10.0.1.100 0100.a0c9.868e.43 84985 seconds automatic
```

The following is sample output from the **show dhcpd state** command:

```
hostname# show dhcpd state
Context Not Configured for DHCP
Interface outside, Not Configured for DHCP
```

```
Interface inside, Not Configured for DHCP
```

The following is sample output from the **show dhcpd statistics** command:

```
hostname# show dhcpd statistics

DHCP UDP Unreachable Errors: 0
DHCP Other UDP Errors: 0

Address pools        1
Automatic bindings   1
Expired bindings     1
Malformed messages   0

Message              Received
BOOTREQUEST          0
DHCPDISCOVER         1
DHCPREQUEST          2
DHCPDECLINE          0
DHCPRELEASE          0
DHCPINFORM           0

Message              Sent
BOOTREPLY            0
DHCPOFFER            1
DHCPACK              1
DHCPNAK              1
```

Related Commands

Command	Description
clear configure dhcpd	Removes all DHCP server settings.
clear dhcpd	Clears the DHCP server bindings and statistic counters.
dhcpd lease	Defines the lease length for DHCP information granted to clients.
show running-config dhcpd	Displays the current DHCP server configuration.

show dhcprelay state

To view the state of the DHCP relay agent, use the **show dhcprelay state** command in privileged EXEC or global configuration mode.

show dhcprelay state

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command displays the DHCP relay agent state information for the current context and each interface.

Examples

The following is sample output from the **show dhcprelay state** command:

```
hostname# show dhcprelay state

Context  Configured as DHCP Relay
Interface outside, Not Configured for DHCP
Interface infrastructure, Configured for DHCP RELAY SERVER
Interface inside, Configured for DHCP RELAY
```

Related Commands

Command	Description
show dhcpd	Displays DHCP server statistics and state information.
show dhcprelay statistics	Displays the DHCP relay statistics.
show running-config dhcprelay	Displays the current DHCP relay agent configuration.

show dhcprelay statistics

To display the DHCP relay statistics, use the **show dhcprelay statistics** command in privileged EXEC mode.

show dhcprelay statistics

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The output of the **show dhcprelay statistics** command increments until you enter the **clear dhcprelay statistics** command.

Examples

The following shows sample output for the **show dhcprelay statistics** command:

```
hostname# show dhcprelay statistics

DHCP UDP Unreachable Errors: 0
DHCP Other UDP Errors: 0

Packets Relayed
BOOTREQUEST          0
DHCPDISCOVER         7
DHCPREQUEST          3
DHCPDECLINE          0
DHCPRELEASE          0
DHCPINFORM           0

BOOTREPLY            0
DHCPOFFER            7
DHCPACK              3
DHCPNAK              0
hostname#
```

Related Commands

Command	Description
clear configure dhcprelay	Removes all DHCP relay agent settings.
clear dhcprelay statistics	Clears the DHCP relay agent statistic counters.
debug dhcprelay	Displays debug information for the DHCP relay agent.
show dhcprelay state	Displays the state of the DHCP relay agent.
show running-config dhcprelay	Displays the current DHCP relay agent configuration.

show disk

To display the contents of the flash memory for the adaptive security appliance only, use the **show disk** command in privileged EXEC mode.

show disk[**0 | 1**] [**filesys | all**] **controller**

Syntax Description

**0	1**	Specifies the internal flash memory (0, the default) or the external flash memory (1).
all	Shows the contents of flash memory plus the file system information.
controller	Specifies the flash controller model number.
filesys	Shows information about the compact flash card.

Defaults

By default, this command shows the internal flash memory.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show disk** command:

```
hostname# show disk
-#- --length-- -----date/time------ path
 11 1301       Feb 21 2005 18:01:34 test.cfg

   Sectors Per Cluster         8
   Number of Clusters      15352
   Number of Data Sectors 122976
   Base Root Sector          123
   Base FAT Sector             1
   Base Data Sector          155
```

The following is sample output from the **show disk controller** command:

```
hostname# show disk:1 controller
Flash Model: TOSHIBA THNCF064MBA
```

Related Commands

Command	Description
dir	Displays the directory contents.

show dns

To show the current resolved DNS addresses for all or specified fully qualified domain name (FQDN) hosts, use the **show dns** command in privileged EXEC mode.

show dns [**host** *fqdn_name*]

Syntax Description

fqdn_name	(Optional) Specifies the FQDN of the selected host.
host	(Optional) Indicates the IP address of the specified host.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Examples

The following is sample output from the **show dns** command:

```
hostname# show dns
Name:   www.example1.com
  Address: 10.1.3.1                              TTL 00:03:01
  Address: 10.1.3.3                              TTL 00:00:36
  Address: 10.4.1.2                              TTL 00:01:01
Name: www.example2.com
  Address: 10.2.4.1                              TTL 00:25:13
  Address: 10.5.2.1                              TTL 00:25:01
Name: server.ddns-exampleuser.com
  Address: fe80::21e:8cff:feb5:4faa              TTL 00:00:41
  Address: 10.10.10.2                            TTL 00:25:01
```

Note If the FQDN host has not been activated yet, this command shows no output.

The following is sample output from the **show dns host** command:

```
hostname# show dns host www.example.com
Name:   www.example.com
Address: 10.1.3.1 TTL 00:03:01
Address: 10.1.9.5 TTL 00:00:36
Address: 10.1.1.2 TTL 00:01:01
```

Related Commands

Command	Description
clear dns-hosts	Clears the DNS cache.
dns domain-lookup	Enables the ASA to perform a name lookup.
dns name-server	Configures a DNS server address.

show dns-hosts

To show the DNS cache, use the **show dns-hosts** command in privileged EXEC mode. The DNS cache includes dynamically learned entries from a DNS server and manually entered names and IP addresses.

show dns-hosts

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Examples

The following is sample output from the **show dns-hosts** command:

```
hostname# show dns-hosts
Host                      Flags      Age Type   Address(es)
ns2.example.com           (temp, OK) 0    IP    10.102.255.44
ns1.example.com           (temp, OK) 0    IP    192.168.241.185
snowmass.example.com      (temp, OK) 0    IP    10.94.146.101
server.example.com        (temp, OK) 0    IP    10.94.146.80
```

Related Commands

Command	Description
clear dns-hosts	Clears the DNS cache.
dns domain-lookup	Enables the ASA to perform a name lookup.
dns name-server	Configures a DNS server address.
dns retries	Specifies the number of times to retry the list of DNS servers when the ASA does not receive a response.
dns timeout	Specifies the amount of time to wait before trying the next DNS server.

Table 11 shows each field description.

Table 48-1 show dns-hosts Fields

Field	Description
Host	Shows the hostname.
Flags	Shows the entry status as a combination of the following: • temp—This entry is temporary because it comes from a DNS server. The ASA removes this entry after 72 hours of inactivity. • perm—This entry is permanent because it was added with the **name** command. • OK—This entry is valid. • ??—This entry is suspect and needs to be revalidated. • EX—This entry is expired.
Age	Shows the number of hours since this entry was last referenced.
Type	Shows the type of DNS record; this value is always IP.
Address(es)	The IP addresses.

Related Commands

Command	Description
clear dns-hosts	Clears the DNS cache.
dns domain-lookup	Enables the ASA to perform a name lookup.
dns name-server	Configures a DNS server address.
dns retries	Specifies the number of times to retry the list of DNS servers when the ASA does not receive a response.
dns timeout	Specifies the amount of time to wait before trying the next DNS server.

show dynamic-filter data

To show information about the Botnet Traffic Filter dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries, use the **show dynamic-filter data** command in privileged EXEC mode.

show dynamic-filter data

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

To view dynamic database information, first enable use and download of the database with the **dynamic-filter use-database** and **dynamic-filter updater-client enable** commands.

Examples

The following is sample output from the **show dynamic-filter data** command:

```
hostname# show dynamic-filter data

Traffic filter is using downloaded database version '907'
Fetched at 18:00:16 UTC Jan 22 2009, size: 674381
Sample names from downloaded database:
  example.com, example.net, example.org,
cisco.example, cisco.invalid, bad.example.com
bad.example.net, bad.example.org, bad.cisco.example
bad.cisco.ivalid
Total entries in Dynamic Filter database:
  Dynamic data: 40909 domain names , 1080 IPv4 addresses
  Local data: 0 domain names , 0 IPv4 addresses
Active rules in Dynamic Filter asp table:
  Dynamic data: 0 domain names , 1080 IPv4 addresses
  Local data: 0 domain names , 0 IPv4 addresses
```

Related Commands

Command	Description
address	Adds an IP address to the blacklist or whitelist.
clear configure dynamic-filter	Clears the running Botnet Traffic Filter configuration.
clear dynamic-filter dns-snoop	Clears Botnet Traffic Filter DNS snooping data.
clear dynamic-filter reports	Clears Botnet Traffic filter report data.
clear dynamic-filter statistics	Clears Botnet Traffic filter statistics.
dns domain-lookup	Enables the ASA to send DNS requests to a DNS server to perform a name lookup for supported commands.
dns server-group	Identifies a DNS server for the ASA.
dynamic-filter ambiguous-is-black	Treats greylisted traffic as blacklisted traffic for action purposes.
dynamic-filter blacklist	Edits the Botnet Traffic Filter blacklist.
dynamic-filter database fetch	Manually retrieves the Botnet Traffic Filter dynamic database.
dynamic-filter database find	Searches the dynamic database for a domain name or IP address.
dynamic-filter database purge	Manually deletes the Botnet Traffic Filter dynamic database.
dynamic-filter drop blacklist	Automatically drops blacklisted traffic.
dynamic-filter enable	Enables the Botnet Traffic Filter for a class of traffic or for all traffic if you do not specify an access list.
dynamic-filter updater-client enable	Enables downloading of the dynamic database.
dynamic-filter use-database	Enables use of the dynamic database.
dynamic-filter whitelist	Edits the Botnet Traffic Filter whitelist.
inspect dns dynamic-filter-snoop	Enables DNS inspection with Botnet Traffic Filter snooping.
name	Adds a name to the blacklist or whitelist.
show asp table dynamic-filter	Shows the Botnet Traffic Filter rules that are installed in the accelerated security path.
show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
show dynamic-filter reports	Generates reports of the top 10 botnet sites, ports, and infected hosts.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

show dynamic-filter dns-snoop

To show the Botnet Traffic Filter DNS snooping summary, or the actual IP addresses and names, use the **show dynamic-filter dns-snoop** command in privileged EXEC mode.

show dynamic-filter dns-snoop [**detail**]

Syntax Description

detail	(Optional) Shows the IP addresses and names snooped from DNS responses.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

All inspected DNS data is included in this output, and not just matching names in the blacklist. DNS data from static entries are not included.

To clear the DNS snooping data, enter the **clear dynamic-filter dns-snoop** command.

Examples

The following is sample output from the **show dynamic-filter dns-snoop** command:

```
hostname# show dynamic-filter dns-snoop

DNS Reverse Cache Summary Information:
75 addresses, 124 names, 997 dnsrc address buckets
```

The following is sample output from the **show dynamic-filter dns-snoop detail** command:

```
hostname# show dynamic-filter dns-snoop detail

DNS Reverse Cache Summary Information:
75 addresses, 124 names, 997 dnsrc address buckets
DNS reverse Cache Information:
[10.67.22.34] flags=0x22, cat=2, unit=0 b:g:w=3:0:0, cookie=0xda148218
    [www3.example.com] cat=2, ttl=3
    [www.bad.example.com] cat=2, ttl=3
    [www.example.com] cat=2, ttl=3
[10.6.68.133] flags=0x2, cat=2, unit=0 b:g:w=1:0:0, cookie=0xda13ed60
    [cisco.example] cat=2, ttl=73
```

```
[10.166.226.25] flags=0x2, cat=2, unit=0 b:g:w=1:0:0, cookie=0xda608cb8
    [cisco.invalid] cat=2, ttl=2
```

Related Commands

Command	Description
address	Adds an IP address to the blacklist or whitelist.

clear dynamic-filter dns-snoop	Clears Botnet Traffic Filter DNS snooping data.
clear dynamic-filter reports	Clears Botnet Traffic filter report data.
clear dynamic-filter statistics	Clears Botnet Traffic filter statistics.
dns domain-lookup	Enables the ASA to send DNS requests to a DNS server to perform a name lookup for supported commands.
dns server-group	Identifies a DNS server for the ASA.
dynamic-filter ambiguous-is-black	Treats greylisted traffic as blacklisted traffic for action purposes.
dynamic-filter blacklist	Edits the Botnet Traffic Filter blacklist.
dynamic-filter database fetch	Manually retrieves the Botnet Traffic Filter dynamic database.
dynamic-filter database find	Searches the dynamic database for a domain name or IP address.
dynamic-filter database purge	Manually deletes the Botnet Traffic Filter dynamic database.
dynamic-filter drop blacklist	Automatically drops blacklisted traffic.
dynamic-filter enable	Enables the Botnet Traffic Filter for a class of traffic or for all traffic if you do not specify an access list.
dynamic-filter updater-client enable	Enables downloading of the dynamic database.
dynamic-filter use-database	Enables use of the dynamic database.
dynamic-filter whitelist	Edits the Botnet Traffic Filter whitelist.
inspect dns dynamic-filter-snoop	Enables DNS inspection with Botnet Traffic Filter snooping.
name	Adds a name to the blacklist or whitelist.
show asp table dynamic-filter	Shows the Botnet Traffic Filter rules that are installed in the accelerated security path.
show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
show dynamic-filter reports	Generates reports of the top 10 botnet sites, ports, and infected hosts.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

show dynamic-filter reports top

To generate reports of the top 10 malware sites, ports, and infected hosts classified by the Botnet Traffic Filter, use the **show dynamic-filter reports top** command in privileged EXEC mode.

show dynamic-filter reports top [**malware-sites** | **malware-ports** | **infected-hosts**]

Syntax Description

malware-ports	(Optional) Shows a report for the top 10 malware ports.
malware-sites	(Optional) Shows a report for the top 10 malware sites.
infected-hosts	(Optional) Shows a report for the top 10 infected hosts.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.
8.2(2)	The **botnet-sites** and **botnet-ports** keywords were changed to **malware-sites** and **malware-ports**. The malware-sites report now includes the number of connections dropped, and the threat level and category of each site. A last clear timestamp was added. For threat events, the severity level was changed from a warning to a notification. Threat events can be triggered every five minutes.

Usage Guidelines

This report is a snapshot of the data, and may not match the top 10 items since the statistics started to be collected.

To clear the report data, enter the **clear dynamic-filter reports top** command.

Examples

The following is sample output from the **show dynamic-filter reports top malware-sites** command:

```
hostname# show dynamic-filter reports top malware-sites
Site                                Connections logged dropped Threat Level Category
-------------------------------------------------------------------------------------

show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
show dynamic-filter dns-snoop	Shows the Botnet Traffic Filter DNS snooping summary, or with the **detail** keyword, the actual IP addresses and names.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

show dynamic-filter reports infected-hosts

To generate reports about infected hosts classified by the Botnet Traffic Filter, use the **show dynamic-filter reports infected-hosts** command in privileged EXEC mode.

show dynamic-filter reports infected-hosts {**max-connections** | **latest-active** | **highest-threat** | **subnet** *ip_address netmask* | **all**}

Syntax Description

all	Shows all buffered infected-hosts information. This display might include thousands of entries. You might want to use ASDM to generate a PDF file instead of using the CLI.
highest-threat	Shows the 20 hosts that connected to the malware sites with the highest threat level.
latest-active	Shows the 20 hosts with the most recent activity. For each host, the display shows detailed information about 5 visited malware sites.
max-connections	Shows the 20 infected hosts with the most number of connections.
subnet *ip_address netmask*	Shows up to 20 hosts within the specified subnet.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.2(2)	This command was introduced.

Usage Guidelines

These reports contain detailed history about infected hosts, showing the correlation between infected hosts, visited malware sites, and malware ports.

To clear the report data, enter the **clear dynamic-filter reports infected-hosts** command.

Examples

The following is sample output from the **show dynamic-filter reports infected hosts all** command:

```
hostname# show dynamic-filter reports infected-hosts all

Total 2 infected-hosts in buffer
Host (interface)                      Latest malicious conn time, filter action  Conn logged, dropped
```

```

name	Adds a name to the blacklist or whitelist.
show asp table dynamic-filter	Shows the Botnet Traffic Filter rules that are installed in the accelerated security path.

Command	Description
show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
show dynamic-filter dns-snoop	Shows the Botnet Traffic Filter DNS snooping summary, or with the **detail** keyword, the actual IP addresses and names.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

show dynamic-filter statistics

To show how many connections were classified as whitelist, blacklist, and greylist connections using the Botnet Traffic Filter, use the **show dynamic-filter statistics** command in privileged EXEC mode.

show dynamic-filter statistics [**interface** *name*] [**detail**]

Syntax Description

detail	(Optional) Shows how many packets at each threat level were classified or dropped.
interface *name*	(Optional) Shows statistics for a particular interface.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.
8.2(2)	The **detail** keyword was added to show how many packets at each threat level were classified or dropped. For threat events, the severity level was changed from a warning to a notification. Threat events can be triggered every five minutes.

Usage Guidelines

The greylist includes addresses that are associated with multiple domain names, but not all of these domain names are on the blacklist.

To clear the statistics, enter the **clear dynamic-filter statistics** command.

Examples

The following is sample output from the **show dynamic-filter statistics** command:

```
hostname# show dynamic-filter statistics
Enabled on interface outside
 Total conns classified 11, ingress 11, egress 0
 Total whitelist classified 0, ingress 0, egress 0
 Total greylist classified 0, dropped 0, ingress 0, egress 0
 Total blacklist classified 11, dropped 5, ingress 11, egress 0
Enabled on interface inside
 Total conns classified 1182, ingress 1182, egress 0
 Total whitelist classified 3, ingress 3, egress 0
 Total greylist classified 0, dropped 0, ingress 0, egress 0
```

```
 Total blacklist classified 1179, dropped 1000, ingress 1179, egress 0
```

The following is sample output from the **show dynamic-filter statistics interface outside detail** command:

```
hostname# show dynamic-filter statistics interface outside detail
Enabled on interface outside
 Total conns classified 2108, ingress 2108, egress 0
 Total whitelist classified 0, ingress 0, egress 0
 Total greylist classified 1, dropped 1, ingress 0, egress 0
   Threat level 5 classified 1, dropped 1, ingress 0, egress 0
   Threat level 4 classified 0, dropped 0, ingress 0, egress 0
   ...
Total blacklist classified 30, dropped 20, ingress 11, egress 2
   Threat level 5 classified 6, dropped 6, ingress 4, egress 2
   Threat level 4 classified 5, dropped 5, ingress 5, egress 0
```

show dynamic-filter reports	Generates reports of the top 10 botnet sites, ports, and infected hosts.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

show eigrp events

To display the EIGRP event log, use the **show eigrp events** command in privileged EXEC mode.

show eigrp [*as-number*] **events** [{*start end*} | **type**]

Syntax Description

as-number	(Optional) Specifies the autonomous system number of the EIGRP process for which you are viewing the event log. Because the ASA only supports one EIGRP routing process, you do not need to specify the autonomous system number.
end	(Optional) Limits the output to the entries with starting with the *start* index number and ending with the *end* index number.
start	(Optional) A number specifying the log entry index number. Specifying a start number causes the output to start with the specified event and end with the event specified by the *end* argument. Valid values are from 1 to 4294967295.
type	(Optional) Displays the events that are being logged.

Defaults

If a *start* and *end* is not specified, all log entries are shown.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The **show eigrp events** output displays up to 500 events. Once the maximum number of events has been reached, new events are added to the bottom of the output and old events are removed from the top of the output.

You can use the **clear eigrp events** command to clear the EIGRP event log.

The **show eigrp events type** command displays the logging status of EIGRP events. By default, neighbor changes, neighbor warning, and DUAL FSM messages are logged. You can disable neighbor change event logging using the **no eigrp log-neighbor-changes** command. You can disable neighbor warning event logging using the **no eigrp log-neighbor-warnings** command. You cannot disable the logging of DUAL FSM events.

Examples

The following is sample output from the **show eigrp events** command:

```
hostname# show eigrp events

Event information for AS 100:
1    12:11:23.500 Change queue emptied, entries: 4
2    12:11:23.500 Metric set: 10.1.0.0/16 53760
3    12:11:23.500 Update reason, delay: new if 4294967295
4    12:11:23.500 Update sent, RD: 10.1.0.0/16 4294967295
5    12:11:23.500 Update reason, delay: metric chg 4294967295
6    12:11:23.500 Update sent, RD: 10.1.0.0/16 4294967295
7    12:11:23.500 Route install: 10.1.0.0/16 10.130.60.248
8    12:11:23.500 Find FS: 10.1.0.0/16 4294967295
9    12:11:23.500 Rcv update met/succmet: 53760 28160
10   12:11:23.500 Rcv update dest/nh: 10.1.0.0/16 10.130.60.248
11   12:11:23.500 Metric set: 10.1.0.0/16 4294967295
```

The following is sample output from the **show eigrp events** command with a start and stop number defined:

```
hostname# show eigrp events 3 8

Event information for AS 100:
3    12:11:23.500 Update reason, delay: new if 4294967295
4    12:11:23.500 Update sent, RD: 10.1.0.0/16 4294967295
5    12:11:23.500 Update reason, delay: metric chg 4294967295
6    12:11:23.500 Update sent, RD: 10.1.0.0/16 4294967295
7    12:11:23.500 Route install: 10.1.0.0/16 10.130.60.248
8    12:11:23.500 Find FS: 10.1.0.0/16 4294967295
```

The following is sample output from the **show eigrp events** command when there are no entries in the EIGRP event log:

```
hostname# show eigrp events

Event information for AS 100:  Event log is empty.
```

The following is sample output from the **show eigrp events type** command:

```
hostname# show eigrp events type

EIGRP-IPv4 Event Logging for AS 100:
      Log Size          500
      Neighbor Changes  Enable
      Neighbor Warnings Enable
      Dual FSM          Enable
```

Related Commands

Command	Description
clear eigrp events	Clears the EIGRP event logging buffer.
eigrp log-neighbor-changes	Enables the logging of neighbor change events.
eigrp log-neighbor-warnings	Enables the logging of neighbor warning events.

show eigrp interfaces

To display the interfaces participating in EIGRP routing, use the **show eigrp interfaces** command in privileged EXEC mode.

show eigrp [*as-number*] **interfaces** [*if-name*] [**detail**]

Syntax Description

as-number	(Optional) Specifies the autonomous system number of the EIGRP process for which you are displaying active interfaces. Because the ASA only supports one EIGRP routing process, you do not need to specify the autonomous system number.
detail	(Optional) Displays detail information.
if-name	(Optional) The name of an interface as specified by the **nameif** command. Specifying an interface name limits the display to the specified interface.

Defaults

If you do not specify an interface name, information for all EIGRP interfaces is displayed.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

Use the **show eigrp interfaces** command to determine on which interfaces EIGRP is active, and to learn information about EIGRP relating to those interfaces.

If an interface is specified, only that interface is displayed. Otherwise, all interfaces on which EIGRP is running are displayed.

If an autonomous system is specified, only the routing process for the specified autonomous system is displayed. Otherwise, all EIGRP processes are displayed.

Examples

The following is sample output from the **show eigrp interfaces** command:

```
hostname# show eigrp interfaces

EIGRP-IPv4 interfaces for process 100
```

```
                    Xmit Queue     Mean   Pacing Time   Multicast   Pending
Interface    Peers  Un/Reliable    SRTT   Un/Reliable   Flow Timer  Routes
mgmt             0        0/0       0      11/434          0          0
outside          1        0/0     337       0/10           0          0
inside           1        0/0      10       1/63         103          0
```

Table 48-2 describes the significant fields shown in the display.

Table 48-2 show eigrp interfaces Field Descriptions

Field	Description
process	Autonomous system number for the EIGRP routing process.
Peers	Number of directly-connected peers.
Xmit Queue Un/Reliable	Number of packets remaining in the Unreliable and Reliable transmit queues.
Mean SRTT	Mean smooth round-trip time interval (in seconds).
Pacing Time Un/Reliable	Pacing time (in seconds) used to determine when EIGRP packets should be sent out the interface (unreliable and reliable packets).
Multicast Flow Timer	Maximum number of seconds in which the ASA will send multicast EIGRP packets.
Pending Routes	Number of routes in the packets in the transmit queue waiting to be sent.

Related Commands

Command	Description
network	Defines the networks and interfaces that participate in the EIGRP routing process.

show eigrp neighbors

To display the EIGRP neighbor table, use the **show eigrp neighbors** command in privileged EXEC mode.

show eigrp [*as-number*] **neighbors** [**detail** | **static**] [*if-name*]

Syntax Description

as-number	(Optional) Specifies the autonomous system number of the EIGRP process for which you are deleting neighbor entries. Because the ASA only supports one EIGRP routing process, you do not need to specify the autonomous system number.
detail	(Optional) Displays detail neighbor information.
if-name	(Optional) The name of an interface as specified by the **nameif** command. Specifying an interface name displays all neighbor table entries that were learned through that interface.
static	(Optional) Displays EIGRP neighbors that are statically defined using the **neighbor** command.

Defaults

If you do not specify an interface name, the neighbors learned through all interfaces are displayed.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

You can use the **clear eigrp neighbors** command to clear the dynamically learned neighbors from the EIGRP neighbor table.

Static neighbors are not included in the output unless you use the **static** keyword.

Examples

The following is sample output from the **show eigrp neighbors** command:

```
hostname# show eigrp neighbors

EIGRP-IPv4 Neighbors for process 100
Address                 Interface     Holdtime Uptime   Q      Seq  SRTT  RTO
```

```
                                   (secs)    (h:m:s)  Count  Num  (ms)  (ms)
172.16.81.28          Ethernet1    13        0:00:41  0      11   4     20
172.16.80.28          Ethernet0    14        0:02:01  0      10   12    24
172.16.80.31          Ethernet0    12        0:02:02  0      4    5     20
```

Table 48-2 describes the significant fields shown in the display.

Table 48-3 show eigrp neighbors Field Descriptions

Field	Description
process	Autonomous system number for the EIGRP routing process.
Address	IP address of the EIGRP neighbor.
Interface	Interface on which the ASA receives hello packets from the neighbor.
Holdtime	Length of time (in seconds) that the ASA waits to hear from the neighbor before declaring it down. This hold time is received from the neighbor in the hello packet, and begins decreasing until another hello packet is received from the neighbor. If the neighbor is using the default hold time, this number will be less than 15. If the peer configures a non-default hold time, the non-default hold time will be displayed. If this value reaches 0, the ASA considers the neighbor unreachable.
Uptime	Elapsed time (in hours:minutes: seconds) since the ASA first heard from this neighbor.
Q Count	Number of EIGRP packets (update, query, and reply) that the ASA is waiting to send.
Seq Num	Sequence number of the last update, query, or reply packet that was received from the neighbor.
SRTT	Smooth round-trip time. This is the number of milliseconds required for an EIGRP packet to be sent to this neighbor and for the ASA to receive an acknowledgment of that packet.
RTO	Retransmission timeout (in milliseconds). This is the amount of time the ASA waits before resending a packet from the retransmission queue to a neighbor.

The following is sample output from the **show eigrp neighbors static** command:

```
hostname# show eigrp neighbors static

EIGRP-IPv4 neighbors for process 100
Static Address                Interface
192.168.1.5                   management
```

Table 48-4 describes the significant fields shown in the display.

Table 48-4 show ip eigrp neighbors static Field Descriptions

Field	Description
process	Autonomous system number for the EIGRP routing process.
Static Address	IP address of the EIGRP neighbor.
Interface	Interface on which the ASA receives hello packets from the neighbor.

The following is sample output from the **show eigrp neighbors detail** command:

```
hostname# show eigrp neighbors detail

EIGRP-IPv4 neighbors for process 100
H   Address                 Interface       Hold Uptime   SRTT   RTO  Q Seq Tye
                                            (sec)         (ms)       Cnt Num

   Version 12.2/1.2, Retrans: 1, Retries: 0
```

Table 48-5 describes the significant fields shown in the display.

Table 48-5 show ip eigrp neighbors details Field Descriptions

Field	Description
process	Autonomous system number for the EIGRP routing process.
H	This column lists the order in which a peering session was established with the specified neighbor. The order is specified with sequential numbering starting with 0.
Address	IP address of the EIGRP neighbor.
Interface	Interface on which the ASA receives hello packets from the neighbor.
Holdtime	Length of time (in seconds) that the ASA waits to hear from the neighbor before declaring it down. This hold time is received from the neighbor in the hello packet, and begins decreasing until another hello packet is received from the neighbor. If the neighbor is using the default hold time, this number will be less than 15. If the peer configures a non-default hold time, the non-default hold time will be displayed. If this value reaches 0, the ASA considers the neighbor unreachable.
Uptime	Elapsed time (in hours:minutes: seconds) since the ASA first heard from this neighbor.
SRTT	Smooth round-trip time. This is the number of milliseconds required for an EIGRP packet to be sent to this neighbor and for the ASA to receive an acknowledgment of that packet.
RTO	Retransmission timeout (in milliseconds). This is the amount of time the ASA waits before resending a packet from the retransmission queue to a neighbor.
Q Count	Number of EIGRP packets (update, query, and reply) that the ASA is waiting to send.
Seq Num	Sequence number of the last update, query, or reply packet that was received from the neighbor.
Version	The software version that the specified peer is running.
Retrans	The number of times that a packet has been retransmitted.

Table 48-5 show ip eigrp neighbors details Field Descriptions

Field	Description
Retries	The number of times an attempt was made to retransmit a packet.
Restart time	Elapsed time (in hours:minutes:seconds) since the specified neighbor has restarted.

Related Commands

Command	Description
clear eigrp neighbors	Clears the EIGRP neighbor table.
debug eigrp neighbors	Displays EIGRP neighbor debugging messages.
debug ip eigrp	Displays EIGRP packet debugging messages.

show eigrp topology

To display the EIGRP topology table, use the **show eigrp topology** command in privileged EXEC mode.

show eigrp [*as-number*] **topology** [*ip-addr* [*mask*] | **active** | **all-links** | **pending** | **summary** | **zero-successors**]

Syntax Description

active	(Optional) Displays only active entries in the EIGRP topology table.
all-links	(Optional) Displays all routes in the EIGRP topology table, even those that are not feasible successors.
as-number	(Optional) Specifies the autonomous system number of the EIGRP process. Because the ASA only supports one EIGRP routing process, you do not need to specify the autonomous system number.
ip-addr	(Optional) Defines the IP address from the topology table to display. When specified with a mask, a detailed description of the entry is provided.
mask	(Optional) Defines the network mask to apply to the *ip-addr* argument.
pending	(Optional) Displays all entries in the EIGRP topology table that are waiting for an update from a neighbor or are waiting to reply to a neighbor.
summary	(Optional) Displays a summary of the EIGRP topology table.
zero-successors	(Optional) Displays available routes in the EIGRP topology table.

Defaults

Only routes that are feasible successors are displayed. Use the **all-links** keyword to display all routes, including those that are not feasible successors.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

You can use the **clear eigrp topology** command to remove the dynamic entries from the topology table.

Examples

The following is sample output from the **show eigrp topology** command:

Command Historyho

```
EIGRP-IPv4 Topology Table for AS(100)/ID(192.168.1.1)

Codes: P - Passive, A - Active, U - Update, Q - Query, R - Reply,
       r - Reply status

P 10.2.1.0 255.255.255.0, 2 successors, FD is 0
          via 10.16.80.28 (46251776/46226176), Ethernet0
          via 10.16.81.28 (46251776/46226176), Ethernet1
P 10.2.1.0 255.255.255.0, 1 successors, FD is 307200
          via Connected, Ethernet1
          via 10.16.81.28 (307200/281600), Ethernet1
          via 10.16.80.28 (307200/281600), Ethernet0
```

Table 48-6 describes the significant fields shown in the displays.

Table 48-6 show eigrp topology Field Information

Field	Description
Codes	State of this topology table entry. Passive and Active refer to the EIGRP state with respect to this destination; Update, Query, and Reply refer to the type of packet that is being sent.
P - Passive	The route is known to be good and no EIGRP computations are being performed for this destination.
A - Active	EIGRP computations are being performed for this destination.
U - Update	Indicates that an update packet was sent to this destination.
Q - Query	Indicates that a query packet was sent to this destination.
R - Reply	Indicates that a reply packet was sent to this destination.
r - Reply status	Flag that is set after the software has sent a query and is waiting for a reply.
address mask	Destination IP address and mask.
successors	Number of successors. This number corresponds to the number of next hops in the IP routing table. If “successors” is capitalized, then the route or next hop is in a transition state.
FD	Feasible distance. The feasible distance is the best metric to reach the destination or the best metric that was known when the route went active. This value is used in the feasibility condition check. If the reported distance of the router (the metric after the slash) is less than the feasible distance, the feasibility condition is met and that path is a feasible successor. Once the software determines it has a feasible successor, it need not send a query for that destination.
via	IP address of the peer that told the software about this destination. The first *n* of these entries, where *n* is the number of successors, is the current successors. The remaining entries on the list are feasible successors.
(*cost*/*adv_cost*)	The first number is the EIGRP metric that represents the cost to the destination. The second number is the EIGRP metric that this peer advertised.
interface	The interface from which the information was learned.

The following is sample output from the **show eigrp topology** used with an IP address. The output shown is for an internal route.

```
hostname# show eigrp topology 10.2.1.0 255.255.255.0

EIGRP-IPv4 (AS 100): Topology Default-IP-Routing-Table(0) entry for entry for 10.2.1.0
255.255.255.0

    State is Passive, Query origin flag is 1, 1 Successor(s), FD is 281600
    Routing Descriptor Blocks:
        0.0.0.0 (Ethernet0/0), from Connected, Send flag is 0x0
            Composite metric is (281600/0), Route is Internal
            Vector metric:
                Minimum bandwidth is 10000 Kbit
                Total delay is 1000 microseconds
                Reliability is 255/255
                Load is 1/255
                Minimum MTU is 1500
                Hop count is 0
```

The following is sample output from the **show eigrp topology** used with an IP address. The output shown is for an external route.

```
hostname# show eigrp topology 10.4.80.0 255.255.255.0

EIGRP-IPv4 (AS 100): Topology Default-IP-Routing-Table(0) entry for entry for 10.4.80.0
255.255.255.0

    State is Passive, Query origin flag is 1, 1 Successor(s), FD is 409600
    Routing Descriptor Blocks:
        10.2.1.1 (Ethernet0/0), from 10.2.1.1, Send flag is 0x0
            Composite metric is (409600/128256), Route is External
            Vector metric:
                Minimum bandwidth is 10000 Kbit
                Total delay is 6000 microseconds
                Reliability is 255/255
                Load is 1/255
                Minimum MTU is 1500
                Hop count is 1
            External data:
                Originating router is 10.89.245.1
                AS number of route is 0
                External protocol is Connected, external metric is 0
                Administrator tag is 0 (0x00000000)
```

Related Commands

Command	Description
clear eigrp topology	Clears the dynamically discovered entries from the EIGRP topology table.

show eigrp traffic

To display the number of EIGRP packets sent and received, use the **show eigrp traffic** command in privileged EXEC mode.

show eigrp [*as-number*] **traffic**

Syntax Description

as-number	(Optional) Specifies the autonomous system number of the EIGRP process for which you are viewing the event log. Because the ASA only supports one EIGRP routing process, you do not need to specify the autonomous system number.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

You can use the **clear eigrp traffic** command to clear the EIGRP traffic statistics.

Examples

The following is sample output from the **show eigrp traffic** command:

```
hostname# show eigrp traffic

EIGRP-IPv4 Traffic Statistics for AS 100
  Hellos sent/received: 218/205
  Updates sent/received: 7/23
  Queries sent/received: 2/0
  Replies sent/received: 0/2
  Acks sent/received: 21/14
  Input queue high water mark 0, 0 drops
  SIA-Queries sent/received: 0/0
  SIA-Replies sent/received: 0/0
  Hello Process ID: 1719439416
  PDM Process ID: 1719439824
```

Table 48-4 describes the significant fields shown in the display.

Table 48-7 show eigrp traffic Field Descriptions

Field	Description
process	Autonomous system number for the EIGRP routing process.
Hellos sent/received	Number of hello packets sent and received.
Updates sent/received	Number of update packets sent and received.
Queries sent/received	Number of query packets sent and received.
Replies sent/received	Number of reply packets sent and received.
Acks sent/received	Number of acknowledgment packets sent and received.
Input queue high water mark/drops	Number of received packets that are approaching the maximum receive threshold and number of dropped packets.
SIA-Queries sent/received	Stuck-in-active queries sent and received.
SIA-Replies sent/received	Stuck-in-active replies sent and received.

Related Commands

Command	Description
debug eigrp packets	Displays debugging information for EIGRP packets sent and received.
debug eigrp transmit	Displays debugging information for EIGRP messages sent.

show environment

To display system environment information for system components, use the **show environment** command in privileged EXEC mode.

show environment [**driver** | **fans** | **power-supply** | **temperature**] [**chassis** | **cpu** | **voltage**]

Syntax Description

chassis	(Optional) Limits the temperature display to the chassis.
cpu	(Optional) Limits the temperature display to the processors. The ASA 5580-40 displays information for 4 processors. The ASA 5580-20 displays information for 2 processors.
driver	(Optional) Displays the environment monitoring (IPMI) driver status. The driver status can be one of the following: • RUNNING—The driver is operational. • STOPPED—An error has caused the driver to stop.
fans	(Optional) Displays the operational status of the cooling fans. The status is one of the following: • OK—The fan is operating normally. • Failed—The fan has failed and should be replaced.
power-supply	(Optional) Displays the operational status of the power supplies. The status for each power supply is one of the following: • OK—The power supply is operating normally. • Failed—The power supply has failed and should be replaced. • Not Present—The specified power supply is not installed. The power supply redundancy status also displays. The redundancy status is one of the following: • OK—The unit is operating normally with full resources. • Lost—The unit has lost redundancy but is operating normally with minimum resources. Any further failures will result in a system shutdown. • N/A—The unit is not configured for power supply redundancy.
temperature	(Optional) Displays the temperature and status of the processors and chassis. The temperature is given in celsius. The status is one of the following: • OK—The temperature is within normal operating range. • Critical—The temperature is outside of normal operating range. Operating ranges are categorized as follows: • Less than 70 degrees—OK • 70-80—Warm • 80-90—Critical • Greater than 90—Unrecoverable
voltage	(Optional) Displays the values for CPU voltage channels 1-24. Excludes the operational status.

Defaults

All operational information, except for the driver, is displayed if no keywords are specified.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.1(1)	This command was introduced.
8.4(2)	The output for an ASA 5585-X SSP was added. In addition, support for a dual SSP installation was added.
8.4.4(1)	Displayed power supply temperature values for the ASA 5515-X, ASA 5525-X, 5545-X, and ASA 5555-X have been changed in the output.
8.6(1)	The output for CPU voltage regulator thermal events in the ASA 5545-X and ASA 5555-X was added. The output for power supply input status was added. The output for voltage sensors was added.

Usage Guidelines

You can display operating environment information on the ASA 5545-X, 5555-X, 5580 and 5585-X. This information includes the operational status of the fans and power supplies, and temperature and status of the CPUs and chassis. The ASA 5580-40 displays information for 4 CPUs; the ASA 5580-20 displays information for 2 CPUs.

Note For a dual SSP installation, only the sensors for the chassis master show output for the cooling fans and power supplies.

Examples

The following is sample generic output from the **show environment** command:

```
hostname# show environment

Cooling Fans:
-----------------------------------
   Power Supplies:
   --------------------------------
   Left Slot (PS0): 6900 RPM - OK  (Power Supply Fan)
   Right Slot (PS1): 7000 RPM - OK  (Power Supply Fan) Power Supplies:
-----------------------------------
   Power Supply Unit Redundancy: OK
   Temperature:
   --------------------------------
   Left Slot (PS0): 26 C - OK  (Power Supply Temperature)
   Right Slot (PS1): 27 C - OK  (Power Supply Temperature)
   Cooling Fans:
   --------------------------------
   Left Slot (PS0): 6900 RPM - OK  (Power Supply Fan)
```

```
   Right Slot (PS1): 7000 RPM - OK  (Power Supply Fan)
Temperature:
---------------------------------
   Processors:
   -------------------------------
   Processor 1: 44.0 C - OK  (CPU1 Core Temperature)
   Processor 2: 45.0 C - OK  (CPU2 Core Temperature)
   Chassis:
   -------------------------------
   Ambient 1: 28.0 C - OK  (Chassis Front Temperature)
   Ambient 2: 40.5 C - OK  (Chassis Back Temperature)
   Ambient 3: 28.0 C - OK  (CPU1 Front Temperature)
   Ambient 4: 36.50 C - OK  (CPU1 Back Temperature)
   Ambient 5: 34.50 C - OK  (CPU2 Front Temperature)
   Ambient 6: 43.25 C - OK  (CPU2 Back Temperature)
   Power Supplies:
   -------------------------------
   Left Slot (PS0): 26 C - OK  (Power Supply Temperature)
   Right Slot (PS1): 27 C - OK  (Power Supply Temperature)
```

The following is sample output from the **show environment driver** command:

```
hostname# show environment driver

Cooling Fans:
---------------------------------

   Chassis Fans:
   -------------------------------
   Cooling Fan 1: 5888 RPM - OK
   Cooling Fan 2: 5632 RPM - OK
   Cooling Fan 3: 5888 RPM - OK

   Power Supplies:
   -------------------------------
   Left Slot (PS0): N/A
   Right Slot (PS1): 8448 RPM - OK

Power Supplies:
---------------------------------

   Left Slot (PS0): Not Present
   Right Slot (PS1): Present

   Left Slot (PS0): N/A
   Right Slot (PS1): 33 C - OK

   Left Slot (PS0): N/A
   Right Slot (PS1): 8448 RPM - OK

Temperature:
---------------------------------

   Processors:
   -------------------------------
   Processor 1: 70.0 C - OK

   Chassis:
   -------------------------------
   Ambient 1: 36.0 C - OK  (Chassis Back Temperature)
   Ambient 2: 31.0 C - OK  (Chassis Front Temperature)
   Ambient 3: 39.0 C - OK  (Chassis Back Left Temperature)

   Power Supplies:
```

```
   --------------------------------
   Left Slot (PS0): N/A
   Right Slot (PS1): 33 C - OK

Voltage:
-----------------------------------
   Channel 1:  1.168 V -  (CPU Core 0.46V-1.4V)
   Channel 2: 11.954 V -  (12V)
   Channel 3:  4.998 V -  (5V)
   Channel 4:  3.296 V -  (3.3V)
   Channel 5:  1.496 V -  (DDR3 1.5V)
   Channel 6:  1.048 V -  (PCH 1.5V)
```

The following is sample output from the **show environment** command for an ASA 5555-X:

```
hostname# show environment

Cooling Fans:
-----------------------------------

   Chassis Fans:
   --------------------------------

   Power Supplies:
   --------------------------------
   Left Slot (PS0): 9728 RPM - OK
   Right Slot (PS1): 0 RPM - OK

Power Supplies:
 -----------------------------------

    Left Slot (PS0): Present
    Right Slot (PS1): Present

    Power Input:
    --------------------------------
    Left Slot (PS0): OK
    Right Slot (PS1): Failure Detected

    Temperature:
    --------------------------------
    Left Slot (PS0): 29 C - OK
    Right Slot (PS1): N/A

   Processors:
   --------------------------------
   Processor 1: 81.0 C - OK

   Chassis:
   --------------------------------
   Ambient 1: 39.0 C - OK  (Chassis Back Temperature)
   Ambient 2: 32.0 C - OK  (Chassis Front Temperature)
   Ambient 3: 47.0 C - OK  (Chassis Back Left Temperature)

   Power Supplies:
   --------------------------------
   Left Slot (PS0): 33 C - OK
   Right Slot (PS1): -128 C - OK
```

The following is sample output from the **show environment** command for an ASA 5585-X chassis master in a dual SSP installation:

```
hostname(config)# show environment
```

```
Cooling Fans:
-----------------------------------

   Power Supplies:
   --------------------------------
   Left Slot (PS0): 7000 RPM - OK  (Fan Module Fan)
   Right Slot (PS1): 6900 RPM - OK  (Power Supply Fan)

Power Supplies:
-----------------------------------
   Power Supply Unit Redundancy: N/A

   Power Supplies:
   --------------------------------
   Left Slot (PS0): 64 C - OK  (Fan Module Temperature)
   Right Slot (PS1): 64 C - OK  (Power Supply Temperature)

   Power Supplies:
   --------------------------------
   Left Slot (PS0): 7000 RPM - OK  (Fan Module Fan)
   Right Slot (PS1): 6900 RPM - OK  (Power Supply Fan)

Temperature:
-----------------------------------

   Processors:
   --------------------------------
   Processor 1: 48.0 C - OK  (CPU1 Core Temperature)
   Processor 2: 47.0 C - OK  (CPU2 Core Temperature)

   Chassis:
   --------------------------------
   Ambient 1: 25.5 C - OK  (Chassis Front Temperature)
   Ambient 2: 37.5 C - OK  (Chassis Back Temperature)
   Ambient 3: 31.50 C - OK  (CPU1 Back Temperature)
   Ambient 4: 27.75 C - OK  (CPU1 Front Temperature)
   Ambient 5: 38.25 C - OK  (CPU2 Back Temperature)
   Ambient 6: 34.0 C - OK  (CPU2 Front Temperature)

   Power Supplies:
   --------------------------------
   Left Slot (PS0): 64 C - OK  (Fan Module Temperature)
   Right Slot (PS1): 64 C - OK  (Power Supply Temperature)

Voltage:
-----------------------------------
   Channel 1:  3.310 V -  (3.3V (U142 VX1))
   Channel 2:  1.492 V -  (1.5V (U142 VX2))
   Channel 3:  1.053 V -  (1.05V (U142 VX3))
   Channel 4:  3.328 V -  (3.3V_STDBY (U142 VP1))
   Channel 5: 11.675 V -  (12V (U142 VP2))
   Channel 6:  4.921 V -  (5.0V (U142 VP3))
   Channel 7:  6.713 V -  (7.0V (U142 VP4))
   Channel 8:  9.763 V -  (IBV (U142 VH))
   Channel 9:  1.048 V -  (1.05VB (U209 VX2))
   Channel 10:  1.209 V -  (1.2V (U209 VX3))
   Channel 11:  1.109 V -  (1.1V (U209 VX4))
   Channel 12:  0.999 V -  (1.0V (U209 VX5))
   Channel 13:  3.324 V -  (3.3V STDBY (U209 VP1))
   Channel 14:  2.504 V -  (2.5V (U209 VP2))
   Channel 15:  1.799 V -  (1.8V (U209 VP3))
   Channel 16:  1.899 V -  (1.9V (U209 VP4))
   Channel 17:  9.763 V -  (IBV (U209 VH))
   Channel 18:  2.048 V -  (VTT CPU0 (U83 VX2))
```

```
Channel 19:  2.048 V -  (VTT CPU1 (U83 VX3))
Channel 20:  2.048 V -  (VCC CPU0 (U83 VX4))
Channel 21:  2.048 V -  (VCC CPU1 (U83 VX5))
Channel 22:  1.516 V -  (1.5VA (U83 VP1))
Channel 23:  1.515 V -  (1.5VB (U83 VP2))
Channel 24:  8.937 V -  (IBV (U83 VH))
```

If the ASA was shut down because of a CPU voltage regulator thermal event, the following warning message appears:

```
WARNING: ASA was previously shut down due to a CPU Voltage Regulator running beyond the
max thermal operating temperature. The chassis and CPU need to be inspected immediately
for ventilation issues.
```

For more information, see syslog message 735024 in the syslog messages guide.

Related Commands

Command	Description
show version	Displays the hardware and software version.

CHAPTER 49

show failover through show ipsec stats traffic Commands

show failover

To display information about the failover status of the unit, use the **show failover** command in privileged EXEC mode.

show failover [**group** *num* | **history** | **interface** | **state** | **statistics**]

Syntax Description

group	Displays the running state of the specified failover group.
history	Displays failover history. The failover history displays past failover state changes and the reason for the state change. History information is cleared with the device is rebooted.
interface	Displays failover and stateful link information.
num	Failover group number.
state	Displays the failover state of both failover units. The information displayed includes the primary or secondary status of the unit, the Active/Standby status of the unit, and the last reported reason for failover. The fail reason remains in the output even when the reason for failure is cleared.
statistics	Displays transmit and receive packet count of failover command interface.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was modified. The output includes additional information.
8.2(2)	This command was modified. The output includes IPv6 addresses for firewall and failover interfaces. The Stateful Failover statitistics outpt includes information for the IPv6 neighbor discover table (IPv6 ND tbl) updates.

Usage Guidelines

The **show failover** command displays the dynamic failover information, interface status, and Stateful Failover statistics.

If both IPv4 and IPv6 addresses are configured on an interface, both addresses appear in the output. Because an interface can have more than one IPv6 address configured on it, only the link-local address is displayed. If there is no IPv4 address configured on the interface, the IPv4 address in the output appears as 0.0.0.0. If there is no IPv6 address configured on an interface, the address is simply omitted from the output.

The Stateful Failover Logical Update Statistics output appears only when Stateful Failover is enabled. The "xerr" and "rerr" values do not indicate errors in failover, but rather the number of packet transmit or receive errors.

Note Stateful Failover, and therefore Stateful Failover statistics output, is not available on the ASA 5505.

In the **show failover** command output, the stateful failover fields have the following values:

- Stateful Obj has these values:
  - xmit—Indicates the number of packets transmitted.
  - xerr—Indicates the number of transmit errors.
  - rcv—Indicates the number of packets received.
  - rerr—Indicates the number of receive errors.
- Each row is for a particular object static count as follows:
  - General—Indicates the sum of all stateful objects.
  - sys cmd—Refers to the logical update system commands, such as **login** or **stay alive**.
  - up time—Indicates the value for the ASA up time, which the active ASA passes on to the standby ASA.
  - RPC services—Remote Procedure Call connection information.
  - TCP conn—Dynamic TCP connection information.
  - UDP conn—Dynamic UDP connection information.
  - ARP tbl—Dynamic ARP table information.
  - Xlate_Timeout—Indicates connection translation timeout information.
  - IPv6 ND tbl—The IPv6 neighbor discovery table information.
  - VPN IKE upd—IKE connection information.
  - VPN IPSEC upd—IPsec connection information.
  - VPN CTCP upd—cTCP tunnel connection information.
  - VPN SDI upd—SDI AAA connection information.
  - VPN DHCP upd—Tunneled DHCP connection information.
  - SIP Session—SIP signalling session information.
  - Route Session—LU statistics of the route synhronization updates

If you do not enter a failover IP address, the **show failover** command displays 0.0.0.0 for the IP address, and monitoring of the interfaces remain in a "waiting" state. You must set a failover IP address for failover to work.

Table 49-1 describes the interface states for failover.

Table 49-1 Failover Interface States

State	Description
Normal	The interface is up and receiving hello packets from the corresponding interface on the peer unit.
Normal (Waiting)	The interface is up but has not yet received a hello packet from the corresponding interface on the peer unit. Verify that a standby IP address has been configured for the interface and that there is connectivity between the two interfaces.
Normal (Not-Monitored)	The interface is up but is not monitored by the failover process. The failure of an interface that is not monitored does not trigger failover.
No Link	The physical link is down.
No Link (Waiting)	The physical link is down and the interface has not yet received a hello packet from the corresponding interface on the peer unit. After restoring the link, verify that a standby IP address has been configured for the interface and that there is connectivity between the two interfaces.
No Link (Not-Monitored)	The physical link is down but is not monitored by the failover process. The failure of an interface that is not monitored does not trigger failover.
Link Down	The physical link is up, but the interface is administratively down.
Link Down (Waiting)	The physical link is up, but the interface is administratively down and the interface has not yet received a hello packet from the corresponding interface on the peer unit. After bringing the interface up (using the **no shutdown** command in interface configuration mode), verify that a standby IP address has been configured for the interface and that there is connectivity between the two interfaces.
Link Down (Not-Monitored)	The physical link is up, but the interface is administratively down but is not monitored by the failover process. The failure of an interface that is not monitored does not trigger failover.
Testing	The interface is in testing mode due to missed hello packets from the corresponding interface on the peer unit.
Failed	Interface testing has failed and the interface is marked as failed. If the interface failure causes the failover criteria to be met, then the interface failure causes a failover to the secondary unit or failover group.

In multiple configuration mode, only the **show failover** command is available in a security context; you cannot enter the optional keywords.

Examples

The following is sample output from the **show failover** command for Active/Standby Failover. The ASAs are ASA 5500 series ASAs, each equipped with a CSC SSM as shown in the details for slot 1 of each ASA. The security appliances use IPv6 addresses on the failover link (folink) and the inside interface.

```
hostname# show failover

Failover On
Cable status: N/A - LAN-based failover enabled
```

```
Failover unit Primary
Failover LAN Interface: folink Ethernet2 (up)
Unit Poll frequency 1 seconds, holdtime 3 seconds

====Configuration State===
        Sync Done
====Communication State===
        Mac set
```

Table 49-2 describes the output of the **show failover state** command.

Table 49-2 show failover state Output Description

Field	Description
Configuration State	Displays the state of configuration synchronization. The following are possible configuration states for the standby unit: • **Config Syncing - STANDBY**—Set while the synchronized configuration is being executed. • **Interface Config Syncing - STANDBY** • **Sync Done - STANDBY**—Set when the standby unit has completed a configuration synchronization from the active unit. The following are possible configuration states for the active unit: • **Config Syncing**—Set on the active unit when it is performing a configuration synchronization to the standby unit. • **Interface Config Syncing** • **Sync Done**—Set when the active unit has completed a successful configuration synchronization to the standby unit. • **Ready for Config Sync**—Set on the active unit when the standby unit signals that it is ready to receive a configuration synchronization.
Communication State	Displays the status of the MAC address synchronization. • **Mac set**—The MAC addresses have been synchronized from the peer unit to this unit. • **Updated Mac**—Used when a MAC address is updated and needs to be synchronized to the other unit. Also used during the transition period where the unit is updating the local MAC addresses synchronized from the peer unit.
Date/Time	Displays a date and timestamp for the failure.
Last Failure Reason	Displays the reason for the last reported failure. This information is not cleared, even if the failure condition is cleared. This information changes only when a failover occurs. The following are possible fail reasons: • **Ifc Failure**—The number of interfaces that failed met the failover criteria and caused failover. • **Comm Failure**—The failover link failed or peer is down. • **Backplane Failure**
State	Displays the Primary/Secondary and Active/Standby status for the unit.
This host/Other host	This host indicates information for the device upon which the command was executed. Other host indicates information for the other device in the failover pair.

The following is sample output from the **show failover history** command:

```
hostname(config)# show failover history
==============================================================================
```

```

Backplane operational

================================================================================
```

Each entry provides the time and date the state change occurred, the beginning state, the resulting state, and the reason for the state change. The newest entries are located at the bottom of the display. Older entries appear at the top. A maximum of 60 entries can be displayed. Once the maximum number of entries has been reached, the oldest entries are removed from the top of the output as new entries are added to the bottom.

Table 49-3 shows the failover states. There are two types of states—stable and transient. Stable states are states that the unit can remain in until some occurrence, such as a failure, causes a state change. A transient state is a state that the unit passes through while reaching a stable state.

Table 49-3 Failover States

States	Description
Disabled	Failover is disabled. This is a stable state.
Failed	The unit is in the failed state. This is a stable state.
Negotiation	The unit establishes the connection with peer and negotiates with peer to determine software version compatibility and Active/Standby role. Depending upon the role that is negotiated, the unit will go through the Standby Unit States or the Active Unit States or enter the failed state. This is a transient state.
Not Detected	The ASA cannot detect the presence of a peer. This can happen when the ASA boots up with failover enabled but the peer is not present or is powered down.
Standby Unit States	
Cold Standby	The unit waits for the peer to reach the Active state. When the peer unit reaches the Active state, this unit progresses to the Standby Config state. This is a transient state.

Table 49-3 Failover States (continued)

States	Description
Sync Config	The unit requests the running configuration from the peer unit. If an error occurs during the configuration synchronization, the unit returns to the Initialization state. This is a transient state.
Sync File System	The unit synchronizes the file system with the peer unit. This is a transient state.
Bulk Sync	The unit receives state information from the peer. This state only occurs when Stateful Failover is enabled. This is a transient state.
Standby Ready	The unit is ready to take over if the active unit fails. This is a stable state.
Active Unit States	
Just Active	The first state the unit enters when becoming the active unit. During this state a message is sent to the peer alerting the peer that the unit is becoming active and the IP and MAC addresses are set for the interfaces. This is a transient state.
Active Drain	Queues messages from the peer are discarded. This is a transient state.
Active Applying Config	The unit is applying the system configuration. This is a transient state.
Active Config Applied	The unit has finished applying the system configuration. This is a transient state.
Active	The unit is active and processing traffic. This is a stable state.

Each state change is followed by a reason for the state change. The reason typically remains the same as the unit progresses through the transient states to the stable state. The following are the possible state change reasons:

- No Error
- Set by the CI config cmd
- Failover state check
- Failover interface become OK
- HELLO not heard from mate
- Other unit has different software version
- Other unit operating mode is different
- Other unit license is different
- Other unit chassis configuration is different
- Other unit card configuration is different
- Other unit want me Active
- Other unit want me Standby
- Other unit reports that I am failed
- Other unit reports that it is failed
- Configuration mismatch
- Detected an Active mate
- No Active unit found

- Configuration synchronization done
- Recovered from communication failure
- Other unit has different set of vlans configured
- Unable to verify vlan configuration
- Incomplete configuration synchronization
- Configuration synchronization failed
- Interface check
- My communication failed
- ACK not received for failover message
- Other unit got stuck in learn state after sync
- No power detected from peer
- No failover cable
- HA state progression failed
- Detect service card failure
- Service card in other unit has failed
- My service card is as good as peer
- LAN Interface become un-configured
- Peer unit just reloaded
- Switch from Serial Cable to LAN-Based fover
- Unable to verify state of config sync
- Auto-update request
- Unknown reason

The following is sample output from the **show failover interface** command. The device has an IPv6 address configured on the failover interface.

```
hostname(config)# sh fail int
        interface folink GigabitEthernet0/2
                System IP Address: 2001:a0a:b00::a0a:b70/64
                My IP Address    : 2001:a0a:b00::a0a:b70
                Other IP Address : 2001:a0a:b00::a0a:b71
```

Related CommandsF

Command	Description
show running-config failover	Displays the **failover** commands in the current configuration.

show failover exec

To display the **failover exec** command mode for the specified unit, use the **show failover exec** command in privileged EXEC mode.

show failover exec {**active** | **standby** | **mate**}

Syntax Description

active	Displays the **failover exec** command mode for the active unit.
mate	Displays the **failover exec** command mode for the peer unit.
standby	Displays the **failover exec** command mode for the standby unit.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The **failover exec** command creates a session with the specified device. By default, that session is in global configuration mode. You can change the command mode of that session by sending the appropriate command (such as the **interface** command) using the **failover exec** command. Changing **failover exec** command modes for the specified device does not change the command mode for the session you are using to access the device. Changing commands modes for your current session to the device does not affect the command mode used by the **failover exec** command.

The **show failover exec** command displays the command mode on the specified device in which commands sent with the **failover exec** command are executed.

Examples

The following is sample output from the **show failover exec** command. This example demonstrates that the command mode for the unit where the **failover exec** commands are being entered does not have to be the same as the **failover exec** command mode where the commands are being executed.

In this example, an administrator logged into the standby unit adds a name to an interface on the active unit. The second time the **show failover exec mate** command is entered in this example shows the peer device in interface configuration mode. Commands sent to the device with the **failover exec** command are executed in that mode.

```
hostname(config)# show failover exec mate
```

```
Active unit Failover EXEC is at config mode

! The following command changes the standby unit failover exec mode
! to interface configuration mode.
hostname(config)# failover exec mate interface GigabitEthernet0/1
hostname(config)# show failover exec mate

Active unit Failover EXEC is at interface sub-command mode

! Because the following command is sent to the active unit, it is replicated
! back to the standby unit.
hostname(config)# failover exec mate nameif test
```

Related Commands

Command	Description
failover exec	Executes the supplied command on the designated unit in a failover pair.

show file

To display information about the file system, use the **show file** command in privileged EXEC mode.

show file descriptors | system | information *filename*

Syntax Description

descriptors	Displays all open file descriptors.
filename	Specifies the filename.
information	Displays information about a specific file, including partner application package files.
system	Displays the size, bytes available, type of media, flags, and prefix information about the disk file system.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
8.2(1)	The capability to view information about partner application package files was added.

Examples

The following is sample output from the **show file descriptors** command:

```
hostname# show file descriptors
No open file descriptors
hostname# show file system
File Systems:
   Size(b)     Free(b)    Type  Flags  Prefixes
* 60985344    60973056    disk    rw     disk:
```

The following is sample output fromthe **show file info** command:

```
hostname# show file info disk0:csc_embd1.0.1000.pkg
type is package (csc)
file size is 17204149 bytes version 1
```

Related Commands

Command	Description
dir	Displays the directory contents.
pwd	Displays the current working directory.

show firewall

To show the current firewall mode (routed or transparent), use the **show firewall** command in privileged EXEC mode.

show firewall

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show firewall** command:

```
hostname# show firewall
Firewall mode: Router
```

Related Commands

Command	Description
firewall transparent	Sets the firewall mode.
show mode	Shows the current context mode, either single or multiple.

show firewall module version

To view the software version number of the ASA Services Module, enter the **show firewall module version** command in privileged EXEC mode.

show firewall switch {**1** | **2**} **module** [*module_number*] **version**

Syntax Description

module_number	(Optional) Specifies the module number.
switch {**1** | **2**}	Applies to VSS users only.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show firewall module version** command:

```
Router# show firewall switch 1 module 2 version
ASA Service Module 2:

Sw Version: 100.7(8)19
```

Related Commands

Command	Description
firewall module	Assigns a VLAN group to an ASA.
firewall vlan-group	Creates a group of VLANs.
show module	Shows all installed modules.

show flash

To display the contents of the internal Flash memory, use the **show flash:** command in privileged EXEC mode.

show flash: all | controller | filesys

Note In the ASA, the **flash** keyword is aliased to **disk0**.

Syntax Description

all	Displays all Flash information.
controller	Displays file system controller information.
filesys	Displays file system information.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show flash:** command:

```
hostname# show flash:
-#- --length-- -----date/time------ path

Related Commands

Command	Description
dir	Displays the directory contents.
show disk0:	Displays the contents of the internal Flash memory.
show disk1:	Displays the contents of the external Flash memory card.

show flow-export counters

To display runtime counters associated with NetFlow data, use the **show flow-export counters** command in privileged EXEC mode.

show flow-export counters

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.1(1)	This command was introduced.
9.0(1)	A new error counter was added for source port allocation failure.

Usage Guidelines

The runtime counters include statistical data as well as error data.

Examples

The following is sample output from the **show flow-export counters** command, which shows runtime counters that are associated with NetFlow data:

```
hostname# show flow-export counters

destination: inside 209.165.200.224 2055
 Statistics:
  packets sent                      1000
 Errors:
  block allocation failure             0
  invalid interface                    0
  template send failure                0
  no route to collector                0
  source port allocation               0
```

Related Commands

Commands	Description
clear flow-export counters	Resets all runtime counters in NetFlow to zero.
flow-export destination	Specifies the IP address or hostname of the NetFlow collector, and the UDP port on which the NetFlow collector is listening.
flow-export template timeout-rate	Controls the interval at which the template information is sent to the NetFlow collector.
logging flow-export-syslogs enable	Enables syslog messages after you have entered the **logging flow-export-syslogs disable** command, and the syslog messages that are associated with NetFlow data.

show fragment

To display the operational data of the IP fragment reassembly module, enter the **show fragment** command in privileged EXEC mode.

show fragment [*interface*]

Syntax Description

interface	(Optional) Specifies the ASA interface.

Defaults

If an *interface* is not specified, the command applies to all interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC mode	•	•	•	•	•

Command History

Release	Modification
7.0(1)	The command was separated into two commands, **show fragment** and **show running-config fragment**, to separate the configuration data from the operational data.

Examples

This example shows how to display the operational data of the IP fragment reassembly module:

```
hostname# show fragment
Interface: inside

```

Related Commands

Command	Description
clear configure fragment	Clears the IP fragment reassembly configuration and resets the defaults.
clear fragment	Clears the operational data of the IP fragment reassembly module.

Command	Description
fragment	Provides additional management of packet fragmentation and improves compatibility with NFS.
show running-config fragment	Displays the IP fragment reassembly configuration.

show gc

To display the garbage collection process statistics, use the **show gc** command in privileged EXEC mode.

show gc

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show gc** command:

```
hostname# show gc

Garbage collection process stats:
Total tcp conn delete response             :            0
Total udp conn delete response             :            0
Total number of zombie cleaned             :            0
Total number of embryonic conn cleaned     :            0
Total error response                       :            0
Total queries generated                    :            0
Total queries with conn present response   :            0
Total number of sweeps                     :          946
Total number of invalid vcid               :            0
Total number of zombie vcid                :            0
```

Related Commands

Command	Description
clear gc	Removes the garbage collection process statistics.

show h225

To display information for H.225 sessions established across the ASA, use the **show h225** command in privileged EXEC mode.

show h225

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show h225** command displays information for H.225 sessions established across the ASA. Along with the **debug h323 h225 event**, **debug h323 h245 event**, and **show local-host** commands, this command is used for troubleshooting H.323 inspection engine issues.

Before using the **show h225**, **show h245**, or **show h323-ras** commands, we recommend that you configure the **pager** command. If there are a lot of session records and the **pager** command is not configured, it may take a while for the **show** output to reach its end. If there is an abnormally large number of connections, check that the sessions are timing out based on the default timeout values or the values set by you. If they are not, then there is a problem that needs to be investigated.

Examples

The following is sample output from the **show h225** command:

```
hostname# show h225
Total H.323 Calls: 1
1 Concurrent Call(s) for
| Local: | 10.130.56.3/1040 | Foreign: 172.30.254.203/1720
| 1. CRV 9861
| Local: | 10.130.56.3/1040 | Foreign: 172.30.254.203/1720
0 Concurrent Call(s) for
| Local: | 10.130.56.4/1050 | Foreign: 172.30.254.205/1720
```

This output indicates that there is currently 1 active H.323 call going through the ASA between the local endpoint 10.130.56.3 and foreign host 172.30.254.203, and for these particular endpoints, there is 1 concurrent call between them, with a CRV (Call Reference Value) for that call of 9861.

For the local endpoint 10.130.56.4 and foreign host 172.30.254.205, there are 0 concurrent Calls. This means that there is no active call between the endpoints even though the H.225 session still exists. This could happen if, at the time of the **show h225** command, the call has already ended but the H.225 session has not yet been deleted. Alternately, it could mean that the two endpoints still have a TCP connection opened between them because they set "maintainConnection" to TRUE, so the session is kept open until they set it to FALSE again, or until the session times out based on the H.225 timeout value in your configuration.

Related Commands

Commands	Description
debug h323	Enables the display of debug information for H.323.
inspect h323	Enables H.323 application inspection.
show h245	Displays information for H.245 sessions established across the ASA by endpoints using slow start.
show h323-ras	Displays information for H.323 RAS sessions established across the ASA.
timeout h225 | h323	Configures idle time after which an H.225 signalling connection or an H.323 control connection will be closed.

show h245

To display information for H.245 sessions established across the ASA by endpoints using slow start, use the **show h245** command in privileged EXEC mode.

show h245

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show h245** command displays information for H.245 sessions established across the ASA by endpoints using slow start. (Slow start is when the two endpoints of a call open another TCP control channel for H.245. Fast start is where the H.245 messages are exchanged as part of the H.225 messages on the H.225 control channel.) Along with the **debug h323 h245 event**, **debug h323 h225 event**, and **show local-host** commands, this command is used for troubleshooting H.323 inspection engine issues.

Examples

The following is sample output from the **show h245** command:

```
hostname# show h245
Total: 1
  | LOCAL | TPKT | FOREIGN | TPKT
1 | 10.130.56.3/1041 | 0 | 172.30.254.203/1245 | 0
  | MEDIA: LCN 258 Foreign 172.30.254.203 RTP 49608 RTCP 49609
  | Local | 10.130.56.3 RTP 49608 RTCP 49609
  | MEDIA: LCN 259 Foreign 172.30.254.203 RTP 49606 RTCP 49607
  | Local | 10.130.56.3 RTP 49606 RTCP 49607
```

There is currently one H.245 control session active across the ASA. The local endpoint is 10.130.56.3, and we are expecting the next packet from this endpoint to have a TPKT header because the TPKT value is 0. (The TKTP header is a 4-byte header preceding each H.225/H.245 message. It gives the length of the message, including the 4-byte header.) The foreign host endpoint is 172.30.254.203, and we are expecting the next packet from this endpoint to have a TPKT header because the TPKT value is 0.

The media negotiated between these endpoints have a LCN (logical channel number) of 258 with the foreign RTP IP address/port pair of 172.30.254.203/49608 and a RTCP IP address/port of 172.30.254.203/49609 with a local RTP IP address/port pair of 10.130.56.3/49608 and a RTCP port of 49609.

The second LCN of 259 has a foreign RTP IP address/port pair of 172.30.254.203/49606 and a RTCP IP address/port pair of 172.30.254.203/49607 with a local RTP IP address/port pair of 10.130.56.3/49606 and RTCP port of 49607.

Related Commands

Commands	Description
debug h323	Enables the display of debug information for H.323.
inspect h323	Enables H.323 application inspection.
show h245	Displays information for H.245 sessions established across the ASA by endpoints using slow start.
show h323-ras	Displays information for H.323 RAS sessions established across the ASA.
timeout h225 | h323	Configures idle time after which an H.225 signalling connection or an H.323 control connection will be closed.

show h323-ras

To display information for H.323 RAS sessions established across the ASA between a gatekeeper and its H.323 endpoint, use the **show h323-ras** command in privileged EXEC mode.

show h323-ras

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show h323-ras** command displays information for H.323 RAS sessions established across the ASA between a gatekeeper and its H.323 endpoint. Along with the **debug h323 ras event** and **show local-host** commands, this command is used for troubleshooting H.323 RAS inspection engine issues.

The **show h323-ras** command displays connection information for troubleshooting H.323 inspection engine issues, and is described in the **inspect protocol h323 {h225 | ras}** command page.

Examples

The following is sample output from the **show h323-ras** command:

```
hostname# show h323-ras
Total: 1
| GK | Caller
| 172.30.254.214 10.130.56.14
hostname#
```

This output shows that there is one active registration between the gatekeeper 172.30.254.214 and its client 10.130.56.14.

Related Commands

Commands	Description
debug h323	Enables the display of debug information for H.323.
inspect h323	Enables H.323 application inspection.

Commands	Description
show h245	Displays information for H.245 sessions established across the ASA by endpoints using slow start.
show h323-ras	Displays information for H.323 RAS sessions established across the ASA.
timeout h225 | h323	Configures idle time after which an H.225 signalling connection or an H.323 control connection will be closed.

show history

To display the previously entered commands, use the **show history** command in user EXEC mode.

show history

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show history** command lets you display previously entered commands. You can examine commands individually with the up and down arrows, enter **^p** to display previously entered lines, or enter **^n** to display the next line.

Examples

The following example shows sample output from the **show history** command in user EXEC mode:

```
hostname> show history
    show history
    help
    show history
```

The following example shows sample output from the **show history** command in privileged EXEC mode:

```
hostname# show history
    show history
    help
    show history
    enable
    show history
```

The following example shows sample output from the **show history** command in global configuration mode:

```
hostname(config)# show history
    show history
```

```
help
show history
enable
show history
config t
show history
```

Related Commands

Command	Description
help	Displays help information for the command specified.

show icmp

To display the ICMP configuration, use the **show icmp** command in privileged EXEC mode.

show icmp

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was previously existing.

Usage Guidelines

The **show icmp** command displays the ICMP configuration.

Examples

The following example shows the ICMP configuration:

```
hostname# show icmp
```

Related Commands

clear configure icmp	Clears the ICMP configuration.
debug icmp	Enables the display of debugging information for ICMP.
icmp	Configures access rules for ICMP traffic that terminates at an ASA interface.
inspect icmp	Enables or disables the ICMP inspection engine.
timeout icmp	Configures the idle timeout for ICMP.

show idb

To display information about the status of interface descriptor blocks, use the **show idb** command in privileged EXEC mode.

show idb

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

IDBs are the internal data structure representing interface resources. See the "Examples" section for a description of the display output.

Examples

The following is sample output from the **show idb** command:

```
hostname# show idb
Maximum number of Software IDBs 280.  In use 23.

                    HWIDBs     SWIDBs
             Active 6          21

```

Table 49-4 shows each field description.

Table 49-4 show idb stats Fields

Field	Description
HWIDBs	Shows the statistics for all HWIDBs. HWIDBs are created for each hardware port in the system.
SWIDBs	Shows the statistics for all SWIDBs. SWIDBs are created for each main and subinterface in the system, and for each interface that is allocated to a context. Some other internal software modules also create IDBs.
HWIDB#	Specifies a hardware interface entry. The IDB sequence number, address, and interface name is displayed in each line.
SWIDB#	Specifies a software interface entry. The IDB sequence number, address, corresponding vPif id, and interface name are displayed in each line.
PEER IDB#	Specifies an interface allocated to a context. The IDB sequence number, address, corresponding vPif id, context id and interface name are displayed in each line.

Related Commands

Command	Description
interface	Configures an interface and enters interface configuration mode.
show interface	Displays the runtime status and statistics of interfaces.

show igmp groups

To display the multicast groups with receivers that are directly connected to the ASA and that were learned through IGMP, use the **show igmp groups** command in privileged EXEC mode.

show igmp groups [[**reserved** | *group*] [*if_name*] [**detail**]] | **summary**]

Syntax Description

detail	(Optional) Provides a detailed description of the sources.
group	(Optional) The address of an IGMP group. Including this optional argument limits the display to the specified group.
if_name	(Optional) Displays group information for the specified interface.
reserved	(Optional) Displays information about reserved groups.
summary	(Optional) Displays group joins summary information.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If you omit all optional arguments and keywords, the **show igmp groups** command displays all directly connected multicast groups by group address, interface type, and interface number.

Examples

The following is sample output from the **show igmp groups** command:

```
hostname#show igmp groups

IGMP Connected Group Membership
Group Address    Interface            Uptime    Expires   Last Reporter
224.1.1.1        inside               00:00:53  00:03:26  192.168.1.6
```

Related Commands

Command	Description
show igmp interface	Displays multicast information for an interface.

show igmp interface

To display multicast information for an interface, use the **show igmp interface** command in privileged EXEC mode.

show igmp interface [*if_name*]

Syntax Description

if_name	(Optional) Displays IGMP group information for the selected interface.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was modified. The **detail** keyword was removed.

Usage Guidelines

If you omit the optional *if_name* argument, the **show igmp interface** command displays information about all interfaces.

Examples

The following is sample output from the **show igmp interface** command:

```
hostname# show igmp interface inside

inside is up, line protocol is up
 Internet address is 192.168.37.6, subnet mask is 255.255.255.0
 IGMP is enabled on interface
 IGMP query interval is 60 seconds
 Inbound IGMP access group is not set
 Multicast routing is enabled on interface
 Multicast TTL threshold is 0
 Multicast designated router (DR) is 192.168.37.33
 No multicast groups joined
```

Related Commands

Command	Description
show igmp groups	Displays the multicast groups with receivers that are directly connected to the ASA and that were learned through IGMP.

show igmp traffic

To display IGMP traffic statistics, use the **show igmp traffic** command in privileged EXEC mode.

show igmp traffic

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show igmp traffic** command:

```
hostname# show igmp traffic

IGMP Traffic Counters
Elapsed time since counters cleared: 00:02:30
                              Received     Sent
Valid IGMP Packets               3           6
Queries                          2           6
Reports                          1           0
Leaves                           0           0
Mtrace packets                   0           0
DVMRP packets                    0           0
PIM packets                      0           0

Errors:
Malformed Packets                0
Martian source                   0
Bad Checksums                    0
```

Related Commands

Command	Description
clear igmp counters	Clears all IGMP statistic counters.
clear igmp traffic	Clears the IGMP traffic counters.

show import webvpn

To list the files, customization objects, translation tables, or plug-ins in flash memory that customize and localize the ASA or the AnyConnect Secure Mobility Client, use the **show import webvpn** command in privileged EXEC mode.

show import webvpn {**AnyConnect-customization** | **customization** | **mst-translation** | **plug-in** | **translation-table** | **url-list** | **webcontent**}[**detailed** | **xml-output**]

Syntax Description

AnyConnect-customization	Displays resource files, executable files, and MS transforms in the ASA flash memory that customize the AnyConnect client GUI.
customization	Displays XML customization objects in the ASA flash memory that customize the clientless VPN portal (filenames base64 decoded).
mst-translation	Displays MS transforms in the ASA flash memory that translate the AnyConnect client installer program.
plug-in	Displays plug-in modules in the ASA flash memory (third-party Java-based client applications, including SSH, VNC, and RDP).
translation-table	Displays translation tables in the ASA flash memory that translate the language of user messages displayed by the clientless portal, Secure Desktop, and plug-ins.
url-list	Displays URL lists in the ASA flash memory used by the clientless portal (filenames base64 decoded).
webcontent	Displays content in ASA flash memory used by the clientless portal, clientless applications, and plugins for online help visible to end users.
detailed	Displays the path in flash memory of the file(s) and the hash.
xml-output	Displays the XML of the file(s).

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.
8.2(1)	The **AnyConnect-customization** keyword was added.

Usage Guidelines

Use the **show import webvpn** command to identify the custom data and the Java-based client applications available to clientless SSL VPN users. The displayed list itemizes all of the requested data types that are in flash memory on the ASA.

Example

The following illustrates the WebVPN data displayed by various **show import webvpn** command:

```
hostname# show import webvpn plug
ssh
rdp
vnc
hostname#

hostname#show import webvpn plug detail

Related Commands

Command	Description
revert webvpn all	Removes all WebVPN data and plug-in current on the ASA.

show interface

To view interface statistics, use the **show interface** command in privileged EXEC mode.

show interface [{*physical_interface* | **redundant***number*}[**.***subinterface*] | *mapped_name* | *interface_name* | **vlan** *number*] [**stats** | **detail**]

Syntax Description

detail	(Optional) Shows detailed interface information, including the order in which the interface was added, the configured state, the actual state, and asymmetrical routing statistics, if enabled by the **asr-group** command. If you show all interfaces, then information about the internal interfaces for SSMs displays, if installed on the ASA 5500 series adaptive security appliance. The internal interface is not user-configurable, and the information is for debugging purposes only.
interface_name	(Optional) Identifies the interface name set with the **nameif** command.
mapped_name	(Optional) In multiple context mode, identifies the mapped name if it was assigned using the **allocate-interface** command.
physical_interface	(Optional) Identifies the interface ID, such as **gigabitethernet 0/1**. See the **interface** command for accepted values.
redundant*number*	(Optional) Identifies the redundant interface ID, such as **redundant1**.
stats	(Default) Shows interface information and statistics. This keyword is the default, so this keyword is optional.
subinterface	(Optional) Identifies an integer between 1 and 4294967293 designating a logical subinterface.
vlan *number*	(Optional) For models with a built-in switch, such as the ASA 5505 adaptive security appliance, specifies the VLAN interface.

Defaults

If you do not identify any options, this command shows basic statistics for all interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was modified to include the new interface numbering scheme, and to add the **stats** keyword for clarity, and the **detail** keyword.
7.0(4)	This command added support for the 4GE SSM interfaces.
7.2(1)	This command added support for switch interfaces.

Release	Modification
8.0(2)	This command added support for redundant interfaces. Also, the delay is added for subinterfaces. Two new counters were added: input reset drops and output reset drops.
8.2(1)	The no buffer number was changed to show the number of failures from block allocations.
8.6(1)	This command added support for the ASA 5512-X through ASA 5555-X shared management interface and the control plane interface for the software module. The management interface is displayed using the **show interface detail** command as Internal-Data0/1; the control plane interface is displayed as Internal-Control0/0.

Usage Guidelines

If an interface is shared among contexts, and you enter this command within a context, the ASA shows only statistics for the current context. When you enter this command in the system execution space for a physical interface, the ASA shows the combined statistics for all contexts.

The number of statistics shown for subinterfaces is a subset of the number of statistics shown for a physical interface.

You cannot use the interface name in the system execution space, because the **nameif** command is only available within a context. Similarly, if you mapped the interface ID to a mapped name using the **allocate-interface** command, you can only use the mapped name in a context. If you set the **visible** keyword in the **allocate-interface** command, the ASA shows the interface ID in the output of the **show interface** command.

Note The number of bytes transmitted or received in the Hardware count and the Traffic Statistics count are different.

In the hardware count, the amount is retrieved directly from hardware, and reflects the Layer 2 packet size. While in traffic statistics, it reflects the Layer 3 packet size.

The count difference is varied based upon the design of the interface card hardware.

For example, for a Fast Ethernet card, the Layer 2 count is 14 bytes greater than the traffic count, because it includes the Ethernet header. On the Gigabit Ethernet card, the Layer 2 count is 18 bytes greater than the traffic count, because it includes both the Ethernet header and the CRC.

See the “Examples” section for a description of the display output.

Examples

The following is sample output from the **show interface** command:

```
hostname# show interface
Interface GigabitEthernet0/0 "outside", is up, line protocol is up
  Hardware is i82546GB rev03, BW 1000 Mbps, DLY 1000 usec
        Auto-Duplex(Full-duplex), Auto-Speed(100 Mbps)
        MAC address 000b.fcf8.c44e, MTU 1500
        IP address 10.86.194.60, subnet mask 255.255.254.0
        1328522 packets input, 124426545 bytes, 0 no buffer
        Received 1215464 broadcasts, 0 runts, 0 giants
```

```
        0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
        9 L2 decode drops
        124606 packets output, 86803402 bytes, 0 underruns
        0 output errors, 0 collisions
        0 late collisions, 0 deferred
        0 input reset drops, 0 output reset drops
        input queue (curr/max packets): hardware (0/7)
        output queue (curr/max packets): hardware (0/13)
  Traffic Statistics for "outside":
        1328509 packets input, 99873203 bytes
        124606 packets output, 84502975 bytes
        524605 packets dropped
      1 minute input rate 0 pkts/sec,  0 bytes/sec
      1 minute output rate 0 pkts/sec,  0 bytes/sec
      1 minute drop rate, 0 pkts/sec
      5 minute input rate 0 pkts/sec,  0 bytes/sec
      5 minute output rate 0 pkts/sec,  0 bytes/sec
      5 minute drop rate, 0 pkts/sec
Interface GigabitEthernet0/1 "inside", is administratively down, line protocol is down
  Hardware is i82546GB rev03, BW 1000 Mbps, DLY 1000 usec
        Auto-Duplex, Auto-Speed
        MAC address 000b.fcf8.c44f, MTU 1500
        IP address 10.10.0.1, subnet mask 255.255.0.0
        0 packets input, 0 bytes, 0 no buffer
        Received 0 broadcasts, 0 runts, 0 giants
        0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
        0 L2 decode drops
        0 packets output, 0 bytes, 0 underruns
        0 output errors, 0 collisions
        0 late collisions, 0 deferred
        0 input reset drops, 0 output reset drops
        input queue (curr/max packets): hardware (0/0)
        output queue (curr/max packets): hardware (0/0)
  Traffic Statistics for "inside":
        0 packets input, 0 bytes
        0 packets output, 0 bytes
        0 packets dropped
      1 minute input rate 0 pkts/sec,  0 bytes/sec
      1 minute output rate 0 pkts/sec,  0 bytes/sec
      1 minute drop rate, 0 pkts/sec
      5 minute input rate 0 pkts/sec,  0 bytes/sec
      5 minute output rate 0 pkts/sec,  0 bytes/sec
      5 minute drop rate, 0 pkts/sec
Interface GigabitEthernet0/2 "faillink", is administratively down, line protocol is down
  Hardware is i82546GB rev03, BW 1000 Mbps, DLY 1000 usec
        Auto-Duplex, Auto-Speed
        Description: LAN/STATE Failover Interface
        MAC address 000b.fcf8.c450, MTU 1500
        IP address 192.168.1.1, subnet mask 255.255.255.0
        0 packets input, 0 bytes, 0 no buffer
        Received 0 broadcasts, 0 runts, 0 giants
        0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
        0 L2 decode drops
        0 packets output, 0 bytes, 0 underruns
        0 output errors, 0 collisions
        0 late collisions, 0 deferred
        0 input reset drops, 0 output reset drops
        input queue (curr/max packets): hardware (0/0)
        output queue (curr/max packets): hardware (0/0)
  Traffic Statistics for "faillink":
        0 packets input, 0 bytes
        1 packets output, 28 bytes
        0 packets dropped
      1 minute input rate 0 pkts/sec,  0 bytes/sec
```

```
      1 minute output rate 0 pkts/sec,  0 bytes/sec
      1 minute drop rate, 0 pkts/sec
      5 minute input rate 0 pkts/sec,  0 bytes/sec
      5 minute output rate 0 pkts/sec,  0 bytes/sec
      5 minute drop rate, 0 pkts/sec
Interface GigabitEthernet0/3 "", is administratively down, line protocol is down
  Hardware is i82546GB rev03, BW 1000 Mbps, DLY 1000 usec
        Auto-Duplex, Auto-Speed
        Active member of Redundant5
        MAC address 000b.fcf8.c451, MTU not set
        IP address unassigned
        0 packets input, 0 bytes, 0 no buffer
        Received 0 broadcasts, 0 runts, 0 giants
        0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
        0 L2 decode drops
        0 packets output, 0 bytes, 0 underruns
        0 output errors, 0 collisions
        0 late collisions, 0 deferred
        0 input reset drops, 0 output reset drops
        input queue (curr/max packets): hardware (0/0)
        output queue (curr/max packets): hardware (0/0)
Interface Management0/0 "", is administratively down, line protocol is down
  Hardware is i82557, BW 100 Mbps, DLY 1000 usec
        Auto-Duplex, Auto-Speed
        Available but not configured via nameif
        MAC address 000b.fcf8.c44d, MTU not set
        IP address unassigned
        0 packets input, 0 bytes, 0 no buffer
        Received 0 broadcasts, 0 runts, 0 giants
        0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
        0 L2 decode drops
        0 packets output, 0 bytes, 0 underruns
        0 output errors, 0 collisions, 0 interface resets
        0 babbles, 0 late collisions, 0 deferred
        0 lost carrier, 0 no carrier
        input queue (curr/max packets): hardware (128/128) software (0/0)
        output queue (curr/max packets): hardware (0/0) software (0/0)
Interface Redundant1 "", is down, line protocol is down
  Redundancy Information:
        Members unassigned
Interface Redundant5 "redundant", is administratively down, line protocol is down
  Hardware is i82546GB rev03, BW 1000 Mbps, DLY 1000 usec
        Auto-Duplex, Auto-Speed
        MAC address 000b.fcf8.c451, MTU 1500
        IP address 10.2.3.5, subnet mask 255.255.255.0
        0 packets input, 0 bytes, 0 no buffer
        Received 0 broadcasts, 0 runts, 0 giants
        0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
        0 L2 decode drops
        0 packets output, 0 bytes, 0 underruns
        0 output errors, 0 collisions
        0 late collisions, 0 deferred
        0 input reset drops, 0 output reset drops
        input queue (curr/max packets): hardware (0/0) software (0/0)
        output queue (curr/max packets): hardware (0/0) software (0/0)
  Traffic Statistics for "redundant":
        0 packets input, 0 bytes
        0 packets output, 0 bytes
        0 packets dropped
      1 minute input rate 0 pkts/sec,  0 bytes/sec
      1 minute output rate 0 pkts/sec,  0 bytes/sec
      1 minute drop rate, 0 pkts/sec
      5 minute input rate 0 pkts/sec,  0 bytes/sec
      5 minute output rate 0 pkts/sec,  0 bytes/sec
```

```
     5 minute drop rate, 0 pkts/sec
  Redundancy Information:
       Member GigabitEthernet0/3(Active), GigabitEthernet0/2
       Last switchover at 15:15:26 UTC Oct 24 2006
Interface Redundant5.1 "", is down, line protocol is down
       VLAN identifier none
       Available but not configured with VLAN or via nameif
```

Table 49-5 shows each field description.

Table 49-5 show interface Fields

Field	Description
Interface *ID*	The interface ID. Within a context, the ASA shows the mapped name (if configured), unless you set the **allocate-interface** command **visible** keyword.
"*interface_name*"	The interface name set with the **nameif** command. In the system execution space, this field is blank because you cannot set the name in the system. If you do not configure a name, the following message appears after the Hardware line: `Available but not configured via nameif`
is *state*	The administrative state, as follows: • up—The interface is not shut down. • administratively down—The interface is shut down with the **shutdown** command.
Line protocol is *state*	The line status, as follows: • up—A working cable is plugged into the network interface. • down—Either the cable is incorrect or not plugged into the interface connector.
VLAN identifier	For subinterfaces, the VLAN ID.
Hardware	The interface type, maximum bandwidth, delay, duplex, and speed. When the link is down, the duplex and speed show the configured values. When the link is up, these fields show the configured values with the actual settings in parentheses. The following list describes the common hardware types: • i82542 - Intel PCI Fiber Gigabit card used on PIX platforms • i82543 - Intel PCI-X Fiber Gigabit card used on PIX platforms • i82546GB - Intel PCI-X Copper Gigabit used on ASA platforms • i82547GI - Intel CSA Copper Gigabit used as backplane on ASA platforms • i82557 - Intel PCI Copper Fast Ethernet used on ASA platforms • i82559 - Intel PCI Copper Fast Ethernet used on PIX platforms • VCS7380 - Vitesse Four Port Gigabit Switch used in SSM-4GE
Media-type	(For 4GE SSM interfaces only) Shows if the interface is set as RJ-45 or SFP.

Table 49-5 show interface Fields (continued)

Field	Description

message area	A message might be displayed in some circumstances. See the following examples:
	• In the system execution space, you might see the following message:
	`Available for allocation to a context`
	• If you do not configure a name, you see the following message:
	`Available but not configured via nameif`
	• If an interface is a member of a redundant interface, you see the following message:
	`Active member of Redundant5`

MAC address	The interface MAC address.
MTU	The maximum size, in bytes, of packets allowed on this interface. If you do not set the interface name, this field shows "MTU not set."
IP address	The interface IP address set using the **ip address** command or received from a DHCP server. In the system execution space, this field shows "IP address unassigned" because you cannot set the IP address in the system.
Subnet mask	The subnet mask for the IP address.
Packets input	The number of packets received on this interface.
Bytes	The number of bytes received on this interface.
No buffer	The number of failures from block allocations.
Received:	
Broadcasts	The number of broadcasts received.
Input errors	The number of total input errors, including the types listed below. Other input-related errors can also cause the input error count to increase, and some datagrams might have more than one error; therefore, this sum might exceed the number of errors listed for the types below.
Runts	The number of packets that are discarded because they are smaller than the minimum packet size, which is 64 bytes. Runts are usually caused by collisions. They might also be caused by poor wiring and electrical interference.
Giants	The number of packets that are discarded because they exceed the maximum packet size. For example, any Ethernet packet that is greater than 1518 bytes is considered a giant.
CRC	The number of Cyclical Redundancy Check errors. When a station sends a frame, it appends a CRC to the end of the frame. This CRC is generated from an algorithm based on the data in the frame. If the frame is altered between the source and destination, the ASA notes that the CRC does not match. A high number of CRCs is usually the result of collisions or a station transmitting bad data.
Frame	The number of frame errors. Bad frames include packets with an incorrect length or bad frame checksums. This error is usually the result of collisions or a malfunctioning Ethernet device.

Table 49-5 show interface Fields (continued)

Field	Description
Overrun	The number of times that the ASA was incapable of handing received data to a hardware buffer because the input rate exceeded the ASA capability to handle the data.
Ignored	This field is not used. The value is always 0.
Abort	This field is not used. The value is always 0.
L2 decode drops	The number of packets dropped because the name is not configured (**nameif** command) or a frame with an invalid VLAN id is received.
Packets output	The number of packets sent on this interface.
Bytes	The number of bytes sent on this interface.
Underruns	The number of times that the transmitter ran faster than the ASA could handle.
Output Errors	The number of frames not transmitted because the configured maximum number of collisions was exceeded. This counter should only increment during heavy network traffic.
Collisions	The number of messages retransmitted due to an Ethernet collision (single and multiple collisions). This usually occurs on an overextended LAN (Ethernet or transceiver cable too long, more than two repeaters between stations, or too many cascaded multiport transceivers). A packet that collides is counted only once by the output packets.
Interface resets	The number of times an interface has been reset. If an interface is unable to transmit for three seconds, the ASA resets the interface to restart transmission. During this interval, connection state is maintained. An interface reset can also happen when an interface is looped back or shut down.
Babbles	Unused. ("babble" means that the transmitter has been on the interface longer than the time taken to transmit the largest frame.)
Late collisions	The number of frames that were not transmitted because a collision occurred outside the normal collision window. A late collision is a collision that is detected late in the transmission of the packet. Normally, these should never happen. When two Ethernet hosts try to talk at once, they should collide early in the packet and both back off, or the second host should see that the first one is talking and wait. If you get a late collision, a device is jumping in and trying to send the packet on the Ethernet while the ASA is partly finished sending the packet. The ASA does not resend the packet, because it may have freed the buffers that held the first part of the packet. This is not a real problem because networking protocols are designed to cope with collisions by resending packets. However, late collisions indicate a problem exists in your network. Common problems are large repeated networks and Ethernet networks running beyond the specification.
Deferred	The number of frames that were deferred before transmission due to activity on the link.
input reset drops	Counts the number of packets dropped in the RX ring when a reset occurs.
output reset drops	Counts the number of packets dropped in the TX ring when a reset occurs.
Rate limit drops	(For 4GE SSM interfaces only) The number of packets dropped if you configured the interface at non-Gigabit speeds and attempted to transmit more than 10 Mbps or 100 Mbps, depending on configuration..

Table 49-5 show interface Fields (continued)

Field	Description
Lost carrier	The number of times the carrier signal was lost during transmission.
No carrier	Unused.
Input queue (curr/max packets):	The number of packets in the input queue, the current and the maximum.
Hardware	The number of packets in the hardware queue.
Software	The number of packets in the software queue. Not available for Gigabit Ethernet interfaces.
Output queue (curr/max packets):	The number of packets in the output queue, the current and the maximum.
Hardware	The number of packets in the hardware queue.
Software	The number of packets in the software queue.
input queue (blocks free curr/low)	The curr/low entry indicates the number of current and all-time-lowest available slots on the interface's Receive (input) descriptor ring. These are updated by the main CPU, so the all-time-lowest (until the interface statistics are cleared or the device is reloaded) watermarks are not highly accurate.
output queue (blocks free curr/low)	The curr/low entry indicates the number of current and all-time-lowest available slots on the interface's Transmit (output) descriptor rings. These are updated by the main CPU, so the all-time-lowest (until the interface statistics are cleared or the device is reloaded) watermarks are not highly accurate.
Traffic Statistics:	The number of packets received, transmitted, or dropped.
Packets input	The number of packets received and the number of bytes.
Packets output	The number of packets transmitted and the number of bytes.
Packets dropped	The number of packets dropped. Typically this counter increments for packets dropped on the accelerated security path (ASP), for example, if a packet is dropped due to an access list deny. See the **show asp drop** command for reasons for potential drops on an interface.
1 minute input rate	The number of packets received in packets/sec and bytes/sec over the last minute.
1 minute output rate	The number of packets transmitted in packets/sec and bytes/sec over the last minute.
1 minute drop rate	The number of packets dropped in packets/sec over the last minute.
5 minute input rate	The number of packets received in packets/sec and bytes/sec over the last 5 minutes.
5 minute output rate	The number of packets transmitted in packets/sec and bytes/sec over the last 5 minutes.
5 minute drop rate	The number of packets dropped in packets/sec over the last 5 minutes.

Table 49-5 show interface Fields (continued)

Field	Description
Redundancy Information:	For redundant interfaces, shows the member physical interfaces. The active interface has "(Active)" after the interface ID. If you have not yet assigned members, you see the following output: `Members unassigned`
Last switchover	For redundant interfaces, shows the last time the active interface failed over to the standby interface.

The following is sample output from the **show interface** command on the ASA 5505, which includes switch ports:

```
hostname# show interface
Interface Vlan1 "inside", is up, line protocol is up
  Hardware is EtherSVI, BW 100 Mbps, DLY 100 usec
        MAC address 00d0.2bff.449f, MTU 1500
        IP address 1.1.1.1, subnet mask 255.0.0.0
  Traffic Statistics for "inside":
        0 packets input, 0 bytes
        0 packets output, 0 bytes
        0 packets dropped
      1 minute input rate 0 pkts/sec,  0 bytes/sec
      1 minute output rate 0 pkts/sec,  0 bytes/sec
      1 minute drop rate, 0 pkts/sec
      5 minute input rate 0 pkts/sec,  0 bytes/sec
      5 minute output rate 0 pkts/sec,  0 bytes/sec
      5 minute drop rate, 0 pkts/sec

    Interface Ethernet0/0 "", is up, line protocol is up
      Hardware is 88E6095, BW 100 Mbps, DLY 1000 usec
            Auto-Duplex(Half-duplex), Auto-Speed(100 Mbps)
            Available but not configured via nameif
            MAC address 00d0.2bfd.6ec5, MTU not set
            IP address unassigned
            407 packets input, 53587 bytes, 0 no buffer
            Received 103 broadcasts, 0 runts, 0 giants
            0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
            0 L2 decode drops
            43 switch ingress policy drops
            0 packets output, 0 bytes, 0 underruns
            0 output errors, 0 collisions, 0 interface resets
            0 babbles, 0 late collisions, 0 deferred
            0 lost carrier, 0 no carrier
            0 rate limit drops
            0 switch egress policy drops
```

Table 49-7 shows each field description for the **show interface** command for switch interfaces, such as those for the ASA 5505 adaptive security appliance. See Table 49-6 for fields that are also shown for the **show interface** command.

Table 49-6 show interface for Switch Interfaces Fields

Field	Description
switch ingress policy drops	This drop is usually seen when a port is not configured correctly. This drop is incremented when a packet cannot be successfully forwarded within switch ports as a result of the default or user configured switch port settings. The following configurations are the likely reasons for this drop: • The **nameif** command was not configured on the VLAN interface. **Note** For interfaces in the same VLAN, even if the **nameif** command was not configured, switching within the VLAN is successful, and this counter does not increment. • The VLAN is shut down. • An access port received an 802.1Q-tagged packet. • A trunk port received a tag that is not allowed or an untagged packet. • The ASA is connected to another Cisco device that has Ethernet keepalives. For example, Cisco IOS software uses Ethernet loopback packets to ensure interface health. This packet is not intended to be received by any other device; the health is ensured just by being able to send the packet. These types of packets are dropped at the switch port, and the counter increments.
switch egress policy drops	Not currently in use.

The following is sample output from the **show interface detail** command. The following example shows detailed interface statistics for all interfaces, including the internal interfaces (if present for your platform) and asymmetrical routing statistics, if enabled by the **asr-group** command:

```
hostname# show interface detail
Interface GigabitEthernet0/0 "outside", is up, line protocol is up
  Hardware is i82546GB rev03, BW 1000 Mbps, DLY 1000 usec
        Auto-Duplex(Full-duplex), Auto-Speed(100 Mbps)
        MAC address 000b.fcf8.c44e, MTU 1500
        IP address 10.86.194.60, subnet mask 255.255.254.0
        1330214 packets input, 124580214 bytes, 0 no buffer
        Received 1216917 broadcasts, 0 runts, 0 giants
        0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort

Table 49-7 shows each field description for the **show interface detail** command. See Table 49-7 for fields that are also shown for the **show interface** command.

Table 49-7 show interface detail Fields

Field	Description
Demux drops	(On Internal-Data interface only) The number of packets dropped because the ASA was unable to demultiplex packets from SSM interfaces. SSM interfaces communicate with the native interfaces across the backplane, and packets from all SSM interfaces are multiplexed on the backplane.
Control Point Interface States:	
Interface number	A number used for debugging that indicates in what order this interface was created, starting with 0.
Interface config status	The administrative state, as follows: • active—The interface is not shut down. • not active—The interface is shut down with the **shutdown** command.
Interface state	The actual state of the interface. In most cases, this state matches the config status above. If you configure high availability, it is possible there can be a mismatch because the ASA brings the interfaces up or down as needed.
Asymmetrical Routing Statistics:	
Received X1 packets	Number of ASR packets received on this interface.
Transmitted X2 packets	Number of ASR packets sent on this interfaces.
Dropped X3 packets	Number of ASR packets dropped on this interface. The packets might be dropped if the interface is down when trying to forward the packet.

The following is sample output from the **show interface detail** command on the ASA 5512-X through ASA 5555-X, which shows combined statistics for the Management 0/0 interface (shown as "Internal-Data0/1") for both the ASA and the software module. The output also shows the Internal-Control0/0 interface, which is used for control traffic between the software module and the ASA.

```
Interface Internal-Data0/1 "ipsmgmt", is down, line protocol is up
  Hardware is , BW Unknown Speed-Capability, DLY 1000 usec
        (Full-duplex), (1000 Mbps)
        Input flow control is unsupported, output flow control is unsupported
        MAC address 0100.0100.0000, MTU not set
        IP address 127.0.1.1, subnet mask 255.255.0.0
        0 packets input, 0 bytes, 0 no buffer
        Received 0 broadcasts, 0 runts, 0 giants
        0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
        0 pause input, 0 resume input
        0 L2 decode drops
        182 packets output, 9992 bytes, 0 underruns
        0 pause output, 0 resume output
        0 output errors, 0 collisions, 0 interface resets
        0 late collisions, 0 deferred
        0 input reset drops, 0 output reset drops

      Interface number is 11
      Interface config status is active
      Interface state is active
```

Related Commands

Command	Description
allocate-interface	Assigns interfaces and subinterfaces to a security context.
clear interface	Clears counters for the **show interface** command.
delay	Changes the delay metric for an interface.
interface	Configures an interface and enters interface configuration mode.
nameif	Sets the interface name.
show interface ip brief	Shows the interface IP address and status.

show interface ip brief

To view interface IP addresses and status, use the **show interface ip brief** command in privileged EXEC mode.

show interface [*physical_interface*[**.***subinterface*] | *mapped_name* | *interface_name* | **vlan** *number*] **ip brief**

Syntax Description

interface_name	(Optional) Identifies the interface name set with the **nameif** command.
mapped_name	(Optional) In multiple context mode, identifies the mapped name if it was assigned using the **allocate-interface** command.
physical_interface	(Optional) Identifies the interface ID, such as **gigabitethernet0/1**. See the **interface** command for accepted values.
subinterface	(Optional) Identifies an integer between 1 and 4294967293 designating a logical subinterface.
vlan *number*	(Optional) For models with a built-in switch, such as the ASA 5505 adaptive security appliance, specifies the VLAN interface.

Defaults

If you do not specify an interface, the ASA shows all interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent[1]	Single	Context	System
Privileged EXEC	•	•	•	•	—

1. Available for the Management 0/0 interface or subinterface only.

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	This command added support for VLAN interfaces, and for the Management 0/0 interface or subinterface in transparent mode.

Usage Guidelines

In multiple context mode, if you mapped the interface ID in the **allocate-interface** command, you can only specify the mapped name or the interface name in a context.

See the "Examples" section for a description of the display output.

Examples

The following is sample output from the **show ip brief** command:

```
hostname# show interface ip brief
```

```
Interface                  IP-Address      OK? Method  Status                Protocol
Control0/0                 127.0.1.1       YES CONFIG  up                    up
GigabitEthernet0/0         209.165.200.226 YES CONFIG  up                    up
GigabitEthernet0/1         unassigned      YES unset   administratively down down
GigabitEthernet0/2         10.1.1.50       YES manual  administratively down down
GigabitEthernet0/3         192.168.2.6     YES DHCP    administratively down down
Management0/0              209.165.201.3   YES CONFIG  up
```

Table 49-7 shows each field description.

Table 49-8 show interface ip brief Fields

Field	Description
Interface	The interface ID or, in multiple context mode, the mapped name if you configured it using the **allocate-interface** command. If you show all interfaces, then information about the internal interface for the AIP SSM displays, if installed on the ASA. The internal interface is not user-configurable, and the information is for debugging purposes only.
IP-Address	The interface IP address.
OK?	This column is not currently used, and always shows “Yes.”
Method	The method by which the interface received the IP address. Values include the following: • unset—No IP address configured. • manual—Configured the running configuration. • CONFIG—Loaded from the startup configuration. • DHCP—Received from a DHCP server.
Status	The administrative state, as follows: • up—The interface is not shut down. • administratively down—The interface is shut down with the **shutdown** command.
Protocol	The line status, as follows: • up—A working cable is plugged into the network interface. • down—Either the cable is incorrect or not plugged into the interface connector.

Related Commands

Command	Description
allocate-interface	Assigns interfaces and subinterfaces to a security context.
interface	Configures an interface and enters interface configuration mode.
ip address	Sets the IP address for the interface or sets the management IP address for a transparent firewall.
nameif	Sets the interface name.
show interface	Displays the runtime status and statistics of interfaces.

show inventory

To display information about all of the Cisco products installed in the networking device that are assigned a product identifier (PID), version identifier (VID), and serial number (SN), use the **show inventory** command in user EXEC or privileged EXEC mode.

show inventory *mod_id* [**slot**]

Syntax Description

mod_id	(Optional) Specifies the module ID.
slot	(Optional) Specifies the SSM slot number (the ASA is slot 0).

Defaults

If you do not specify a slot to show inventory for an item, the inventory information of all SSMs (including the power supply) is displayed.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	—	•
User EXEC	•	•	—	—	•

Command History

Release	Modification
7.0(1)	Minor editorial changes.
8.4(2)	The output for an SSP was added. In addition, support for a dual SSP installation was added.
8.6(1)	The output for the ASA 5512-X, 5515-X, 5525-X, 5545-X, and 5555-X (the chassis, redundant power supplies, and I/O expansion card) was added.
9.1(1)	The output for the ASA CX module was added.

Usage Guidelines

The **show inventory** command retrieves and displays inventory information about each Cisco product in the form of a UDI, which is a combination of three separate data elements: the product identifier (PID), the version identifier (VID), and the serial number (SN).

The PID is the name by which the product can be ordered; it has been historically called the “Product Name” or “Part Number.” This is the identifier that you use to order an exact replacement part.

The VID is the version of the product. Whenever a product has been revised, the VID is incremented according to a rigorous process derived from Telcordia GR-209-CORE, an industry guideline that governs product change notices.

The SN is the vendor-unique serialization of the product. Each manufactured product has a unique serial number assigned at the factory, which cannot be changed in the field. The serial number is the means by which to identify an individual, specific instance of a product.

The UDI refers to each product as an entity. Some entities, such as a chassis, have subentities like slots. Each entity appears on a separate line in a logically ordered presentation that is arranged hierarchically by Cisco entities.

Use the **show inventory** command without options to display a list of Cisco entities installed in the networking device that are assigned a PID.

If a Cisco entity is not assigned a PID, that entity is not retrieved or displayed.

Note When two SSPs are installed in the same chassis, the number of the module indicates the physical location of the module in the chassis. The chassis master is always the SSP installed in slot 0. Only those sensors with which the SSP is associated are displayed in the output.

The term *module* in the output is equivalent to physical slot. In the description of the SSP itself, the output includes module: 0 when it is installed in physical slot 0, and module: 1 otherwise. When the target SSP is the chassis master, the **show inventory** command output includes the power supplies and/or cooling fans. Otherwise, these components are omitted.

Examples

The following is sample output from the **show inventory** command without any keywords or arguments. This sample output displays a list of Cisco entities installed in an ASA that are each assigned a PID.

```
hostname# show inventory
Name:"Chassis", DESCR:"ASA 5540 Adaptive Security Appliance"
PID:ASA5540           , VID:V01 , SN:P3000000998

Name:"slot 1", DESCR:"ASA 5500 Series Security Services Module-20"
PID:ASA-SSM-20        , VID:V01 , SN:P0000000999

Name:"power supply", DESCR:"ASA 5500 Series 180W AC Power Supply"
PID:ASA-180W-PWR-AC   , VID:V01 , SN:123456789AB

hostname# show inventory 0
Name:"Chassis", DESCR:"ASA 5540 Adaptive Security Appliance"
PID:ASA5540           , VID:V01 , SN:P3000000998

hostname# show inventory 1
Name:"slot 1", DESCR:"ASA 5500 Series Security Services Module-20"
PID:ASA-SSM-20        , VID:V01 , SN:P0000000999
```

The following example shows the output of the **show inventory** command on a chassis master for a dual SSP installation:

```
hostname(config)# show inventory
Name: "module 0", DESCR: "ASA 5585-X Security Services Processor-40 w 6GE,4 SFP+"
PID: ASA5585-SSP-40    , VID: V01     , SN: JAF1436ACLJ

Name: "Chassis", DESCR: "ASA 5585-X"
PID: ASA5585           , VID: V01     , SN: 123456789AB

Name: "fan", DESCR: "ASA 5585-X Fan Module"
PID: ASA5585-FAN       , VID: V01     , SN: POG1434000G

Name: "power supply 0", DESCR: "ASA 5585-X AC Power Supply"
PID: ASA5585-PWR-AC    , VID: V01     , SN: POG1434002K
```

The following example shows the output of the **show inventory** command for an ASA CX module with a supported hard disk and a known model number:

```
hostname(config)# show inventory

Name: "Chassis", DESCR: "ASA 5555 Adaptive Security Appliance"
PID: ASA5555           , VID: V00     , SN: FCH1504V0D1

Name: "module 1", DESCR: "ASA 5545-X/5555-X Interface Card 6-port 10/100/1000, RJ-45"
PID: ASA-IC-6GE-CU-C   , VID: N/A     , SN: N/A

Name: "power supply 0", DESCR: ""
PID:                   , VID: N/A     , SN:

Name: "power supply 1", DESCR: "ASA 5545-X/5555-X AC Power Supply"
PID: ASA-PWR-AC        , VID: N/A     , SN: 1341CH

Name: "Storage Device 1", DESCR: "Micron 128 GB SSD MLC, Model Number: C400-MTFDDAC128MAM"
PID: N/A               , VID: N/A     , SN: 1143034653F2
```

Table 49-9 describes the fields shown in the display.

Table 49-9 Field Descriptions for show inventory

Field	Description
Name	Physical name (text string) assigned to the Cisco entity. For example, console, SSP, or a simple component number (port or module number), such as “1,” depending on the physical component naming syntax of the device. Equivalent to the entPhysicalName MIB variable in RFC 2737.
DESCR	Physical description of the Cisco entity that characterizes the object. Equivalent to the entPhysicalDesc MIB variable in RFC 2737.
PID	Entity product identifier. Equivalent to the entPhysicalModelName MIB variable in RFC 2737.
VID	Entity version identifier. Equivalent to the entPhysicalHardwareRev MIB variable in RFC 2737.
SN	Entity serial number. Equivalent to the entPhysicalSerialNum MIB variable in RFC 2737.

Related Commands

Command	Description
show diag	Displays diagnostic information about the controller, interface processor, and port adapters for a networking device.
show tech-support	Displays general information about the router when it reports a problem.

show ip address

To view interface IP addresses or, for transparent mode, the management IP address, use the **show ip address** command in privileged EXEC mode.

show ip address [*physical_interface*[**.***subinterface*] | *mapped_name* | *interface_name* | **vlan** *number*]

Syntax Description

interface_name	(Optional) Identifies the interface name set with the **nameif** command.
mapped_name	(Optional) In multiple context mode, identifies the mapped name if it was assigned using the **allocate-interface** command.
physical_interface	(Optional) Identifies the interface ID, such as **gigabitethernet0/1**. See the **interface** command for accepted values.
subinterface	(Optional) Identifies an integer between 1 and 4294967293 designating a logical subinterface.
vlan *number*	(Optional) For models with a built-in switch, such as the ASA 5505 adaptive security appliance, specifies the VLAN interface.

Defaults

If you do not specify an interface, the ASA shows all interface IP addresses.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command added support for VLAN interfaces.

Usage Guidelines

This command shows the primary IP addresses (called “System” in the display) for when you configure high availability as well as the current IP addresses. If the unit is active, then the system and current IP addresses match. If the unit is standby, then the current IP addresses show the standby addresses.

Examples

The following is sample output from the **show ip address** command:

```
hostname# show ip address
System IP Addresses:
Interface               Name         IP address      Subnet mask       Method
GigabitEthernet0/0      mgmt         10.7.12.100     255.255.255.0     CONFIG
GigabitEthernet0/1      inside       10.1.1.100      255.255.255.0     CONFIG
GigabitEthernet0/2.40   outside      209.165.201.2   255.255.255.224   DHCP
```

```
GigabitEthernet0/3       dmz          209.165.200.225 255.255.255.224   manual
Current IP Addresses:
Interface                Name         IP address      Subnet mask       Method
GigabitEthernet0/0       mgmt         10.7.12.100     255.255.255.0     CONFIG
GigabitEthernet0/1       inside       10.1.1.100      255.255.255.0     CONFIG
GigabitEthernet0/2.40    outside      209.165.201.2   255.255.255.224   DHCP
GigabitEthernet0/3       dmz          209.165.200.225 255.255.255.224   manual
```

Table 49-7 shows each field description.

Table 49-10 show ip address Fields

Field	Description
Interface	The interface ID or, in multiple context mode, the mapped name if you configured it using the **allocate-interface** command.
Name	The interface name set with the **nameif** command.
IP address	The interface IP address.
Subnet mask	The IP address subnet mask.
Method	The method by which the interface received the IP address. Values include the following: • unset—No IP address configured. • manual—Configured the running configuration. • CONFIG—Loaded from the startup configuration. • DHCP—Received from a DHCP server.

Related Commands

Command	Description
allocate-interface	Assigns interfaces and subinterfaces to a security context.
interface	Configures an interface and enters interface configuration mode.
nameif	Sets the interface name.
show interface	Displays the runtime status and statistics of interfaces.
show interface ip brief	Shows the interface IP address and status.

show ip address dhcp

To view detailed information about the DHCP lease or server for an interface, use the **show ip address dhcp** command in privileged EXEC mode.

show ip address {*physical_interface*[**.***subinterface*] | *mapped_name* | *interface_name*} **dhcp** {**lease** | **server**}

show ip address {*physical_interface*[**.***subinterface*] | *mapped_name* | *interface_name*} **dhcp lease** {**proxy** | **server**} {**summary**}

Syntax Description

interface_name	Identifies the interface name set with the **nameif** command.
lease	Shows information about the DHCP lease.
mapped_name	In multiple context mode, identifies the mapped name if it was assigned using the **allocate-interface** command.
physical_interface	Identifies the interface ID, such as **gigabitethernet0/1**. See the **interface** command for accepted values.
proxy	Shows proxy entries in the IPL table.
server	Shows server entries in the IPL table.
subinterface	Identifies an integer between 1 and 4294967293 designating a logical subinterface.
summary	Shows summary for the entry.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent[1]	Single	Context	System
Privileged EXEC	•	—	•	•	—

1. Available for the Management 0/0 interface or subinterface only.

Command History

Release	Modification
7.0(1)	This command was changed to include the **lease** and **server** keywords to accommodate the new server functionality.
7.2(1)	This command added support for VLAN interfaces, and for the Management 0/0 interface or subinterface in transparent mode.
9.1(4)	This command was changed to include the **proxy** and **summary** keywords to accommodate the new server functionality.

Usage Guidelines

See the "Examples" section for a description of the display output.

Examples

The following is sample output from the **show ip address dhcp lease** command:

```
hostname# show ip address outside dhcp lease
Temp IP Addr:209.165.201.57 for peer on interface:outside
Temp sub net mask:255.255.255.224
   DHCP Lease server:209.165.200.225, state:3 Bound
   DHCP Transaction id:0x4123
   Lease:259200 secs, Renewal:129600 secs, Rebind:226800 secs
   Temp default-gateway addr:209.165.201.1
   Temp ip static route0: dest 10.9.0.0 router 10.7.12.255
   Next timer fires after:111797 secs
   Retry count:0, Client-ID:cisco-0000.0000.0000-outside
   Proxy: TRUE  Proxy Network: 10.1.1.1
   Hostname: device1
```

Table 49-7 shows each field description.

Table 49-11 show ip address dhcp lease Fields

Field	Description
Temp IP Addr	The IP address assigned to the interface.
Temp sub net mask	The subnet mask assigned to the interface.
DHCP Lease server	The DHCP server address.
state	The state of the DHCP lease, as follows: • Initial—The initialization state, where the ASA begins the process of acquiring a lease. This state is also shown when a lease ends or when a lease negotiation fails. • Selecting—The ASA is waiting to receive DHCPOFFER messages from one or more DHCP servers, so it can choose one. • Requesting—The ASA is waiting to hear back from the server to which it sent its request. • Purging—The ASA is removing the lease because the client has released the IP address or there was some other error. • Bound—The ASA has a valid lease and is operating normally. • Renewing—The ASA is trying to renew the lease. It regularly sends DHCPREQUEST messages to the current DHCP server, and waits for a reply. • Rebinding—The ASA failed to renew the lease with the original server, and now sends DHCPREQUEST messages until it gets a reply from any server or the lease ends. • Holddown—The ASA started the process to remove the lease. • Releasing—The ASA sends release messages to the server indicating that the IP address is no longer needed.
DHCP transaction id	A random number chosen by the client, used by the client and server to associate the request messages.

Table 49-11 show ip address dhcp lease Fields (continued)

Field	Description
Lease	The length of time, specified by the DHCP server, that the interface can use this IP address.
Renewal	The length of time until the interface automatically attempts to renew this lease.
Rebind	The length of time until the ASA attempts to rebind to a DHCP server. Rebinding occurs if the ASA cannot communicate with the original DHCP server, and 87.5 percent of the lease time has expired. The ASA then attempts to contact any available DHCP server by broadcasting DHCP requests.
Temp default-gateway addr	The default gateway address supplied by the DHCP server.
Temp ip static route0	The default static route.
Next timer fires after	The number of seconds until the internal timer triggers.
Retry count	If the ASA is attempting to establish a lease, this field shows the number of times the ASA tried sending a DHCP message. For example, if the ASA is in the Selecting state, this value shows the number of times the ASA sent discover messages. If the ASA is in the Requesting state, this value shows the number of times the ASA sent request messages.
Client-ID	The client ID used in all communication with the server.
Proxy	Specifies if this interface is a proxy DHCP client for VPN clients, True or False.
Proxy Network	The requested network.
Hostname	The client hostname.

The following is sample output from the **show ip address dhcp server** command:

```
hostname# show ip address outside dhcp server

   DHCP server: ANY (255.255.255.255)
    Leases:   0
    Offers:   0      Requests: 0     Acks: 0     Naks: 0
    Declines: 0      Releases: 0     Bad:  0

   DHCP server: 40.7.12.6
    Leases:   1
    Offers:   1      Requests: 17     Acks: 17     Naks: 0
    Declines: 0      Releases: 0     Bad:  0
    DNS0:   171.69.161.23,   DNS1:  171.69.161.24
    WINS0:  172.69.161.23,   WINS1: 172.69.161.23
    Subnet: 255.255.0.0   DNS Domain: cisco.com
```

Table 49-12 shows each field description.

Table 49-12 show ip address dhcp server Fields

Field	Description
DHCP server	The DHCP server address from which this interface obtained a lease. The top entry (“ANY”) is the default server and is always present.
Leases	The number of leases obtained from the server. For an interface, the number of leases is typically 1. If the server is providing address for an interface that is running proxy for VPN, there will be several leases.
Offers	The number of offers from the server.
Requests	The number of requests sent to the server.
Acks	The number of acknowledgements received from the server.
Naks	The number of negative acknowledgements received from the server.
Declines	The number of declines received from the server.
Releases	The number of releases sent to the server.
Bad	The number of bad packets received from the server.
DNS0	The primary DNS server address obtained from the DHCP server.
DNS1	The secondary DNS server address obtained from the DHCP server.
WINS0	The primary WINS server address obtained from the DHCP server.
WINS1	The secondary WINS server address obtained from the DHCP server.
Subnet	The subnet address obtained from the DHCP server.
DNS Domain	The domain obtained from the DHCP server.

Related Commands

Command	Description
interface	Configures an interface and enters interface configuration mode.
ip address dhcp	Sets the interface to obtain an IP address from a DHCP server.
nameif	Sets the interface name.
show interface ip brief	Shows the interface IP address and status.
show ip address	Displays the IP addresses of interfaces.

show ip address pppoe

To view detailed information about the PPPoE connection, use the **show ip address pppoe** command in privileged EXEC mode.

show ip address {*physical_interface*[**.***subinterface*] | *mapped_name* | *interface_name* | **vlan** *number*} **pppoe**

Syntax Description

interface_name	Identifies the interface name set with the **nameif** command.
mapped_name	In multiple context mode, identifies the mapped name if it was assigned using the **allocate-interface** command.
physical_interface	Identifies the interface ID, such as **gigabitethernet0/1**. See the **interface** command for accepted values.
subinterface	Identifies an integer between 1 and 4294967293 designating a logical subinterface.
vlan *number*	(Optional) For models with a built-in switch, such as the ASA 5505 adaptive security appliance, specifies the VLAN interface.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent[1]	Single	Context	System
Privileged EXEC	•	•	•	•	—

1. Available for the Management 0/0 interface or subinterface only.

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

See the “Examples” section for a description of the display output.

Examples

The following is sample output from the **show ip address pppoe** command:

```
hostname# show ip address outside pppoe
```

Related Commands

Command	Description
interface	Configures an interface and enters interface configuration mode.
ip address ppoe	Sets the interface to obtain an IP address from a PPPoE server.
nameif	Sets the interface name.
show interface ip brief	Shows the interface IP address and status.
show ip address	Displays the IP addresses of interfaces.

show ip audit count

To show the number of signature matches when you apply an audit policy to an interface, use the **show ip audit count** command in privileged EXEC mode.

show ip audit count [**global** | **interface** *interface_name*]

Syntax Description

global	(Default) Shows the number of matches for all interfaces.
interface *interface_name*	(Optional) Shows the number of matches for the specified interface.

Defaults

If you do not specify a keyword, this command shows the matches for all interfaces (**global**).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To create an audit policy, use the **ip audit name** command, and to apply the policy, use the **ip audit interface** command.

Examples

The following is sample output from the **show ip audit count** command:

```
hostname# show ip audit count
IP AUDIT GLOBAL COUNTERS

1000 I Bad IP Options List        0
1001 I Record Packet Route        0
1002 I Timestamp                  0

6190 A statd Buffer Overflow      0

IP AUDIT INTERFACE COUNTERS: inside
...
```

Related Commands

Command	Description
clear ip audit count	Clears the count of signature matches for an audit policy.
ip audit interface	Assigns an audit policy to an interface.
ip audit name	Creates a named audit policy that identifies the actions to take when a packet matches an attack signature or an informational signature.
show running-config ip audit attack	Shows the configuration for the **ip audit attack** command.

show ip verify statistics

To show the number of packets dropped because of the Unicast RPF feature, use the **show ip verify statistics** command in privileged EXEC mode. Use the **ip verify reverse-path** command to enable Unicast RPF.

show ip verify statistics [interface *interface_name*]

Syntax Description

interface *interface_name*	(Optional) Shows statistics for the specified interface.

Defaults

This command shows statistics for all interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show ip verify statistics** command:

```
hostname# show ip verify statistics
interface outside: 2 unicast rpf drops
interface inside: 1 unicast rpf drops
interface intf2: 3 unicast rpf drops
```

Related Commands

Command	Description
clear configure ip verify reverse-path	Clears the **ip verify reverse-path** configuration.
clear ip verify statistics	Clears the Unicast RPF statistics.
ip verify reverse-path	Enables the Unicast Reverse Path Forwarding feature to prevent IP spoofing.
show running-config ip verify reverse-path	Shows the **ip verify reverse-path** configuration.

show ips

To show all available IPS virtual sensors that are configured on the AIP SSM, use the **show ips** command in privileged EXEC mode.

show ips [**detail**]

Syntax Description

detail	(Optional) Shows the sensor ID number as well as the name.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

In multiple context mode, this command shows all virtual sensors when entered in the system execution space, but only shows the virtual sensors assigned to the context in the context execution space. See the **allocate-ips** command to assign virtual sensors to contexts.

Virtual sensors are available in IPS Version 6.0 and above.

Examples

The following is sample output from the **show ips** command:

```
hostname# show ips
Sensor name
------------
ips1
ips2
```

The following is sample output from the **show ips detail** command:

```
hostname# show ips detail
Sensor name              Sensor ID
------------             ---------
ips1                     1
ips2                     2
```

Related Commands

Command	Description
allocate-ips	Assigns a virtual sensor to a security context.
ips	Diverts traffic to the AIP SSM.

show ipsec sa

To display a list of IPsec SAs, use the **show ipsec sa** command in global configuration mode or privileged EXEC mode. You can also use the alternate form of this command: **show crypto ipsec sa**.

show ipsec sa [**assigned-address** *hostname or IP address* | **entry** | **identity** | **inactive** | **map** *map-name* | **peer** *peer-addr*] [**detail**]

Syntax Description

assigned-address	(Optional) Dispay IPsec SAs for the specified hostname or IP address.
detail	(Optional) Displays detailed error information on what is displayed.
entry	(Optional) Displays IPsec SAs sorted by peer address
identity	(Optional) Displays IPsec SAs for sorted by identity, not including ESPs. This is a condensed form.
inactive	(Optional) Displays IPsec SAs that are unable to pass traffic.
map *map-name*	(Optional) Displays IPsec SAs for the specified crypto map.
peer *peer-addr*	(Optional) Displays IPsec SAs for specified peer IP addresses.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Added support for OSPFv3 and multiple context mode.
9.1(4)	Output has been updated to reflect the assigned IPv6 address and to indicate the GRE Transport Mode security association when doing IKEv2 dual traffic.

Examples

The following example, entered in global configuration mode, displays IPsec SAs, including the assigned IPv6 address and the Tansport Mode and GRE encapsulation indication.

```
hostname(config)# sho ipsec sa
interface: outside
    Crypto map tag: def, seq num: 1, local addr: 75.2.1.23

      local ident (addr/mask/prot/port): (75.2.1.23/255.255.255.255/47/0)
      remote ident (addr/mask/prot/port): (75.2.1.60/255.255.255.255/47/0)
```

```
    current_peer: 75.2.1.60, username: rashmi
    dynamic allocated peer ip: 65.2.1.100
    dynamic allocated peer ip(ipv6): 2001:1000::10

      local ident (addr/mask/prot/port): (0.0.0.0/0.0.0.0/0/0)
hostname(config)#
```

Note Fragmentation statistics are pre-fragmentation statistics if the IPsec SA policy states that fragmentation occurs before IPsec processing. Post-fragmentation statistics appear if the SA policy states that fragmentation occurs after IPsec processing.

The following example, entered in global configuration mode, displays IPsec SAs for a crypto map named def.

```
hostname(config)# show ipsec sa map def
cryptomap: def
    Crypto map tag: def, local addr: 172.20.0.17

      local ident (addr/mask/prot/port): (0.0.0.0/0.0.0.0/0/0)

Related Commands

Command	Description
clear configure isakmp	Clears all the ISAKMP configuration.
clear configure isakmp policy	Clears all ISAKMP policy configuration.
clear isakmp sa	Clears the IKE runtime SA database.
isakmp enable	Enables ISAKMP negotiation on the interface on which the IPsec peer communicates with the ASA.
show running-config isakmp	Displays all the active ISAKMP configuration.

show ipsec sa summary

To display a summary of IPsec SAs, use the **show ipsec sa summary** command in global configuration mode or privileged EXEC mode.

show ipsec sa summary

Syntax Description

This command has no arguments or variables.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Examples

The following example, entered in global configuration mode, displays a summary of IPsec SAs by the following connection types:

- IPsec
- IPsec over UDP
- IPsec over NAT-T
- IPsec over TCP
- IPsec VPN load balancing

```
hostname(config)# show ipsec sa summary

Current IPsec SA's:           Peak IPsec SA's:
IPsec            :     2        Peak Concurrent SA  :    14
IPsec over UDP   :     2        Peak Concurrent L2L :     0
IPsec over NAT-T :     4        Peak Concurrent RA  :    14
IPsec over TCP   :     6
IPsec VPN LB     :     0
Total            :    14
hostname(config)#
```

Related Commands

Command	Description
clear ipsec sa	Removes IPsec SAs entirely or based on specific parameters.
show ipsec sa	Displays a list of IPsec SAs.
show ipsec stats	Displays a list of IPsec statistics.

show ipsec stats

To display a list of IPsec statistics, use the **show ipsec stats** command in global configuration mode or privileged EXEC mode.

show ipsec stats

Syntax Description

This command has no keywords or variables.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	ESPv3 statistics are shown with IPsec subsystems, and support for multiple context mode was added.

Usage Guidelines

The following table describes what the output entries indicate.

Output	Description
IPsec Global Statistics	This section pertains to the total number of IPsec tunnels that the ASA supports.
Active tunnels	The number of IPsec tunnels that are currently connected.
Previous tunnels	The number of IPsec tunnels that have been connected, including the active ones.
Inbound	This section pertains to inbound encrypted traffic that is received through IPsec tunnels.
Bytes	The number of bytes of encrypted traffic that has been received.
Decompressed bytes	The number of bytes of encrypted traffic that were received after decompression was performed, if applicable. This counter should always be equal to the previous one if compression is not enabled.

Output (continued)	Description (continued)
Packets	The number of encrypted IPsec packets that were received.
Dropped packets	The number of encrypted IPsec packets that were received and dropped because of errors.
Replay failures	The number of anti-replay failure that were detected on received, encrypted IPsec packets.
Authentications	The number of successful authentications performed on received, encrypted IPsec packets.
Authentication failures	The number of authentications failure detected on received, encrypted IPsec packets.
Decryptions	The number of successful decryptions performed on received, encrypted IPsec packets.
Decryption failures	The number of decryptions failures detected on received, encrypted IPsec packets.
Decapsulated fragments needing reassembly	The number of decryption IPsec packets that include IP fragments to be reassembled.
Outbound	This section pertains to outbound cleartext traffic to be transmitted through IPsec traffic.
Bytes	The number of bytes of cleartext traffic to be encrypted and transmitted through IPsec tunnels.
Uncompressed bytes	The number of bytes of uncompressed cleartext traffic to be encrypted and transmitted through IPsec tunnels. The counter should always be equal to the previous one if compression is not enabled
Packets	The number of cleartext packets to be encrypted and transmitted through IPsec tunnels.
Dropped packets	The number of cleartext packets to be encrypted and transmitted through IPsec tunnels that have been dropped because of errors.
Authentications	The number of successful authentications performed on packets to be transmitted through IPsec tunnels.
Authentication failures	The number of authentication failures that were detected on packets to be transmitted through IPsec tunnels.
Encryptions	The number of successful encryptions that were performed on packets to be transmitted through IPsec tunnels.
Encryption failures	The number of encryption failures that were detected on packets to be transmitted through IPsec tunnels.
Fragmentation successes	The number of successful fragmentation operations that were performed as part of outbound IPsec packet transformation.
Pre-fragmentation successes	The number of successful prefragmentation operations that were performed as part of outbound IPsec packet transformation. Prefragmentation occurs before the cleartext packet is encrypted and encapsulated as one or more IPsec packets.

Output (continued)	Description (continued)
Post-fragmentation successes	The number of successful prefragmentation operations that were performed as part of outbound IPsec packet transformation. Post-fragmentation occurs after the cleartext packet is encrypted and encapsulated as an IPsec packet, which results in multiple IP fragments. These fragments must be reassembled before decryption.
Fragmentation failures	The number of fragmentation failures that have occurred during outbound IPsec packet transformation.
Pre-fragmentation failures	The number of prefragmentation failures that have occurred during outbound IPsec packet transformation. Prefragmentation occurs before the cleartext packet is encrypted and encapsulated as one or more IPsec packets.
Post-fragmentation failure	The number of post-fragmentation failure that have occurred during outbound IPsec packet transformation. Post-fragmentation occurs after the cleartext packet is encrypted and encapsulated as an IPsec packet, which results in multiple IP fragments. These fragments must be reassembled before decryption.
Fragments created	The number of fragments that were created as part of IPsec transformation.
PMTUs sent	The number of path MTU messages that were sent by the IPsec system. IPsec will send a PMTU message to an inside host that is sending packets that are too large to be transmitted through an IPsec tunnel after encapsulation. The PMTU message is a request for the host to lower its MTU and send smaller packets for transmission through the IPsec tunnel.
PMTUs recvd	The number of path MTU messages that were received by the IPsec system. IPsec will receive a path MTU message from a downstream network element if the packets it is sending through the tunnel are too large to traverse that network element. IPsec will usually lower its tunnel MTU when a path MTU message is received.
Protocol failures	The number of malformed IPsec packets that have been received.
Missing SA failures	The number of IPsec operations that have been requested for which the specified IPsec security association does not exist.
System capacity failures	The number of IPsec operations that cannot be completed because the capacity of the IPsec system is not high enough to support the data rate.

Examples

The following example, entered in global configuration mode, displays IPsec statistics:

```
hostname(config)# show ipsec stats

IPsec Global Statistics
-----------------------
Active tunnels: 2
Previous tunnels: 9
```

```
Inbound
    Bytes: 4933013
    Decompressed bytes: 4933013
    Packets: 80348
    Dropped packets: 0
    Replay failures: 0
    Authentications: 80348
    Authentication failures: 0
    Decryptions: 80348
    Decryption failures: 0
    Decapsulated fragments needing reassembly: 0
Outbound
    Bytes: 4441740
    Uncompressed bytes: 4441740
    Packets: 74029
    Dropped packets: 0
    Authentications: 74029
    Authentication failures: 0
    Encryptions: 74029
    Encryption failures: 0
    Fragmentation successes: 3
        Pre-fragmentation successes:2
        Post-fragmentation successes: 1
    Fragmentation failures: 2
        Pre-fragmentation failures:1
        Post-fragmentation failures: 1
    Fragments created: 10
    PMTUs sent: 1
    PMTUs recvd: 2
Protocol failures: 0
Missing SA failures: 0
System capacity failures: 0
hostname(config)#
```

Related Commands

Command	Description
clear ipsec sa	Clears IPsec SAs or counters based on specified parameters.
crypto ipsec transform-set	Defines a transform set.
show ipsec sa	Displays IPsec SAs based on specified parameters.
show ipsec sa summary	Displays a summary of IPsec SAs.

CHAPTER 50

show ipv6 access-list through show ipv6 traffic Commands

show ipv6 access-list

To display the IPv6 access list, use the **show ipv6 access-list** command in privileged EXEC mode. The IPv6 access list determines what IPv6 traffic can pass through the ASA.

show ipv6 access-list [*id* [*source-ipv6-prefix/prefix-length* | **any** | **host** *source-ipv6-address*]]

Syntax Description

any	(Optional) An abbreviation for the IPv6 prefix ::/0.
host *source-ipv6-address*	(Optional) IPv6 address of a specific host. When provided, only the access rules for the specified host are displayed.
id	(Optional) The access list name. When provided, only the specified access list is displayed.
source-ipv6-prefix /prefix-length	(Optional) IPv6 network address and prefix. When provided, only the access rules for the specified IPv6 network are displayed.

Defaults

Displays all IPv6 access lists.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show ipv6 access-list** command provides output similar to the **show ip access-list** command, except that it is IPv6-specific.

Examples

The following is sample output from the **show ipv6 access-list** command. It shows IPv6 access lists named inbound, tcptraffic, and outbound.

```
hostname# show ipv6 access-list
IPv6 access list inbound
    permit tcp any any eq bgp reflect tcptraffic (8 matches) sequence 10
    permit tcp any any eq telnet reflect tcptraffic (15 matches) sequence 20
    permit udp any any reflect udptraffic sequence 30
IPv6 access list tcptraffic (reflexive) (per-user)
    permit tcp host 2001:0DB8:1::1 eq bgp host 2001:0DB8:1::2 eq 11000 timeout 300 (time
        left 243) sequence 1
    permit tcp host 2001:0DB8:1::1 eq telnet host 2001:0DB8:1::2 eq 11001 timeout 300
        (time left 296) sequence 2
```

```
IPv6 access list outbound
    evaluate udptraffic
    evaluate tcptraffic
```

Related Commands

Command	Description
ipv6 access-list	Creates an IPv6 access list.

show ipv6 dhcprelay binding

To display the relay binding entries created by the relay agent, use the **show ipv6 dhcprelay binding** command in privileged EXEC mode.

show ipv6 dhcprelay binding

Syntax Description

This command has no keywords or variables.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The **show ipv6 dhcprelay binding** command allows you to check the relay binding entries that the relay agent has created.

Examples

The following is sample output from the **show ipv6 dhcprelay binding** command:

```
hostname# show ipv6 dhcprelay binding
1 in use, 2 most used

Client: fe80::204:23ff:febb:b094 (inside)
  DUID: 000100010f9a59d1000423bbb094, Timeout in 60 seconds

Above binding is created for client with link local address of fe80::204:23ff:febb:b094 on
the inside interface using DHCPv6 id of 000100010f9a59d1000423bbb094, and will timeout in
60 seconds.

There will be limit of 1000 bindings for each context.
```

Related Commands

Command	Description
show ipv6 dhcprelay statistics	Shows the IPv6 DHCP relay agent information.

show ipv6 dhcprelay statistics

To display the IPv6 DHCP relay agent statistics, use the **show ipv6 dhcprelay statistics** command in privileged EXEC mode.

show ipv6 dhcprelay statistics

Syntax Description

This command has no keywords or variables.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The **show ipv6 dhcprelay statistics** command allows you to view IPv6 DHCP relay agent information.

Examples

The following is sample output from the **show ipv6 dhcprelay statistics** command:

```
hostname# show ipv6 dhcprelay statistics
Relay Messages:
  SOLICIT                                    1
  ADVERTISE                                  2
  REQUEST                                    1
  CONFIRM                                    1
  RENEW                                    496
  REBIND                                     0
  REPLY                                    498
  RELEASE                                    0
  DECLINE                                    0
  RECONFIGURE                                0
  INFORMATION-REQUEST                        0
  RELAY-FORWARD                            499
  RELAY-REPLY                              500

Relay Errors:
  Malformed message:                         0
  Block allocation/duplication failures:     0
  Hop count limit exceeded:                  0
  Forward binding creation failures:         0
```

```
  Reply binding lookup failures:               0
  No output route:                             0
  Conflict relay server route:                 0
  Failed to add server NP rule:                0
  Unit or context is not active:               0

Total Relay Bindings Created:                498
```

Related Commands

Command	Description
show ipv6 dhcprelay binding	Shows the relay binding entries created by the relay agent.

show ipv6 interface

To display the status of interfaces configured for IPv6, use the **show ipv6 interface** command in privileged EXEC mode.

show ipv6 interface [**brief**] [*if_name* [**prefix**]]

Syntax Description

brief	Displays a brief summary of IPv6 status and configuration for each interface.
if_name	(Optional) The internal or external interface name, as designated by the **nameif** command. The status and configuration for only the designated interface is shown.
prefix	(Optional) Prefix generated from a local IPv6 prefix pool. The prefix is the network portion of the IPv6 address.

Defaults

Displays all IPv6 interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show ipv6 interface** command provides output similar to the **show interface** command, except that it is IPv6-specific. If the interface hardware is usable, the interface is marked *up*. If the interface can provide two-way communication, the line protocol is marked *up*.

When an interface name is not specified, information on all IPv6 interfaces is displayed. Specifying an interface name displays information about the specified interface.

Examples

The following is sample output from the **show ipv6 interface** command:

```
hostname# show ipv6 interface outside
interface ethernet0 "outside" is up, line protocol is up
  IPv6 is enabled, link-local address is 2001:0DB8::/29 [TENTATIVE]
  Global unicast address(es):
    2000::2, subnet is 2000::/64
  Joined group address(es):
    FF02::1
```

```
    FF02::1:FF11:6770
  MTU is 1500 bytes
  ND DAD is enabled, number of DAD attempts: 1
  ND reachable time is 30000 milliseconds
  ND advertised reachable time is 0 milliseconds
  ND advertised retransmit interval is 0 milliseconds
  ND router advertisements are sent every 200 seconds
  ND router advertisements live for 1800 seconds
```

The following is sample output from the **show ipv6 interface** command when entered with the **brief** keyword:

```
hostname# show ipv6 interface brief
outside [up/up]
    unassigned
inside [up/up]
    fe80::20d:29ff:fe1d:69f0
    fec0::a:0:0:a0a:a70
vlan101 [up/up]
    fe80::20d:29ff:fe1d:69f0
    fec0::65:0:0:a0a:6570
dmz-ca [up/up]
    unassigned
```

The following is sample output from the **show ipv6 interface** command. It shows the characteristics of an interface which has generated a prefix from an address.

```
hostname# show ipv6 interface inside prefix
IPv6 Prefix Advertisements inside
Codes: A - Address, P - Prefix-Advertisement, O - Pool
       U - Per-user prefix, D - Default       N - Not advertised, C - Calendar

AD      fec0:0:0:a::/64 [LA] Valid lifetime 2592000, preferred lifetime 604800
```

show ipv6 mld traffic

To display the Multicast Listener Discovery (MLD) traffic counter information, use the **show ipv6 mld traffic** command in privileged EXEC mode.

show ipv6 mld traffic

Syntax Description

This command has no keywords or variables.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.2(4)	This command was introduced.

Usage Guidelines

The **show ipv6 mld traffic** command allows you to check if the expected number of MLD messages have been received and sent.

The following information is provided by the **show ipv6 mld traffic** command:

- Elapsed time since counters cleared—The amount of time since the counters were cleared.
- Valid MLD Packets—The number of valid MLD packets that are received and sent.
- Queries—The number of valid queries that are received and sent.
- Reports—The number of valid reports that are received and sent.
- Leaves—The number of valid leaves received and sent.
- Mtraee packets—The number of multicast trace packets that are received and sent.
- Errors—The types of errors and the numberof errors that have occurred.

Examples

The following is sample output from the **show ipv6 mld traffic** command:

```
hostname# show ipv6 mld traffic
show ipv6 mld traffic
MLD Traffic Counters
Elapsed time since counters cleared: 00:01:19
                   Received           Sent
Valid MLD Packets  1                  3
```

```
Queries            1                   0
Reports            0                   3
Leaves             0                   0
Mtrace packets     0              0
Errors:
Malformed Packets  0
Martian source     0
Non link-local source 0
Hop limit is not equal to 1 0
```

Related Commands

Command	Description
clear ipv6 mld traffic	Resets all MLD traffic counters.

show ipv6 neighbor

To display the IPv6 neighbor discovery cache information, use the **show ipv6 neighbor** command in privileged EXEC mode.

show ipv6 neighbor [*if_name* | *address*]

Syntax Description

address	(Optional) Displays neighbor discovery cache information for the supplied IPv6 address only.
if_name	(Optional) Displays cache information for the supplied interface name, as configured by the **nameif** command only.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The following information is provided by the **show ipv6 neighbor** command:

- IPv6 Address—The IPv6 address of the neighbor or interface.
- Age—The time (in minutes) since the address was confirmed to be reachable. A hyphen (-) indicates a static entry.
- Link-layer Addr—The MAC address. If the address is unknown, a hyphen (-) is displayed.
- State—The state of the neighbor cache entry.

Note Reachability detection is not applied to static entries in the IPv6 neighbor discovery cache; therefore, the descriptions for the INCMP (Incomplete) and REACH (Reachable) states are different for dynamic and static cache entries.

The following are possible states for dynamic entries in the IPv6 neighbor discovery cache:

- INCMP—(Incomplete) Address resolution is being performed on the entry. A neighbor solicitation message has been sent to the solicited-node multicast address of the target, but the corresponding neighbor advertisement message has not yet been received.

  - REACH—(Reachable) Positive confirmation was received within the last ReachableTime milliseconds that the forward path to the neighbor was functioning properly. While in REACH state, the device takes no special action as packets are sent.
  - STALE—More than ReachableTime milliseconds have elapsed since the last positive confirmation was received that the forward path was functioning properly. While in STALE state, the device takes no action until a packet is sent.
  - DELAY—More than ReachableTime milliseconds have elapsed since the last positive confirmation was received that the forward path was functioning properly. A packet was sent within the last DELAY_FIRST_PROBE_TIME seconds. If no reachability confirmation is received within DELAY_FIRST_PROBE_TIME seconds of entering the DELAY state, send a neighbor solicitation message and change the state to PROBE.
  - PROBE—A reachability confirmation is actively sought by resending neighbor solicitation messages every RetransTimer milliseconds until a reachability confirmation is received.
  - ????—Unknown state.

  The following are possible states for static entries in the IPv6 neighbor discovery cache:

  - INCMP—(Incomplete) The interface for this entry is down.
  - REACH—(Reachable) The interface for this entry is up.

- Interface

  The interface from which the address was reachable.

Examples

The following is sample output from the **show ipv6 neighbor** command when entered with an interface:

```
hostname# show ipv6 neighbor inside
IPv6 Address                              Age Link-layer Addr State Interface
2000:0:0:4::2                               0 0003.a0d6.141e  REACH inside
FE80::203:A0FF:FED6:141E                    0 0003.a0d6.141e  REACH inside
3001:1::45a                                 - 0002.7d1a.9472  REACH inside
```

The following is sample output from the **show ipv6 neighbor** command when entered with an IPv6 address:

```
hostname# show ipv6 neighbor 2000:0:0:4::2
IPv6 Address                              Age Link-layer Addr State Interface
2000:0:0:4::2                               0 0003.a0d6.141e  REACH inside
```

Related Commands

Command	Description
clear ipv6 neighbors	Deletes all entries in the IPv6 neighbor discovery cache, except static entries.
ipv6 neighbor	Configures a static entry in the IPv6 neighbor discovery cache.

show ipv6 ospf

To display general information about OSPFv3 routing processes, use the **show ipv6 ospf** command in user EXEC or privileged EXEC mode.

show ipv6 ospf [*process_id*] [*area_id*]

Syntax Description

area_id	(Optional) Shows information about a specified area only.
process_id	(Optional) Specifies an internal ID that is locally assigned and can be any positive integer. This ID is the number assigned administratively when the OSPFv3 routing process is enabled.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—
User EXEC	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The **show ipv6 ospf** command lists the following settings:

- Event logging
- Router type
- Redistribution route type
- SPF schedule delay
- Hold time between two consecutive SPFs
- Wait time between two consecutive SPFs
- Minimum LSA interval
- Minimum LSA arrival

Examples

The following is sample output from the **show ipv6 ospf** command:

```
hostname# show ipv6 ospf
```

```
Routing Process "ospfv3 1" with ID 10.9.4.1
Event-log enabled, Maximum number of events: 1000, Mode: cyclic
It is an autonomous system boundary router
Redistributing External Routes from,
   ospf 2
Initial SPF schedule delay 5000 msecs
Minimum hold time between two consecutive SPFs 10000 msecs
Maximum wait time between two consecutive SPFs 10000 msecs
Minimum LSA interval 5 secs
Minimum LSA arrival 1000 msecs
```

Related Commands

Command	Description
show ipv6 ospf border-routers	Shows the internal OSPFv3 routing table entries to an area border router (ABR) and an autonomous system boundary router (ASBR).
show ipv6 ospf database	Shows lists of information related to the OSPFv3 database for a specific router.

show ipv6 ospf border-routers

To display the internal OSPFv3 routing table entries to an area border router (ABR) and an autonomous system boundary router (ASBR), use the **show ipv6 ospf border-routers** command in user EXEC or privileged EXEC mode.

show ipv6 ospf [*process_id*] **border-routers**

Syntax Description

process_id	(Optional) Specifies an internal ID that is locally assigned and can be any positive integer. This ID is the number assigned administratively when the OSPFv3 routing process is enabled.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—
User EXEC	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The **show ipv6 ospf border-routers** command lists the following settings:

- Intra-area route
- Inter-area route
- IPv6 address
- Interface type
- Area ID
- SPF number

Examples

The following is sample output from the **show ipv6 ospf border-routers** command:

```
hostname# show ipv6 ospf border-routers
OSPFv3 Process 1 internal Routing Table

Codes: i - Intra-area route, I - Inter-area route
```

```
i 172.16.4.4 [2] via FE80::205:5FFF:FED3:5808, FastEthernet0/0, ABR, Area 1, SPF 13
i 172.16.4.4 [1] via FE80::205:5FFF:FED3:5406, POS4/0, ABR, Area 0, SPF 8
i 172.16.3.3 [1] via FE80::205:5FFF:FED3:5808, FastEthernet0/0, ASBR, Area 1, SPF 3
```

Related Commands

Command	Description
show ipv6 ospf	Shows all IPv6 settings in the OSPFv3 routing process.
show ipv6 ospf database	Shows lists of information related to the OSPFv3 database for a specific router.

show ipv6 ospf database

To display lists of information related to the OSPFv3 database for a specific router, use the **show ipv6 ospf database** command in user EXEC or privileged EXEC mode.

show ipv6 ospf [*process_id*] [*area_id*] **database** [**external | inter-area prefix | inter-area-router | network | nssa-external | router | area | as | ref-lsa |** [*destination-router-id*] [**prefix** *ipv6-prefix*] [*link-state-id*]] [**link** [**interface** *interface-name*] [**adv-router** *router-id*] | **self-originate**] [**internal**] [**database-summary**]

Syntax Description

adv-router *router-id*	(Optional) Displays all the LSAs of the advertising router. The router ID must be in the form documented in RFC 2740, in which the address is specified in hexadecimal using 16-bit values between colons.
area	(Optional) Displays information only about area LSAs.
area_id	(Optional) Displays information about a specified area only.
as	(Optional) Filters unknown autonomous system (AS) LSAs.
database-summary	(Optional) Displays how many of each type of LSA exists for each area in the database and the total.
destination-router-id	(Optional) Displays information about a specified destination router only.
external	(Optional) Displays information only about the external LSAs.
interface	Optional) Displays information about the LSAs filtered by interface context.
interface-name	(Optional) Specifies the LSA interface name.
internal	(Optional) Displays information only about the internal LSAs.
inter-area prefix	(Optional) Displays information only about LSAs based on inter-area prefix.
inter-area router	(Optional) Displays information only about LSAs based on inter-area router LSAs.
link	(Optional) Displays information about link LSAs. When it follows the **unknown** keyword, the **link** keyword filters link-scope LSAs.
link-state-id	(Optional) Specifies an integer used to differentiate LSAs. In network and link LSAs, the link-state ID matches the interface index.
network	(Optional) Displays information about network LSAs.
nssa-external	(Optional) Displays information only about the not so stubby area (NSSA) external LSAs.
prefix *ipv6-prefix*	(Optional) Displays the link-local IPv6 address of the neighbor. The IPv6 prefix must be in the form documented in RFC 2373, in which the address is specified in hexadecimal using 16-bit values between colons.
process_id	(Optional) Specifies an internal ID that is locally assigned and can be any positive integer. This ID is the number assigned administratively when the OSPF routing process is enabled.
ref-lsa	(Optional) Further filters the prefix LSA type.
router	(Optional) Displays information about router LSAs.
self-originate	(Optional) Displays only self-originated LSAs from the local router.

Defaults No default behavior or values.

Command Modes The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
	Routed	Transparent	Single	Multiple Context	System
Privileged EXEC	•	—	•	—	—
User EXEC	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines The various forms of the command provide information about different OSPFv3 LSAs.

Examples The following is sample output from the **show ipv6 ospf database** command:

```
hostname# show ipv6 ospf database

            OSPFv3 Router with ID (172.16.4.4) (Process ID 1)

                Router Link States (Area 0)

ADV Router         Age         Seq#        Fragment ID   Link count  Bits
172.16.4.4         239         0x80000003  0             1           B
172.16.6.6         239         0x80000003  0             1           B

            Inter Area Prefix Link States (Area 0)

Related Commands

Command	Description
show ipv6 ospf	Shows all IPv6 settings in the OSPFv3 routing process.
show ipv6 ospf border-routers	Shows the internal OSPFv3 routing table entries to an area border router (ABR) and an autonomous system boundary router (ASBR).

show ipv6 ospf events

To display OSPFv3 internal event information, use the **show ipv6 ospf events** command in user EXEC or privileged EXEC mode.

show ipv6 ospf [*process_id*] **events**

Syntax Description

process_id	(Optional) Specifies an internal ID that is locally assigned and can be any positive integer. This ID is the number assigned administratively when the OSPF routing process is enabled.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—
User EXEC	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to display OSPFv3 events information.

Examples

The following is sample output from the **show ipv6 ospf events** command:

```
hostname# show ipv6 ospf events

OSPFv3 Router with ID (10.1.3.2) (Process ID 10)

show ipv6 ospf border-routers	Shows the internal OSPFv3 routing table entries to an area border router (ABR) and an autonomous system boundary router (ASBR).

show ipv6 ospf flood-list

To display a list of OSPFv3 LSAs waiting to be flooded over an interface, use the **show ipv6 ospf flood-list** command in user EXEC or privileged EXEC mode.

show ipv6 ospf [*process_id*] [*area_id*] **flood-list** *interface-type interface-number*

Syntax Description

area_id	(Optional) Displays information about a specified area only.
interface-number	Specifies the interface number over which the LSAs are flooded.
interface-type	Specifies the interface type over which the LSAs are flooded.
process_id	(Optional) Specifies an internal ID that is locally assigned and can be any positive integer. This ID is the number assigned administratively when the OSPFv3 routing process is enabled.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—
User EXEC	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to display OSPFv3 packet pacing information.

Examples

The following is sample output from the **show ipv6 ospf flood-list** command:

```
hostname# show ipv6 ospf flood-list

OSPFv3 Router with ID (172.16.6.6) (Process ID 1)

 Interface POS4/0, Queue length 1
 Link state retransmission due in 14 msec

 0x2001  0               172.16.6.6      0x80000031  0      0x1971

 Interface FastEthernet0/0, Queue length 0
```

```
Interface ATM3/0, Queue length 0
```

Related Commands

Command	Description
show ipv6 ospf	Shows all IPv6 settings in the OSPFv3 routing process.
show ipv6 ospf border-routers	Shows the internal OSPFv3 routing table entries to an area border router (ABR) and an autonomous system boundary router (ASBR).

show ipv6 ospf interface

To display OSPFv3-related interface information, use the **show ipv6 ospf interface** command in user EXEC or privileged EXEC mode.

show ipv6 ospf [*process_id*] [*area_id*] **interface** [*type-number*] [**brief**]

Syntax Description

area_id	(Optional) Displays information about a specified area only.
brief	(Optional) Displays brief overview information for OSPFv3 interfaces, states, addresses and masks, and areas on the router.
process_id	(Optional) Specifies an internal ID that is locally assigned and can be any positive integer. This ID is the number assigned administratively when the OSPF routing process is enabled.
type-number	(Optional) Specifies the interface type and number.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—
User EXEC	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to display overview information for OSPFv3 interfaces, states, addresses and masks, and areas on the router.

Examples

The following is sample output from the **show ipv6 ospf interface** command:

```
hostname# show ipv6 ospf interface

ATM3/0 is up, line protocol is up

show ipv6 ospf border-routers	Shows the internal OSPFv3 routing table entries to an area border router (ABR) and an autonomous system boundary router (ASBR).

show ipv6 ospf statistic

To display various OSPFv3 statistics, use the **show ipv6 ospf statistic** command in user EXEC or privileged EXEC mode.

show ipv6 ospf [*process_id*] **statistic** [**detail**]

Syntax Description

detail	(Optional) Specifies detailed SPF information, including the trigger points.
process_id	(Optional) Specifies an internal ID that is locally assigned and can be any positive integer. This ID is the number assigned administratively when the OSPF routing process is enabled.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Use this command to show a list of all summary address redistribution information that has been configured under an OSPFv3 process.

Examples

The following is sample output from the **show ipv6 ospf summary-prefix** command:

```
hostname# show ipv6 ospf summary-prefix

OSPFv3 Process 1, Summary-prefix

FEC0::/24 Metric 16777215, Type 0, Tag 0
```

Related Commands

Command	Description
show ipv6 ospf	Shows all IPv6 settings in the OSPFv3 routing process.
show ipv6 ospf border-routers	Shows the internal OSPFv3 routing table entries to an area border router (ABR) and an autonomous system boundary router (ASBR).

show ipv6 ospf timers

To display OSPFv3 timers information, use the **show ipv6 ospf timers** command in user EXEC or privileged EXEC mode.

show ipv6 ospf [*process_id*] **timers** [**lsa-group | rate-limit**]

Syntax Description

lsa-group	(Optional) Specifies OSPFv3 LSA group information.
process_id	(Optional) Specifies an internal ID that is locally assigned and can be any positive integer. This ID is the number assigned administratively when the OSPF routing process is enabled.
rate-limit	(Optional) Specifies OSPFv3 LSA rate limit information.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—
User EXEC	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to show LSA information that has been configured under an OSPFv3 process.

Examples

The following is sample output from the **show ipv6 ospf timers lsa-group** command:

```
hostname# show ipv6 ospf timers lsa-group

OSPFv3 Router with ID (10.10.13.101) (Process ID 1)

Group size 5, Head 2, Search Index 4, Interval 240 sec
Next update due in 0:00:13
Current time 96532
Index 0 Timestamp 96546
Index 1 Timestamp 96788
Index 2 Timestamp 97048
Index 3 Timestamp 97293
Index 4 Timestamp 97548

Failure Head 0, Last 0 LSA group failure logged
```

```
            OSPFv3 Router with ID (10.10.10.102) (Process ID 5709)

Group size 5, Head 2, Search Index 4, Interval 240 sec
Next update due in 0:00:22
Current time 96532
Index 0 Timestamp 96555
Index 1 Timestamp 96801
Index 2 Timestamp 97041
Index 3 Timestamp 97287
Index 4 Timestamp 97546

Failure Head 0, Last 0 LSA group failure logged
```

The following is sample output from the **show ipv6 ospf timers rate-limit** command:

```
hostname# show ipv6 ospf timers rate-limit

List of LSAs that are in rate limit Queue
```

Related Commands

Command	Description
show ipv6 ospf	Shows all IPv6 settings in the OSPFv3 routing process.
show ipv6 ospf border-routers	Shows the internal OSPFv3 routing table entries to an area border router (ABR) and an autonomous system boundary router (ASBR).

show ipv6 ospf traffic

To display OSPFv3 traffic-related statistics for currently available interfaces, use the **show ipv6 ospf traffic** command in user EXEC or privileged EXEC mode.

show ipv6 ospf [*process_id*] **traffic** [*interface_name*]

Syntax Description

interface_name	(Optional) Specifies the name of the interface (for example, interface GigabitEthernet0/0). Use this option to segregate traffic to a specific interface.
process_id	(Optional) Specifies an internal ID that is locally assigned and can be any positive integer. This ID is the number assigned administratively when the OSPF routing process is enabled.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—
User EXEC	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to show OSPFv3 traffic-related information for available interfaces.

Examples

The following is sample output from the **show ipv6 ospf traffic** command:

```
hostname# show ipv6 ospf 10 traffic inside

Interface inside

Last clearing of interface traffic counters never

OSPFv3 packets received/sent
  Type          Packets               Bytes
  RX Invalid                      0 0
  RX Hello                     1232 53132
  RX DB des                      27 896
  RX LS req                       3 216
  RX LS upd                      28 2436
```

```
RX LS ack                        14 1064

```

Related Commands

Command	Description
show ipv6 ospf	Shows all IPv6 settings in the OSPFv3 routing process.
show ipv6 ospf border-routers	Shows the internal OSPFv3 routing table entries to an area border router (ABR) and an autonomous system boundary router (ASBR).

show ipv6 ospf virtual-links

To displayparameters and the current state of OSPFv3 virtual links, use the **show ipv6 ospf virtual-links** command in user EXEC or privileged EXEC mode.

show ipv6 ospf virtual-links

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—
User EXEC	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to show parameters and the current state of OSPFv3 virtual links.

Examples

The following is sample output from the **show ipv6 ospf virtual-links** command:

```
hostname# show ipv6 ospf virtual-links

Virtual Link OSPF_VL0 to router 172.16.6.6 is up
  Interface ID 27, IPv6 address FEC0:6666:6666::
  Run as demand circuit
  DoNotAge LSA allowed.
  Transit area 2, via interface ATM3/0, Cost of using 1
  Transmit Delay is 1 sec, State POINT_TO_POINT,
  Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
    Hello due in 00:00:06
```

Related Commands

Command	Description
show ipv6 ospf	Shows all IPv6 settings in the OSPFv3 routing process.
show ipv6 ospf border-routers	Shows the internal OSPFv3 routing table entries to an area border router (ABR) and an autonomous system boundary router (ASBR).

show ipv6 route

To display the contents of the IPv6 routing table, use the **show ipv6 route** command in privileged EXEC mode.

show ipv6 route [**failover**] [**cluster**] [**interface**] [**ospf**] [**summary**]

Syntax Description

cluster	(Optional) Displays the IPv6 routing table sequence number, IPv6 reconvergence timer status, and IPv6 routing entries sequence number in a cluster.
failover	(Optional) Displays the IPv6 routing table sequence number, IPv6 reconvergence timer status, and IPv6 routing entries sequence number.
interface	(Optional) Displays IPv6 interface-specific routes.
ospf	(Optional) Displays OSPFv3 routes.
summary	(Optional) Displays IPv6 route summaries.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Added support for the **failover, cluster, ospf, interface,** and **summary** keywords.

Usage Guidelines

The **show ipv6 route** command provides output similar to the **show route** command, except that the information is IPv6-specific.

The following information appears in the IPv6 routing table:

- Codes—Indicates the protocol that derived the route. Values are as follows:
  - C—Connected
  - L—Local
  - S—Static
  - R—RIP derived
  - B—BGP derived
  - I1—ISIS L1—Integrated IS-IS Level 1 derived

  - I2—ISIS L2—Integrated IS-IS Level 2 derived
  - IA—ISIS interarea—Integrated IS-IS interarea derived
- fe80::/10—Indicates the IPv6 prefix of the remote network.
- [0/0]—The first number in the brackets is the administrative distance of the information source; the second number is the metric for the route.
- via ::—Specifies the address of the next router to the remote network.
- inside—Specifies the interface through which the next router to the specified network can be reached.

Note The **clustering** and **failover** keywords do not appear unless these features are configured on the ASA.

Examples

The following is sample output from the **show ipv6 route** command:

```
hostname# show ipv6 route

IPv6 Routing Table - 7 entries
Codes: C - Connected, L - Local, S - Static, R - RIP, B - BGP
       U - Per-user Static route
       I1 - ISIS L1, I2 - ISIS L2, IA - ISIS interarea
       O - OSPF intra, OI - OSPF inter, OE1 - OSPF ext 1, OE2 - OSPF ext 2
L   fe80::/10 [0/0]
     via ::, inside
     via ::, vlan101
L   fec0::a:0:0:a0a:a70/128 [0/0]
     via ::, inside
C   fec0:0:0:a::/64 [0/0]
     via ::, inside
L   fec0::65:0:0:a0a:6570/128 [0/0]
     via ::, vlan101
C   fec0:0:0:65::/64 [0/0]
     via ::, vlan101
L   ff00::/8 [0/0]
     via ::, inside
     via ::, vlan101
S   ::/0 [0/0]
     via fec0::65:0:0:a0a:6575, vlan101
```

The following is sample output from the **show ipv6 route failover** command:

```
hostname# show ipv6 route failover

IPv6 Routing Table - 6 entries
Codes: C - Connected, L - Local, S - Static
       O - OSPF intra, OI - OSPF inter, OE1 - OSPF ext 1, OE2 - OSPF ext 2
           ON1 - OSPF NSSA ext 1, ON2 - OSPF NSSA ext 2
IPv6 Routing table seq num 0
IPv6 Reconvergence timer expired

O   2009::1/128 [110/10]
     via fe80::217:94ff:fe85:4401, inside seq 0
OE2  2011::/64 [110/20]
     via fe80::217:94ff:fe85:4401, inside seq 0
S   4001::1/128 [0/0]
     via 4001::2, inside seq 0
C   7001::1/128 [0/0]
     via ::, outside seq 0
```

```
L   fe80::/10 [0/0]
     via ::, inside seq 0
     via ::, outside seq 0
L   ff00::/8 [0/0]
     via ::, inside seq 0
     via ::, outside seq 0
```

The following is sample output from the **show ipv6 route cluster** command on the master unit:

```
hostname/LB1/master(config)# show ipv6 route cluster

IPv6 Routing Table - 5 entries
Codes: C - Connected, L - Local, S - Static
       O - OSPF intra, OI - OSPF inter, OE1 - OSPF ext 1, OE2 - OSPF ext 2
            ON1 - OSPF NSSA ext 1, ON2 - OSPF NSSA ext 2
IPv6 Routing table seq num 2
IPv6 Reconvergence timer expired

OE2  2001::/58 [110/20]
     via fe80::21f:9eff:fe2a:78ba, inside seq 2
...
```

The following is sample output from the **show ipv6 route cluster** command on the slave unit during a role change:

```
hostname/LB2/slave(config)# cluster master
INFO: Wait for existing master to quit. Use "show cluster info"
to check status. Use "cluster remove unit <name>" to force
master unit out of the cluster if for some reason it refuses
to quit within reasonable time
hostname/LB2/slave(config)#
hostname/LB2/master(config)#
hostname/LB2/master(config)# show ipv6 route cluster

IPv6 Routing Table - 5 entries
Codes: C - Connected, L - Local, S - Static
       O - OSPF intra, OI - OSPF inter, OE1 - OSPF ext 1, OE2 - OSPF ext 2
            ON1 - OSPF NSSA ext 1, ON2 - OSPF NSSA ext 2
IPv6 Routing table seq num 3
IPv6 Reconvergence timer expires in 61 secs

OE2  2001::/58 [110/20]
     via fe80::21f:9eff:fe2a:78ba, inside seq 2
...
```

Related Commands

Command	Description
debug ipv6 route	Displays debugging messages for IPv6 routing table updates and route cache updates.
ipv6 route	Adds a static entry to the IPv6 routing table.

show ipv6 routers

To display IPv6 router advertisement information received from on-link routers, use the **show ipv6 routers** command in privileged EXEC mode.

show ipv6 routers [*if_name*]

Syntax Description

if_name	(Optional) The internal or external interface name, as designated by the **nameif** command, that you want to display information about.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

When an interface name is not specified, information on all IPv6 interfaces is displayed. Specifying an interface name displays information about the specified interface.

Examples

The following is sample output from the **show ipv6 routers** command when entered without an interface name:

```
hostname# show ipv6 routers
Router FE80::83B3:60A4 on outside, last update 3 min
  Hops 0, Lifetime 6000 sec, AddrFlag=0, OtherFlag=0
  Reachable time 0 msec, Retransmit time 0 msec
  Prefix 3FFE:C00:8007::800:207C:4E37/96 autoconfig
    Valid lifetime -1, preferred lifetime -1
Router FE80::290:27FF:FE8C:B709 on inside, last update 0 min
  Hops 64, Lifetime 1800 sec, AddrFlag=0, OtherFlag=0
  Reachable time 0 msec, Retransmit time 0 msec
```

Related Commands

Command	Description
ipv6 route	Adds a static entry to the IPv6 routing table.

show ipv6 traffic

To display statistics about IPv6 traffic, use the **show ipv6 traffic** command in privileged EXEC mode.

show ipv6 traffic

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the **clear ipv6 traffic** command to clear the traffic counters.

Examples

The following is sample output from the **show ipv6 traffic** command:

```
hostname# show ipv6 traffic
IPv6 statistics:
  Rcvd:  545 total, 545 local destination
         0 source-routed, 0 truncated
         0 format errors, 0 hop count exceeded
         0 bad header, 0 unknown option, 0 bad source
         0 unknown protocol, 0 not a router
         218 fragments, 109 total reassembled
         0 reassembly timeouts, 0 reassembly failures
  Sent:  228 generated, 0 forwarded
         1 fragmented into 2 fragments, 0 failed
         0 encapsulation failed, 0 no route, 0 too big
  Mcast: 168 received, 70 sent

ICMP statistics:
  Rcvd: 116 input, 0 checksum errors, 0 too short
        0 unknown info type, 0 unknown error type
        unreach: 0 routing, 0 admin, 0 neighbor, 0 address, 0 port
        parameter: 0 error, 0 header, 0 option
        0 hopcount expired, 0 reassembly timeout,0 too big
        0 echo request, 0 echo reply
        0 group query, 0 group report, 0 group reduce
```

```
        0 router solicit, 60 router advert, 0 redirects
        31 neighbor solicit, 25 neighbor advert
  Sent: 85 output, 0 rate-limited
        unreach: 0 routing, 0 admin, 0 neighbor, 0 address, 0 port
        parameter: 0 error, 0 header, 0 option
        0 hopcount expired, 0 reassembly timeout,0 too big
        0 echo request, 0 echo reply
        0 group query, 0 group report, 0 group reduce
        0 router solicit, 18 router advert, 0 redirects
        33 neighbor solicit, 34 neighbor advert

UDP statistics:
  Rcvd: 109 input, 0 checksum errors, 0 length errors
        0 no port, 0 dropped
  Sent: 37 output

TCP statistics:
  Rcvd: 85 input, 0 checksum errors
  Sent: 103 output, 0 retransmitted
```

Related Commands

Command	Description
clear ipv6 traffic	Clears IPv6 traffic counters.

CHAPTER 51

show isakmp ipsec-over-tcp stats through show ospf virtual-links Commands

show isakmp ipsec-over-tcp stats

To display runtime statistics for IPsec over TCP, use the **show isakmp ipsec-over tcp stats** command in global configuration mode or privileged EXEC mode.

show isakmp ipsec-over-tcp stats

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	The **show isakmp ipsec-over-tcp stats** command was introduced.
7.2(1)	The **show isakmp ipsec-over-tcp stats** command was deprecated. The **show crypto isakmp ipsec-over-tcp stats** command replaces it.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

The output from this command includes the following fields:

- Embryonic connections
- Active connections
- Previous connections
- Inbound packets
- Inbound dropped packets
- Outbound packets
- Outbound dropped packets
- RST packets
- Received ACK heart-beat packets
- Bad headers
- Bad trailers
- Timer failures

- Checksum errors
- Internal errors

Examples

The following example, issued in global configuration mode, displays ISAKMP statistics:

```
hostname(config)# show isakmp ipsec-over-tcp stats
Global IPsec over TCP Statistics
--------------------------------
Embryonic connections: 2
Active connections: 132
Previous connections: 146
Inbound packets: 6000
Inbound dropped packets: 30
Outbound packets: 0
Outbound dropped packets: 0
RST packets: 260
Received ACK heart-beat packets: 10
Bad headers: 0
Bad trailers: 0
Timer failures: 0
Checksum errors: 0
Internal errors: 0
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto isakmp	Clears all the ISAKMP configuration.
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.
clear crypto isakmp sa	Clears the IKE runtime SA database.
crypto isakmp enable	Enables ISAKMP negotiation on the interface on which the IPsec peer communicates with the ASA.
show running-config crypto isakmp	Displays all the active ISAKMP configuration.

show isakmp sa

To display the IKE runtime SA database, use the **show isakmp sa** command in global configuration mode or privileged EXEC mode.

show isakmp sa [**detail**]

Syntax Description

detail	Displays detailed output about the SA database.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	•	—
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	The **show isakmp sa** command was introduced.
7.2(1)	This command was deprecated. The **show crypto isakmp sa** command replaces it.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

The output from this command includes the following fields:

Detail not specified.

IKE Peer	Type	Dir	Rky	State
209.165.200.225	L2L	Init	No	MM_Active

Detail specified.

IKE Peer	Type	Dir	Rky	State	Encrypt	Hash	Auth	Lifetime
209.165.200.225	L2L	Init	No	MM_Active	3des	md5	preshrd	86400

Examples

The following example, entered in global configuration mode, displays detailed information about the SA database:

```
hostname(config)# show isakmp sa detail

IKE Peer  Type  Dir   Rky  State      Encrypt Hash  Auth    Lifetime
1 209.165.200.225 User  Resp  No   AM_Active  3des    SHA   preshrd 86400

IKE Peer  Type  Dir   Rky  State      Encrypt Hash  Auth    Lifetime
2 209.165.200.226 User  Resp  No   AM_ACTIVE  3des    SHA   preshrd 86400

IKE Peer  Type  Dir   Rky  State      Encrypt Hash  Auth    Lifetime
3 209.165.200.227 User  Resp  No   AM_ACTIVE  3des    SHA   preshrd 86400

IKE Peer  Type  Dir   Rky  State      Encrypt Hash  Auth    Lifetime
4 209.165.200.228 User  Resp  No   AM_ACTIVE  3des    SHA   preshrd 86400

hostname(config)#
```

- Initiator Tunnels
- Initiator Fails
- Responder Fails
- System Capacity Fails

- Auth Fails
- Decrypt Fails
- Hash Valid Fails
- No Sa Fails

Examples

The following example, issued in global configuration mode, displays ISAKMP statistics:

```
hostname(config)# show isakmp stats
Global IKE Statistics
Active Tunnels: 132
Previous Tunnels: 132
In Octets: 195471
In Packets: 1854
In Drop Packets: 925
In Notifys: 0
In P2 Exchanges: 132
In P2 Exchange Invalids: 0
In P2 Exchange Rejects: 0
In P2 Sa Delete Requests: 0
Out Octets: 119029
Out Packets: 796
Out Drop Packets: 0
Out Notifys: 264
Out P2 Exchanges: 0
Out P2 Exchange Invalids: 0
Out P2 Exchange Rejects: 0
Out P2 Sa Delete Requests: 0
Initiator Tunnels: 0
Initiator Fails: 0
Responder Fails: 0
System Capacity Fails: 0
Auth Fails: 0
Decrypt Fails: 0
Hash Valid Fails: 0
No Sa Fails: 0
hostname(config)#
```

Related Commands

Command	Description
clear configure isakmp	Clears all the ISAKMP configuration.
clear configure isakmp policy	Clears all ISAKMP policy configuration.
clear isakmp sa	Clears the IKE runtime SA database.
isakmp enable	Enables ISAKMP negotiation on the interface on which the IPsec peer communicates with the ASA.
show running-config isakmp	Displays all the active ISAKMP configuration.

show kernel

To display information that the Linux brctl utility provides that you can use for debugging, use the **show kernel** command in privileged EXEC mode.

show kernel [process | bridge | cgroup-controller | ifconfig | module]

Syntax Description

bridge	Displays tap bridges.
cgroup-controller	Displays the cgroup-controller statistics.
ifconfig	Displays the tap and bridge interface statistics.
module	Displays the modules that are installed and running.
process	Displays the current status of the active kernel processes running on the ASA.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
8.0(2)	This command was introduced.
8.4(1)	The **cgroup-controller** keyword was added.
8.6(1)	The **ifconfig**, **module**, and **bridge** keywords were added.

Usage Guidelines

This command displays statistics for the various processes running on the kernel.

Examples

The following example displays output from the **show kernel process** command:

```
hostname# show kernel process

PID PPID PRI NI      VSIZE      RSS      WCHAN STAT  RUNTIME COMMAND
  1    0  16  0     991232      268 3725684979    S       78 init

hostname#
```

Table 51-1 shows each field description.

Table 51-1 show kernel process Fields

Field	Description
PID	The process ID.
PPID	The parent process ID.
PRI	The priority of the process.
NI	The nice value, which is used in priority computation. The values range from 19 (nicest) to -19 (not nice to others),
VSIZE	The virtual memory size in bytes.
RSS	The resident set size of the process, in kilobytes.
WCHAN	The channel in which the process is waiting.
STAT	The state of the process: • R—Running • S—Sleeping in an interruptible wait • D—Waiting in an uninterruptible disk sleep • Z—zombie • T—Traced or stopped (on a signal) • P—Paging
RUNTIME	The number of jiffies that the process has been scheduled in user mode and kernel mode. The runtime is the sum of utime and stime.
COMMAND	The process name.

The following example displays output from the **show kernel module** command:

```
hostname# show kernel module

Module                  Size  Used by    Tainted: P
cpp_base              861808  2
kvm_intel              44104  8
kvm                   174304  1 kvm_intel
msrif                   4180  0
tscsync                 3852  0
```

The following example displays output for the **show kernel ifconfig** commands:

```
hostname# show kernel ifconfig

Related Commands

Command	Description
show module	Shows information about the installed modules in the ASA.

show kernel bridge

To display the Linux bridges, their member ports, and MAC addresses that have been learned at each port that you can use for debugging, use the **show kernel bridge** command in privileged EXEC mode.

show kernel bridge [**mac-address** *bridge name*]

Syntax Description

bridge name	Displays the bridge name.
mac-address	Displays the MAC address associated with each port.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
8.6(1)	This command was introduced.

Usage Guidelines

This command shows the Linux bridges, their member ports, and the MAC addresses that have been learned at each port (including remote MAC addresses) that you can use for debugging.

Examples

The following example displays output from the **show kernel bridge** command:

```
hostname# show kernel bridge

bridge name    bridge id        STP enabled interfaces
br0        8000.0e3cd8a8909f    no        tap1
                                tap3
br1       8000.26d29f51a490     no        tap2
                                tap4
                                tap5hostname#
```

The following example displays output from the **show kernel bridge mac-address** command:

```
hostname# show kernel bridge mac-address br1

port no    mac addr       is local?   ageing timer
 1    00:21:d8:cb:dc:f7    no          12.93
 3    00:22:bd:d8:7d:da    no          12.93
 2    26:d2:9f:51:a4:90    yes          0.00
 1    4e:a4:e0:73:1f:ab    yes          0.00
```

```
3     52:04:38:3d:79:c0    yes          0.00
```

Related Commands

Command	Description
show kernel	Shows information about the installed modules in the ASA.

show lacp

To display EtherChannel LACP information such as traffic statistics, system identifier, and neighbor details, enter this command in privileged EXEC mode.

show lacp {[*channel_group_number*] {**counters** | **internal** | **neighbor**} | **sys-id**}

Syntax Description

channel_group_number	(Optional) Specifies the EtherChannel channel group number, between 1 and 48, and only shows information about this channel group.
counters	Shows counters for the number of LACPDUs and markers sent and received.
internal	Shows internal information.
neighbor	Shows neighbor information.
sys-id	Shows the LACP system ID.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.4(1)	We introduced this command.

Examples

The following is sample output from the **show lacp sys-id** command:

```
hostname# show lacp sys-id
32768,001c.c4e5.cfee
```

The following is sample output from the **show lacp counters** command:

```
hostname# show lacp counters

Related Commands

Command	Description
channel-group	Adds an interface to an EtherChannel.
interface port-channel	Configures an EtherChannel.
lacp max-bundle	Specifies the maximum number of active interfaces allowed in the channel group.
lacp port-priority	Sets the priority for a physical interface in the channel group.
lacp system-priority	Sets the LACP system priority.
port-channel load-balance	Configures the load-balancing algorithm.
port-channel min-bundle	Specifies the minimum number of active interfaces required for the port-channel interface to become active.
show port-channel	Displays EtherChannel information in a detailed and one-line summary form. This command also displays the port and port-channel information.
show port-channel load-balance	Displays port-channel load-balance information along with the hash result and member interface selected for a given set of parameters.

show lacp cluster

To show the cLACP system MAC and ID, use the **show lacp cluster** command in privileged EXEC mode.

show lacp cluster {**system-mac** | **system-id**}

Syntax Description

system-mac	Shows the system ID and whether it was auto-generated or entered manually.
system-id	Shows the system ID and priority.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

Set the cLACP system ID and priority using the **clacp system-mac** command.

Examples

The following is sample output from the **show lacp cluster system-mac** command:

```
hostname(cfg-cluster)# show lacp cluster system-mac
lacp cluster system MAC is automatically generated: a300.010a.010a.
```

The following is sample output from the **show lacp cluster system-id** command:

```
hostname(cfg-cluster)# show lacp cluster system-id
5    ,a300.010a.010a
```

Related Commands

Command	Description
clacp system-mac	Sets the cLACP system ID and priority.

show local-host

To display the network states of local hosts, use the **show local-host** command in privileged EXEC mode.

show local-host | include interface [*ip_address*] [**detail**] [**all**][**brief**] [**connection** {**tcp** *start*[*-end*] | **udp** *start*[*-end*] | **embryonic** *start*[*-end*]}]

Syntax Description

all	(Optional) Includes local hosts connecting to the ASA and from the ASA.
brief	(Optional) Displays brief information on local hosts.
connection	(Optional) Displays three types of filters based on the number and type of connections: TCP, UDP and embryonic. These filters can be used individually or jointly.
detail	(Optional) Displays the detailed network states of local host information, including more information about active xlates and network connections.
include interface	Specifies the IP addresses being used on each interface.
ip_address	(Optional) Specifies the local host IP address.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.2(1)	For models with host limits, this command now shows which interface is considered to be the outside interface.
7.2(4)	Two new options, **connection** and **brief**, were added to the **show local-host** command so that the output is filtered by the number of connections for the inside hosts.
9.1(2)	The Smart Call Home information sent to Cisco for telemetry-based alerts from the **show local-host** command has been changed to the **show local-host	include interface** command.

Usage Guidelines

The **show local-host** command lets you display the network states of local hosts. A local-host is created for any host that forwards traffic to, or through, the ASA.

This command lets you show the translation and connection slots for the local hosts. This command provides information for hosts that are configured with the **nat 0 access-list** command when normal translation and connection states may not apply.

This command also displays the connection limit values. If a connection limit is not set, the value displays as 0 and the limit is not applied.

For models with host limits, In routed mode, hosts on the inside (Work and Home zones) count towards the limit only when they communicate with the outside (Internet zone). Internet hosts are not counted towards the limit. Hosts that initiate traffic between Work and Home are also not counted towards the limit. The interface associated with the default route is considered to be the Internet interface. If there is no default route, hosts on all interfaces are counted toward the limit. In transparent mode, the interface with the lowest number of hosts is counted towards the host limit.

In the event of a SYN attack (with TCP intercept configured), the **show local-host** command output includes the number of intercepted connections in the usage count. This field typically displays only full open connections.

In the **show local-host** command output, the **TCP embryonic count to host counter** is used when a maximum embryonic limit (TCP intercept watermark) is configured for a host using a static connection. This counter shows the total embryonic connections to the host from other hosts. If this total exceeds the maximum configured limit, TCP intercept is applied to new connections to the host.

Examples

The following is sample output from the **show local-host** command:

```
hostname# show local-host
Interface inside: 0 active, 0 maximum active, 0 denied
Interface outside: 1 active, 2 maximum active, 0 denied
```

The following is sample output from the **show local-host** command on an ASA with host limits:

```
hostname# show local-host
Detected interface 'outside' as the Internet interface. Host limit applies to all other
interfaces.

Current host count: 3, towards licensed host limit of: 50

Interface inside: 1 active, 1 maximum active, 0 denied
Interface outside: 0 active, 0 maximum active, 0 denied
```

The following is sample output from the **show local-host** command on an ASA with host limits. But without a default route, the host limits apply to all interfaces. The default route interface might not be detected if the default route or the interface that the route uses is down.

```
hostname# show local-host
Unable to determine Internet interface from default route. Host limit applied to all
interfaces.

Current host count: 3, towards licensed host limit of: 50

Interface c1in: 1 active, 1 maximum active, 0 denied
Interface c1out: 0 active, 0 maximum active, 0 denied
```

The following is sample output from the **show local-host** command on an ASA with unlimited hosts:

```
hostname# show local-host
Licensed host limit: Unlimited

Interface c1in: 1 active, 1 maximum active, 0 denied
Interface c1out: 0 active, 0 maximum active, 0 denied
```

The following examples show the network states of local hosts:

```
hostname# show local-host all

The following example shows all hosts who have at least four UDP connections and have between one to 10 TCP connections at the same time:

```
hostname# show local-host connection udp 4 tcp 1-10
Interface mng: 0 active, 3 maximum active, 0 denied
Interface INSIDE: 4 active, 5 maximum active, 0 denied
local host: <10.1.1.11>,
       TCP flow count/limit = 1/unlimited TCP embryonic count to host = 0 TCP intercept
       watermark = unlimited UDP flow count/limit = 4/unlimited
Xlate:
       Global 192.168.1.24 Local 10.1.1.11 Conn: UDP out 192.168.1.10:80 in
       10.1.1.11:1730 idle 0:00:21 bytes 0 flags - UDP out 192.168.1.10:80 in
       10.1.1.11:1729 idle 0:00:22 bytes 0 flags - UDP out 192.168.1.10:80 in
       10.1.1.11:1728 idle 0:00:23 bytes 0 flags - UDP out 192.168.1.10:80 in
       10.1.1.11:1727 idle 0:00:24 bytes 0 flags - TCP out 192.168.1.10:22 in
       10.1.1.11:27337 idle 0:01:55 bytes 2641 flags UIO Interface OUTSIDE: 3 active, 5
       maximum active, 0 denied
```

The following example shows local-host addresses and connection counters using the **brief** option:

```
hostname# show local-host connection udp 2
Interface mng: 0 active, 3 maximum active, 0 denied
Interface INSIDE: 4 active, 5 maximum active, 0 denied
local host: <10.1.1.11>,
       TCP flow count/limit = 1/unlimited
       TCP embryonic count to host = 0
       TCP intercept watermark = unlimited UDP flow count/limit = 4/unlimited
Interface OUTSIDE: 3 active, 5 maximum active, 0 denied
```

The following examples shows the output when using the **brief** and **connection** options:

```
hostname# show local-host brief
Interface inside: 1 active, 1 maximum active, 0 denied
Interface outside: 1 active, 1 maximum active, 0 denied
Interface mgmt: 5 active, 6 maximum active, 0 denied

hostname# show local-host connection
Interface inside: 1 active, 1 maximum active, 0 denied
Interface outside: 1 active, 1 maximum active, 0 denied
Interface mgmt: 5 active, 6 maximum active, 0 denied
```

Related Commands

Command	Description
clear local-host	Releases network connections from local hosts displayed by the **show local-host** command.
nat	Associates a network with a pool of global IP addresses.

show logging

To show the logs in the buffer or other logging settings, use the **show logging** command in privileged EXEC mode.

show logging [**message** [*syslog_id* | **all**] | **asdm** | **queue** | **setting**]

Syntax Description

all	(Optional) Displays all syslog message IDs, along with whether they are enabled or disabled.
asdm	(Optional) Displays ASDM logging buffer content.
message	(Optional) Displays messages that are at a non-default level. See the **logging message** command to set the message level.
queue	(Optional) Displays the syslog message queue.
setting	(Optional) Displays the logging setting, without displaying the logging buffer.
syslog_id	(Optional) Specifies a message number to display.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0(2)	Indicates whether a syslog server is configured to use an SSL/TLS connection.
8.4(1)	For the **show logging** command, the output includes an enry for the current state of the audit block.

Usage Guidelines

If the **logging buffered** command is in use, the **show logging** command without any keywords shows the current message buffer and the current settings.

The **show logging queue** command allows you to display the following:

- Number of messages that are in the queue
- Highest number of messages recorded that are in the queue
- Number of messages that are discarded because block memory was not available to process them
- Separate queues for traps and other syslog messages

Note Zero is an acceptable number for the configured queue size and represents the maximum queue size allowed. The output for the **show logging queue** command will display the actual queue size if the the configured queue size is zero.

Examples

The following is sample output from the **show logging** command:

```
hostname(config)# show logging
Syslog logging: enabled
    Facility: 20
    Timestamp logging: enabled
    Standby logging:disabled
    Debug-trace logging: disabled
    Console logging: level informational, 3962 messages logged
    Monitor logging: disabled
    Buffer logging: disabled
    Trap logging: level informational, facility 20, 20549 messages logged
        Logging to inside 10.2.5.3 tcp/50001 connected
    Permit-hostdown state
    History logging: disabled
    Device ID: disabled
    Mail logging: disabled
    ASDM logging: disabled
```

Note Valid values of *state* are enabled, disabled, disabled-blocking, and disabled-not blocking.

The following is sample output from the **show logging** command with a secure syslog server configured:

```
hostname(config)# logging host inside 10.0.0.1 TCP/1500 secure
hostname(config)# show logging
Syslog logging: disabled
    Facility:
    Timestamp logging: disabled
    Deny Conn when Queue Full: disabled
    Console logging: level debugging, 135 messages logged
    Monitor logging: disabled
    Buffer logging: disabled
    Trap logging: list show _syslog, facility, 20, 21 messages logged
        Logging to inside 10.0.0.1 tcp/1500 SECURE
    History logging: disabled
    Device ID: disabled
    Mail logging: disabled
    ASDM logging disabled
```

The following is sample output from the **show logging queue** command:

```
hostname(config)# show logging queue
Logging Queue length limit: 512 msg(s)
0 msg(s) discarded due to queue overflow
0 msg(s) discarded due to memory allocation failure
Current 0 msgs on queue, 0 msgs most on queue
```

The following is sample output from the **show logging message all** command:

```
hostname(config)# show logging message all

syslog 111111: default-level alerts (enabled)
syslog 101001: default-level alerts (enabled)
```

```
syslog 101002: default-level alerts (enabled)
syslog 101003: default-level alerts (enabled)
syslog 101004: default-level alerts (enabled)
syslog 101005: default-level alerts (enabled)
syslog 102001: default-level alerts (enabled)
syslog 103001: default-level alerts (enabled)
syslog 103002: default-level alerts (enabled)
syslog 103003: default-level alerts (enabled)
syslog 103004: default-level alerts (enabled)
syslog 103005: default-level alerts (enabled)
syslog 103011: default-level alerts (enabled)
syslog 103012: default-level informational (enabled)
```

Related Commands

Command	Description
logging asdm	Enables logging to ASDM
logging buffered	Enables logging to the buffer.
logging host	Defines a syslog server.
logging message	Sets the message level or disables messages.
logging queue	Configures the logging queue.

show logging flow-export-syslogs

To display all of the syslog messages whose information is also captured by NetFlow and that will be affected by the **logging flow-export-syslogs enable | disable** commands, use the **show logging flow-export-syslogs** command in privileged EXEC mode.

show logging flow-export-syslogs

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.1(1)	This command was introduced.

Usage Guidelines

After you enter the **logging flow-export syslogs disable** command, make sure that you know which syslog messages have been disabled. The disabled syslog messages are as follows:

Syslog Message	Description
106015	A TCP flow was denied because the first packet was not a SYN packet.
106023	A flow that is denied by an ingress ACL or an egress ACL that is attached to an interface through the **access-group** command.
106100	A flow that is permitted or denied by an ACL.
302013 and 302014	A TCP connection and deletion.
302015 and 302016	A UDP connection and deletion.
302017 and 302018	A GRE connection and deletion.
302020 and 302021	An ICMP connection and deletion.
313001	An ICMP packet to the ASA was denied.
313008	An ICMPv6 packet to the ASA was denied.
710003	An attempt to connect to the ASA was denied.

Examples

The following is sample output from the **show logging flow-export-syslogs** command, which lists the syslog messages that will be disabled:

```
hostname(config)# show logging flow-export-syslogs

Syslog ID          Type                 Status
302013           Flow Created          Enabled
302015           Flow Created          Enabled
302017           Flow Created          Enabled
302020           Flow Created          Enabled
302014           Flow Deleted          Enabled
302016           Flow Deleted          Enabled
302018           Flow Deleted          Enabled
302021           Flow Deleted          Enabled
106015           Flow Denied           Enabled
106023           Flow Denied           Enabled
313001           Flow Denied           Enabled
313008           Flow Denied           Enabled
710003           Flow Denied           Enabled
106100           Flow Created/Denied   Enabled
```

Related Commands

Commands	Description
flow-export destination *interface-name ipv4-address | hostname udp-port*	Specifies the IP address or hostname of the NetFlow collector, and the UDP port on which the NetFlow collector is listening.
flow-export template timeout-rate *minutes*	Controls the interval at which the template information is sent to the NetFlow collector.
logging flow-export-syslogs enable	Enables syslog messages after you have entered the **logging flow-export-syslogs disable** command, and the syslog messages that are associated with NetFlow data.
show flow-export counters	Displays a set of runtime counters for NetFlow.

show logging rate-limit

To display disallowed syslog messages, use the **show logging rate-limit** command in privileged EXEC mode.

show logging rate-limit

Syntax Description

This command has no arguments or keywords.

Defaults

This command has no default settings.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

After the information is cleared, nothing more displays until the hosts reestablish their connections.

Examples

The following example shows sample output from the **show logging rate-limit** command:

```
hostname(config)# show logging rate-limit
%ASA-7-710005: TCP request discarded from 171.69.39.0/2678 to management:10.89.130.244/443

```

Related Commands

Command	Description
show logging	Displays the enabled logging options.

show mac-address-table

To show the MAC address table, use the **show mac-address-table** command in privileged EXEC mode.

show mac-address-table [*interface_name* | **count** | **static**]

Syntax Description

count	(Optional) Lists the total number of dynamic and static entries.
interface_name	(Optional) Identifies the interface name for which you want to view MAC address table entries.
static	(Optional) Lists only static entries.

Defaults

If you do not specify an interface, all interface MAC address entries are shown.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	—	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show mac-address-table** command:

```
hostname# show mac-address-table
interface          mac address       type      Time Left
------------------------------------------------------------------------
outside            0009.7cbe.2100    static      -
inside             0010.7cbe.6101    static      -
inside             0009.7cbe.5101    dynamic     10
```

The following is sample output from the **show mac-address-table** command for the inside interface:

```
hostname# show mac-address-table inside
interface          mac address       type      Time Left
------------------------------------------------------------------------
inside             0010.7cbe.6101    static      -
inside             0009.7cbe.5101    dynamic     10
```

The following is sample output from the **show mac-address-table count** command:

```
hostname# show mac-address-table count
Static     mac-address bridges (curr/max): 0/65535
Dynamic    mac-address bridges (curr/max): 103/65535
```

Related Commands

Command	Description
firewall transparent	Sets the firewall mode to transparent.
mac-address-table aging-time	Sets the timeout for dynamic MAC address entries.
mac-address-table static	Adds a static MAC address entry to the MAC address table.
mac-learn	Disables MAC address learning.

show management-access

To display the name of the internal interface configured for management access, use the show management-access command in privileged EXEC mode.

show management-access

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **management-access** command lets you define an internal management interface using the IP address of the firewall interface specified in *mgmt_if*. (The interface names are defined by the **nameif** command and displayed in quotes, " ", in the output of the **show interface** command.)

Examples

The following example shows how to configure a firewall interface named "inside" as the management access interface and display the result:

```
hostname(config)# management-access inside
hostname(config)# show management-access
management-access inside
```

Related Commands

Command	Description
clear configure management-access	Removes the configuration of an internal interface for management access of the ASA.
management-access	Configures an internal interface for management access.

show memory

To display a summary of the maximum physical memory and current free memory available to the operating system, use the **show memory** command in privileged EXEC mode.

[**cluster exec**] **show memory** [**detail**]

Syntax Description

cluster exec	(Optional) In a clustering environment, enables you to issue the **show memory** command in one unit and run the command in all the other units at the same time.
detail	(Optional) Displays a detailed view of free and allocated system memory.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	The **cluster exec** option was added.

Usage Guidelines

The **show memory** command lets you display a summary of the maximum physical memory and current free memory available to the operating system. Memory is allocated as needed.

You can also display the information from the **show memory** command using SNMP.

You can use the **show memory detail** output with the **show memory binsize** command to debug memory leaks.

The **show memory detail** command output can be broken down into three sections: Summary, DMA Memory, and HEAP Memory. The summary displays how the total memory is allocated. Memory that is not tied to DMA or reserved is considered the HEAP. The Free Memory value is the unused memory in the HEAP. The Allocated memory in use value is how much of the HEAP has been allocated. The breakdown of HEAP allocation is displayed later in the output. Reserved memory and DMA Reserved memory are used by different system processes and primarily VPN services.

Values displayed in the allocated memory statistics total (bytes) column do not reflect real values (MEMPOOL_GLOBAL_SHARED POOL STATS) in the **show memory detail** command output.

The output shows that the block of size 49,152 was allocated then returned to the free pool, and another block of size 131,072 was allocated. In this case, you would think that free memory decreased by 131,072-49,152=81,920 bytes, but it actually decreased by 100,000 bytes (see the Free memory line).

```
hostname# show memory detail

MEMPOOL_GLOBAL_SHARED POOL STATS:           MEMPOOL_GLOBAL_SHARED POOL STATS:

        49152            10         491520           49152             9         442368
        65536           125        8192000           65536           125        8192000
        98304             3         294912           98304             3         294912
       131072            18        2359296          131072            19        2490368
```

The following output confirms that a block of size 150,000 was allocated, instead of 131,072:

```
hostname# show memory binsize 131072
MEMPOOL_DMA pool bin stats:
MEMPOOL_GLOBAL_SHARED pool bin stats:
pc = 0x8eda524, size = 150000   , count = 1
pc = 0x8f08054, size = 163904   , count = 1
pc = 0x846e477, size = 139264   , count = 1
pc = 0x8068691, size = 393216   , count = 3
pc = 0x8eea09b, size = 131072   , count = 1
pc = 0x88ca830, size = 141212   , count = 1
pc = 0x9589e93, size = 593580   , count = 4
pc = 0x9589bd2, size = 616004   , count = 4
pc = 0x8f2e060, size = 327808   , count = 2
pc = 0x8068284, size = 182000   , count = 1

0x8eda524 <logger_buffer_init_int+148 at syslog/main.c:403>
```

The approximate number of total bytes shown in the **show memory detail** command output is by design. There are two reasons for this:

- For each fragment size, if you had to get the sum of all fragments, a performance impact would occur because there can be very large number of allocations for a single fragment size and to get the accurate value, you need to walk over thousands of chunks.

- For each binsize, you need to walk through the doubly linked list of allocations and there could be many allocations. In this case, you cannot hog the CPU for an extended period and would need to suspend allocations periodically. After you resume allocations, other processes may have allocated or deallocated memory and memory states may have changed. As a result, the total bytes column gives an approximate value instead of the real value.

Examples

The following is sample output from the **show memory** command:

```
hostname# show memory
Free memory:       845044716 bytes (79%)
Used memory:       228697108 bytes (21%)
-------------     ----------------
Total memory:     1073741824 bytes (100%)
```

The following is sample output from the **show memory detail** command:

```
hostname# show memory detail
Free memory:                   130546920 bytes (49%)
Used memory:                   137888536 bytes (51%)
Allocated memory in use:        33030808 bytes (12%)
Reserved memory:                65454208 bytes (24%)
DMA Reserved memory:            39403520 bytes (15%)
-----------------------------------------------------
Total memory:                  268435456 bytes (100%)
Dynamic Shared Objects(DSO):           0 bytes
DMA memory:
  Unused memory:                 3212128 bytes (8%)
  Crypto reserved memory:        2646136 bytes (7%)
  Crypto free:                   1605536 bytes (4%)
  Crypto used:                   1040600 bytes (3%)
  Block reserved memory:        33366816 bytes (85%)
  Block free:                   31867488 bytes (81%)
  Block used:                    1499328 bytes (4%)
  Used memory:                    178440 bytes (0%)
-----------------------------------------------------
  Total memory:                 39403520 bytes (100%)
  HEAP memory:
  Free memory:                 130546920 bytes (80%)
  Used memory:                  33030808 bytes (20%)
  Init used memory by library:   4218752 bytes (3%)
  Allocated memory:            28812056 bytes (18%)
-----------------------------------------------------
  Total memory:                 163577728 bytes (100%)

Least free memory: 122963528 bytes (75%)
Most used memory:   40614200 bytes (25%)

<More>
```

The following is sample output from the **show memory** command on the ASA 5525 after enabling the **jumbo-frame reservation** command and issuing the **write memory** command and the **reload** command:

```
hostname# show memory
Free memory:        3008918624 bytes (70%)
Used memory:        1286048672 bytes (30%)
-------------       ----------------------
Total memory:       4294967296 bytes (100%)
```

The following is sample output from the **show memory** command on the ASA 5525 without enabling the **jumbo-frame reservation** command:

```
hostname# show memory
Free memory:        3318156400 bytes (77%)
Used memory:         976810896 bytes (23%)
-------------       ------------------
Total memory:       4294967296 bytes (100%)
```

The following is sample output from the **show memory** command on the ASA 5515 after enabling the **jumbo-frame reservation** command:

```
hostname# show memory
Free memory:        3276619472 bytes (76%)
Used memory:        1018347824 bytes (24%)
-------------       ------------------
Total memory:       4294967296 bytes (100%)
```

The following is sample output from the **show memory** command on the ASA 5515 without enabling the **jumbo-frame reservation** command:

```
hostname# show memory
Free memory:        3481145472 bytes (81%)
Used memory:         813821824 bytes (19%)
-------------       ------------------
Total memory:       4294967296 bytes (100%)
```

The following is sample output from the **show memory** command on the ASA 5585 after enabling the **jumbo-frame reservation** command:

```
hostname# show memory
Free memory:        8883297824 bytes (69%)
Used memory:        4001604064 bytes (31%)
-------------       ------------------
Total memory:      12884901888 bytes (100%)
```

The following is sample output from the **show memory** command on the ASA 5585 without enabling the **jumbo-frame reservation** command:

```
hostname# show memory
Free memory:        9872205104 bytes (77%)
Used memory:        3012696784 bytes (23%)
-------------       ------------------
Total memory:      12884901888 bytes (100%)
```

The following is sample output from the **show memory** command on the ASA 5520, which does not support the **jumbo-frame** command:

```
hostname# show memory
ree memory:         206128232 bytes (38%)
Used memory:         330742680 bytes (62%)
-------------       -----------------
Total memory:        536870912 bytes (100%)
```

The following is sample output from the **show memory** command on the ASA 5505, which does not support the **jumbo-frame** command:

```
hostname# show memory
Free memory:           48457848 bytes (18%)
Used memory:          219977608 bytes (82%)
-------------         -----------------
Total memory:         268435456 bytes (100%
```

Related Commands

Command	Description
show memory profile	Displays information about the memory usage (profiling) of the ASA.
show memory binsize	Displays summary information about the chunks allocated for a specific bin size.

show memory api

To display the malloc stack APIs that are registered in the system , use the **show memory api** command in privileged EXEC mode.

show memory api

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command displays the malloc stack APIs that are registered in the system.

If any of the memory debugging features are turned on (that is, delay-free-poisoner, memory tracker, or memory profiler), their APIs appear in the **show memory api** command output.

Examples

This following is sample output from the **show memory api** command:

```
hostname# show memory api
Resource Manager (0) ->
Tracking (0) ->
Delayed-free-poisoner (0) ->
Core malloc package (0)
```

Related Commands

Command	Description
show memory profile	Displays information about the memory usage (profiling) of the ASA.
show memory binsize	Displays summary information about the chunks allocated for a specific bin size.

show memory app-cache

To observe memory usage by application, use the **show memory app-cache** command in privileged EXEC mode.

show memory app-cache [**threat-detection** | **host** | **flow** | **tcb** | **http** | **access-list**] [**detail**]

Syntax Descriptions

access-list	(Optional) Shows the application level memory cache for access lists.
detail	(Optional) Shows a detailed view of free and allocated system memory.
flow	(Optional) Shows the application level memory cache for flows.
host	(Optional) Shows application level memory cache for hosts.
http	(Optional) Shows application level memory cache for HTTP.
tcb	(Optional) Shows application level memory cache for TCB.
threat-detection	(Optional) Shows application level memory cache for threat detection.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.0(1)	This command was introduced.
8.1(1)	The **access-list** and **http** options were added.

Usage Guidelines

This command enables you to observe memory usage by application.

Examples

The following is sample output from the **show memory app-cache threat-detection** command:

```
hostname(config)# show memory app-cache threat-detection
LIMIT COUNT ALLOC FAILED BYTES USED
TOTAL 1350 460 115167 0 130926168
```

The following is sample output from the **show memory app-cache threat-detection detail** command:

```
hostname(config)# show memory app-cache threat-detection detail
CACHE NAME LIMIT COUNT ALLOC FAILED BYTES USED

Related Commands

Command	Description
show memory profile	Displays information about the memory usage (profiling) of the ASA.
show memory binsize	Displays summary information about the chunks allocated for a specific bin size.
show memory	Displays a summary of the maximum physical memory and current free memory available to the operating system.

show memory binsize

To display summary information about the chunks allocated for a specific bin size, use the **show memory binsize** command in privileged EXEC mode.

show memory binsize *size*

Syntax Description

size	Displays chunks (memory blocks) of a specific bin size. The bin size is from the "fragment size" column of the **show memory detail** command output.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command has no usage guidelines.

Examples

The following example displays summary information about a chunk allocated to a bin size of 500:

```
hostname# show memory binsize 500
pc = 0x00b33657, size = 460      , count = 1
```

Related Commands

Command	Description
show memory-caller address	Displays the address ranges configured on the ASA.
show memory profile	Displays information about the memory usage (profiling) of the ASA.
show memory	Displays a summary of the maximum physical memory and current free memory available to the operating system.

show memory delayed-free-poisoner

To display a summary of the **memory delayed-free-poisoner** queue usage, use the **show memory delayed-free-poisoner** command in privileged EXEC mode.

show memory delayed-free-poisoner

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the **clear memory delayed-free-poisoner** command to clear the queue and statistics.

Examples

This following is sample output from the **show memory delayed-free-poisoner** command:

```
hostname# show memory delayed-free-poisoner
delayed-free-poisoner statistics:
         3335600:  memory held in queue
            6095:  current queue count
               0:  elements dequeued
               3:  frees ignored by size
            1530:  frees ignored by locking
              27:  successful validate runs
               0:  aborted validate runs
        01:09:36:  local time of last validate
```

Table 51-2 describes the significant fields in the **show memory delayed-free-poisoner** command output.

Table 51-2 **show memory delayed-free-poisoner *Command Output Descriptions***

Field	Description
memory held in queue	The memory that is held in the delayed free-memory poisoner tool queue. Such memory is normally in the "Free" quantity in the **show memory** output if the delayed free-memory poisoner tool is not enabled.
current queue count	The number of elements in the queue.
elements dequeued	The number of elements that have been removed from the queue. This number begins to increase when most or all of the otherwise free memory in the system ends up in being held in the queue.
frees ignored by size	The number of free requests not placed into the queue because the request was too small to hold required tracking information.
frees ignored by locking	The number of free requests intercepted by the tool not placed into the queue because the memory is in use by more than one application. The last application to free the memory back to the system ends up placing such memory regions into the queue.
successful validate runs	The number of times since monitoring was enabled or cleared using the **clear memory delayed-free-poisoner** command that the queue contents were validated (either automatically or by the **memory delayed-free-poisoner validate** command).
aborted validate runs	The number of times since monitoring was enabled or cleared using the **clear memory delayed-free-poisoner** command that requests to check the queue contents have been aborted because more than one task (either the periodic run or a validate request from the CLI) attempted to use the queue at a time.
local time of last validate	The local system time when the last validate run completed.

Related Commands

Command	Description
clear memory delayed-free-poisoner	Clears the delayed free-memory poisoner tool queue and statistics.
memory delayed-free-poisoner enable	Enables the delayed free-memory poisoner tool.
memory delayed-free-poisoner validate	Forces validation of the elements in the delayed free-memory poisoner tool queue.

show memory profile

To display information about the memory usage (profiling) of the ASA, use the **show memory profile** command in privileged EXEC mode.

show memory profile [**peak**] [**detail | collated | status**]

Syntax Description

collated	(Optional) Collates the memory information displayed.
detail	(Optional) Displays detailed memory information.
peak	(Optional) Displays the peak capture buffer rather than the "in use" buffer.
status	(Optional) Displays the current state of memory profiling and the peak capture buffer**.**

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	—	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the **show memory profile** command to troubleshoot memory usage level and memory leaks. You can still see the profile buffer contents even if profiling has been stopped. Starting profiling clears the buffer automatically.

Note The ASA might experience a temporary reduction in performance when memory profiling is enabled.

Examples

The following is sample output from the **show memory profile** command:

```
hostname# show memory profile
Range: start = 0x004018b4, end = 0x004169d0, increment = 00000004
Total = 0
```

The output of the **show memory profile detail** command is divided into six data columns and one header column, at the far left. The address of the memory bucket corresponding to the first data column is given at the header column (the hexidecimal number). The data itself is the number of bytes that is held by the text/code that falls in the bucket address. A period (.) in the data column means no memory is held by

the text at this bucket. Other columns in the row correspond to the bucket address that is greater than the increment amount from the previous column. For example, the address bucket of the first data column in the first row is 0x001069e0. The address bucket of the second data column in the first row is 0x001069e4 and so on. Normally the header column address is the next bucket address; that is, the address of the last data column of the previous row plus the increment. All rows without any usage are suppressed. More than one such contiguous row can be suppressed, indicated with three periods at the header column (...).

The following is sample output from the **show memory profile detail** command:

```
hostname# show memory profile detail
Range: start = 0x00100020, end = 0x00e006e0, increment = 00000004
Total = 48941152
...
0x001069e0 . 24462 . . . .
...
0x00106d88 . 1865870 . . . .
...
0x0010adf0 . 7788 . . . .
...
0x00113640 . . . . 433152 .
...
0x00116790 2480 . . . . .
<snip>
```

The following is sample output from the **show memory profile collated** command:

```
hostname# show memory profile collated
Range: start = 0x00100020, end = 0x00e006e0, increment = 00000004
Total = 48941152
24462 0x001069e4
1865870 0x00106d8c
7788 0x0010adf4
433152 0x00113650
2480 0x00116790
<More>
```

The following is sample output from the **show memory profile peak** command, which shows the peak capture buffer:

```
hostname# show memory profile peak
Range: start = 0x004018b4, end = 0x004169d0, increment = 00000004
Total = 102400
```

The following is sample output from the **show memory profile peak detail** command, which shows the peak capture buffer and the number of bytes that is held by the text/code that falls in the corresponding bucket address:

```
hostname# show memory profile peak detail
Range: start = 0x004018b4, end = 0x004169d0, increment = 00000004
Total = 102400
...
0x00404c8c . . 102400 . . .
```

The following is sample output from the **show memory profile status** command, which shows the current state of memory profiling and the peak capture buffer:

```
hostname# show memory profile status
InUse profiling: ON
Peak profiling: OFF
Memory used by profile buffers: 11518860 bytes
Profile:
0x00100020-0x00bfc3a8(00000004)
```

Related Commands

Command	Description
memory profile enable	Enables the monitoring of memory usage (memory profiling).
memory profile text	Configures a program text range of memory to profile.
clear memory profile	Clears the memory buffers held by the memory profiling function.

show memory top-usage

To display the top number of allocated fragment sizes from the **show memory detail** command, use the **show memory top-usage** command in privileged EXEC mode.

show memory top-usage [*num*]

Syntax Description

num	(Optional) Shows the number of bin sizes to list. Valid values are from 1-64.

Defaults

The default for *num* is 10.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.4(6)	This command was introduced.

Usage Guidelines

Use the **show memory top-usage** command to display the top number of allocated fragment sizes from the **show memory detail** command.

This command does not use clustering and does not need to be disabled when clustering is enabled.

Examples

The following is sample output from the **show memory top-usage** command:

```
hostname# show memory top-usage 3
MEMPOOL_DMA pool binsize allocated byte totals:

----- allocated memory statistics -----

 fragment size       count          total

Related Commands

Command	Description
show memory tracking	Shows all currently collected information.

show memory tracking

To display currently allocated memory tracked by the tool, use the **show memory tracking** command in privileged EXEC mode.

show memory tracking [**address** | **dump** | **detail**]

Syntax Description

address	(Optional) Shows memory tracking by address.
detail	(Optional) Shows the internal memory tracking state.
dump	(Optional) Shows the memory tracking address.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	—	•	•

Command History

Release	Modification
7.0(8)	This command was introduced.

Usage Guidelines

Use the **show memory tracking** command to show currently allocated memory tracked by the tool.

Examples

The following is sample output from the **show memory tracking** command:

```
hostname# show memory tracking
memory tracking by caller:
17 bytes from 1 allocates by 0x080c50c2
37 bytes from 1 allocates by 0x080c50f6
57 bytes from 1 allocates by 0x080c5125
20481 bytes from 1 allocates by 0x080c5154
```

The following is sample output from the **show memory tracking address** command:

```
hostname# show memory tracking address
memory tracking by caller:
17 bytes from 1 allocates by 0x080c50c2
37 bytes from 1 allocates by 0x080c50f6
57 bytes from 1 allocates by 0x080c5125
20481 bytes from 1 allocates by 0x080c5154

memory tracking by address:
37 byte region @ 0xa893ae80 allocated by 0x080c50f6
```

```
57 byte region @ 0xa893aed0 allocated by 0x080c5125
20481 byte region @ 0xa8d7cc50 allocated by 0x080c5154
17 byte region @ 0xa8a6f370 allocated by 0x080c50c2
```

The following is sample output from the **show memory tracking dump** command:

```
hostname# show memory tracking dump
Tracking data for the 57 byte region at 0xa893aed0:

Related Commands

Command	Description
clear memory tracking	Clears all currently collected information.

show memory webvpn

To generate memory usage statistics for WebVPN, use the **show memory webvpn** command in privileged EXEC mode.

show memory webvpn [**allobjects | blocks | dumpstate** [**cache | disk0 | disk1 | flash | ftp | system | tftp**] | **pools | profile** [**clear | dump | start | stop**] | **usedobjects** {{**begin | exclude | grep | include**} **line** *line*}]

Syntax Description

allobjects	Displays WebVPN memory consumption details for pools, blocks , and all used and freed objects.
begin	Begins with the line that matches.
blocks	Displays WebVPN memory consumption details for memory blocks.
cache	Specifies a filename for a WebVPN memory cache state dump.
clear	Clears the WebVPN memory profile.
disk0	Specifies a filename for WebVPN memory disk0 state dump.
disk1	Specifies a filename for WebVPN memory disk1 state dump:.
dump	Puts WebVPN memory profile into a file.
dumpstate	Puts WebVPN memory state into a file.
exclude	Excludes the line(s) that match.
flash	Specifies a filename for the WebVPN memory flash state dump.
ftp	Specifies a filename for the WebVPN memory FTP state dump.
grep	Includes or excludes lines that match.
include	Includes the line(s) that match.
line	Identifies the line(s) to match.
line	Specifies the line(s) to match.
pools	Shows WebVPN memory consumption details for memory pools.
profile	Obtains the WebVPN memory profile and places it in a file.
system	Specifies a filename for the WebVPN memory system state dump.
start	Starts gathering the WebVPN memory profile.
stop	Stops getting the WebVPN memory profile.
tftp	Specifies a filename for a WebVPN memory TFTP state dump.
usedobjects	Displays WebVPN memory consumption details for used objects.

Defaults

No default behavior or value.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—
Global configuration	•	—	•	—	—
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Examples

The following is sample output from the **show memory webvpn allobjects** command:

```
hostname# show memory webvpn allobjects
Arena 0x36b14f8 of 4094744 bytes (61 blocks of size 66048), maximum 134195200
130100456 free bytes (97%; 1969 blocks, zone 0)
Arena is dynamically allocated, not contiguous
Features: GroupMgmt: SET, MemDebugLog: unset
Pool 0xd719a78 ("cp_entries" => "pool for class cpool entries") (next 0xd6d91d8)
Size: 66040 (1% of current, 0% of limit)
Object frame size: 32
Load related limits: 70/50/30
Callbacks: !init/!prep/!f2ca/!dstr/!dump
Blocks in use:
Block 0xd719ac0..0xd729cb8 (size 66040), pool "cp_entries"
Watermarks { 0xd7098f8 <= 0xd70bb60 <= 0xd719a60 } = 57088 ready
Block size 66040 not equal to arena block 66048 (realigned-to-8)
Used objects: 0
Top allocated count: 275
Objects dump:
0. Object 0xd70bb50: FREED (by "jvclass_pool_free")
```

Related Commands

Command	Description
memory-size	Sets the amount of memory on the ASA that WebVPN services can use.

show memory-caller address

To display the address ranges configured on the ASA, use the **show memory-caller address** command in privileged EXEC mode.

show memory-caller address

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You must first configure an address ranges with the **memory caller-address** command before you can display them with the **show memory-caller address** command.

Examples

The following examples show how to configure the address ranges with the **memory caller-address** command, and the resulting output of the **show memory-caller address** command:

```
hostname# memory caller-address 0x00109d5c 0x00109e08
hostname# memory caller-address 0x009b0ef0 0x009b0f14
hostname# memory caller-address 0x00cf211c 0x00cf4464

hostname# show memory-caller address
Move down stack frame for the addresses:
pc = 0x00109d5c-0x00109e08
pc = 0x009b0ef0-0x009b0f14
pc = 0x00cf211c-0x00cf4464
```

If address ranges are not configured before entering the **show memory-caller address** command, no addresses display:

```
hostname# show memory-caller address
Move down stack frame for the addresses:
```

Related Commands

Command	Description
memory caller-address	Configures a block of memory for the caller PC.

show mfib

To display MFIB in terms of forwarding entries and interfaces, use the **show mfib** command in user EXEC or privileged EXEC mode.

show mfib [*group* [*source*]] [**verbose**] [**cluster**]

Syntax Description

cluster	(Optional) Displays the MFIB epoch number and the current timer value.
group	(Optional) Displays the IP address of the multicast group.
source	(Optional) Displays the IP address of the multicast route source. This is a unicast IP address in four-part dotted-decimal notation.
verbose	(Optional) Displays additional information about the entries.

Defaults

Without the optional arguments, information for all groups is shown.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC or Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	The **cluster** keyword was added. Applies to the ASA 5580 and 5585-X only.

Examples

The following is sample output from the **show mfib** command:

```
hostname# show mfib 224.0.2.39
Entry Flags: C - Directly Connected, S - Signal, IA - Inherit A flag,
             AR - Activity Required, D - Drop
Forwarding counts: Pkt Count/Pkts per second/Avg Pkt Size/Kbits per second
Other counts: Total/RPF failed/Other drops
Interface flags: A - Accept, F - Forward, NS - Negate Signalling
             IC - Internal Copy, NP - Not platform switched
             SP - Signal Present
Interface Counts: FS Pkt Count/PS Pkt Count
(*,224.0.1.39) Flags: S K
  Forwarding: 0/0/0/0, Other: 0/0/0
```

Related Commands

Command	Description
show mfib verbose	Displays detail information about the forwarding entries and interfaces.

show mfib active

To display active multicast sources, use the **show mfib active** command in user EXEC or privileged EXEC mode.

show mfib [*group*] **active** [*kbps*]

Syntax Description

group	(Optional) IP address of the multicast group.
kbps	(Optional) Limits the display to multicast streams that are greater-than or equal to this value.

This command has no arguments or keywords.

Defaults

The default value for *kbps* is 4. If a *group* is not specified, all groups are shown.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC or Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The output for the show mfib active command displays either positive or negative numbers for the rate PPS. The ASA displays negative numbers when RPF packets fail or when the router observes RPF packets with an interfaces out (OIF) list. This type of activity may indicate a multicast routing problem.

Examples

The following is sample output from the **show mfib active** command:

```
hostname# show mfib active
Active IP Multicast Sources - sending >= 4 kbps

Group: 224.2.127.254, (sdr.cisco.com)
   Source: 192.168.28.69 (mbone.ipd.anl.gov)
     Rate: 1 pps/4 kbps(1sec), 4 kbps(last 1 secs), 4 kbps(life avg)

Group: 224.2.201.241, ACM 97
   Source: 192.168.52.160 (webcast3-e1.acm97.interop.net)
     Rate: 9 pps/93 kbps(1sec), 145 kbps(last 20 secs), 85 kbps(life avg)

Group: 224.2.207.215, ACM 97
   Source: 192.168.52.160 (webcast3-e1.acm97.interop.net)
```

```
Rate: 3 pps/31 kbps(1sec), 63 kbps(last 19 secs), 65 kbps(life avg)
```

Related Commands

Command	Description
show mroute active	Displays active multicast streams.

show mfib count

To display MFIB route and packet count data, use the **show mfib count** command in user EXEC or privileged EXEC mode.

show mfib [*group* [*source*]] **count**

Syntax Description

group	(Optional) IP address of the multicast group.
source	(Optional) IP address of the multicast route source. This is a unicast IP address in four-part dotted-decimal notation.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC or Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command displays packet drop statistics.

Examples

The following sample output from the **show mfib count** command:

```
hostname# show mfib count
MFIB global counters are :
* Packets [no input idb] : 0
* Packets [failed route lookup] : 0
* Packets [Failed idb lookup] : 0
* Packets [Mcast disabled on input I/F] : 0
```

Related Commands

Command	Description
clear mfib counters	Clears MFIB router packet counters.
show mroute count	Displays multicast route counters.

show mfib interface

To display packet statistics for interfaces that are related to the MFIB process, use the **show mfib interface** command in user EXEC or privileged EXEC mode.

show mfib interface [*interface*]

Syntax Description

interface	(Optional) Interface name. Limits the display to the specified interface.

Defaults

Information for all MFIB interfaces is shown.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC or Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example is sample output from the **show mfib interface** command:

```
hostname# show mfib interface
IP Multicast Forwarding (MFIB) status:
    Configuration Status: enabled
    Operational Status: running
MFIB interface       status    CEF-based output
                               [configured,available]
           Ethernet0   up    [        no,       no]
           Ethernet1   up    [        no,       no]
           Ethernet2   up    [        no,       no]
```

Related Commands

Command	Description
show mfib	Displays MFIB information in terms of forwarding entries and interfaces.

show mfib reserved

To display reserved groups, use the **show mfib reserved** command in user EXEC or privileged EXEC mode.

show mfib reserved [**count** | **verbose** | **active** [*kpbs*]]

Syntax Description

active	(Optional) Displays active multicast sources.
count	(Optional) Displays packet and route count data.
kpbs	(Optional) Limits the display to active multicast sources greater than or equal to this value.
verbose	(Optional) Displays additional information.

Defaults

The default value for *kbps* is 4.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
User EXEC or Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command displays MFIB entries in the range 224.0.0.0 through 224.0.0.225.

Examples

The following is sample output from the **show mfib reserved** command:

```
hostname# command example
Entry Flags: C - Directly Connected, S - Signal, IA - Inherit A flag,
             AR - Activity Required, D - Drop Forwarding Counts: Pkt Count/Pkts per
second/Avg Pkt Size/Kbits per second Other counts: Total/RPF failed/Other drops Interface
Flags: A - Accept, F - Forward, NS - Negate Signalling
             IC - Internal Copy, NP - Not platform switched
             SP - Signal Present
Interface Counts: FS Pkt Count/PS Pkt Count
(*,224.0.0.0/4) Flags: C K
   Forwarding: 0/0/0/0, Other: 0/0/0
(*,224.0.0.0/24) Flags: K
   Forwarding: 0/0/0/0, Other: 0/0/0
(*,224.0.0.1) Flags:
   Forwarding: 0/0/0/0, Other: 0/0/0
   outside Flags: IC
```

```
dmz Flags: IC
inside Flags: IC
```

Related Commands

Command	Description
show mfib active	Displays active multicast streams.

show mfib status

To display the general MFIB configuration and operational status, use the **show mfib status** command in user EXEC or privileged EXEC mode.

show mfib status

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC or Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show mfib status** command:

```
hostname# show mfib status
IP Multicast Forwarding (MFIB) status:
    Configuration Status: enabled
    Operational Status: running
```

Related Commands

Command	Description
show mfib	Displays MFIB information in terms of forwarding entries and interfaces.

show mfib summary

To display summary information about the number of MFIB entries and interfaces, use the **show mfib summary** command in user EXEC or privileged EXEC mode.

show mfib summary

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC or Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show mfib summary** command:

```
hostname# show mfib summary
IPv6 MFIB summary:

  54     total entries [1 (S,G), 7 (*,G), 46 (*,G/m)]

  17     total MFIB interfaces
```

Related Commands

Command	Description

show mfib	Displays MFIB information in terms of forwarding entries and interfaces.
show mfib summary	Displays summary information about the number of MFIB entries and interfaces.

show mgcp

To display MGCP configuration and session information, use the **show mgcp** command in privileged EXEC mode.

show mgcp {**commands** | **sessions**} [**detail**]

Syntax Description

commands	Lists the number of MGCP commands in the command queue.
detail	(Optional) Lists additional information about each command (or session) in the output.
sessions	Lists the number of existing MGCP sessions.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show mgcp commands** command lists the number of MGCP commands in the command queue. The **show mgcp sessions** command lists the number of existing MGCP sessions. The **detail** option includes additional information about each command (or session) in the output.

Examples

The following are examples of the **show mgcp** command options:

```
hostname# show mgcp commands
1 in use, 1 most used, 200 maximum allowed
CRCX, gateway IP: host-pc-2, transaction ID: 2052, idle: 0:00:07
hostname#

hostname# show mgcp commands detail
1 in use, 1 most used, 200 maximum allowed
CRCX, idle: 0:00:10
        Gateway IP | host-pc-2
        Transaction ID  2052
        Endpoint name | aaln/1
        Call ID | 9876543210abcdef
```

```
        Connection ID |
        Media IP | 192.168.5.7
        Media port | 6058
hostname#

hostname# show mgcp sessions
1 in use, 1 most used
Gateway IP host-pc-2, connection ID 6789af54c9, active 0:00:11
hostname#

hostname# show mgcp sessions detail
1 in use, 1 most used
Session active 0:00:14
        Gateway IP | host-pc-2
        Call ID | 9876543210abcdef
        Connection ID | 6789af54c9
        Endpoint name | aaln/1
        Media lcl port  6166
        Media rmt IP | 192.168.5.7
        Media rmt port  6058
hostname#
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
debug mgcp	Enables MGCP debug information.
inspect mgcp	Enables MGCP application inspection.
mgcp-map	Defines an MGCP map and enables MGCP map configuration mode.
show conn	Displays the connection state for different connection types.

show mmp

To display information about existing MMP sessions, use the **show mmp** command in privileged EXEC mode.

show mmp [*address*]

Syntax Description

address	Specifies the IP address of an MMP client/server.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Examples

The following example shows the use of the **show mmp** command to display information about existing MMP sessions:

```
hostname# show mmp 10.0.0.42
MMP session:: inside:10.0.0.42/5443 outside:172.23.62.204/2442
session-id=71AD3EB1-7BE8-42E0-8DC3-E96E41D4ADD5
data:: rx-bytes=1258, tx-bytes=1258
```

Related Commands

Command	Description
debug mmp	Displays inspect MMP events.
inspect mmp	Configures the MMP inspection engine.
show debug mmp	Displays current debug settings for the MMP inspection module.

show mode

To show the security context mode for the running software image and for any image in Flash memory, use the **show mode** command in privileged EXEC mode.

show mode

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show mode** command. The following example shows the current mode and the mode for the non-running image “image.bin”:

```
hostname# show mode flash:/image.bin
Firewall mode: multiple
```

The mode can be multiple or single.

Related Commands

Command	Description
context	Creates a security context in the system configuration and enters context configuration mode.
mode	Sets the context mode to single or multiple.

show module

To show information about a module installed on the ASA, use the **show module** command in user EXEC mode.

show module [*id* | **all**] [**details** | **recover** | **log** [**console**]]]

Syntax Description

all	(Default) Shows information for all modules.
console	(Optional) Shows console log information for the module.
details	(Optional) Shows additional information, including remote management configuration for modules.
id	Specifies the module ID. For a hardware module, specify the slot number, which can be **0** (for the ASA) or **1** (for an installed module). For a software module, specify the module name, either **ips** or **cxsc**.
ips	(Optional) Shows information for the IPS SSP software module.
log	(Optional) Shows log information for the module.
recover	(Optional) Shows the settings for the **hw-module** or **sw-module module recover** command.

Defaults

By default, information for all modules is shown.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context[1]	System
User EXEC	•	•	•	•	•

1. The **show module recover** command is only available in the system execution space.

Command History

Release	Modification
7.0(1)	This command was introduced.
7.1(1)	This command was modified to include more detail in the output.
8.2(1)	Information about the SSC is included in the output.
8.2(5)	Information about support for the ASA 5585-X and for the IPS SSP on the ASA 5585-X was added.
8.4(4.1)	We added support for the ASA CX module.
8.6(1)	For the ASA 5512-X through ASA 5555-X: the **log** and **console** keywords were added; the **ips** device ID was added.
9.1(1)	We added support for the ASA CX software module by adding the **cxsc** module ID.

Usage Guidelines

This command shows information about the modules installed in the ASA. The ASA itself also appears as a module in the display (in slot 0).

Examples

The following is sample output from the **show module** command. Module 0 is the base device; module 1 is a CSC SSM.

```
hostname# show module
Mod Card Type                                    Model              Serial No.
--- -------------------------------------------- ------------------ -----------
  0 ASA 5520 Adaptive Security Appliance         ASA5520            P3000000034
  1 ASA 5500 Series Security Services Module-20  ASA-SSM-20         0

Mod MAC Address Range                 Hw Version   Fw Version   Sw Version
--- --------------------------------- ------------ ------------ ---------------
  0 000b.fcf8.c30d to 000b.fcf8.c311  1.0          1.0(10)0     7.1(0)5
  1 000b.fcf8.012c to 000b.fcf8.012c  1.0          1.0(10)0     CSC SSM 5.0 (Build#1187)

Mod SSM Application Name           SSM Application Version
--- ------------------------------ --------------------------
  1 CSC SSM scan services are not
  1 CSC SSM                        5.0 (Build#1187)

Mod Status             Data Plane Status     Compatibility
--- ------------------ --------------------- -------------
  0 Up Sys             Not Applicable
  1 Up                 Up
```

Table 26-3 describes each field listed in the output.

Table 51-3 show module Output Fields

Field	Description
Mod	The module number, 0 or 1.
Ports	The number of ports.
Card Type	For the device shown in module 0, the type is the platform model. For the SSM in module 1, the type is the SSM type.
Model	The model number for this module.
Serial No.	The serial number.
MAC Address Range	The MAC address range for interfaces on this SSM or, for the device, the built-in interfaces.
Hw Version	The hardware version.
Fw Version	The firmware version.
Sw Version	The software version.
SSM Application Name	The name of the application running on the SSM.
SSM Application Version	The version of the application running on the SSM.

Table 51-3 show module Output Fields (continued)

Field	Description
Status	For the device in module 0, the status is Up Sys. The status of the SSM in module 1 can be any of the following: • Initializing—The SSM is being detected and the control communication is being initialized by the device. • Up—The SSM has completed initialization by the device. • Unresponsive—The device encountered an error while communicating with this SSM. • Reloading—The SSM is reloading. • Shutting Down—The SSM is shutting down. • Down—The SSM is shut down. • Recover—The SSM is attempting to download a recovery image. • No Image Present—The IPS software has not been installed.
Data Plane Status	The current state of the data plane.
Compatibility	The compatibility of the SSM relative to the rest of the device.
Slot	The physical slot number (used only in dual SSP mode).

The output of the **show module details** command varies according to which module is installed. For example, output for the CSC SSM includes fields about components of the CSC SSM software.

The following is generic sample output from the **show module 1 details** command:

```
hostname# show module 1 details
Getting details from the Service Module, please wait...
ASA 5500 Series Security Services Module-20
Model:              ASA-SSM-20
Hardware version:   V1.0
Serial Number:      12345678
Firmware version:   1.0(7)2
Software version:   4.1(1.1)S47(0.1)
MAC Address Range:  000b.fcf8.0156 to 000b.fcf8.0156
Data plane Status:  Up
Status:             Up
Mgmt IP addr:       10.89.147.13
Mgmt web ports:     443
Mgmt TLS enabled:   true
```

Table 26-4 describes each field listed in the output.

Table 51-4 show module details Output Fields

Field	Description
Mgmt IP addr	Shows the IP address for the SSM management interface.
Mgmt web ports	Shows the ports configured for the SSM management interface.
Mgmt TLS enabled	Shows whether transport layer security is enabled (true or false) for connections to the management interface of the SSM.

The following is sample output from the **show module 1 recover** command:

```
hostname# show module 1 recover
Module 1 recover parameters. . .
Boot Recovery Image: Yes
Image URL:           tftp://10.21.18.1/ids-oldimg
Port IP Address:     10.1.2.10
Port Mask :          255.255.255.0
Gateway IP Address:  10.1.2.254
```

The following is sample output from the **show module 1 details** command when an SSC is installed:

```
hostname# show module 1 details
Getting details from the Service Module, please wait...

```

Related Commands

Command	Description
debug module-boot	Shows debugging messages about the module booting process.
hw-module module recover	Recovers an module by loading a recovery image from a TFTP server.
hw-module module reset	Shuts down an module and performs a hardware reset.
hw-module module reload	Reloads the module software.
hw-module module shutdown	Closes the module software in preparation for being powered off without losing configuration data.

show monitor-interface

To display information about the interfaces monitored for failover, use the **show monitor-interface** command in privileged EXEC mode.

show monitor-interface

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
8.2(2)	This command was modified. The output includes IPv6 addresses.

Usage Guidelines

Because an interface can have more than one IPv6 address configured on it, only the link-local address is displayed in the **show monitor-interface** command. If both IPv4 and IPv6 addresses are configured on an interface, both addresses appear in the output. If there is no IPv4 address configured on the interface, the IPv4 address in the output appears as 0.0.0.0. If there is no IPv6 address configured on an interface, the address is simply omitted from the output.

Monitored failover interfaces can have the following status:

- Unknown—Initial status. This status can also mean the status cannot be determined.
- Normal—The interface is receiving traffic.
- Normal (Waiting)—The interface is up but has not yet received a hello packet from the corresponding interface on the peer unit. Verify that a standby IP address has been configured for the interface and that there is connectivity between the two interfaces.
- Testing—Hello messages are not heard on the interface for five poll times.
- Link Down—The interface or VLAN is administratively down.
- No Link—The physical link for the interface is down.
- Failed—No traffic is received on the interface, yet traffic is heard on the peer interface.

Examples

The following is sample output from the **show monitor-interface** command:

```
hostname# show monitor-interface

This host: Primary - Active
                Interface outside (10.86.94.88): Normal (Waiting)
                Interface management (192.168.1.1): Normal (Waiting)
                Interface failif (0.0.0.0/fe80::223:4ff:fe77:fed): Normal (Waiting)
        Other host: Secondary - Failed
                Interface outside (0.0.0.0): Unknown (Waiting)
                Interface management (0.0.0.0): Unknown (Waiting)
                Interface failif (0.0.0.0): Unknown (Waiting)
```

Related Commands

Command	Description
monitor-interface	Enables health monitoring on a specific interface

show mrib client

To display information about the MRIB client connections, use the **show mrib client** command in user EXEC or privileged EXEC mode.

show mrib client [**filter**] [**name** *client_name*]

Syntax Description

filter	(Optional) Displays client filter. Used to view information about the MRIB flags that each client owns and the flags in which each clients is interested.
name *client_name*	(Optional) Name of a multicast routing protocol that acts as a client of MRIB, such as PIM or IGMP.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC or Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **filter** option is used to display the route and interface level flag changes that various MRIB clients have registered. This command option also shows what flags are owned by the MRIB clients.

Examples

The following sample output from the **show mrib client** command using the **filter** keyword:

```
hostname# show mrib client filter
MFWD:0 (connection id 0)
interest filter:
entry attributes: S C IA D
interface attributes: F A IC NS DP SP
groups:
include 0.0.0.0/0
interfaces:
include All
ownership filter:
groups:
include 0.0.0.0/0
interfaces:
include All
igmp:77964 (connection id 1)
```

```
ownership filter:
interface attributes: II ID LI LD
groups:
include 0.0.0.0/0
interfaces:
include All
pim:49287 (connection id 5)
interest filter:
entry attributes: E
interface attributes: SP II ID LI LD
groups:
include 0.0.0.0/0
interfaces:
include All
ownership filter:
entry attributes: L S C IA D
interface attributes: F A IC NS DP
groups:
include 0.0.0.0/0
interfaces:
include All
```

Related Commands

Command	Description
show mrib route	Displays MRIB table entries.

show mrib route

To display entries in the MRIB table, use the **show mrib route** command in user EXEC or privileged EXEC mode.

show mrib route [[*source* | *] [*group*[*/prefix-length*]]]

Syntax Description

*	(Optional) Display shared tree entries.
/prefix-length	(Optional) Prefix length of the MRIB route. A decimal value that indicates how many of the high-order contiguous bits of the address comprise the prefix (the network portion of the address). A slash mark must precede the decimal value.
group	(Optional) IP address or name of the group.
source	(Optional) IP address or name of the route source.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC or Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The MFIB table maintains a subset of entries and flags updated from MRIB. The flags determine the forwarding and signaling behavior according to a set of forwarding rules for multicast packets.

In addition to the list of interfaces and flags, each route entry shows various counters. Byte count is the number of total bytes forwarded. Packet count is the number of packets received for this entry. The **show mfib count** command displays global counters independent of the routes.

Examples

The following is sample output from the **show mrib route** command:

```
hostname# show mrib route
IP Multicast Routing Information Base
Entry flags: L - Domain-Local Source, E - External Source to the Domain,
    C - Directly-Connected Check, S - Signal, IA - Inherit Accept, D - Drop
Interface flags: F - Forward, A - Accept, IC - Internal Copy,
    NS - Negate Signal, DP - Don't Preserve, SP - Signal Present,
    II - Internal Interest, ID - Internal Disinterest, LI - Local Interest,
```

```
LD - Local Disinterest

Related Commands

Command	Description
show mfib count	Displays route and packet count data for the MFIB table.
show mrib route summary	Displays a summary of the MRIB table entries.

show mroute

To display the IPv4 multicast routing table, use the **show mroute** command in privileged EXEC mode.

show mroute [*group* [*source*] | **reserved**] [**active** [*rate*] | **count** | **pruned** | **summary**]

Syntax Description

active *rate*	(Optional) Displays only active multicast sources. Active sources are those sending at the specified *rate* or higher. If the *rate* is not specified, active sources are those sending at a rate of 4 kbps or higher.
count	(Optional) Displays statistics about the group and source, including number of packets, packets per second, average packet size, and bits per second.
group	(Optional) IP address or name of the multicast group as defined in the DNS hosts table.
pruned	(Optional) Displays pruned routes.
reserved	(Optional) Displays reserved groups.
source	(Optional) Source hostname or IP address.
summary	(Optional) Displays a one-line, abbreviated summary of each entry in the multicast routing table.

Defaults

If not specified, the *rate* argument defaults to 4 kbps.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show mroute** command displays the contents of the multicast routing table. The ASA populates the multicast routing table by creating (S,G) and (*,G) entries based on PIM protocol messages, IGMP reports, and traffic. The asterisk (*) refers to all source addresses, the “S” refers to a single source address, and the “G” is the destination multicast group address. In creating (S, G) entries, the software uses the best path to that destination group found in the unicast routing table (through RPF).

To view the **mroute** commands in the running configuration, use the **show running-config mroute** command.

Examples

The following is sample output from the **show mroute** command:

```
hostname(config)# show mroute

Multicast Routing Table
Flags: D - Dense, S - Sparse, B - Bidir Group, s - SSM Group,
       C - Connected, L - Local, I - Received Source Specific Host Report,
       P - Pruned, R - RP-bit set, F - Register flag, T - SPT-bit set,
       J - Join SPT
Timers: Uptime/Expires
Interface state: Interface, State

(*, 239.1.1.40), 08:07:24/never, RP 0.0.0.0, flags: DPC
  Incoming interface: Null
  RPF nbr: 0.0.0.0
  Outgoing interface list:
    inside, Null, 08:05:45/never
    tftp, Null, 08:07:24/never

(*, 239.2.2.1), 08:07:44/never, RP 140.0.0.70, flags: SCJ
  Incoming interface: outside
  RPF nbr: 140.0.0.70
  Outgoing interface list:
    inside, Forward, 08:07:44/never
```

The following fields are shown in the **show mroute** output:

- **Flags**—Provides information about the entry.
  - **D—Dense**. Entry is operating in dense mode.
  - **S—Sparse**. Entry is operating in sparse mode.
  - **B—Bidir Group**. Indicates that a multicast group is operating in bidirectional mode.
  - **s—SSM Group**. Indicates that a multicast group is within the SSM range of IP addresses. This flag is reset if the SSM range changes.
  - **C—Connected**. A member of the multicast group is present on the directly connected interface.
  - **L—Local**. The ASA itself is a member of the multicast group. Groups are joined locally by the **igmp join-group** command (for the configured group).
  - **I—Received Source Specific Host Report**. Indicates that an (S, G) entry was created by an (S, G) report. This (S, G) report could have been created by IGMP. This flag is set only on the DR.
  - **P—Pruned**. Route has been pruned. The software keeps this information so that a downstream member can join the source.
  - **R—RP-bit set**. Indicates that the (S, G) entry is pointing toward the RP.
  - **F—Register flag**. Indicates that the software is registering for a multicast source.
  - **T—SPT-bit set**. Indicates that packets have been received on the shortest path source tree.
  - **J—Join SPT**. For (*, G) entries, indicates that the rate of traffic flowing down the shared tree is exceeding the SPT-Threshold set for the group. (The default SPT-Threshold setting is 0 kbps.) When the J - Join shortest path tree (SPT) flag is set, the next (S, G) packet received down the shared tree triggers an (S, G) join in the direction of the source, thereby causing the ASA to join the source tree.

    For (S, G) entries, indicates that the entry was created because the SPT-Threshold for the group was exceeded. When the J - Join SPT flag is set for (S, G) entries, the ASA monitors the traffic rate on the source tree and attempts to switch back to the shared tree for this source if the traffic rate on the source tree falls below the SPT-Threshold of the group for more than 1 minute.

Note The ASA measures the traffic rate on the shared tree and compares the measured rate to the SPT-Threshold of the group once every second. If the traffic rate exceeds the SPT-Threshold, the J - Join SPT flag is set on the (*, G) entry until the next measurement of the traffic rate. The flag is cleared when the next packet arrives on the shared tree and a new measurement interval is started.

If the default SPT-Threshold value of 0 kbps is used for the group, the J - Join SPT flag is always set on (*, G) entries and is never cleared. When the default SPT-Threshold value is used, the ASA immediately switches to the shortest path source tree when traffic from a new source is received.

- **Timers:Uptime/Expires**—Uptime indicates per interface how long (in hours, minutes, and seconds) the entry has been in the IP multicast routing table. Expires indicates per interface how long (in hours, minutes, and seconds) until the entry will be removed from the IP multicast routing table.
- **Interface state**—Indicates the state of the incoming or outgoing interface.
  - **Interface**—The interface name listed in the incoming or outgoing interface list.
  - **State**—Indicates that packets will either be forwarded, pruned, or null on the interface depending on whether there are restrictions due to access lists or a time-to-live (TTL) threshold.
- **(*, 239.1.1.40)** and **(* , 239.2.2.1)**—Entries in the IP multicast routing table. The entry consists of the IP address of the source followed by the IP address of the multicast group. An asterisk (*) in place of the source indicates all sources.
- **RP**—Address of the RP. For routers and access servers operating in sparse mode, this address is always 224.0.0.0.
- **Incoming interface**—Expected interface for a multicast packet from the source. If the packet is not received on this interface, it is discarded.
- **RPF nbr**—IP address of the upstream router to the source.
- **Outgoing interface list**—Interfaces through which packets will be forwarded.

Related Commands

Command	Description
clear configure mroute	Removes the **mroute** commands from the running configuration.
mroute	Configures a static multicast route.
show mroute	Displays IPv4 multicast routing table.
show running-config mroute	Displays configured multicast routes.

show nac-policy

To show the NAC policy usage statistics and the assignment of NAC policies to group policies, use the **show nac-policy** command in privileged EXEC mode.

show nac-policy [*nac-policy-name*]

Syntax Description

nac-policy-name	(Optional) Name of the NAC policy for which to display usage statistics.

Defaults

If you do not specify a name, the CLI lists all NAC policy names along with their respective statistics.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	—	•

Command History

Release	Modification
8.0(2)	This command was introduced.

Examples

The following example shows the data for the NAC policies named framework1 and framework2:

```
asa2(config)# show nac-policy
nac-policy framework1 nac-framework
  applied session count = 0
  applied group-policy count = 2
  group-policy list:    GroupPolicy2    GroupPolicy1
nac-policy framework2 nac-framework is not in use.
```

The first line of each NAC policy indicates its name and type (nac-framework). The CLI shows the text "is not in use" next to the policy type if the policy is not assigned to any group policies. Otherwise, the CLI displays the usage data for the group policy. Table 51-5 explains the fields in the **show nac-policy** command.

Table 51-5 show nac-policy Command Fields

Field	Description
applied session count	Cumulative number of VPN sessions to which this ASA applied the NAC policy.

Table 51-5 show nac-policy Command Fields (continued)

Field	Description
applied group-policy count	Cumulative number of group polices to which this ASA applied the NAC policy.
group-policy list	List of group policies to which this NAC policy is assigned. In this case, the usage of a group policy does not determine whether it appears in this list; if the NAC policy is assigned to a group policy in the running configuration, then the group policy appears in this list.

Related Commands

clear nac-policy	Resets the NAC policy usage statistics.
show vpn-session.db	Displays information about VPN sessions, including NAC results.
show vpn-session_summary.db	Displays the number IPsec, Cisco WebVPN, and NAC sessions.

show nameif

To view the interface name set using the **nameif** command, use the **show nameif** command in privileged EXEC mode.

show nameif [*physical_interface*[**.***subinterface*] | *mapped_name*]

Syntax Description

mapped_name	(Optional) In multiple context mode, identifies the mapped name if it was assigned using the **allocate-interface** command.
physical_interface	(Optional) Identifies the interface ID, such as **gigabitethernet0/1**. See the **interface** command for accepted values.
subinterface	(Optional) Identifies an integer between 1 and 4294967293 designating a logical subinterface.

Defaults

If you do not specify an interface, the ASA shows all interface names.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

In multiple context mode, if you mapped the interface ID in the **allocate-interface** command, you can only specify the mapped name in a context. The output for this command shows only the mapped name in the Interface column.

Examples

The following is sample output from the **show nameif** command:

```
hostname# show nameif
Interface               Name                    Security
GigabitEthernet0/0      outside                 0
GigabitEthernet0/1      inside                  100
GigabitEthernet0/2      test2                   50
```

Related Commands

Command	Description
allocate-interface	Assigns interfaces and subinterfaces to a security context.
interface	Configures an interface and enters interface configuration mode.
nameif	Sets the interface name.
show interface ip brief	Shows the interface IP address and status.

show nat

To display statistics of NAT policies, use the **show nat** command in privileged EXEC mode.

show nat [**interface** *name*] [*ip_addr mask* | {**object** | **object-group**} *name*]
[**translated** [**interface** *name*] [*ip_addr mask* | {**object** | **object-group**} *name*]] [**detail**]
[**divert-table** [**ipv6**] [**interface** *name*]]

Syntax Description

detail	(Optional) Includes more verbose expansion of the object fields.
divert-table	(Optional) Shows the NAT divert table.
interface *name*	(Optional) Specifies the source interface.
ip_addr mask	(Optional) Specifies an IP address and subnet mask.
ipv6	(Optional) Shows IPv6 entries in the divert table.
object *name*	(Optional) Specifies a network object or service object.
object-group *name*	(Optional) Specifies a network object group
translated	(Optional) Specifies the translated parameters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.
9.0(1)	This command now supports IPv6 traffic, as well as translations between IPv4 and IPv6.

Usage Guidelines

Use the **show nat** command to show runtime representation of the NAT policy. Use the **detail** optional keyword to expand the object and view the object values. Use the additional selector fields to limit the **show nat** command output.

Examples

The following is sample output from the **show nat** command:

```
hostname# show nat
   Manual NAT Policies (Section 1)
   1 (any) to (any) source dynamic S S' destination static D' D
       translate_hits = 0, untranslate_hits = 0
```

```
   Auto NAT Policies (Section 2)
   1 (inside) to (outside) source dynamic A 2.2.2.2
       translate_hits = 0, untranslate_hits = 0

   Manual NAT Policies (Section 3)
   1 (any) to (any) source dynamic C C' destination static B' B service R R'
       translate_hits = 0, untranslate_hits = 0

hostname# show nat detail
   Manual NAT Policies (Section 1)
   1 (any) to (any) source dynamic S S' destination static D' D
       translate_hits = 0, untranslate_hits = 0
       Source - Real: 1.1.1.2/32, Mapped: 2.2.2.3/32
       Destination - Real: 10.10.10.0/24, Mapped: 20.20.20.0/24

   Auto NAT Policies (Section 2)
   1 (inside) to (outside) source dynamic A 2.2.2.2
       translate_hits = 0, untranslate_hits = 0
       Source - Real: 1.1.1.1/32, Mapped: 2.2.2.2/32

   Manual NAT Policies (Section 3)
    1 (any) to (any) source dynamic C C' destination static B' B service R R'
       translate_hits = 0, untranslate_hits = 0
       Source - Real: 11.11.11.10-11.11.11.11, Mapped: 192.168.10.10/32
       Destination - Real: 192.168.1.0/24, Mapped: 10.75.1.0/24
       Service - Real: tcp source eq 10 destination eq ftp-data , Mapped: tcp source eq
       100 destination eq 200
```

The following is sample output from the **show nat detail** command between IPv6 and IPv4:

```
hostname# show nat detail
1 (in) to (outside) source dynamic inside_nw outside_map destination static inside_map any
translate_hits = 0, untranslate_hits = 0
Source - Origin: 2001::/96, Translated: 192.168.102.200-192.168.102.210
Destination - Origin: 2001::/96, Translated: 0.0.0.0/0
```

The following is sample output from the **show nat divert ipv6** command:

```
hostname# show nat divert ipv6
Divert Table
id=0xcb9ea518, domain=divert-route
type=static, hits=0, flags=0x21, protocol=0
src ip/id=2001::/ffff:ffff:ffff:ffff:ffff:ffff::, port=0-0
dst ip/id=2001::/ffff:ffff:ffff:ffff:ffff:ffff::, port=0-0
input_ifc=in, output_ifc=outside
id=0xcf24d4b8, domain=divert-route
type=static, hits=0, flags=0x20, protocol=0
src ip/id=::/::, port=0-0
dst ip/id=2222::/ffff:ffff:ffff:ffff:ffff:ffff::, port=0-0
input_ifc=in, output_ifc=mgmt
```

Related Commands

Command	Description
clear nat counters	Clears NAT policy counters.
nat	Identifies addresses on one interface that are translated to mapped addresses on another interface.

show nat pool

To display statistics of NAT pool usage, use the **show nat pool** command in privileged EXEC mode.

show nat pool

Syntax Description

This command has no arguments or keywords.

Defaults

This command has no default settings.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.
8.4(3)	The output was modified to show the destination address for extended PAT. The PAT range was also modified depending on the use of the **flat** and **include-reserve** keywords.
9.0(1)	This command now supports IPv6 traffic.

Usage Guidelines

A NAT pool is created for each mapped protocol/IP address/port range, where the port ranges are 1-511, 512-1023, and 1024-65535 by default. If you use the **flat** keyword for a PAT pool in the **nat** command, you will see fewer, larger ranges.

Each NAT pool exists for at least 10 minutes after the last usage. The 10 minute hold-down timer is canceled if you clear the translations with **clear xlate**.

Examples

The following is sample output for the NAT pools created by a dynamic PAT rule shown by the **show running-config object network** command.

```
hostname(config)# show running-config object network
object network myhost
 host 10.10.10.10
 nat (pppoe2,inside) dynamic 10.76.11.25

hostname# show nat pool
TCP inside, address 10.76.11.25, range 1-511, allocated 0
TCP inside, address 10.76.11.25, range 512-1023, allocated 0
TCP inside, address 10.76.11.25, range 1024-65535, allocated 1
```

The following is sample output from the **show nat pool** command showing use of the PAT pool **flat** option. Without the **include-reserve** keyword, two ranges are shown; the lower range is used when a source port below 1024 is mapped to the same port.

```
hostname# show nat pool

ICMP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1-65535, allocated 2
TCP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1-1024, allocated 0
TCP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1024-65535, allocated 2
UDP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1-1024, allocated 0
UDP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1024-65535, allocated 2
```

The following is sample output from the **show nat pool** command showing use of the PAT pool **flat include-reserve** options.

```
hostname# show nat pool

ICMP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1-65535, allocated 2
TCP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1-65535, allocated 2
UDP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1-65535, allocated 2
```

The following is sample output from the **show nat pool** command showing use of the PAT pool **extended flat include-reserve** options. The important items are the parenthetical addresses. These are the destination addresses used to extend PAT.

```
ICMP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1-65535, allocated 0
ICMP PAT pool outside:dynamic-pat, address 172.16.2.200(172.16.2.99), range 1-65535,
allocated 2
TCP PAT pool outside:dynamic-pat, address 172.16.2.200(172.16.2.100), range 1-65535,
allocated 1
UDP PAT pool outside:dynamic-pat, address 172.16.2.200(172.16.2.100), range 1-65535,
allocated 1
TCP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1-65535, allocated 0
ICMP PAT pool outside:dynamic-pat, address 172.16.2.200(172.16.2.100), range 1-65535,
allocated 1
TCP PAT pool outside:dynamic-pat, address 172.16.2.200(172.16.2.99), range 1-65535,
allocated 2
UDP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1-65535, allocated 0
```

Related Commands

Command	Description
nat	Identifies addresses on one interface that are translated to mapped addresses on another interface.
show nat	Displays NAT policy statistics.

show ntp associations

To view NTP association information, use the **show ntp associations** command in user EXEC mode.

show ntp associations [**detail**]

Syntax Description

detail	(Optional) Shows additional details about each association.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
User EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

See the “Examples” section for a description of the display output.

Examples

The following is sample output from the **show ntp associations** command:

```
hostname> show ntp associations
     address         ref clock     st  when  poll  reach  delay  offset    disp
 ~172.31.32.2      172.31.32.1       5    29  1024  377     4.2   -8.59     1.6
+~192.168.13.33    192.168.1.111     3    69   128  377     4.1    3.48     2.3
*~192.168.13.57    192.168.1.111     3    32   128  377     7.9   11.18     3.6
* master (synced), # master (unsynced), + selected, - candidate, ~ configured
```

Table 51-6 shows each field description.

Table 51-6 show ntp associations Fields

Field	Description
(leading characters in display lines)	The first characters in a display line can be one or more of the following characters: • * —Synchronized to this peer. • # —Almost synchronized to this peer. • + —Peer selected for possible synchronization. • - —Peer is a candidate for selection. • ~ —Peer is statically configured, but not synchronized.
address	The address of the NTP peer.
ref clock	The address of the reference clock of the peer.
st	The stratum of the peer.
when	The time since the last NTP packet was received from the peer.
poll	The polling interval (in seconds).
reach	The peer reachability (as a bit string, in octal).
delay	The round-trip delay to the peer (in milliseconds).
offset	The relative time of the peer clock to the local clock (in milliseconds).
disp	The dispersion value.

The following is sample output from the **show ntp associations detail** command:

```
hostname> show ntp associations detail
172.23.56.249 configured, our_master, sane, valid, stratum 4

```

Table 51-7 shows each field description.

Table 51-7 show ntp associations detail Fields

Field	Description
IP-address configured	The server (peer) IP address.
(status)	• our_master—The ASA is synchronized to this peer. • selected—Peer is selected for possible synchronization. • candidate—Peer is a candidate for selection.

Table 51-7 show ntp associations detail Fields (continued)

Field	Description
(sanity)	• sane—The peer passes basic sanity checks. • insane—The peer fails basic sanity checks.
(validity)	• valid—The peer time is believed to be valid. • invalid—The peer time is believed to be invalid. • leap_add—The peer is signalling that a leap second will be added. • leap-sub—The peer is signalling that a leap second will be subtracted.
stratum	The stratum of the peer.
(reference peer)	unsynced—The peer is not synchronized to any other machine. ref ID—The address of the machine that the peer is synchronized to.
time	The last time stamp the peer received from its master.
our mode client	Our mode relative to the peer, which is always client.
peer mode server	The mode of the peer relative to the server.
our poll intvl	Our poll interval to the peer.
peer poll intvl	The peer poll interval to us.
root delay	The delay along the path to the root (ultimate stratum 1 time source).
root disp	The dispersion of the path to the root.
reach	The peer reachability (as a bit string in octal).
sync dist	The peer synchronization distance.
delay	The round-trip delay to the peer.
offset	The offset of the peer clock relative to our clock.
dispersion	The dispersion of the peer clock.
precision	The precision of the peer clock (in hertz).
version	The NTP version number that the peer is using.
org time	The originate time stamp.
rcv time	The receive time stamp.
xmt time	The transmit time stamp.
filtdelay	The round-trip delay (in milliseconds) of each sample.
filtoffset	The clock offset (in milliseconds) of each sample.
filterror	The approximate error of each sample.

Related Commands

Command	Description
ntp authenticate	Enables NTP authentication.
ntp authentication-key	Sets an encrypted authentication key to synchronize with an NTP server.
ntp server	Identifies an NTP server.

Command	Description
ntp trusted-key	Provides a key ID for the ASA to use in packets for authentication with an NTP server.
show ntp status	Shows the status of the NTP association.

show ntp status

To show the status of each NTP association, use the **show ntp status** command in user EXEC mode.

show ntp status

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

See the “Examples” section for a description of the display output.

Examples

The following is sample output from the **show ntp status** command:

```
hostname> show ntp status
Clock is synchronized, stratum 5, reference is 172.23.56.249
nominal freq is 99.9984 Hz, actual freq is 100.0266 Hz, precision is 2**6
reference time is c02128a9.73c1954b (20:29:29.452 UTC Fri Feb 22 2002)
clock offset is -0.2403 msec, root delay is 42.51 msec
root dispersion is 135.01 msec, peer dispersion is 125.21 msec
```

Table 51-8 shows each field description.

Table 51-8 show ntp status Fields

Field	Description
Clock	• synchronized—The ASA is synchronized to an NTP server. • unsynchronized—The ASA is not synchronized to an NTP server.
stratum	NTP stratum of this system.
reference	The address of the NTP server to which the ASA is synchronized.
nominal freq	The nominal frequency of the system hardware clock.

Table 51-8 show ntp status Fields (continued)

Field	Description
actual freq	The measured frequency of the system hardware clock.
precision	The precision of the clock of this system (in hertz).
reference time	The reference time stamp.
clock offset	The offset of the system clock to the synchronized peer.
root delay	The total delay along the path to the root clock.
root dispersion	The dispersion of the root path.
peer dispersion	The dispersion of the synchronized peer.

Related Commands

Command	Description
ntp authenticate	Enables NTP authentication.
ntp authentication-key	Sets an encrypted authentication key to synchronize with an NTP server.
ntp server	Identifies an NTP server.
ntp trusted-key	Provides a key ID for the ASA to use in packets for authentication with an NTP server.
show ntp associations	Shows the NTP servers with which the ASA is associated.

show object-group

To display object group information and the relevant hit count if the object group is of the network object-group type, use the **show object-group** command in privileged EXEC mode.

show object-group [**protocol** | **service** | **icmp-type** | **id** *object-group name*]

Syntax Description

icmp-type	(Optional) An ICMP-type object group.
id	(Optional) Identifies the existing object group.
object-group name	(Optional) Assigns a given name to the object group.
protocol	(Optional) Protocol-type object group.
service	(Optional) Service-type object.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

A routine attempt to show object groups also shows the object hit count if the object group is of the network object-group type. Hit counts do not display for service, protocol, and icmp-type object groups.

Examples

The following is sample output from the **show object-group** command and shows information about the network object group named “Anet”:

```
hostname# show object-group id Anet
Object-group network Anet (hitcnt=10)
   Description OBJ SEARCH ALG APPLIED
   network-object 1.1.1.0 255.255.255.0 (hitcnt=4)
   network-object 2.2.2.0 255.255.255.0 (hitcnt=6)
```

The following is sample output from the **show object-group** command and shows information about a service group:

```
hostname (config)# show object-group service
object-group service B-Serobj
   description its a service group
```

```
   service-object tcp eq bgp

   object-group protocol C-grp-proto
   protocol-object ospf
```

The following is sample output from the **show object-group** command and shows information about a protocol:

```
hostname (config)# show object-group protocol
object-group protocol C-grp-proto
   protocol-object ospf
```

Related Commands

Command	Description
clear object-group	Clears the network objects hit count for a given object group.
show access list	Shows all access lists, relevant expanded access list entries, and hit counts.

show ospf

To display the general information about the OSPF routing processes, use the **show ospf** command in privileged EXEC mode.

show ospf [*pid* [*area_id*]]

Syntax Description

area_id	(Optional) ID of the area that is associated with the OSPF address range.
pid	(Optional) The ID of the OSPF process.

Defaults

Lists all OSPF processes if no *pid* is specified.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

If the *pid* is included, only information for the specified routing process is included.

Examples

The following is sample output from the **show ospf** command, showing how to display general information about a specific OSPF routing process:

```
hostname# show ospf 5
 Routing Process "ospf 5" with ID 127.0.0.1 and Domain ID 0.0.0.5
 Supports only single TOS(TOS0) routes
 Supports opaque LSA
 SPF schedule delay 5 secs, Hold time between two SPFs 10 secs
 Minimum LSA interval 5 secs. Minimum LSA arrival 1 secs
 Number of external LSA 0. Checksum Sum 0x     0
 Number of opaque AS LSA 0. Checksum Sum 0x     0
 Number of DCbitless external and opaque AS LSA 0
 Number of DoNotAge external and opaque AS LSA 0
 Number of areas in this router is 0. 0 normal 0 stub 0 nssa
 External flood list length 0
```

The following is sample output from the **show ospf** command, showing how to display general information about all OSPF routing processes:

```
hostname# show ospf
 Routing Process "ospf 5" with ID 127.0.0.1 and Domain ID 0.0.0.5
 Supports only single TOS(TOS0) routes
 Supports opaque LSA
 SPF schedule delay 5 secs, Hold time between two SPFs 10 secs
 Minimum LSA interval 5 secs. Minimum LSA arrival 1 secs
 Number of external LSA 0. Checksum Sum 0x     0
 Number of opaque AS LSA 0. Checksum Sum 0x     0
 Number of DCbitless external and opaque AS LSA 0
 Number of DoNotAge external and opaque AS LSA 0
 Number of areas in this router is 0. 0 normal 0 stub 0 nssa
 External flood list length 0

 Routing Process "ospf 12" with ID 172.23.59.232 and Domain ID 0.0.0.12
 Supports only single TOS(TOS0) routes
 Supports opaque LSA
 SPF schedule delay 5 secs, Hold time between two SPFs 10 secs
 Minimum LSA interval 5 secs. Minimum LSA arrival 1 secs
 Number of external LSA 0. Checksum Sum 0x     0
 Number of opaque AS LSA 0. Checksum Sum 0x     0
 Number of DCbitless external and opaque AS LSA 0
 Number of DoNotAge external and opaque AS LSA 0
 Number of areas in this router is 0. 0 normal 0 stub 0 nssa
 External flood list length 0
```

Related Commands

Command	Description
router ospf	Enables OSPF routing and configures global OSPF routing parameters.

show ospf border-routers

To display the internal OSPF routing table entries to ABRs and ASBRs, use the **show ospf border-routers** command in privileged EXEC mode.

show ospf border-routers

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Examples

The following is sample output from the show **ospf border-routers** command:

```
hostname# show ospf border-routers

OSPF Process 109 internal Routing Table

Codes: i - Intra-area route, I - Inter-area route

i 192.168.97.53 [10] via 192.168.1.53, fifth, ABR, Area 0, SPF 20
i 192.168.103.51 [10] via 192.168.96.51, outside, ASBR, Area 192.168.12.0, SPF 14
i 192.168.103.52 [10] via 192.168.96.51, outside, ABR/ASBR, Area 192.168.12.0, SPF 14
```

Related Commands

Command	Description
router ospf	Enables OSPF routing and configures global OSPF routing parameters.

show ospf database

To display the information contained in the OSPF topological database on the ASA, use the **show ospf database** command in privileged EXEC mode.

show ospf [*pid* [*area_id*]] **database** [**router** | **network** | **summary** | **asbr-summary** | **external** | **nssa-external**] [*lsid*] [**internal**] [**self-originate** | **adv-router** *addr*]

show ospf [*pid* [*area_id*]] **database database-summary**

Syntax Description

addr	(Optional) Router address.
adv-router	(Optional) Advertised router.
area_id	(Optional) ID of the area that is associated with the OSPF address range.
asbr-summary	(Optional) Displays an ASBR list summary.
database	Displays the database information.
database-summary	(Optional) Displays the complete database summary list.
external	(Optional) Displays routes external to a specified autonomous system.
internal	(Optional) Routes that are internal to a specified autonomous system.
lsid	(Optional) LSA ID.
network	(Optional) Displays the OSPF database information about the network.
nssa-external	(Optional) Displays the external not-so-stubby-area list.
pid	(Optional) ID of the OSPF process.
router	(Optional) Displays the router.
self-originate	(Optional) Displays the information for the specified autonomous system.
summary	(Optional) Displays a summary of the list.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The OSPF routing-related **show** commands are available in privileged mode on the ASA. You do not need to be in an OSPF configuration mode to use the OSPF-related **show** commands.

Examples

The following is sample output from the **show ospf database** command:

```
hostname# show ospf database
OSPF Router with ID(192.168.1.11) (Process ID 1)

                Router Link States(Area 0)
Link ID   ADV Router   Age   Seq# Checksum Link count
192.168.1.8 192.168.1.8 1381 0x8000010D    0xEF60 2

```

Related Commands

Command	Description
router ospf	Enables OSPF routing and configures global OSPF routing parameters.

show ospf flood-list

To display a list of OSPF LSAs waiting to be flooded over an interface, use the **show ospf flood-list** command in privileged EXEC mode.

show ospf flood-list *interface_name*

Syntax Description

interface_name	The name of the interface for which to display neighbor information.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The OSPF routing-related **show** commands are available in privileged mode on the ASA. You do not need to be in an OSPF configuration mode to use the OSPF-related **show** commands.

Examples

The following is sample output from the **show ospf flood-list** command:

```
hostname# show ospf flood-list outside

  Interface outside, Queue length 20
  Link state flooding due in 12 msec

  Type  LS ID          ADV RTR          Seq NO       Age   Checksum
     5  10.2.195.0     192.168.0.163    0x80000009   0     0xFB61
     5  10.1.192.0     192.168.0.163    0x80000009   0     0x2938
     5  10.2.194.0     192.168.0.163    0x80000009   0     0x757
     5  10.1.193.0     192.168.0.163    0x80000009   0     0x1E42
     5  10.2.193.0     192.168.0.163    0x80000009   0     0x124D
     5  10.1.194.0     192.168.0.163    0x80000009   0     0x134C
```

Related Commands

Command	Description
router ospf	Enables OSPF routing and configures global OSPF routing parameters.

show ospf interface

To display the OSPF-related interface information, use the **show ospf interface** command in privileged EXEC mode.

show ospf interface [*interface_name*]

Syntax Description

interface_name	(Optional) Name of the interface for which to display the OSPF-related information.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

When used without the *interface_name* argument, the OSPF information for all interfaces is shown.

Examples

The following is sample output from the **show ospf interface** command:

```
hostname# show ospf interface inside
inside is up, line protocol is up
Internet Address 192.168.254.202, Mask 255.255.255.0, Area 0.0.0.0
AS 201, Router ID 192.77.99.1, Network Type BROADCAST, Cost: 10
Transmit Delay is 1 sec, State OTHER, Priority 1
Designated Router id 192.168.254.10, Interface address 192.168.254.10
Backup Designated router id 192.168.254.28, Interface addr 192.168.254.28
Timer intervals configured, Hello 10, Dead 60, Wait 40, Retransmit 5
Hello due in 0:00:05
Neighbor Count is 8, Adjacent neighbor count is 2
  Adjacent with neighbor 192.168.254.28 (Backup Designated Router)
  Adjacent with neighbor 192.168.254.10 (Designated Router)
```

Related Commands

Command	Description
interface	Enters interface configuration mode.

show ospf neighbor

To display the OSPF-neighbor information on a per-interface basis, use the **show ospf neighbor** command in privileged EXEC mode.

show ospf neighbor [**detail** | *interface_name* [*nbr_router_id*]]

Syntax Description

detail	(Optional) Lists detail information for the specified router.
interface_name	(Optional) Name of the interface for which to display neighbor information.
nbr_router_id	(Optional) Router ID of the neighbor router.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Examples

The following is sample output from the **show ospf neighbor** command. It shows how to display the OSPF-neighbor information on a per-interface basis.

```
hostname# show ospf neighbor outside

Neighbor 192.168.5.2, interface address 10.225.200.28
    In the area 0 via interface outside
    Neighbor priority is 1, State is FULL, 6 state changes
    DR is 10.225.200.28 BDR is 10.225.200.30
    Options is 0x42
    Dead timer due in 00:00:36
    Neighbor is up for 00:09:46
  Index 1/1, retransmission queue length 0, number of retransmission 1
    First 0x0(0)/0x0(0) Next 0x0(0)/0x0(0)
    Last retransmission scan length is 1, maximum is 1
    Last retransmission scan time is 0 msec, maximum is 0 msec
```

Related Commands

Command	Description
neighbor	Configures OSPF routers interconnecting to non-broadcast networks.
router ospf	Enables OSPF routing and configures global OSPF routing parameters.

show ospf request-list

To display a list of all LSAs that are requested by a router, use the **show ospf request-list** command in privileged EXEC mode.

show ospf request-list *nbr_router_id interface_name*

Syntax Description

interface_name	Name of the interface for which to display neighbor information. Displays the list of all LSAs that are requested by the router from this interface.
nbr_router_id	Router ID of the neighbor router. Displays the list of all LSAs that are requested by the router from this neighbor.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Examples

The following is sample output from the **show ospf request-list** command:

```
hostname# show ospf request-list 192.168.1.12 inside

          OSPF Router with ID (192.168.1.11) (Process ID 1)

  Neighbor 192.168.1.12, interface inside address 172.16.1.12

  Type   LS ID          ADV RTR        Seq NO       Age   Checksum
     1   192.168.1.12   192.168.1.12   0x8000020D   8     0x6572
```

Related Commands

Command	Description
show ospf retransmission-list	Displays a list of all LSAs waiting to be resent.

show ospf retransmission-list

To display a list of all LSAs waiting to be resent, use the **show ospf retransmission-list** command in privileged EXEC mode.

show ospf retransmission-list *nbr_router_id interface_name*

Syntax Description

interface_name	Name of the interface for which to display neighbor information.
nbr_router_id	Router ID of the neighbor router.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The OSPF routing-related **show** commands are available in privileged mode on the ASA. You do not need to be in an OSPF configuration mode to use the OSPF-related **show** commands.

The *nbr_router_id* argument displays the list of all LSAs that are waiting to be resent for this neighbor.

The *interface_name* argument displays the list of all LSAs that are waiting to be resent for this interface.

Examples

The following is sample output from the **show ospf retransmission-list** command, where the *nbr_router_id* argument is 192.168.1.11 and the *if_name* argument is outside:

```
hostname# show ospf retransmission-list 192.168.1.11 outside

         OSPF Router with ID (192.168.1.12) (Process ID 1)

  Neighbor 192.168.1.11, interface outside address 172.16.1.11
  Link state retransmission due in 3764 msec, Queue length 2

  Type   LS ID          ADV RTR        Seq NO       Age   Checksum
     1   192.168.1.12   192.168.1.12   0x80000210   0     0xB196
```

Related Commands

Command	Description
show ospf request-list	Displays a list of all LSAs that are requested by a router.

show ospf summary-address

To display a list of all summary address redistribution information that is configured under an OSPF process, use the **show ospf summary-address** command in privileged EXEC mode.

show ospf summary-address

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Examples

The following shows sample output from the **show ospf summary-address** command. It shows how to display a list of all summary address redistribution information before a summary address has been configured for an OSPF process with the ID of 5.

```
hostname# show ospf 5 summary-address

OSPF Process 2, Summary-address

10.2.0.0/255.255.0.0 Metric -1, Type 0, Tag 0
10.2.0.0/255.255.0.0 Metric -1, Type 0, Tag 10
```

Related Commands

Command	Description
summary-address	Creates aggregate addresses for OSPF.

show ospf traffic

To display a list of different types of packets that have been processed (sent or received) by a particular OSPF instance, use the **show ospf traffic** command in privileged EXEC mode. With this command, you can get a snapshot of the different types of OSPF packets that are being being processed without enabling debugging. If there are two OSPF instances configured, the show ospf traffic command displays the statistics for both instances with the process ID of each instance. You can also display the statistics for a single instance by using the **show ospf** *process_id* **traffic** command.

show ospf traffic

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

With this command, you can get a snapshot of the different types of OSPF packets that are being being processed without enabling debugging. If there are two OSPF instances configured, the **show ospf traffic** command displays the statistics for both instances with the process ID of each instance. You can also display the statistics for a single instance by using the **show ospf** *process_id* **traffic** command.

Examples

The following shows sample output from the **show ospf traffic** command.

```
hostname# show ospf traffic

OSPF statistics (Process ID 70):

       Rcvd: 244 total, 0 checksum errors
             234 hello, 4 database desc, 1 link state req
             3 link state updates, 2 link state acks
       Sent: 485 total
             472 hello, 7 database desc, 1 link state req
             3 link state updates, 2 link state acks
```

Related Commands

Command	Description
show ospf virtual-links	Displays the parameters and the current state of OSPF virtual links.

show ospf virtual-links

To display the parameters and the current state of OSPF virtual links, use the **show ospf virtual-links** command in privileged EXEC mode.

show ospf virtual-links

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Examples

The following is sample output from the **show ospf virtual-links** command:

```
hostname# show ospf virtual-links

Virtual Link to router 192.168.101.2 is up
Transit area 0.0.0.1, via interface Ethernet0, Cost of using 10
Transmit Delay is 1 sec, State POINT_TO_POINT
Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
Hello due in 0:00:08
Adjacency State FULL
```

Related Commands

Command	Description
area virtual-link	Defines an OSPF virtual link.

CHAPTER 52

show nac-policy through show ospf virtual-links Commands

show nac-policy

To show the NAC policy usage statistics and the assignment of NAC policies to group policies, use the **show nac-policy** command in privileged EXEC mode.

show nac-policy [*nac-policy-name*]

Syntax Description

nac-policy-name	(Optional) Name of the NAC policy for which to display usage statistics.

Defaults

If you do not specify a name, the CLI lists all NAC policy names along with their respective statistics.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	—	•

Command History

Release	Modification
8.0(2)	This command was introduced.

Examples

The following example shows the data for the NAC policies named framework1 and framework2:

```
asa2(config)# show nac-policy
nac-policy framework1 nac-framework
  applied session count = 0
  applied group-policy count = 2
  group-policy list:    GroupPolicy2    GroupPolicy1
nac-policy framework2 nac-framework is not in use.
```

The first line of each NAC policy indicates its name and type (nac-framework). The CLI shows the text "is not in use" next to the policy type if the policy is not assigned to any group policies. Otherwise, the CLI displays the usage data for the group policy. Table 52-1 explains the fields in the **show nac-policy** command.

Table 52-1 show nac-policy Command Fields

Field	Description
applied session count	Cumulative number of VPN sessions to which this ASA applied the NAC policy.

Table 52-1 show nac-policy Command Fields

Field	Description
applied group-policy count	Cumulative number of group polices to which this ASA applied the NAC policy.
group-policy list	List of group policies to which this NAC policy is assigned. In this case, the usage of a group policy does not determine whether it appears in this list; if the NAC policy is assigned to a group policy in the running configuration, then the group policy appears in this list.

Related Commands

clear nac-policy	Resets the NAC policy usage statistics.
show vpn-session.db	Displays information about VPN sessions, including NAC results.
show vpn-session_summary.db	Displays the number IPSec, Cisco WebVPN, and NAC sessions.

show nameif

To view the interface name set using the **nameif** command, use the show nameif command in privileged EXEC mode.

show nameif [*physical_interface*[**.***subinterface*] | *mapped_name*]

Syntax Description

mapped_name	(Optional) In multiple context mode, identifies the mapped name if it was assigned using the **allocate-interface** command.
physical_interface	(Optional) Identifies the interface ID, such as **gigabitethernet0/1**. See the **interface** command for accepted values.
subinterface	(Optional) Identifies an integer between 1 and 4294967293 designating a logical subinterface.

Defaults

If you do not specify an interface, the ASA shows all interface names.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

In multiple context mode, if you mapped the interface ID in the **allocate-interface** command, you can only specify the mapped name in a context. The output for this command shows only the mapped name in the Interface column.

Examples

The following is sample output from the **show nameif** command:

```
hostname# show nameif
Interface               Name                    Security
GigabitEthernet0/0      outside                 0
GigabitEthernet0/1      inside                  100
GigabitEthernet0/2      test2                   50
```

Related Commands

Command	Description
allocate-interface	Assigns interfaces and subinterfaces to a security context.
interface	Configures an interface and enters interface configuration mode.
nameif	Sets the interface name.
show interface ip brief	Shows the interface IP address and status.

show nat

To display statistics of NAT policies, use the **show nat** command in privileged EXEC mode.

show nat [**interface** *name*] [*ip_addr mask* | {**object** | **object-group**} *name*]
[**translated** [**interface** *name*] [*ip_addr mask* | {**object** | **object-group**} *name*]] [**detail**]
[**divert-table** [**ipv6**] [**interface** *name*]]

Syntax Description

detail	(Optional) Includes more verbose expansion of the object fields.
divert-table	(Optional) Shows the NAT divert table.
interface *name*	(Optional) Specifies the source interface.
ip_addr mask	(Optional) Specifies an IP address and subnet mask.
ipv6	(Optional) Shows IPv6 entries in the divert table.
object *name*	(Optional) Specifies a network object or service object.
object-group *name*	(Optional) Specifies a network object group
translated	(Optional) Specifies the translated parameters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.
9.0(1)	This command now supports IPv6 traffic, as well as translations between IPv4 and IPv6.

Usage Guidelines

Use the **show nat** command to show runtime representation of the NAT policy. Use the **detail** optional keyword to expand the object and view the object values. Use the additional selector fields to limit the **show nat** command output.

Examples

The following is sample output from the **show nat** command:

```
hostname# show nat
   Manual NAT Policies (Section 1)
   1 (any) to (any) source dynamic S S' destination static D' D
       translate_hits = 0, untranslate_hits = 0
```

```
   Auto NAT Policies (Section 2)
   1 (inside) to (outside) source dynamic A 2.2.2.2
       translate_hits = 0, untranslate_hits = 0

   Manual NAT Policies (Section 3)
   1 (any) to (any) source dynamic C C' destination static B' B service R R'
       translate_hits = 0, untranslate_hits = 0

hostname# show nat detail
   Manual NAT Policies (Section 1)
   1 (any) to (any) source dynamic S S' destination static D' D
       translate_hits = 0, untranslate_hits = 0
       Source - Real: 1.1.1.2/32, Mapped: 2.2.2.3/32
       Destination - Real: 10.10.10.0/24, Mapped: 20.20.20.0/24

   Auto NAT Policies (Section 2)
   1 (inside) to (outside) source dynamic A 2.2.2.2
       translate_hits = 0, untranslate_hits = 0
       Source - Real: 1.1.1.1/32, Mapped: 2.2.2.2/32

   Manual NAT Policies (Section 3)
    1 (any) to (any) source dynamic C C' destination static B' B service R R'
       translate_hits = 0, untranslate_hits = 0
       Source - Real: 11.11.11.10-11.11.11.11, Mapped: 192.168.10.10/32
       Destination - Real: 192.168.1.0/24, Mapped: 10.75.1.0/24
       Service - Real: tcp source eq 10 destination eq ftp-data , Mapped: tcp source eq
       100 destination eq 200
```

The following is sample output from the **show nat detail** command between IPv6 and IPv4:

```
hostname# show nat detail
1 (in) to (outside) source dynamic inside_nw outside_map destination static inside_map any
translate_hits = 0, untranslate_hits = 0
Source - Origin: 2001::/96, Translated: 192.168.102.200-192.168.102.210
Destination - Origin: 2001::/96, Translated: 0.0.0.0/0
```

The following is sample output from the **show nat divert ipv6** command:

```
hostname# show nat divert ipv6
Divert Table
id=0xcb9ea518, domain=divert-route
type=static, hits=0, flags=0x21, protocol=0
src ip/id=2001::/ffff:ffff:ffff:ffff:ffff:ffff::, port=0-0
dst ip/id=2001::/ffff:ffff:ffff:ffff:ffff:ffff::, port=0-0
input_ifc=in, output_ifc=outside
id=0xcf24d4b8, domain=divert-route
type=static, hits=0, flags=0x20, protocol=0
src ip/id=::/::, port=0-0
dst ip/id=2222::/ffff:ffff:ffff:ffff:ffff:ffff::, port=0-0
input_ifc=in, output_ifc=mgmt
```

Related Commands

Command	Description
clear nat counters	Clears NAT policy counters.
nat	Identifies addresses on one interface that are translated to mapped addresses on another interface.

show nat divert-table

To display statistics of NAT divert table, use the **show nat divert-table** command in privileged EXEC mode.

show nat divert-table [**ipv6**] [**interface** *name*]

Syntax Description

divert-table	Shows the NAT divert table.
ipv6	(Optional) Shows IPv6 entries in the divert table.
interface *name*	(Optional) Specifies the source interface.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(2)	This command was introduced.

Usage Guidelines

Use the **show nat divert-table** command to show runtime representation of the NAT divert table. Use the **ipv6** optional keyword to view the IPv6 entries in the divert table. Use the **interface** optional keyword to view the NAT divert table for the specific source interface.

Examples

The following is sample output from the **show nat divert-table** command:

```
hostname# show nat divert-table
Divert Table
id=0xad1521b8, domain=twice-nat section=1 ignore=no
        type=none, hits=0, flags=0x9, protocol=0

        dst ip/id=172.27.48.0, mask=255.255.255.255, port=0-0
        input_ifc=folink, output_ifc=NP Identity Ifc
```

Related Commands

Command	Description
clear nat counters	Clears NAT policy counters.
nat	Identifies addresses on one interface that are translated to mapped addresses on another interface.
show nat	Displays runtime representation of the NAT policies.

show nat pool

To display statistics of NAT pool usage, use the **show nat pool** command in privileged EXEC mode.

show nat pool [**cluster**]

Syntax Description

cluster	(Optional) When ASA clustering is enabled, shows the current assignment of a PAT address to the owner unit and backup unit.

Defaults

This command has no default settings.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.
8.4(3)	The output was modified to show the destination address for extended PAT. The PAT range was also modified depending on the use of the **flat** and **include-reserve** keywords.
9.0(1)	This command now supports IPv6 traffic. We added the **cluster** keyword to show the current assignment of a PAT address to the owner unit and backup unit.

Usage Guidelines

A NAT pool is created for each mapped protocol/IP address/port range, where the port ranges are 1-511, 512-1023, and 1024-65535 by default. If you use the **flat** keyword for a PAT pool in the **nat** command, you will see fewer, larger ranges.

Each NAT pool exists for at least 10 minutes after the last usage. The 10 minute hold-down timer is canceled if you clear the translations with **clear xlate**.

Examples

The following is sample output for the NAT pools created by a dynamic PAT rule shown by the **show running-config object network** command.

```
hostname(config)# show running-config object network
object network myhost
 host 10.10.10.10
 nat (pppoe2,inside) dynamic 10.76.11.25

hostname# show nat pool
```

```
TCP inside, address 10.76.11.25, range 1-511, allocated 0
TCP inside, address 10.76.11.25, range 512-1023, allocated 0
TCP inside, address 10.76.11.25, range 1024-65535, allocated 1
```

The following is sample output from the **show nat pool** command showing use of the PAT pool **flat** option. Without the **include-reserve** keyword, two ranges are shown; the lower range is used when a source port below 1024 is mapped to the same port.

```
hostname# show nat pool

ICMP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1-65535, allocated 2
TCP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1-1024, allocated 0
TCP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1024-65535, allocated 2
UDP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1-1024, allocated 0
UDP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1024-65535, allocated 2
```

The following is sample output from the **show nat pool** command showing use of the PAT pool **flat include-reserve** options.

```
hostname# show nat pool

ICMP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1-65535, allocated 2
TCP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1-65535, allocated 2
UDP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1-65535, allocated 2
```

The following is sample output from the **show nat pool** command showing use of the PAT pool **extended flat include-reserve** options. The important items are the parenthetical addresses. These are the destination addresses used to extend PAT.

```
ICMP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1-65535, allocated 0
ICMP PAT pool outside:dynamic-pat, address 172.16.2.200(172.16.2.99), range 1-65535,
allocated 2
TCP PAT pool outside:dynamic-pat, address 172.16.2.200(172.16.2.100), range 1-65535,
allocated 1
UDP PAT pool outside:dynamic-pat, address 172.16.2.200(172.16.2.100), range 1-65535,
allocated 1
TCP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1-65535, allocated 0
ICMP PAT pool outside:dynamic-pat, address 172.16.2.200(172.16.2.100), range 1-65535,
allocated 1
TCP PAT pool outside:dynamic-pat, address 172.16.2.200(172.16.2.99), range 1-65535,
allocated 2
UDP PAT pool outside:dynamic-pat, address 172.16.2.200, range 1-65535, allocated 0
```

Related Commands

Command	Description
nat	Identifies addresses on one interface that are translated to mapped addresses on another interface.
show nat	Displays NAT policy statistics.

show ntp associations

To view NTP association information, use the **show ntp associations** command in user EXEC mode.

show ntp associations [**detail**]

Syntax Description

detail	(Optional) Shows additional details about each association.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
User EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

See the "Examples" section for a description of the display output.

Examples

The following is sample output from the **show ntp associations** command:

```
hostname> show ntp associations
     address         ref clock     st  when  poll  reach  delay  offset    disp
 ~172.31.32.2      172.31.32.1       5    29  1024  377     4.2   -8.59     1.6
+~192.168.13.33    192.168.1.111     3    69   128  377     4.1    3.48     2.3
*~192.168.13.57    192.168.1.111     3    32   128  377     7.9   11.18     3.6
* master (synced), # master (unsynced), + selected, - candidate, ~ configured
```

Table 52-2 shows each field description.

Table 52-2 show ntp associations Fields

Field	Description
(leading characters in display lines)	The first characters in a display line can be one or more of the following characters: • * —Synchronized to this peer. • # —Almost synchronized to this peer. • + —Peer selected for possible synchronization. • - —Peer is a candidate for selection. • ~ —Peer is statically configured, but not synchronized.
address	The address of the NTP peer.
ref clock	The address of the reference clock of the peer.
st	The stratum of the peer.
when	The time since the last NTP packet was received from the peer.
poll	The polling interval (in seconds).
reach	The peer reachability (as a bit string, in octal).
delay	The round-trip delay to the peer (in milliseconds).
offset	The relative time of the peer clock to the local clock (in milliseconds).
disp	The dispersion value.

The following is sample output from the **show ntp associations detail** command:

```
hostname> show ntp associations detail

Table 52-3 shows each field description.

Table 52-3 show ntp associations detail Fields

Field	Description
IP-address configured	The server (peer) IP address.
(status)	• our_master—The ASA is synchronized to this peer. • selected—Peer is selected for possible synchronization. • candidate—Peer is a candidate for selection.

Table 52-3 show ntp associations detail Fields (continued)

Field	Description
(sanity)	• sane—The peer passes basic sanity checks. • insane—The peer fails basic sanity checks.
(validity)	• valid—The peer time is believed to be valid. • invalid—The peer time is believed to be invalid. • leap_add—The peer is signalling that a leap second will be added. • leap-sub—The peer is signalling that a leap second will be subtracted.
stratum	The stratum of the peer.
(reference peer)	unsynced—The peer is not synchronized to any other machine. ref ID—The address of the machine that the peer is synchronized to.
time	The last time stamp the peer received from its master.
our mode client	Our mode relative to the peer, which is always client.
peer mode server	The mode of the peer relative to the server.
our poll intvl	Our poll interval to the peer.
peer poll intvl	The peer poll interval to us.
root delay	The delay along the path to the root (ultimate stratum 1 time source).
root disp	The dispersion of the path to the root.
reach	The peer reachability (as a bit string in octal).
sync dist	The peer synchronization distance.
delay	The round-trip delay to the peer.
offset	The offset of the peer clock relative to our clock.
dispersion	The dispersion of the peer clock.
precision	The precision of the peer clock (in hertz).
version	The NTP version number that the peer is using.
org time	The originate time stamp.
rcv time	The receive time stamp.
xmt time	The transmit time stamp.
filtdelay	The round-trip delay (in milliseconds) of each sample.
filtoffset	The clock offset (in milliseconds) of each sample.
filterror	The approximate error of each sample.

Related Commands

Command	Description
ntp authenticate	Enables NTP authentication.
ntp authentication-key	Sets an encrypted authentication key to synchronize with an NTP server.
ntp server	Identifies an NTP server.

Command	Description
ntp trusted-key	Provides a key ID for the ASA to use in packets for authentication with an NTP server.
show ntp status	Shows the status of the NTP association.

show ntp status

To show the status of each NTP association, use the **show ntp status** command in user EXEC mode.

show ntp status

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
	Routed	Transparent	Single	Multiple	
				Context	System
User EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

See the “Examples” section for a description of the display output.

Examples

The following is sample output from the **show ntp status** command:

```
hostname> show ntp status
Clock is synchronized, stratum 5, reference is 172.23.56.249
nominal freq is 99.9984 Hz, actual freq is 100.0266 Hz, precision is 2**6
reference time is c02128a9.73c1954b (20:29:29.452 UTC Fri Feb 22 2002)
clock offset is -0.2403 msec, root delay is 42.51 msec
root dispersion is 135.01 msec, peer dispersion is 125.21 msec
```

Table 52-4 shows each field description.

Table 52-4 show ntp status Fields

Field	Description
Clock	• synchronized—The ASA is synchronized to an NTP server. • unsynchronized—The ASA is not synchronized to an NTP server.
stratum	NTP stratum of this system.
reference	The address of the NTP server to which the ASA is synchronized.
nominal freq	The nominal frequency of the system hardware clock.

Table 52-4 show ntp status Fields

Field	Description
actual freq	The measured frequency of the system hardware clock.
precision	The precision of the clock of this system (in hertz).
reference time	The reference time stamp.
clock offset	The offset of the system clock to the synchronized peer.
root delay	The total delay along the path to the root clock.
root dispersion	The dispersion of the root path.
peer dispersion	The dispersion of the synchronized peer.

Related Commands

Command	Description
ntp authenticate	Enables NTP authentication.
ntp authentication-key	Sets an encrypted authentication key to synchronize with an NTP server.
ntp server	Identifies an NTP server.
ntp trusted-key	Provides a key ID for the ASA to use in packets for authentication with an NTP server.
show ntp associations	Shows the NTP servers with which the ASA is associated.

show object-group

To display object group information and the relevant hit count if the object group is of the network object-group type, use the **show object-group** command in privileged EXEC mode.

show object-group [protocol | service | icmp-type | id *object-group name*]

Syntax Description

icmp-type	(Optional) An ICMP-type object group.
id	(Optional) Identifies the existing object group.
object-group name	(Optional) Assigns a given name to the object group.
protocol	(Optional) Protocol-type object group.
service	(Optional) Service-type object.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

A routine attempt to show object groups also shows the object hit count if the object group is of the network object-group type. Hit counts do not display for service, protocol, and icmp-type object groups.

Examples

The following is sample output from the **show object-group** command and shows information about the network object group named “Anet”:

```
hostname# show object-group id Anet
Object-group network Anet (hitcnt=10)
   Description OBJ SEARCH ALG APPLIED
   network-object 1.1.1.0 255.255.255.0 (hitcnt=4)
   network-object 2.2.2.0 255.255.255.0 (hitcnt=6)
```

The following is sample output from the **show object-group** command and shows information about a service group:

```
hostname (config)# show object-group service
object-group service B-Serobj
   description its a service group
```

```
   service-object tcp eq bgp

   object-group protocol C-grp-proto
   protocol-object ospf
```

The following is sample output from the **show object-group** command and shows information about a protocol:

```
hostname (config)# show object-group protocol
object-group protocol C-grp-proto
   protocol-object ospf
```

Related Commands

Command	Description
clear object-group	Clears the network objects hit count for a given object group.
show access list	Shows all access lists, relevant expanded access list entries, and hit counts.

show ospf

To display the general information about the OSPF routing processes, use the **show ospf** command in privileged EXEC mode.

show ospf [*pid* [*area_id*]]

Syntax Description

area_id	(Optional) ID of the area that is associated with the OSPF address range.
pid	(Optional) The ID of the OSPF process.

Defaults

Lists all OSPF processes if no *pid* is specified.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

If the *pid* is included, only information for the specified routing process is included.

Examples

The following is sample output from the **show ospf** command, showing how to display general information about a specific OSPF routing process:

```
hostname# show ospf 5
 Routing Process "ospf 5" with ID 127.0.0.1 and Domain ID 0.0.0.5
 Supports only single TOS(TOS0) routes
 Supports opaque LSA
 SPF schedule delay 5 secs, Hold time between two SPFs 10 secs
 Minimum LSA interval 5 secs. Minimum LSA arrival 1 secs
 Number of external LSA 0. Checksum Sum 0x     0
 Number of opaque AS LSA 0. Checksum Sum 0x     0
 Number of DCbitless external and opaque AS LSA 0
 Number of DoNotAge external and opaque AS LSA 0
 Number of areas in this router is 0. 0 normal 0 stub 0 nssa
 External flood list length 0
```

The following is sample output from the **show ospf** command, showing how to display general information about all OSPF routing processes:

```
hostname# show ospf
 Routing Process "ospf 5" with ID 127.0.0.1 and Domain ID 0.0.0.5
 Supports only single TOS(TOS0) routes
 Supports opaque LSA
 SPF schedule delay 5 secs, Hold time between two SPFs 10 secs
 Minimum LSA interval 5 secs. Minimum LSA arrival 1 secs
 Number of external LSA 0. Checksum Sum 0x     0
 Number of opaque AS LSA 0. Checksum Sum 0x     0
 Number of DCbitless external and opaque AS LSA 0
 Number of DoNotAge external and opaque AS LSA 0
 Number of areas in this router is 0. 0 normal 0 stub 0 nssa
 External flood list length 0

 Routing Process "ospf 12" with ID 172.23.59.232 and Domain ID 0.0.0.12
 Supports only single TOS(TOS0) routes
 Supports opaque LSA
 SPF schedule delay 5 secs, Hold time between two SPFs 10 secs
 Minimum LSA interval 5 secs. Minimum LSA arrival 1 secs
 Number of external LSA 0. Checksum Sum 0x     0
 Number of opaque AS LSA 0. Checksum Sum 0x     0
 Number of DCbitless external and opaque AS LSA 0
 Number of DoNotAge external and opaque AS LSA 0
 Number of areas in this router is 0. 0 normal 0 stub 0 nssa
 External flood list length 0
```

Related Commands

Command	Description
router ospf	Enables OSPF routing and configures global OSPF routing parameters.

show ospf border-routers

To display the internal OSPF routing table entries to ABRs and ASBRs, use the **show ospf border-routers** command in privileged EXEC mode.

show ospf border-routers

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Examples

The following is sample output from the show **ospf border-routers** command:

```
hostname# show ospf border-routers

OSPF Process 109 internal Routing Table

Codes: i - Intra-area route, I - Inter-area route

i 192.168.97.53 [10] via 192.168.1.53, fifth, ABR, Area 0, SPF 20
i 192.168.103.51 [10] via 192.168.96.51, outside, ASBR, Area 192.168.12.0, SPF 14
i 192.168.103.52 [10] via 192.168.96.51, outside, ABR/ASBR, Area 192.168.12.0, SPF 14
```

Related Commands

Command	Description
router ospf	Enables OSPF routing and configures global OSPF routing parameters.

show ospf database

To display the information contained in the OSPF topological database on the ASA, use the **show ospf database** command in privileged EXEC mode.

show ospf [*pid* [*area_id*]] **database** [**router** | **network** | **summary** | **asbr-summary** | **external** | **nssa-external**] [*lsid*] [**internal**] [**self-originat**e | **adv-router** *addr*]

show ospf [*pid* [*area_id*]] **database database-summary**

Syntax Description

addr	(Optional) Router address.
adv-router	(Optional) Advertised router.
area_id	(Optional) ID of the area that is associated with the OSPF address range.
asbr-summary	(Optional) Displays an ASBR list summary.
database	Displays the database information.
database-summary	(Optional) Displays the complete database summary list.
external	(Optional) Displays routes external to a specified autonomous system.
internal	(Optional) Routes that are internal to a specified autonomous system.
lsid	(Optional) LSA ID.
network	(Optional) Displays the OSPF database information about the network.
nssa-external	(Optional) Displays the external not-so-stubby-area list.
pid	(Optional) ID of the OSPF process.
router	(Optional) Displays the router.
self-originate	(Optional) Displays the information for the specified autonomous system.
summary	(Optional) Displays a summary of the list.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The OSPF routing-related **show** commands are available in privileged mode on the ASA. You do not need to be in an OSPF configuration mode to use the OSPF-related **show** commands.

Examples

The following is sample output from the **show ospf database** command:

```
hostname# show ospf database
OSPF Router with ID(192.168.1.11) (Process ID 1)

                Router Link States(Area 0)
Link ID   ADV Router   Age   Seq# Checksum Link count
192.168.1.8 192.168.1.8 1381 0x8000010D    0xEF60 2
192.168.1.11 192.168.1.11 1460 0x800002FE    0xEB3D 4

Related Commands

Command	Description
router ospf	Enables OSPF routing and configures global OSPF routing parameters.

show ospf flood-list

To display a list of OSPF LSAs waiting to be flooded over an interface, use the **show ospf flood-list** command in privileged EXEC mode.

show ospf flood-list *interface_name*

Syntax Description

interface_name	The name of the interface for which to display neighbor information.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The OSPF routing-related **show** commands are available in privileged mode on the ASA. You do not need to be in an OSPF configuration mode to use the OSPF-related **show** commands.

Examples

The following is sample output from the **show ospf flood-list** command:

```
hostname# show ospf flood-list outside

  Interface outside, Queue length 20
  Link state flooding due in 12 msec

  Type  LS ID          ADV RTR          Seq NO       Age   Checksum
     5  10.2.195.0     192.168.0.163    0x80000009   0     0xFB61
     5  10.1.192.0     192.168.0.163    0x80000009   0     0x2938
     5  10.2.194.0     192.168.0.163    0x80000009   0     0x757
     5  10.1.193.0     192.168.0.163    0x80000009   0     0x1E42
     5  10.2.193.0     192.168.0.163    0x80000009   0     0x124D
     5  10.1.194.0     192.168.0.163    0x80000009   0     0x134C
```

Related Commands

Command	Description
router ospf	Enables OSPF routing and configures global OSPF routing parameters.

show ospf interface

To display the OSPF-related interface information, use the **show ospf interface** command in privileged EXEC mode.

show ospf interface [*interface_name*]

Syntax Description

interface_name	(Optional) Name of the interface for which to display the OSPF-related information.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

When used without the *interface_name* argument, the OSPF information for all interfaces is shown.

Examples

The following is sample output from the **show ospf interface** command:

```
hostname# show ospf interface outside
out is up, line protocol is up
  Internet Address 10.0.3.4 mask 255.255.255.0, Area 0
  Process ID 2, Router ID 10.0.3.4, Network Type BROADCAST, Cost: 10
  Transmit Delay is 1 sec, State WAITING, Priority 1
  No designated router on this network
  No backup designated router on this network
  Timer intervals configured, Hello 10 msec, Dead 1, Wait 1, Retransmit 5
    Hello due in 5 msec
    Wait time before Designated router selection 0:00:11
  Index 1/1, flood queue length 0
  Next 0x00000000(0)/0x00000000(0)
  Last flood scan length is 0, maximum is 0
  Last flood scan time is 0 msec, maximum is 0 msec
  Neighbor Count is 0, Adjacent neighbor count is 0
  Suppress hello for 0 neighbor(s)
```

Related Commands

Command	Description
interface	Enters interface configuration mode.

show ospf neighbor

To display the OSPF-neighbor information on a per-interface basis, use the **show ospf neighbor** command in privileged EXEC mode.

show ospf neighbor [**detail** | *interface_name* [*nbr_router_id*]]

Syntax Description

detail	(Optional) Lists detail information for the specified router.
interface_name	(Optional) Name of the interface for which to display neighbor information.
nbr_router_id	(Optional) Router ID of the neighbor router.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Examples

The following is sample output from the **show ospf neighbor** command. It shows how to display the OSPF-neighbor information on a per-interface basis.

```
hostname# show ospf neighbor outside

Neighbor 192.168.5.2, interface address 10.225.200.28
    In the area 0 via interface outside
    Neighbor priority is 1, State is FULL, 6 state changes
    DR is 10.225.200.28 BDR is 10.225.200.30
    Options is 0x42
    Dead timer due in 00:00:36
    Neighbor is up for 00:09:46
  Index 1/1, retransmission queue length 0, number of retransmission 1
    First 0x0(0)/0x0(0) Next 0x0(0)/0x0(0)
    Last retransmission scan length is 1, maximum is 1
    Last retransmission scan time is 0 msec, maximum is 0 msec
```

Related Commands

Command	Description
neighbor	Configures OSPF routers interconnecting to non-broadcast networks.
router ospf	Enables OSPF routing and configures global OSPF routing parameters.

show ospf request-list

To display a list of all LSAs that are requested by a router, use the **show ospf request-list** command in privileged EXEC mode.

show ospf request-list *nbr_router_id interface_name*

Syntax Description

interface_name	Name of the interface for which to display neighbor information. Displays the list of all LSAs that are requested by the router from this interface.
nbr_router_id	Router ID of the neighbor router. Displays the list of all LSAs that are requested by the router from this neighbor.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Examples

The following is sample output from the **show ospf request-list** command:

```
hostname# show ospf request-list 192.168.1.12 inside

          OSPF Router with ID (192.168.1.11) (Process ID 1)

  Neighbor 192.168.1.12, interface inside address 172.16.1.12

  Type   LS ID          ADV RTR        Seq NO       Age   Checksum
     1   192.168.1.12   192.168.1.12   0x8000020D   8     0x6572
```

Related Commands

Command	Description
show ospf retransmission-list	Displays a list of all LSAs waiting to be resent.

show ospf retransmission-list

To display a list of all LSAs waiting to be resent, use the **show ospf retransmission-list** command in privileged EXEC mode.

show ospf retransmission-list *nbr_router_id interface_name*

Syntax Description

interface_name	Name of the interface for which to display neighbor information.
nbr_router_id	Router ID of the neighbor router.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The OSPF routing-related **show** commands are available in privileged mode on the ASA. You do not need to be in an OSPF configuration mode to use the OSPF-related **show** commands.

The *nbr_router_id* argument displays the list of all LSAs that are waiting to be resent for this neighbor.

The *interface_name* argument displays the list of all LSAs that are waiting to be resent for this interface.

Examples

The following is sample output from the **show ospf retransmission-list** command, where the *nbr_router_id* argument is 192.168.1.11 and the *if_name* argument is outside:

```
hostname# show ospf retransmission-list 192.168.1.11 outside

          OSPF Router with ID (192.168.1.12) (Process ID 1)

  Neighbor 192.168.1.11, interface outside address 172.16.1.11
  Link state retransmission due in 3764 msec, Queue length 2

  Type   LS ID          ADV RTR        Seq NO       Age   Checksum
     1   192.168.1.12   192.168.1.12   0x80000210   0     0xB196
```

Related Commands

Command	Description
show ospf request-list	Displays a list of all LSAs that are requested by a router.

show ospf summary-address

To display a list of all summary address redistribution information that is configured under an OSPF process, use the **show ospf summary-address** command in privileged EXEC mode.

show ospf summary-address

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Examples

The following shows sample output from the **show ospf summary-address** command. It shows how to display a list of all summary address redistribution information before a summary address has been configured for an OSPF process with the ID of 5.

```
hostname# show ospf 5 summary-address

OSPF Process 2, Summary-address

10.2.0.0/255.255.0.0 Metric -1, Type 0, Tag 0
10.2.0.0/255.255.0.0 Metric -1, Type 0, Tag 10
```

Related Commands

Command	Description
summary-address	Creates aggregate addresses for OSPF.

show ospf traffic

To display a list of different types of packets that have been processed (sent or received) by a particular OSPF instance, use the **show ospf traffic** command in privileged EXEC mode. With this command, you can get a snapshot of the different types of OSPF packets that are being being processed without enabling debugging. If there are two OSPF instances configured, the show ospf traffic command displays the statistics for both instances with the process ID of each instance. You can also display the statistics for a single instance by using the **show ospf** *process_id* **traffic** command.

show ospf traffic

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

With this command, you can get a snapshot of the different types of OSPF packets that are being being processed without enabling debugging. If there are two OSPF instances configured, the **show ospf traffic** command displays the statistics for both instances with the process ID of each instance. You can also display the statistics for a single instance by using the **show ospf** *process_id* **traffic** command.

Examples

The following shows sample output from the **show ospf traffic** command.

```
hostname# show ospf traffic

OSPF statistics (Process ID 70):

       Rcvd: 244 total, 0 checksum errors
             234 hello, 4 database desc, 1 link state req
             3 link state updates, 2 link state acks
       Sent: 485 total
             472 hello, 7 database desc, 1 link state req
             3 link state updates, 2 link state acks
```

Related Commands

Command	Description
show ospf virtual-links	Displays the parameters and the current state of OSPF virtual links.

show ospf virtual-links

To display the parameters and the current state of OSPF virtual links, use the **show ospf virtual-links** command in privileged EXEC mode.

show ospf virtual-links

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Examples

The following is sample output from the **show ospf virtual-links** command:

```
hostname# show ospf virtual-links

Virtual Link to router 192.168.101.2 is up
Transit area 0.0.0.1, via interface Ethernet0, Cost of using 10
Transmit Delay is 1 sec, State POINT_TO_POINT
Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
Hello due in 0:00:08
Adjacency State FULL
```

Related Commands

Command	Description
area virtual-link	Defines an OSPF virtual link.

CHAPTER 53

show pager through show route Commands

show pager

To display a default or static route for an interface, use the **show pager** command in privileged EXEC mode.

show pager

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
4.0(1)	This command was introduced.

Examples

The following is sample output from the **show pager** command:

```
hostname(config)# show pager
pager lines 0
```

Related Commands

Command	Description
clear configure pager	Removes the number of lines set to display in a Telnet session before the "---More---" prompt appears from the running configuration.
terinal pager	Sets the number of lines to display in a Telnet session before the "---More---" prompt appears. This command is not saved to the running configuration.
show running-config pager	Displays the number of lines set to display in a Telnet session before the "---More---" prompt appears in the running configuration.

show password encryption

To show the password encryption configuration settings, use the **show password encryption** command in privileged EXEC mode.

show password encryption

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
8.3(1)	This command was introduced.
8.4(1)	Allows you to show password encryption in user context.

Usage Guidelines

If the key has been saved using the **write memory** command, "saved" appears next to the key hash. If there is no key or it has been removed from the running configuration, "Not set" appears instead of the hash value.

Examples

The following is sample output from the **show password encryption** command:

```
hostname# show password encryption
Password Encryption: Enabled
Master key hash: 0x35859e5e 0xc607399b 0x35a3438f 0x55474935 0xbec1ee7d(not saved)
```

Related Commands

Command	Description
password encryption aes	Enables password encryption.
key config-key password-encrypt	Sets the pass phrase used for generating the encryption key.

show perfmon

To display information about the performance of the ASA, use the **show perfmon** command in privileged EXEC mode.

show perfmon [**detail**]

Syntax Description

detail	(Optional) Shows additional statsistics. These statistics match those gathered by the Global and Per-protocol connection objects of the Cisco Unified Firewall MIB.

Defaults

This command has no default settings.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	Support for this command was introduced on the ASA.
7.2(1)	The **detail** keyword was added.

Usage Guidelines

This command output does not display in a Telnet session.

The **perfmon** command shows performance statistics continuously at defined intervals. The **show perfmon** command allows you to display the information immediately.

Examples

The following is sample output for the **show perfmon** command:

```
hostname(config)# show perfmon
Context: my_context
PERFMON STATS:    Current      Average
Xlates               0/s          0/s
Connections          0/s          0/s
TCP Conns            0/s          0/s
UDP Conns            0/s          0/s
URL Access           0/s          0/s
URL Server Req       0/s          0/s
WebSns Req           0/s          0/s
TCP Fixup            0/s          0/s
TCP Intercept        0/s          0/s
HTTP Fixup           0/s          0/s
FTP Fixup            0/s          0/s
```

```
AAA Authen           0/s          0/s
AAA Author           0/s          0/s
AAA Account          0/s          0/s
```

The following is sample output for the **show perfmon detail** command:

```
hostname(config)# show perfmon detail
PERFMON STATS:    Current      Average
Xlates               0/s          0/s
Connections          0/s          0/s
TCP Conns            0/s          0/s
UDP Conns            0/s          0/s
URL Access           0/s          0/s
URL Server Req       0/s          0/s
TCP Fixup            0/s          0/s
HTTP Fixup           0/s          0/s
FTP Fixup            0/s          0/s
AAA Authen           0/s          0/s
AAA Author           0/s          0/s
AAA Account          0/s          0/s
TCP Intercept        0/s          0/s

SETUP RATES:
Connections for 1 minute = 0/s; 5 minutes = 0/s
TCP Conns for 1 minute = 0/s; 5 minutes = 0/s
UDP Conns for 1 minute = 0/s; 5 minutes = 0/s
```

Related Commands

Command	Description
perfmon	Displays detailed performance monitoring information at defined intervals.

show phone-proxy

To show phone-proxy specific information, use the **show phone-proxy** command in global configuration mode.

show phone-proxy [media-sessions [detail] | signaling-sessions [detai] | secure-phones]

Syntax Description

detail	Displays detailed information.
media-sessions	Displays the corresponding media sessions stored by the Phone Proxy. In addition, displays the media-termination address configured for the interface between which the media sessions are established.
secure-phones	Displays the phones capable of secure mode stored in the database.
signaling-sessions	Displays the corresponding signaling sessions stored by the Phone Proxy.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.0(4)	The command was introduced.
8.2(1)	The command was updated so that specifying the **media-sessions** keyword also displays the media-termination address configured for the interface between which the media sessions are established.

Examples

The following example shows the use of the **show phone proxy** command to show Phone Proxy specific information:

```
hostname(config)# show phone-proxy
Phone-Proxy 'mypp': Runtime Proxy ref_cnt 2
Cluster Mode: nonsecure
Run-time proxies:
Proxy 0xd55f6fd8: Class-map: secsip, Inspect: sip
Proxy 0xd58a93a8: Class-map: secsccp, Inspect: skinny
phoneproxy(config)# show phone-proxy secure-phones
mypp: 5 in use, 5 most used
Interface  IP Address     Port  MAC            Timeout Idle
outside    69.181.112.219 10889 001e.7ac4.da9c 0:05:00 0:01:36
outside    98.208.25.87   14159 001c.581c.0663 0:05:00 0:00:04
outside    98.208.25.87   14158 0007.0e36.4804 0:05:00 0:00:13
outside    98.208.25.87   14157 001e.7ac4.deb8 0:05:00 0:00:21
```

```
outside    128.107.254.69 49875 001b.0cad.1f69 0:05:00 0:00:04
hostname(config)#
```

The following example shows the use of the **show phone proxy** command to display the phones capable of secure mode stored in the database:

```
hostname(config)# show phone-proxy secure-phones
asa_phone_proxy: 3 in use, 4 most used

Interface/IP Address      MAC               Timeout    Idle
------------------------  ----------        ---------  ------
outside:69.181.112.219    001e.7ac4.da9c    0:05:00    0:00:16
outside:69.181.112.219    0002.b9eb.0aad    0:05:00    0:00:58
outside:98.208.49.30      0007.0e36.4804    0:05:00    0:00:09
hostname(config)#
```

The following example shows the use of the **show phone proxy** command to show output from a successful call and the media-termination address configured for the interface between which the media sessions are established:

```
hostname(config)# show phone-proxy media-sessions
Media-session: 128.106.254.3/1168 refcnt 6
  <---> RTP connection to 192.168.200.106/25038 tx_pkts 485 rx_pkts 491
Media-session: 128.106.254.3/1170 refcnt 6
  <---> SRTP connection to 98.208.25.87/1030 tx_pkts 484 rx_pkts 485
```

Related Commands

Command	Description
debug phone-proxy	Displays debug messages for the Phone Proxy instance.
phone proxy	Configures the Phone Proxy instance.

show pim df

To display the bidirectional DF "winner" for a rendezvous point (RP) or interface, use the **show pim df** command in user EXEC or privileged EXEC mode.

show pim df [**winner**] [*rp_address* | *if_name*]

Syntax Description

rp_address	Can be either one of the following: • Name of the RP, as defined in the Domain Name System (DNS) hosts table or with the domain **ipv4 host** command. • IP address of the RP. This is a multicast IP address in four-part dotted-decimal notation.
if_name	The physical or logical interface name.
winner	(Optional) Displays the DF election winner per interface per RP.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC or Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command also displays the winner metric towards the RP.

Examples

The following is sample output from the **show pim df** command:

```
hostname# show pim df
RP           Interface   DF Winner   Metrics

172.16.1.3   Loopback3   172.17.3.2  [110/2]
172.16.1.3   Loopback2   172.17.2.2  [110/2]
172.16.1.3   Loopback1   172.17.1.2  [110/2]
172.16.1.3   inside      10.10.2.3   [0/0]
172.16.1.3   inside      10.10.1.2   [110/2]
```

show pim group-map

To display group-to-protocol mapping table, use the **show pim group-map** command in user EXEC or privileged EXEC mode.

show pim group-map [**info-source**] [*group*]

Syntax Description

group	(Optional) Can be either one of the following: • Name of the multicast group, as defined in the DNS hosts table or with the domain **ipv4 host** command. • IP address of the multicast group. This is a multicast IP address in four-part dotted-decimal notation.
info-source	(Optional) Displays the group range information source.

Defaults

Displays group-to-protocol mappings for all groups.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
User EXEC or Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command displays all group protocol address mappings for the RP. Mappings are learned on the ASA from different clients.

The PIM implementation on the ASA has various special entries in the mapping table. Auto-rp group ranges are specifically denied from sparse-mode group range. SSM group range also does not fall under sparse-mode. Link Local multicast groups (224.0.0.0–224.0.0.225, as defined by 224.0.0.0/24) are also denied from the sparse-mode group range. The last entry shows all remaining groups in Sparse-Mode with a given RP.

If multiple RPs are configured with the **pim rp-address** command, then the appropriate group range is displayed with their corresponding RPs.

Examples

The following is sample output form the **show pim group-map** command:

```
hostname# show pim group-map
Group Range      Proto   Client Groups   RP address   Info
```

```
224.0.1.39/32*   DM      static 1        0.0.0.0
224.0.1.40/32*   DM      static 1        0.0.0.0
224.0.0.0/24*    NO      static 0        0.0.0.0
232.0.0.0/8*     SSM     config 0        0.0.0.0
224.0.0.0/4*     SM      autorp 1        10.10.2.2    RPF: POS01/0/3,10.10.3.2
```

In lines 1 and 2, Auto-RP group ranges are specifically denied from the sparse mode group range.

In line 3, link-local multicast groups (224.0.0.0 to 224.0.0.255 as defined by 224.0.0.0/24) are also denied from the sparse mode group range.

In line 4, the PIM Source Specific Multicast (PIM-SSM) group range is mapped to 232.0.0.0/8.

The last entry shows that all the remaining groups are in sparse mode mapped to RP 10.10.3.2.

Related Commands

Command	Description
multicast-routing	Enables multicast routing on the ASA.
pim rp-address	Configures the address of a PIM rendezvous point (RP).

show pim interface

To display interface-specific information for PIM, use the **show pim interface** command in user EXEC or privileged EXEC mode.

show pim interface [*if_name* | **state-off** | **state-on**]

Syntax Description

if_name	(Optional) The name of an interface. Including this argument limits the displayed information to the specified interface.
state-off	(Optional) Displays interfaces with PIM disabled.
state-on	(Optional) Displays interfaces with PIM enabled.

Defaults

If you do not specify an interface, PIM information for all interfaces is shown.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC or privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The PIM implementation on the ASA considers the ASA itself a PIM neighbor. Therefore, the neighbor count column in the output of this command shows one more than the actual number of neighbors.

Examples

The following example displays PIM information for the inside interface:

```
hostname# show pim interface inside
Address     Interface      Ver/     Nbr     Query      DR     DR
                           Mode     Count   Intvl      Prior
172.16.1.4 inside          v2/S     2       100 ms     1      172.16.1.4
```

Related Commands

Command	Description
multicast-routing	Enables multicast routing on the ASA.

show pim join-prune statistic

To display PIM join/prune aggregation statistics, use the **show pim join-prune statistics** command in user EXEC or privileged EXEC mode.

show pim join-prune statistics [*if_name*]

Syntax Description

if_name	(Optional) The name of an interface. Including this argument limits the displayed information to the specified interface.

Defaults

If an interface is not specified, this command shows the join/prune statistics for all interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC or Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Clear the PIM join/prune statistics with the **clear pim counters** command.

Examples

The following is sample output from the **show pim join-prune statistic** command:

```
hostname# show pim join-prune statistic

PIM Average Join/Prune Aggregation for last (1K/10K/50K) packets
Interface          Transmitted             Received

            inside   0 /    0 /    0         0 /    0 /    0
  GigabitEthernet1   0 /    0 /    0         0 /    0 /    0
         Ethernet0   0 /    0 /    0         0 /    0 /    0
         Ethernet3   0 /    0 /    0         0 /    0 /    0
  GigabitEthernet0   0 /    0 /    0         0 /    0 /    0
         Ethernet2   0 /    0 /    0         0 /    0 /    0
```

Related Commands

Command	Description
clear pim counters	Clears the PIM traffic counters.

show pim neighbor

To display entries in the PIM neighbor table, use the **show pim neighbor** command in user EXEC or privileged EXEc mode.

show pim neighbor [**count** | **detail**] [*interface*]

Syntax Description

interface	(Optional) The name of an interface. Including this argument limits the displayed information to the specified interface.
count	(Optional) Displays the total number of PIM neighbors and the number of PIM neighbors on each interface.
detail	(Optional) Displays additional address of the neighbor learned through the upstream-detection hello option.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC or Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command is used to determine the PIM neighbors known to this router through PIM hello messages. Also, this command indicates that an interface is a designated router (DR) and when the neighbor is capable of bidirectional operation.

The PIM implementation on the ASA considers the ASA itself to be a PIM neighbor. Therefore, the ASA interface is shown in the output of this command. The IP address of the ASA is indicated by an asterisk next to the address.

Examples

The following is sample output from the **show pim neighbor** command:

```
hostname# show pim neighbor inside
Neighbor Address    Interface    Uptime     Expires   DR  pri  Bidir
10.10.1.1           inside       03:40:36   00:01:41  1        B
10.10.1.2*          inside       03:41:28   00:01:32  1   (DR) B
```

Related Commands

Command	Description
multicast-routing	Enables multicast routing on the ASA.

show pim range-list

To display range-list information for PIM, use the **show pim range-list** command in user EXEC or privileged EXEC mode.

show pim range-list [*rp_address*]

Syntax Description

rp_address	Can be either one of the following: • Name of the RP, as defined in the Domain Name System (DNS) hosts table or with the domain **ipv4 host** command. • IP address of the RP. This is a multicast IP address in four-part dotted-decimal notation.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC or Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command is used to determine the multicast forwarding mode to group mapping. The output also indicates the rendezvous point (RP) address for the range, if applicable.

Examples

The following is sample output from the **show pim range-list** command:

```
hostname# show pim range-list
config SSM Exp: never Src: 0.0.0.0
  230.0.0.0/8 Up: 03:47:09
config BD RP: 172.16.1.3 Exp: never Src: 0.0.0.0
  239.0.0.0/8 Up: 03:47:16
config BD RP: 172.18.1.6 Exp: never Src: 0.0.0.0
  239.100.0.0/16 Up: 03:47:10
config SM RP: 172.18.2.6 Exp: never Src: 0.0.0.0
  235.0.0.0/8 Up: 03:47:09
```

Related Commands

Command	Description
show pim group-map	Displays group-to-PIM mode mapping and active RP information.

show pim topology

To display PIM topology table information, use the **show pim topology** command in user EXEC or privileged EXEC mode.

show pim topology [*group*] [*source*]

Syntax Description

group	(Optional) Can be one of the following: • Name of the multicast group, as defined in the DNS hosts table or with the domain **ipv4 host** command. • IP address of the multicast group. This is a multicast IP address in four-part dotted-decimal notation.
source	(Optional) Can be one of the following: • Name of the multicast source, as defined in the DNS hosts table or with the domain **ipv4 host** command. • IP address of the multicast source. This is a multicast IP address in four-part dotted-decimal notation.

Defaults

Topology information for all groups and sources is shown.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC or Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the PIM topology table to display various entries for a given group, (*, G), (S, G), and (S, G)RPT, each with its own interface list.

PIM communicates the contents of these entries through the MRIB, which is an intermediary for communication between multicast routing protocols, such as PIM, local membership protocols, such as Internet Group Management Protocol (IGMP), and the multicast forwarding engine of the system.

The MRIB shows on which interface the data packet should be accepted and on which interfaces the data packet should be forwarded, for a given (S, G) entry. Additionally, the Multicast Forwarding Information Base (MFIB) table is used during forwarding to decide on per-packet forwarding actions.

Note For forwarding information, use the **show mfib route** command.

Examples

The following is sample output from the **show pim topology** command:

```
hostname# show pim topology

IP PIM Multicast Topology Table
Entry state: (*/S,G)[RPT/SPT] Protocol Uptime Info
Entry flags: KAT - Keep Alive Timer, AA - Assume Alive, PA - Probe Alive,
    RA - Really Alive, LH - Last Hop, DSS - Don't Signal Sources,
    RR - Register Received, SR

Related Commands

Command	Description
show pim topology	Displays the PIM topology table.

show pim topology route-count

To display PIM topology table entry counts, use the **show pim topology route-count** command in user EXEC or privileged EXEC mode.

show pim topology route-count [**detail**]

Syntax Description

detail	(Optional) Displays more detailed count information on a per-group basis.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
User EXEC or Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command displays the count of entries in the PIM topology table. To display more information about the entries, use the **show pim topology** command.

Examples

The following is sample output from the **show pim topology route-count** command:

```
hostname# show pim topology route-count

PIM Topology Table Summary
  No. of group ranges = 5
  No. of (*,G) routes = 0
  No. of (S,G) routes = 0
  No. of (S,G)RPT routes = 0
```

Related Commands

Command	Description
show pim topology	Displays the PIM topology table.

show pim traffic

To display PIM traffic counters, use the **show pim traffic** command in user EXEC or privileged EXEC mode.

show pim traffic

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC or Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Clear the PIM traffic counters with the **clear pim counters** command.

Examples

The following is sample output from the **show pim traffic** command:

```
hostname# show pim traffic

PIM Traffic Counters
Elapsed time since counters cleared: 3d06h

                                Received     Sent
Valid PIM Packets                      0        9485

Packet Sent on Loopback Errors                     0
Packets Received on PIM-disabled Interface         0
Packets Received with Unknown PIM Version          0
```

Related Commands

Command	Description
clear pim counters	Clears the PIM traffic counters.

show pim tunnel

To display information about the PIM tunnel interfaces, use the **show pim tunnel** command in user EXEC or privileged EXEC mode.

show pim tunnel [*if_name*]

Syntax Description

if_name	(Optional) The name of an interface. Including this argument limits the displayed information to the specified interface.

Defaults

If an interface is not specified, this command shows the PIM tunnel information for all interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC or Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

PIM register packets are sent through the virtual encapsulation tunnel interface from the source first hop DR router to the RP. On the RP, a virtual decapsulation tunnel is used to represent the receiving interface of the PIM register packets. This command displays tunnel information for both types of interfaces.

Register tunnels are the encapsulated (in PIM register messages) multicast packets from a source that is sent to the RP for distribution through the shared tree. Registering applies only to SM, not SSM and bidirectional PIM.

Examples

The following is sample output from the **show pim tunnel** command:

```
hostname# show pim tunnel

Interface     RP Address Source Address

Encapstunnel0 10.1.1.1   10.1.1.1
Decapstunnel0 10.1.1.1   -
```

Related Commands

Command	Description
show pim topology	Displays the PIM topology table.

show port-channel

To display EtherChannel information in a detailed and one-line summary form or to display the port and port-channel information, use the **show port-channel** command in privileged EXEC mode.

show port-channel [*channel_group_number*] [**brief** | **detail** | **port** | **protocol** | **summary**]

Syntax Description

brief	(Default) Shows a brief display.
channel_group_number	(Optional) Specifies the EtherChannel channel group number, between 1 and 48, and only shows information about this channel group.
detail	(Optional) Shows a detailed display.
port	(Optional) Shows information for each interface.
protocol	(Optional) Shows the EtherChannel protocol, such as LACP if enabled.
summary	(Optional) Shows a summary of port-channels.

Command Default

The default is **brief**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.4(1)	We introduced this command.

Examples

The following is sample output from the **show port-channel** command:

```
hostname# show port-channel
        Channel-group listing:
        ----------------------

Group: 1
----------

```
hostname# show port-channel protocol
        Channel-group listing:
        ----------------------

Group: 1
----------
Protocol: LACP
```

Related Commands

Command	Description
channel-group	Adds an interface to an EtherChannel.
interface port-channel	Configures an EtherChannel.
lacp max-bundle	Specifies the maximum number of active interfaces allowed in the channel group.
lacp port-priority	Sets the priority for a physical interface in the channel group.
lacp system-priority	Sets the LACP system priority.
port-channel load-balance	Configures the load-balancing algorithm.
port-channel min-bundle	Specifies the minimum number of active interfaces required for the port-channel interface to become active.

Command	Description
show lacp	Displays LACP information such as traffic statistics, system identifier, and neighbor details.
show port-channel load-balance	Displays port-channel load-balance information along with the hash result and member interface selected for a given set of parameters.

show port-channel load-balance

For EtherChannels, to display the current port-channel load-balance algorithm, and optionally to view the member interface selected for a given set of parameters, enter this command in privileged EXEC mode.

show port-channel *channel_group_number* **load-balance** [**hash-result** {**ip** | **ipv6** | **mac** | **l4port** | **mixed** | **vlan-only** *number*} *parameters*]

Syntax Description

channel_group_number	Specifies the EtherChannel channel group number, between 1 and 48.
hash-result	(Optional) Shows the member interface chosen after hashing values you enter for the current load-balancing algorithm.
ip	(Optional) Specifies IPv4 packet parameters.
ipv6	(Optional) Specifies IPv6 packet parameters.
l4port	(Optional) Specifies port packet parameters.
mac	(Optional) Specifies MAC addresss packet parameters.
mixed	(Optional) Specifies a combination of IP or IPv6 parameters, along with ports and/or the VLAN ID.
parameters	(Optional) Packet parameters, depending on the type. For example, for **ip**, you can specify the source IP address, the destination IP address, and/or the VLAN ID.
vlan-only	(Optional) Specifies the VLAN ID for a packet.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Release	Modification
8.4(1)	We introduced this command.

Usage Guidelines

By default, the ASA balances the packet load on interfaces according to the source and destination IP address (**src-dst-ip**) of the packet. To change the algorithm, see the **port-channel load-balance** command.

This command lets you view the current load-balancing algorithm, but, with the **hash-result** keyword, also lets you test which member interface will be chosen for a packet with given parameters. This command only tests against the current load-balancing algorithm. For example, if the algorithm is src-dst-ip, then enter the IPv4 or IPv6 source and destination IP addresses. If you enter other arguments not used by the current algorithm, they are ignored, and the unentered values actually used by the algorithm default to 0. For example, if the algorithm is vlan-src-ip, then enter:

```
show port-channel 1 load-balance hash-result ip source 10.1.1.1 vlan 5
```

If you enter the following, then the vlan-src-ip algorithm assumes a source IP address of 0.0.0.0 and VLAN 0, and ignores the values you enter:

```
show port-channel 1 load-balance hash-result l4port source 90 destination 100
```

Examples

The following is sample output from the **show port-channel 1 load-balance** command:

```
hostname# show port-channel 1 load-balance
EtherChannel Load-Balancing Configuration:
       src-dst-ip

EtherChannel Load-Balancing Addresses UsedPer-Protocol:
Non-IP: Source XOR Destination MAC address
 IPv4: Source XOR Destination IP address
 IPv6: Source XOR Destination IP address
```

The following is sample output from the **show port-channel 1 load-balance hash-result** command, where the entered parameters match the current algorithm (src-dst-ip):

```
hostname# show port-channel 1 load-balance hash-result ip source 10.1.1.1 destination
10.5.5.5
Would select GigabitEthernet2/1 based on algorithm src-dst-ip
```

The following is sample output from the **show port-channel 1 load-balance hash-result** command, where the entered parameters do not match the current algorithm (src-dst-ip), and the hash uses 0 values:

```
hostname# show port-channel 1 load-balance hash-result l4port source 5
Would select GigabitEthernet3/2 of Port-channel1 based on algorithm src-dst-ip
```

Related Commands

Command	Description
channel-group	Adds an interface to an EtherChannel.
interface port-channel	Configures an EtherChannel.
lacp max-bundle	Specifies the maximum number of active interfaces allowed in the channel group.
lacp port-priority	Sets the priority for a physical interface in the channel group.
lacp system-priority	Sets the LACP system priority.
port-channel load-balance	Configures the load-balancing algorithm.
port-channel min-bundle	Specifies the minimum number of active interfaces required for the port-channel interface to become active.

Command	Description
show lacp	Displays LACP information such as traffic statistics, system identifier and neighbor details.
show port-channel	Displays EtherChannel information in a detailed and one-line summary form. This command also displays the port and port-channel information.

show power inline

For models with PoE interfaces, such as the ASA 5505, use the **show power inline** command in user EXEC mode to show power status of the interfaces.

show power inline

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
User EXEC	•	•	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

You can use PoE interfaces to connect devices that require power, such as an IP phone or a wireless access point.

Examples

The following is sample output from the **show power inline** command:

```
hostname# show power inline

  Interface     Power   Device
  -----------   -----   ------
  Ethernet0/0    n/a    n/a
  Ethernet0/1    n/a    n/a
  Ethernet0/2    n/a    n/a
  Ethernet0/3    n/a    n/a
  Ethernet0/4    n/a    n/a
  Ethernet0/5    n/a    n/a
  Ethernet0/6    On     Cisco
  Ethernet0/7    Off    n/a
```

Table 53-1 shows each field description:

Table 53-1 show power inline Fields

Field	Description
Interface	Shows all interfaces on the ASA, including ones that do not have PoE available.
Power	Shows whether the power is On or Off. If a device does not need power, if there is no device on that interface, or if the interface is shut down the value is Off. If the interface does not support PoE, then the value is n/a.
Device	Shows the type of device obtaining power, either Cisco or IEEE. If the device does not draw power, the value is n/a. The display shows Cisco when the device is a Cisco powered device. IEEE indicates that the device is an IEEE 802.3af- compliant powered device.

Related Commands

Command	Description
clear configure interface	Clears all configuration for an interface.
clear interface	Clears counters for the **show interface** command.
interface	Configures an interface and enters interface configuration mode.
show interface	Displays the runtime status and statistics of interfaces.

show priority-queue statistics

To display the priority-queue statistics for an interface, use the **show priority-queue statistics** command in privileged EXEC mode.

show priority-queue statistics [*interface-name*]

Syntax Description

interface-name	(Optional) Specifies the name of the interface for which you want to show the best-effort and low-latency queue details.

Defaults

If you omit the interface name, this command shows priority-queue statistics for all configured interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

This example shows the use of the **show priority-queue statistics** command for the interface named test, and the command output. In this output, BE indicates the best-effort queue, and LLQ represents the low-latency queue:

```
hostname# show priority-queue statistics test

Priority-Queue Statistics interface test

Queue Type      = BE
Packets Dropped   = 0
Packets Transmit  = 0
Packets Enqueued  = 0
Current Q Length  = 0
Max Q Length      = 0

Queue Type      = LLQ
Packets Dropped   = 0
Packets Transmit  = 0
Packets Enqueued  = 0
Current Q Length  = 0
Max Q Length      = 0
hostname#
```

Related Commands

Command	Description
clear configure priority-queue	Removes the priority-queue configuration from the named interface.
clear priority-queue statistics	Clears the priority-queue statistics counters for an interface or for all configured interfaces.
priority-queue	Configures priority queueing on an interface.
show running-config priority-queue	Shows the current priority-queue configuration on the named interface.

show processes

To display a list of the processes that are running on the ASA, use the **show processes** command in privileged EXEC mode.

show processes [**cpu-usage** [[**non-zero**][**sorted**]] [**cpu-hog | memory | internals**]

Syntax Description

cpu-hog	Shows number and detail of processes that are hogging the CPU (that is, using the CPU for more than 100 milliseconds).
cpu-usage	Shows percentage of CPU used by each process for the last 5 seconds, 1 minute and 5 minutes.
internals	Shows internal details of each process.
memory	Shows memory allocation for each process.
non-zero	(Optional) Shows processes with non-zero CPU usage.
sorted	(Optional) Shows sorted CPU usage for processes.

Defaults

By default, this command displays the processes running on the ASA.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	Support for this command was introduced.
7.0(4)	The runtime value was enhanced to display accurracy within one millisecond.
7.2(1)	The output display was enhanced to display more detailed information about processes that hog the CPU.
8.0(1)	Added the **cpu-usage** keyword.

Usage Guidelines

Processes are lightweight threads that require only a few instructions. The **show processes** commands display a list of the processes that are running on the ASA, as follows:

Command	Data Displayed	Description
show processes	PC	Program counter.
show processes	Stack Pointer	Stack pointer.
show processes	STATE	Address of thread queue.

Command	Data Displayed	Description
show processes	Runtime	Number of milliseconds that the thread has been running based on CPU clock cycles. The accurracy is within one millisecond for complete and accurate accounting of process CPU usage based on CPU clock cycles (<10ns resolution) instead of clock ticks (10ms resolution).
show processes	SBASE	Stack base address.
show processes	Stack	Current number of bytes in use and the total size of the stack.
show processes	Process	Function of the thread.
show processes cpu-usage	MAXHOG	Maximum CPU hog runtime in milliseconds.
show processes cpu-usage	NUMHOG	Number of CPU hog runs.
show processes cpu-usage	LASTHOG	Last CPU hog runtime in milliseconds.
show processes cpu-usage	PC	Instruction pointer of the CPU hogging process.
show processes cpu-usage	Traceback	Stack trace of the CPU hogging process. The traceback can have up to 14 addresses.
show processes internals	Invoked Calls	Number of times the scheduler ran the process.
show processes internals	Giveups	Number of times the process yielded the CPU back to the scheduler.

Use the **show processes cpu-usage** command to narrow down a particular process on the ASA that might be using the CPU of the ASA. You can use the **sorted** and **non-zero** commands to further customize the output of the **show processes cpu-usage** command.

With the scheduler and total summary lines, you can run two consecutive **show proccesses** commands and compare the output to determine:

- Consumption of 100% of the CPU.
- Percentage of CPU used by each thread, determined by comparing the runtime delta of a thread to the total runtime delta.

Examples

The following example shows how to display a list of processes that are running on the ASA:

```
hostname(config)# show processes

    PC       SP       STATE       Runtime    SBASE     Stack Process
Hsi 00102aa0 0a63f288 0089b068     117460 0a63e2d4 3600/4096 arp_timer
Lsi 00102aa0 0a6423b4 0089b068         10 0a64140c 3824/4096 FragDBGC
Hwe 004257c8 0a7cacd4 0082dfd8          0 0a7c9d1c 3972/4096 udp_timer
Lwe 0011751a 0a7cc438 008ea5d0         20 0a7cb474 3560/4096 dbgtrace
<--- More --->

-     -        -         -        638515    -         -     scheduler
-     -        -         -       2625389    -         -     total
```

The following example shows how to display the percentage of CPU used by each process:

```
hostname(config)# show proc cpu-usage non-zero
PC         Thread      5Sec    1Min    5Min    Process
0818af8e   d482f92c    0.1%    0.1%    0.1%    Dispatch Unit
08bae136   d48180f0    0.1%    0.0%    0.2%    ssh
-------------------------------------
```

The following example shows how to display the number and detail of processes that are hogging the CPU:

```
hostname(config)# show processes cpu-hog
Process:      Unicorn Admin Handler, NUMHOG: 1, MAXHOG: 13, LASTHOG: 13
LASTHOG At:   08:30:15 PST Jan 20 2011
PC:           0x08413a62
Call stack:   0x084f6c5d  0x08412cc3  0x08407a85  0x0806e0ea  0x08a4b17d  0x0806e0ea
0x0849bffd
              0x084950cd  0x0849530c  0x08495636  0x0849bc59  0x080680cc

(other lines deleted for brevity)
```

The following example shows how to display the memory allocation for each process:

```
hostname(config)# show processes memory

-------------------------------------------------------------
Allocs   Allocated       Frees         Freed         Process
          (bytes)                      (bytes)
-------------------------------------------------------------
23512    13471545        6             180           *System Main*
0        0               0             0             lu_rx
2        8324            16            19488         vpnlb_thread
```

The following example shows how to display the internal details of each process:

```
hostname# show processes internals

     Invoked      Giveups  Process
           1            0  block_diag
    19108445     19108445  Dispatch Unit
           1            0  CF OIR
           1            0  Reload Control Thread

(other lines deleted for brevity)
```

show quota management-session

To show statistics for the current management session:, use the **show quota management-session** command in privileged EXEC mode.

show quota management-session

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
9.1(2)	This command was introduced.

Usage Guidelines

This command shows the following statistics for the current management session:

- Limit
- Warning level
- Current count
- High water mark
- Number of warnings generated
- Number of errors generated

Examples

The following example shows statistics for the current management session:

```
hostname# show quota management-session
quota management-session limit 250
quota management-session warning level 225
quota management-session level 1
quota management-session high water 1
quota management-session errors 0
quota management-session warnings 0
```

Related Commands

Command	Description
show running-config quota management-session	Shows the current value of the management session quota.
quota management-session	Sets the number of simultaneous ASDM, SSH, and Telnet sessions allowed on the device.

show reload

To display the reload status on the ASA, use the **show reload** command in privileged EXEC mode.

show reload

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command has no usage guidelines.

Examples

The following example shows that a reload is scheduled for 12:00 a.m. (midnight) on Saturday, April 20:

```
hostname# show reload
Reload scheduled for 00:00:00 PDT Sat April 20 (in 12 hours and 12 minutes)
```

Related Commands

Command	Description
reload	Reboots and reloads the configuration.

show resource allocation

To show the resource allocation for each resource across all classes and class members, use the **show resource allocation** command in privileged EXEC mode.

show resource allocation [**detail**]

Syntax Description

detail	Shows additional information.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	—	•	•

Command History

Release	Modification
7.2(1)	This command was introduced.
9.0(1)	A new resource class, routes, was created to set the maximum number of routing table entries in each context. New resource types, vpn other and vpn burst other, were created to set the maximum number of site-to-site VPN tunnels in each context.

Usage Guidelines

This command shows the resource allocation, but does not show the actual resources being used. See the **show resource usage** command for more information about actual resource usage.

Examples

The following is sample output from the **show resource allocation** command. The display shows the total allocation of each resource as an absolute value and as a percentage of the available system resources.

```
hostname# show resource allocation
Resource                    Total       % of Avail
 Conns [rate]               35000           N/A
 Inspects [rate]            35000           N/A
 Syslogs [rate]             10500           N/A
 Conns                     305000           30.50%
 Hosts                      78842           N/A
 SSH                           35           35.00%
 Telnet                        35           35.00%
 Routes                     25000           0.00%
 Xlates                     91749           N/A
```

```
Other VPN Sessions            20           2.66%
Other VPN Burst               20           2.66%
All                       unlimited
```

Table 53-2 shows each field description.

Table 53-2 show resource allocation Fields

Field	Description
Resource	The name of the resource that you can limit.
Total	The total amount of the resource that is allocated across all contexts. The amount is an absolute number of concurrent instances or instances per second. If you specified a percentage in the class definition, the ASA converts the percentage to an absolute number for this display.
% of Avail	The percentage of the total system resources that is allocated across all contexts, if available. If a resource does not have a system limit, this column shows N/A.

The following is sample output from the **show resource allocation detail** command:

```
hostname# show resource allocation detail
Resource Origin:
    A    Value was derived from the resource 'all'
    C    Value set in the definition of this class
    D    Value set in default class
Resource         Class          Mmbrs  Origin      Limit      Total    Total %
Conns [rate]     default          all      CA  unlimited
                 gold               1       C      34000      34000     N/A

Table 53-3 shows each field description.

Table 53-3 show resource allocation detail Fields

Field	Description
Resource	The name of the resource that you can limit.
Class	The name of each class, including the default class. The All contexts field shows the total values across all classes.
Mmbrs	The number of contexts assigned to each class.
Origin	The origin of the resource limit, as follows: • A—You set this limit with the **all** option, instead of as an individual resource. • C—This limit is derived from the member class. • D—This limit was not defined in the member class, but was derived from the default class. For a context assigned to the default class, the value will be "C" instead of "D." The ASA can combine "A" with "C" or "D."
Limit	The limit of the resource per context, as an absolute number. If you specified a percentage in the class definition, the ASA converts the percentage to an absolute number for this display.
Total	The total amount of the resource that is allocated across all contexts in the class. The amount is an absolute number of concurrent instances or instances per second. If the resource is unlimited, this display is blank.
% of Avail	The percentage of the total system resources that is allocated across all contexts in the class, if available. If the resource is unlimited, this display is blank. If the resource does not have a system limit, this column shows N/A.

Related Commands

Command	Description
class	Creates a resource class.
context	Adds a security context.
limit-resource	Sets the resource limit for a class.
show resource types	Shows the resource types for which you can set limits.
show resource usage	Shows the resource usage of the ASA.

show resource types

To view the resource types for which the ASA tracks usage, use the **show resource types** command in privileged EXEC mode.

show resource types

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	This command shows additional resource types that you can manage for each context.
9.0(1)	A new resource class, routes, was created to set the maximum number of routing table entries in each context. New resource types, vpn other and vpn burst other, were created to set the maximum number of site-to-site VPN tunnels in each context.

Examples

The following sample display shows the resource types:

```
hostname# show resource types

Rate limited resource types:
  Conns           Connections/sec
  Inspects        Inspects/sec
  Syslogs         Syslogs/sec

Absolute limit types:
  Conns           Connections
  Hosts           Hosts
  Mac-addresses   MAC Address table entries
  ASDM            ASDM Connections
  SSH             SSH Sessions
  Telnet          Telnet Sessions
  Xlates          XLATE Objects
  Routes          Routing Table Entries
  Other-vpn       Other VPN licenses
```

```
Other-vpn-burst Allowable burst for Other VPN licenses
All             All Resources
```

Related Commands

Command	Description
clear resource usage	Clears the resource usage statistics
context	Adds a security context.
show resource usage	Shows the resource usage of the ASA.

show resource usage

To view the resource usage of the ASA or for each context in multiple mode, use the **show resource usage** command in privileged EXEC mode.

show resource usage [**context** *context_name* | **top** *n* | **all** | **summary** | **system** | **detail**] [**resource** {[**rate**] *resource_name* | **all**}] [**counter** *counter_name* [*count_threshold*]]

Syntax Description

context *context_name*	(Multiple mode only) Specifies the context name for which you want to view statistics. Specify **all** for all contexts; the ASA lists the context usage for each context.
count_threshold	Sets the number above which resources are shown. The default is 1. If the usage of the resource is below the number you set, then the resource is not shown. If you specify **all** for the counter name, then the *count_threshold* applies to the current usage. **Note** To show all resources, set the *count_threshold* to **0**.
counter *counter_name*	Shows counts for the following counter types: • **current**—Shows the active concurrent instances or the current rate of the resource. • **peak**—Shows the peak concurrent instances, or the peak rate of the resource since the statistics were last cleared, either using the **clear resource usage** command or because the device rebooted. • **denied**—Shows the number of instances that were denied because they exceeded the resource limit shown in the Limit column. • **all**—(Default) Shows all statistics.
detail	Shows the resource usage of all resources, including those you cannot manage. For example, you can view the number of TCP intercepts.

resource [**rate**] *resource_name*	Shows the usage of a specific resource. Specify **all** (the default) for all resources. Specify **rate** to show the rate of usage of a resource. Resources that are measured by rate include **conns**, **inspects**, and **syslogs**. You must specify the **rate** keyword with these resource types. The conns resource is also measured as concurrent connections; only use the **rate** keyword to view the connections per second. Resources include the following types: • **asdm**—ASDM management sessions. • **conns**—TCP or UDP connections between any two hosts, including connections between one host and multiple other hosts. • **inspects**—Application inspections. • **hosts**—Hosts that can connect through the ASA. • **mac-addresses**—For transparent firewall mode, the number of MAC addresses allowed in the MAC address table. • **routes—**Routing Table entries. • **ssh**—SSH sessions. • **syslogs**—System log messages. • **telnet**—Telnet sessions. • (Multiple mode only) **VPN Other**—Site-to-site VPN sessions. • (Multiple mode only) **VPN Burst Other**—Site-to-site VPN burst sessions. • **xlates**—NAT translations.
summary	(Multiple mode only) Shows all context usage combined.
system	(Multiple mode only) Shows all context usage combined, but shows the system limits for resources instead of the combined context limits.
top *n*	(Multiple mode only) Shows the contexts that are the top *n* users of the specified resource. You must specify a single resource type, and not **resource all**, with this option.

Defaults

For multiple context mode, the default context is **all**, which shows resource usage for every context. For single mode, the context name is ignored and the output shows the “context” as “System.”

The default resource name is **all**, which shows all resource types.

The default counter name is **all**, which shows all statistics.

The default count threshold is **1**.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	This command shows the denied resources, because you can limit the resources for each context.
9.0(1)	A new resource class, routes, was created to set the maximum number of routing table entries in each context. New resource types, vpn other and vpn burst other, were created to set the maximum number of site-to-site VPN tunnels in each context.

Examples

The following is sample output from the **show resource usage context** command, which shows the resource usage for the admin context:

```
hostname# show resource usage context admin

Resource              Current         Peak      Limit    Denied  Context
Telnet                      1            1          5         0  admin
Conns                      44           55        N/A         0  admin
Hosts                      45           56        N/A         0  admin
```

The following is sample output from the **show resource usage summary** command, which shows the resource usage for all contexts and all resources. This sample shows the limits for six contexts.

```
hostname# show resource usage summary

Resource              Current         Peak      Limit     Denied Context
Syslogs [rate]           1743         2132      12000(U)       0 Summary
Conns                     584          763     100000(S)       0 Summary
Xlates                   8526         8966      93400          0 Summary
Hosts                     254          254     262144          0 Summary
Conns [rate]              270          535      42200       1704 Summary
Inspects [rate]           270          535     100000(S)       0 Summary
Other VPN Sessions          0           10         10        740 Summary
Other VPN Burst             0           10         10        730 Summary
U = Some contexts are unlimited and are not included in the total.
S = System: Combined context limits exceed the system limit; the system limit is shown.
```

The following is sample output from the **show resource usage system** command, which shows the resource usage for all contexts, but it shows the system limit instead of the combined context limits:

```
hostname# show resource usage system

Resource              Current         Peak      Limit    Denied  Context
Telnet                      3            5        100         0  System
SSH                         5            7        100         0  System
Conns                      40           55        N/A         0  System
Hosts                      44           56        N/A         0  System
```

The following is sample output from the **show resource usage detail counter all 0** command, which shows all resources, and not only those you can manage:

```
hostname# show resource usage detail counter all 0

Resource              Current         Peak      Limit         Denied Context

Related Commands

Command	Description
class	Creates a resource class.
clear resource usage	Clears the resource usage statistics
context	Adds a security context.
limit-resource	Sets the resource limit for a class.
show resource types	Shows a list of resource types.

show rip database

To display the information that is stored in the RIP topological database, use the **show rip database** command in privileged EXEC mode.

show rip database [*ip_addr* [*mask*]]

Syntax Description

ip_addr	(Optional) Limits the display routes for the specified network address.
mask	(Optional) Specifies the network mask for the optional network address.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The RIP routing-related **show** commands are available in privileged EXEC mode on the ASA. You do not need to be in an RIP configuration mode to use the RIP-related **show** commands.

The RIP database contains all of the routes learned through RIP. Routes that appear in this database may not necessarily appear in the routing table. See the *Cisco Security Appliance Command Line Configuration Guide* for information about how the routing table is populated from the routing protocol databases.

Examples

The following is sample output from the **show rip database** command:

```
hostname# show rip database

10.0.0.0/8    auto-summary
10.11.11.0/24    directly connected, GigabitEthernet0/2
10.1.0.0/8    auto-summary
10.11.0.0/16    int-summary
10.11.10.0/24    directly connected, GigabitEthernet0/3
192.168.1.1/24
    [2] via 10.11.10.5, 00:00:14, GigabitEthernet0/3
```

The following is sample output from the **show rip database** command with a network address and mask:

```
Router# show rip database 172.19.86.0 255.255.255.0
```

```
172.19.86.0/24
    [1] via 172.19.67.38, 00:00:25, GigabitEthernet0/2
    [2] via 172.19.70.36, 00:00:14, GigabitEthernet0/3
```

Related Commands

Command	Description
router rip	Enables RIP routing and configures global RIP routing parameters.

show route

To display the routing table, use the **show route** command in privileged EXEC mode.

show route [*interface_name* [*ip_address* [*netmask* [**static**]]]] [**failover**] [**cluster]**

Syntax Description

cluster	(Optional) Displays the routing information base (RIB) epoch number (sequence number), the current timer value, and the network descriptor block epoch number (sequence number).
failover	(Optional) Displays the current sequence number of the routing table and routing entries after failover has occurred, and a standby unit becomes the active unit.
interface_name	(Optional) Limits the display to route entries that use the specified interface.
ip_address	(Optional) Limits the display to routes to the specified destination.
netmask	(Optional) Defines the network mask to apply to the specified destination.
static	(Optional) Limits the display to static routes.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
8.4(1)	The **failover** keyword was added. The output shows the RIB epoch number (sequence number), current timer value, and network descriptor block epoch number (sequence number).
9.0(1)	The **cluster** keyword was added. Applies to the dynamic routing protocols (EIGRP, OSPF, and RIP) and is only available on the ASA 5580 and 5585-X.

Usage Guidelines

The **show route** command provides output similar to the **show ipv6 route** command, except that the information is IPv4-specific.

Note The **clustering** and **failover** keywords do not appear unless these features are configured on the ASA.

The **show route** command lists the "best" routes for new connections. When you send a permitted TCP SYN to the backup interface, the ASA can only respond using the same interface. If there is no default route in the RIB on that interface, the ASA drops the packet because of no adjacency. Everything that is configured as shown in the **show running-config route** command is maintained in certain data structures in the system.

You can check the backend interface-specific routing table with the **show asp table routing** command. This design is similar to OSPF or EIGRP, in which the protocol-specific route database is not the same as the global routing table, which only displays the "best" routes. This behavior is by design.

Examples

The following is sample output from the **show route** command:

```
hostname# show route

Codes: C - connected, S - static, I - IGRP, R - RIP, M - mobile, B - BGP
       D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2, E - EGP
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default, U - per-user static route, o - ODR
       P - periodic downloaded static route

Gateway of last resort is 10.86.194.1 to network 0.0.0.0

C    10.86.194.0 255.255.255.0 is directly connected, outside
C    10.40.10.0 255.255.255.0 is directly connected, inside
C    192.168.2.0 255.255.255.0 is directly connected, faillink
C    192.168.3.0 255.255.255.0 is directly connected, statelink
```

The following is sample output of the **show route** command on the ASA 5505. The output displays the internal loopback address, which is used by the VPN hardware client for individual user authentication.

```
hostname(config)# show route

Codes: C - connected, S - static, I - IGRP, R - RIP, M - mobile, B - BGP
       D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2, E - EGP
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default, U - per-user static route, o - ODR
       P - periodic downloaded static route

Gateway of last resort is 10.86.194.1 to network 0.0.0.0

C    127.1.0.0 255.255.0.0 is directly connected, _internal_loopback
C    10.86.194.0 255.255.254.0 is directly connected, outside
S*   0.0.0.0 0.0.0.0 [1/0] via 10.86.194.1, outside
```

The following is sample output of the **show route failover** command, which shows the synchronization of OSPF and EIGRP routes to the standby unit after failover:

```
hostname(config)# show route failover

Codes: C - connected, S - static, I - IGRP, R - RIP, M - mobile, B - BGP
       D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2, E - EGP
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default, U - per-user static route, o - ODR
       P - periodic downloaded static route
```

```
Gateway of last resort is 10.86.194.1 to network 0.0.0.0
Routing table sequence number 1
Reconvergence timer 00.20 (Running)

S    10.10.10.0 255.0.0.0 [1/0] via 10.10.10.1, mgmt, seq 1
                        [1/0] via 10.10.10.2, mgmt, seq 1
D    209.165.200.224 255.255.255.0 [90/28416] via 200.165.200.225, 0:00:15, outside, seq 1

O   198.51.100.0 255.255.255.0 [110/28416] via 198.51.100.10, 0:24:45, inside, seq 0

O   198.51.100.0 255.255.255.0 [110/28416] via 198.51.100.10, 0:24:45, inside, seq 2
D   209.165.200.224 255.255.255.0 [90/28416] via 200.165.200.225, 0:00:15, outside, seq 2
```

Note When you use the **show ip route** command in the Cisco IOS, the **longer-prefix** keyword is available. When you use this keyword in the Cisco IOS, the route is only displayed if the specified network and mask pair match.

On the ASA, the **longer-prefix** keyword is the default behavior for the **show rout**e command; that is, no additional keyword is needed in the CLI. Because of this, you cannot see the route when you type **ip**. To obtain the supernet route, the mask value needs to be passed with the IP address.

CHAPTER 54

show running-config through show running-config cts Commands

show running-config

To display the configuration that is currently running on the ASA, use the **show running-config** command in privileged EXEC mode.

show running-config [**all**] [*command*]

Syntax Description

all	Displays the entire operating configuration, including defaults.
command	Displays the configuration associated with a specific command.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was modified.
8.3(1)	The command output displays encrypted passwords.

Usage Guidelines

The **show running-config** command displays the active configuration in memory (including saved configuration changes) on the ASA.

You can use the **running-config** keyword only in the **show running-config** command. You cannot use this keyword with **no** or **clear**, or as a standalone command, because the CLI treats it as an unsupported command. When you enter the **?**, **no ?**, or **clear ?** keywords, the **running-config** keyword is not listed in the command list.

To display the saved configuration in flash memory on the ASA, use the **show configuration** command.

The **show running-config** command output displays encrypted, masked, or clear text passwords when password encryption is either enabled or disabled.

Note ASDM commands appear in the configuration after you use it to connect to or configure the ASA.

Examples

The following is sample output from the **show running-config** command:

```
hostname# show running-config
: Saved
:
ASA Version 9.0(1)
```

```

Related Commands

Command	Description
configure	Configures the ASA from the terminal.

show running-config aaa

To show the AAA configuration in the running configuration, use the **show running-config aaa** command in privileged EXEC mode.

show running-config aaa [**accounting** | **authentication** | **authorization** | **mac-exempt** | **proxy-limit**]

Syntax Description

accounting	(Optional) Show accounting-related AAA configuration.
authentication	(Optional) Show authentication-related AAA configuration.
authorization	(Optional) Show authorization-related AAA configuration.
mac-exempt	(Optional) Show MAC address exemption AAA configuration.
proxy-limit	(Optional) Show the number of concurrent proxy connections allowed per user.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show running-config aaa** command:

```
hostname# show running-config aaa
aaa authentication match infrastructure_authentication_radiusvrs infrastructure radiusvrs
aaa accounting match infrastructure_authentication_radiusvrs infrastructure radiusvrs
aaa authentication secure-http-client
aaa local authentication attempts max-fail 16
hostname#
```

Related Commands

Command	Description
aaa authentication match	Enables authentication for traffic that is identified by an access list.
aaa authorization match	Enables authorization for traffic that is identified by an access list.

Command	Description
aaa accounting match	Enables accounting for traffic that is identified by an access list.
aaa max-exempt	Specifies the use of a predefined list of MAC addresses to exempt from authentication and authorization.
aaa proxy-limit	Configure the uauth session limit by setting the maximum number of concurrent proxy connections allowed per user.

show running-config aaa-server

To display AAA server configuration, use the **show running-config aaa-server** command in privileged EXEC mode.

show running-config [**all**] **aaa-server** [*server-tag*] [(*interface-name*)] [**host** *hostname*]

Syntax Description

all	(Optional) Shows the running configuration, including default configuration values.
host *hostname*	(Optional) The symbolic name or IP address of the particular host for which you want to display AAA server statistics.
(interface-name)	(Optional) The network interface where the AAA server resides.
server-tag	(Optional) The symbolic name of the server group.

Defaults

Omitting the *server-tag* value displays the configurations for all AAA servers.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was modified to adhere to CLI guidelines.

Usage Guidelines

Use this command to display the settings for a particular server group. Use the **all** parameter to display the default as well as the explicitly configured values.

Examples

To display the running configuration for the default AAA server group, use the following command:

```
hostname(config)# show running-config default aaa-server

aaa-server group1 protocol tacacs+ accounting-mode simultaneous
reactivation-mode depletion deadtime 10
max-failed-attempts 4
hostname(config)#
```

Related Commands

Command	Description
show aaa-server	Displays AAA server statistics.
clear configure aaa-server	Clears the AAA server configuration.

show running-config aaa-server host

To display AAA server statistics for a particular server, use the **show running-config aaa-server** command in global configuration or privileged EXEC mode.

show/clear aaa-server

show running-config [**all**] **aaa-server** *server-tag* [(*interface-name*)] **host** *hostname*

Syntax Description

all	(Optional) Shows the running configuration, including default configuration values.
server-tag	The symbolic name of the server group.

Defaults

Omitting the default keyword displays only the explicitly configured configuration values, not the default values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	—	—	•
Global configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was modified to adhere to CLI guidelines.

Usage Guidelines

Use this command to display the statistics for a particular server group. Use the default parameter to display the default as well as the explicitly configured values.

Examples

To display the running configuration for the server group svrgrp1, use the following command:

```
hostname(config)# show running-config default aaa-server svrgrp1
```

Related Commands

Command	Description
show running-config aaa-server	Displays AAA server settings for the indicated server, group, or protocol.
clear configure aaa	Removes the settings for all AAA servers across all groups.

show running-config access-group

To display the access group information, use the **show running-config access-group** command in privileged EXEC mode.

show running-config access-group

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show running-config access-group** command:

```
hostname# show running-config access-group
access-group 100 in interface outside
```

Related Commands

Command	Description
access-group	Binds an access list to an interface.
clear configure access-group	Removes access groups from all the interfaces.

show running-config access-list

To display the access-list configuration that is running on the ASA, use the **show running-config access-list** command in privileged EXEC mode.

show running-config [**default**] **access-list** [**alert-interval** | **deny-flow-max**]

show running-config [**default**] **access-list** *id* [*saddr_ip*]

Syntax Description

alert-interval	Shows the alert interval for generating syslog message 106001, which alerts that the system has reached a deny flow maximum.
deny-flow-max	Shows the maximum number of concurrent deny flows that can be created.
id	Identifies the access list that is displayed.
saddr_ip	Shows the access list elements that contain the specified source IP address.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	Added keyword **running-config**.

Usage Guidelines

The **show running-config access-list** command allows you to display the current running access list configuration on the ASA.

Examples

The following is sample output from the **show running-config access-list** command:

```
hostname# show running-config access-list
access-list allow-all extended permit ip any any
```

Related Commands

Command	Description
access-list ethertype	Configures an access list that controls traffic based on its EtherType.
access-list extended	Adds an access list to the configuration and configures policy for IP traffic through the firewall.

Command	Description
access-list ethertype	Configures an access list that controls traffic based on its EtherType.
clear access-list	Clears an access list counter.
clear configure access-list	Clears an access list from the running configuration.

show running-config alias

To display the overlapping addresses with dual NAT commands in the configuration, use the **show running-config alias** command in privileged EXEC mode.

show running-config alias {*interface_name*}

Syntax Description

interface_name	Internal network interface name that the destination_ip overwrites.

Defaults

This command has no default settings.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	—	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

This example shows how to display alias information:

```
hostname# show running-config alias
```

Related Commands

Command	Description
alias	Creates an alias.
clear configure alias	Deletes an alias.

show running-config arp

To show static ARP entries created by the **arp** command in the running configuration, use the **show running-config arp** command in privileged EXEC mode.

show running-config arp

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show running-config arp** command:

```
hostname# show running-config arp
arp inside 10.86.195.11 0008.023b.9893
```

Related Commands

Command	Description
arp	Adds a static ARP entry.
arp-inspection	For transparent firewall mode, inspects ARP packets to prevent ARP spoofing.
show arp	Shows the ARP table.
show arp statistics	Shows ARP statistics.

show running-config arp timeout

To view the ARP timeout configuration in the running configuration, use the **show running-config arp timeout** command in privileged EXEC mode.

show running-config arp timeout

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from **show arp timeout**.

Examples

The following is sample output from the **show running-config arp timeout** command:

```
hostname# show running-config arp timeout
arp timeout 20000 seconds
```

Related Commands

Command	Description
arp	Adds a static ARP entry.
arp timeout	Sets the time before the ASA rebuilds the ARP table.
arp-inspection	For transparent firewall mode, inspects ARP packets to prevent ARP spoofing.
show arp statistics	Shows ARP statistics.

show running-config arp-inspection

To view the ARP inspection configuration in the running configuration, use the **show running-config arp-inspection** command in privileged EXEC mode.

show running-config arp-inspection

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	—	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from **show arp timeout**.

Examples

The following is sample output from the **show running-config arp-inspection** command:

```
hostname# show running-config arp-inspection

arp-inspection inside1 enable no-flood
```

Related Commands

Command	Description
arp	Adds a static ARP entry.
arp-inspection	For transparent firewall mode, inspects ARP packets to prevent ARP spoofing.
clear configure arp-inspection	Clears the ARP inspection configuration.
firewall transparent	Sets the firewall mode to transparent.
show arp statistics	Shows ARP statistics.

show running-config asdm

To display the **asdm** commands in the running configuration, use the **show running-config asdm** command in privileged EXEC mode.

show running-config asdm [**group** | **location**]

Syntax Description

group	(Optional) Limits the display to the **asdm group** commands in the running configuration.
location	(Optional) Limits the display to the **asdm location** commands in the running configuration.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was changed from the **show running-config pdm** command to the **show running-config asdm** command.

Usage Guidelines

To remove the **asdm** commands from the configuration, use the **clear configure asdm** command.

Note On ASAs running in multiple context mode, the **show running-config asdm group** and **show running-config asdm location** commands are only available in the system execution space.

Examples

The following is sample output from the **show running-configuration asdm** command:

```
hostname# show running-config asdm
asdm image flash:/ASDM
asdm history enable
hostname#
```

Related Commands

Command	Description
show asdm image	Displays the current ASDM image file.

show running-config auth-prompt

To displays the current authentication prompt challenge text, use the **show running-config auth-prompt** command in global configuration mode.

show running-config [**default**] **auth-prompt**

Syntax Description

default	(Optional) Display the default authentication prompt challenge text.

Defaults

Display the configured authentication prompt challenge text.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was modified for this release to conform to CLI guidelines.

Usage Guidelines

After you configure the authentication prompt with the **auth-prompt** command, use the **show running-config auth-prompt** command to view the current prompt text.

Examples

The following example shows the output of the **show running-config auth-prompt** command:

```
hostname(config)# show running-config auth-prompt
auth-prompt prompt Please login:
auth-prompt accept You're in!
auth-prompt reject Try again.
hostname(config)#
```

Related Commands

auth-prompt	Set the user authorization prompts.
clear configure auth-prompt	Reset the user authorization prompts to the default value.

show running-config banner

To display the specified banner and all the lines that are configured for it, use the **show running-config banner** command in privileged EXEC mode.

show running-config banner [**exec | login | motd**]

Syntax Description

exec	(Optional) Displays the banner before the enable prompt.
login	(Optional) Displays the banner before the password login prompt when accessing the ASA using Telnet.
motd	(Optional) Displays the message-of-the-day banner.

Defaults

This command has no default settings.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	The **running-config** keyword was added.

Usage Guidelines

The **show running-config banner** command displays the specified banner keyword and all the lines configured for it. If a keyword is not specified, then all banners display.

Examples

This example shows how to display the message-of-the-day (motd) banner:

```
hostname# show running-config banner motd
```

Related Commands

Command	Description
banner	Creates a banner.
clear configure banner	Deletes a banner.

show running-config call-home

To display the Call Home running configuration, use the **show running-config call-home** command in privileged EXEC mode.

[**cluster exec**] **show running-config call-home**

Syntax Description

cluster exec	(Optional) In a clustering environment, enables you to issue the **show running-config call-home** command in one unit and run the command in all the other units at the same time.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.2(2)	This command was introduced.
9.1(3)	A new type of Smart Call Home message has been added to include the output of the **show cluster history** command and **show cluster info** command.

Examples

The following is sample output from the **cluster exec show running-config call-home** command:

```
hostname# cluster exec show running-config call-home

Related Commands

Command	Description
call-home	Enters call home configuration mode.
call-home send alert-group	Sends a specific alert group message.
service call-home	Enables or disables Call Home.

show running-config class

To show the resource class configuration, use the **show running-config class** command in privileged EXEC mode.

show running-config class

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	—	•

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following is sample output from the **show running-config class** command:

```
hostname# show running-config class

class default
  limit-resource All 0
  limit-resource Mac-addresses 65535
  limit-resource ASDM 5
  limit-resource SSH 5
  limit-resource Telnet 5
```

Related Commands

Command	Description
class	Configures a resource class.
clear configure class	Clears the class configuration.
context	Configures a security context.
limit-resource	Sets the resource limit for a class.
member	Assigns a context to a resource class.

show running-config class-map

To display the information about the class map configuration, use the **show running-config class-map** command in privileged EXEC mode.

show running-config [**all**] **class-map** [*class_map_name* | **type** {**management** | **regex** | **inspect** [*protocol*]}]

Syntax Description

all	(Optional) Shows all commands, including the commands you have not changed from the default.
class_map_name	(Optional) Shows the running configuration for a class map name.
inspect	(Optional) Shows inspection class maps.
management	(Optional) Shows management class maps.
protocol	(Optional) Specifies the type of application map you want to show. Available types include: • **dns** • **ftp** • **h323** • **http** • **im** • **p2p-donkey** • **sip**
regex	(Optional) Shows regular expression class maps.
type	(Optional) Specifies the type of class map you want to show. To show Layer 3/4 class maps, to not specify the type.

Defaults

The **class-map class-default** command, which contains a single **match any** command is the default class map.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	Added keyword **running-config**.

Examples

The following is sample output from the **show running-config class-map** command:

```
hostname# show running-config class-map
class-map tcp-port
  match port tcp eq ftp
hostname#
```

Related Commands

Command	Description
class-map	Applies a traffic class to an interface.
clear configure class-map	Removes all of the traffic map definitions.

show running-config client-update

To display global client-update configuration information, use the **show running-config client-update** command in global configuration mode or in tunnel-group ipsec-attributes configuration mode.

show running-config client-update

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	—	—	•
Tunnel-group ipsec-attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.1(1)	Added tunnel-group ipsec-attributes configuration mode.

Usage Guidelines

Use this command to display global client-update configuration information.

Examples

This example shows a **show running-config client-update** command in global configuration mode and its output for a configuration with client-update enabled:

```
hostname(config)# show running-config client-update
hostname(config)# client-update enable
```

Related Commands

Command	Description
clear configure client-update	Clears the entire client-update configuration.
client-update	Configures client-update.

show running-config clock

To show the clock configuration in the running configuration, use the **show running-config clock** command in privileged EXEC mode.

show running-config [**all**] **clock**

Syntax Description

all	(Optional) Shows all **clock** commands, including the commands you have not changed from the default.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **all** keyword also displays the exact day and time for the **clock summer-time** command, as well as the default setting for the offset, if you did not originally set it.

Examples

The following is sample output from the **show running-config clock** command. Only the **clock summer-time** command was set.

```
hostname# show running-config clock
clock summer-time EDT recurring
```

The following is sample output from the **show running-config all clock** command. The default setting for the unconfigured **clock timezone** command displays, and the detailed information for the **clock summer-time** command displays.

```
hostname# show running-config all clock
clock timezone UTC 0
clock summer-time EDT recurring 1 Sun Apr 2:00 last Sun Oct 2:00 60
```

Related Commands

Command	Description
clock set	Manually sets the clock on the ASA.

Command	Description
clock summer-time	Sets the date range to show daylight saving time.
clock timezone	Sets the time zone.

show running-config cluster

To show the cluster configuration, use the **show running-config cluster** command in privileged EXEC mode.

show running-config [**all**] **cluster**

Syntax Description

all	(Optional) Shows the running configuration, including default configuration values.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

Use the **clear configure cluster** command to clear the cluster configuration.

Examples

The following is sample output from the **show running-config cluster** command:

```
hostname(config)# show running-config cluster
cluster group cluster1
 local-unit asa1
 cluster-interface Port-channel2 ip 10.10.10.1 255.255.255.0
 priority 2
 health-check holdtime 0.9
 clacp system-mac auto system-priority 5
```

Related Commands

Command	Description
clacp system-mac	When using spanned EtherChannels, the ASA uses cLACP to negotiate the EtherChannel with the neighbor switch.
clear configure cluster	Clears the cluster configuration.
cluster group	Names the cluster and enters cluster configuration mode.
cluster-interface	Specifies the cluster control link interface.

Command	Description
cluster interface-mode	Sets the cluster interface mode.
conn-rebalance	Enables connection rebalancing.
console-replicate	Enables console replication from slave units to the master unit.
enable (cluster group)	Enables clustering.
health-check	Enables the cluster health check feature, which includes unit health monitoring and interface health monitoring.
key	Sets an authentication key for control traffic on the cluster control link.
local-unit	Names the cluster member.
mtu cluster-interface	Specifies the maximum transmission unit for the cluster control link interface.
priority (cluster group)	Sets the priority of this unit for master unit elections.

show running-config command-alias

To display the command aliases that are configured, use the **show running-config command-alias** command in privileged EXEC mode.

show running-config [**all**] **command-alias**

Syntax Description

all	(Optional) Displays all command aliases configured, including defaults.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If you do not enter the **all** keyword, only non-default command aliases appear.

Examples

The following is sample output from the **show running-config all command-alias** command, which displays all command aliases that are configured on the ASA, *including* defaults:

```
hostname# show running-config all command-alias
command-alias exec h help
command-alias exec lo logout
command-alias exec p ping
command-alias exec s show
command-alias exec save copy running-config startup-config
```

The following is sample output from the **show running-config all command-alias** command, which displays all command aliases that are configured on the ASA, *excluding* defaults:

```
hostname# show running-config command-alias
command-alias exec save copy running-config startup-config
hostname#
```

Related Commands

Command	Description
command-alias	Creates a command alias.
clear configure command-alias	Deletes all non-default command aliases.

show running-config compression

To display the compression configuration in the running configuration, use the **show running-config compression** command from privileged EXEC mode:

show running-config compression

Defaults

There is no default behavior for this command.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Examples

The following example shows the compression configuration within the running configuration:

```
hostname# show running-config compression
compression svc http-comp
```

Related Commands

Command	Description
compression	Enables compression for all SVC, WebVPN, and Port Forwarding connections.

show running-config console timeout

To display the console connection timeout value, use the **show running-config console timeout** command in privileged EXEC mode.

show running-config console timeout

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show running-config console timeout** command:

```
hostname# show running-config console timeout
console timeout 0
```

Related Commands

Command	Description
console timeout	Sets the idle timeout for a console connection to the ASA.
clear configure console	Resets the console connection settings to defaults.

show running-config context

To show the context configuration in the system execution space, use the **show running-config context** command in privileged EXEC mode.

show running-config [**all**] **context**

Syntax Description

all	(Optional) Shows all commands, including the commands you have not changed from the default. If you use the **mac-address auto** command, then you can view the assigned MAC addresses using the **all** keyword.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0(5)/8.2(2)	When using the **all** keyword, you can view assigned MAC addresses to shared interfaces when you configure the **mac-address auto** command.

Usage Guidelines

If you use the **mac-address auto** command to generate unique MAC addresses for shared interfaces, the **all** option is required to view the assigned MAC addresses. Although the **mac-address auto** command is user-configurable in global configuration mode only, the **mac-address auto** command appears as a read-only entry in the configuration for each context along with the assigned MAC address. Only shared interfaces that are configured with a **nameif** command within the context have a MAC address assigned.

Note If you manually assign a MAC address to an interface, but also have auto-generation enabled, the auto-generated address continues to show in the configuration even though the manual MAC address is the one that is in use. If you later remove the manual MAC address, the auto-generated one shown will be used.

Examples

The following output from the **show running-config all context admin** command shows the primary and standby MAC address assigned to the Management0/0 interface:

```
hostname# show running-config all context admin
```

```
context admin
  allocate-interface Management0/0
  mac-address auto Management0/0 a24d.0000.1440 a24d.0000.1441
  config-url disk0:/admin.cfg
```

The following output from the **show running-config all context** command shows all the MAC addresses (primary and standby) for all context interfaces. Note that because the GigabitEthernet0/0 and GigabitEthernet0/1 main interfaces are not configured with a **nameif** command inside the contexts, no MAC addresses have been generated for them.

```
hostname# show running-config all context

admin-context admin
context admin
  allocate-interface Management0/0
  mac-address auto Management0/0 a2d2.0400.125a a2d2.0400.125b
  config-url disk0:/admin.cfg
!

context CTX1
  allocate-interface GigabitEthernet0/0
  allocate-interface GigabitEthernet0/0.1-GigabitEthernet0/0.5
  mac-address auto GigabitEthernet0/0.1 a2d2.0400.11bc a2d2.0400.11bd
  mac-address auto GigabitEthernet0/0.2 a2d2.0400.11c0 a2d2.0400.11c1
  mac-address auto GigabitEthernet0/0.3 a2d2.0400.11c4 a2d2.0400.11c5
  mac-address auto GigabitEthernet0/0.4 a2d2.0400.11c8 a2d2.0400.11c9
  mac-address auto GigabitEthernet0/0.5 a2d2.0400.11cc a2d2.0400.11cd
  allocate-interface GigabitEthernet0/1
  allocate-interface GigabitEthernet0/1.1-GigabitEthernet0/1.3
  mac-address auto GigabitEthernet0/1.1 a2d2.0400.120c a2d2.0400.120d
  mac-address auto GigabitEthernet0/1.2 a2d2.0400.1210 a2d2.0400.1211
  mac-address auto GigabitEthernet0/1.3 a2d2.0400.1214 a2d2.0400.1215
  config-url disk0:/CTX1.cfg
!

context CTX2
  allocate-interface GigabitEthernet0/0
  allocate-interface GigabitEthernet0/0.1-GigabitEthernet0/0.5
  mac-address auto GigabitEthernet0/0.1 a2d2.0400.11ba a2d2.0400.11bb
  mac-address auto GigabitEthernet0/0.2 a2d2.0400.11be a2d2.0400.11bf
  mac-address auto GigabitEthernet0/0.3 a2d2.0400.11c2 a2d2.0400.11c3
  mac-address auto GigabitEthernet0/0.4 a2d2.0400.11c6 a2d2.0400.11c7
  mac-address auto GigabitEthernet0/0.5 a2d2.0400.11ca a2d2.0400.11cb
  allocate-interface GigabitEthernet0/1
  allocate-interface GigabitEthernet0/1.1-GigabitEthernet0/1.3
  mac-address auto GigabitEthernet0/1.1 a2d2.0400.120a a2d2.0400.120b
  mac-address auto GigabitEthernet0/1.2 a2d2.0400.120e a2d2.0400.120f
  mac-address auto GigabitEthernet0/1.3 a2d2.0400.1212 a2d2.0400.1213
  config-url disk0:/CTX2.cfg
!
```

Related Commands

Command	Description
admin-context	Sets the admin context.
allocate-interface	Assigns interfaces to a context.
changeto	Changes between contexts or the system execution space.
config-url	Specifies the location of the context configuration.

Command	Description
context	Creates a security context in the system configuration and enters context configuration mode.
mac-address auto	Automatically generates unique MAC addresses for shared interfaces.

show running-config crypto

To display the entire crypto configuration including IPsec, crypto maps, dynamic crypto maps, and ISAKMP, use the **show running-config crypto** command in global configuration or privileged EXEC mode.

show running-config crypto

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.2(3)	Added **crypto engine large-mod-accel** command.

Examples

The following is sample output from the **show running-config crypto** command:

```
hostname# show running-config crypto
crypto ipsec transform-set example1 esp-aes esp-sha-hmac
crypto ipsec security-association lifetime seconds 28800
crypto ipsec security-association lifetime kilobytes 4608000
crypto engine large-mod-accel
crypto map mymap 10 match address L2L
crypto map mymap 10 set peer 75.5.33.1
crypto map mymap 10 set transform-set myset
crypto map mymap 10 set security-association lifetime seconds 28800
crypto map mymap 10 set security-association lifetime kilobytes 4608000
crypto map mymap interface outside
crypto isakmp enable outside
crypto isakmp policy 10
 authentication pre-share
 encryption aes
 hash sha
 group 2
 lifetime 86400
```

Related Commands

Command	Description
clear configure isakmp	Clears all the ISAKMP configuration.
clear configure isakmp policy	Clears all ISAKMP policy configuration.
clear isakmp sa	Clears the IKE runtime SA database.
isakmp enable	Enables ISAKMP negotiation on the interface on which the IPsec peer communicates with the ASA.
show isakmp sa	Displays IKE runtime SA database with additional information.

show running-config crypto dynamic-map

To view a dynamic crypto map, use the **show running-config crypto dynamic-map** command in global configuration or privileged EXEC mode.

show running-config crypto dynamic-map

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Examples

The following example entered in global configuration mode, displays all configuration information about crypto dynamic maps:

```
hostname(config)# show running-config crypto dynamic-map

Crypto Map Template "dyn1" 10

        access-list 152 permit ip host 172.21.114.67 any
        Current peer: 0.0.0.0
        Security association lifetime: 4608000 kilobytes/120 seconds
        PFS (Y/N): N
        Transform sets={ tauth, t1, }
```

Related Commands

Command	Description
clear configure isakmp	Clears all the ISAKMP configuration.
clear configure isakmp policy	Clears all ISAKMP policy configuration.
clear isakmp sa	Clears the IKE runtime SA database.

Command	Description
isakmp enable	Enables ISAKMP negotiation on the interface on which the IPsec peer communicates with the ASA.
show isakmp sa	Displays IKE runtime SA database with additional information.

show running-config crypto engine

To show if large modulus operations are switched to hardware, use the **crypto engine large-mod-accel** command in privileged EXEC mode.

show running-config crypto engine

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.2(3)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

This command is available only with the ASA models 5510, 5520, 5540, and 5550. If the CLI displays `crypto engine large-mod-accel` in response, the ASA is configured to run large modulus operations on the hardware instead of the software. The **crypto engine large-mod-accel** command specifies this switch.

If you enter this command and the CLI responds only by redisplaying the prompt, the ASA is configured to run large modulus operations on the software.

Example

The following example response to this command shows that large modulus operations are configured to run on hardware:

```
hostname# show running-config crypto engine
crypto engine large-mod-accel
```

Related Commands

Command	Description
crypto engine large-mod-accel	Switches large modulus operations from software to hardware.
clear configure crypto engine	Returns large modulus operations to software.

show running-config crypto ipsec

To display the complete IPsec configuration, use the **show running-config crypto ipsec** command in global configuration or privileged EXEC mode.

show running-config crypto ipsec

Syntax Description

This command has no default behavior or values.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Examples

The following example issued in global configuration mode, displays information about the IPsec configuration:

```
hostname(config)# show running-config crypto ipsec
crypto ipsec transform-set ttt esp-3des esp-md5-hmac
```

Related Commands

Command	Description
clear configure isakmp	Clears all the ISAKMP configuration.
clear configure isakmp policy	Clears all ISAKMP policy configuration.
clear isakmp sa	Clears the IKE runtime SA database.
isakmp enable	Enables ISAKMP negotiation on the interface on which the IPsec peer communicates with the ASA.
show isakmp sa	Displays IKE runtime SA database with additional information.

show running-config crypto isakmp

To display the complete ISAKMP configuration, use the **show running-config crypto isakmp** command in global configuration or privileged EXEC mode.

show running-config crypto isakmp

Syntax Description

This command has no default behavior or values.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	The **show running-config isakmp** command was introduced.
7.2(1)	This command was deprecated. The **show running-config crypto isakmp** command replaces it.
9.0(1)	Support for multiple context mode was added.

Examples

The following example issued in global configuration mode, displays information about the ISKAKMP configuration:

```
hostname(config)# show running-config crypto isakmp
crypto isakmp enable inside
crypto isakmp policy 1 authentication pre-share
crypto isakmp policy 1 encryption 3des
crypto isakmp policy 1 hash md5
crypto isakmp policy 1 group 2
crypto isakmp policy 1 lifetime 86400
hostname(config)#
```

Related Commands

Command	Description
clear configure crypto isakmp	Clears all the ISAKMP configuration.
clear configure crypto isakmp policy	Clears all ISAKMP policy configuration.
clear crypto isakmp sa	Clears the IKE runtime SA database.

Command	Description
crypto isakmp enable	Enables ISAKMP negotiation on the interface on which the IPsec peer communicates with the ASA.
show crypto isakmp sa	Displays IKE runtime SA database with additional information.

show running-config crypto map

To display all configuration for all crypto maps, use the **show running-config crypto map** command in global configuration or privileged EXEC mode.

show running-config crypto map

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Examples

The following example entered in privileged EXEC mode, displays all configuration information for all crypto maps:

```
hostname# show running-config crypto map
crypto map abc 1 match address xyz
crypto map abc 1 set peer 209.165.200.225
crypto map abc 1 set transform-set ttt
crypto map abc interface test
```

Related Commands

Command	Description
clear configure isakmp	Clears all the ISAKMP configuration.
clear configure isakmp policy	Clears all ISAKMP policy configuration.
clear isakmp sa	Clears the IKE runtime SA database.
isakmp enable	Enables ISAKMP negotiation on the interface on which the IPsec peer communicates with the ASA.
show isakmp sa	Displays IKE runtime SA database with additional information.

show running-config ctl-file

To show configured CTL file instances, use the **show running-config ctl-file** command in privileged EXEC mode.

show running-config [**all**] **ctl-file** [*ctl_name*]

Syntax Description

ctl_name	(Optional) Specifies the name of the CTL file instance.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Examples

The following example shows the use of the **show running-config ctl-file** command to show configured CTL file instances:

```
hostname# show running-config all ctl-file asa_ctl
```

Related Commands

Command	Description
ctl-file (global)	Specifies the CTL file to create for Phone Proxy configuration or the CTL file to parse from Flash memory.
ctl-file (phone-proxy)	Specifies the CTL file to use for Phone Proxy configuration.
phone-proxy	Configures the Phone Proxy instance.

show running-config cts

To display all currently configured Cisco TrustSec (CTS) commands, use the **show running-config cts** command in privileged EXEC mode.

show running-config [**all**] **cts** [**server-group**] [**sxp**]

Syntax Description

all	Shows all default CTS configuration values and the Security eXchange Protocol (SXP) configuration.
server-group	Shows the server group configuration.
sxp	Shows the SXP configuration.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Examples

The following is sample output of the **show running-config cts** command:

```
hostname# show running-config cts
cts server-group ise
cts sxp enable
cts sxp default password *****
cts sxp reconciliation period 10
cts sxp retry period 3
cts sxp connection peer 10.0.0.248 password default mode peer speaker
```

The following is sample output of the **show running-config all cts** command:

```
hostname# show running-config all cts

cts server-group ctsgroup

no cts sxp enable
no cts sxp default password
cts sxp retry period 120
cts sxp reconcile period 120
```

Related Commands

Command	Description
show cts	Shows the SXP connections for the running configuration.
show cts environment	Shows the health and status of the environment data refresh operation.

CHAPTER 55

show running-config ddns through show running-config isakmp Commands

show running-config ddns

To display the DDNS update methods of the running configuration, use the **show running-config ddns** command in privileged EXEC mode.

show running-config [**all**] **ddns** [**update**]

Syntax Description

all	(Optional) Shows the running configuration, including default configuration values.
update	(Optional) Specifies that DDNS update method information be displayed.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example displays the DDNS methods in the running configuration with test in the name:

```
hostname# show running-config all ddns | grep test
ddns update method test
```

Related Commands

Command	Description
ddns (DDNS-update-method mode)	Specifies a DDNS update method type for a created DDNS method.
ddns update (interface config mode)	Associates an ASA interface with a DDNS update method or a DDNS update hostname.
ddns update method (global config mode)	Creates a method for dynamically updating DNS resource records.
show ddns update interface	Displays the interfaces associated with each configured DDNS method.
show ddns update method	Displays the type and interval for each configured DDNS method. a DHCP server to perform DDNS updates.

show running-config dhcp-client

To display the DHCP client update parameters in the running configuration, use the **show running-config dhcp-client** command in privileged EXEC mode.

show running-config [**all**] **dhcp-client**

Syntax Description

all	(Optional) Shows the running configuration including default configuration values.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example displays DHCP client update parameters in the running configuration that specify updates for both A and PTR records:

```
hostname# show running-config all dhcp-client | grep both
dhcp-client update dns server both
```

Related Commands

Command	Description
dhcp-client update dns	Configures the update parameters that the DHCP client passes to the DHCP server.
dhcpd update dns	Enables a DHCP server to perform DDNS updates.
clear configure dhcp-client	Clears the DHCP client configuration.

show running-config dhcpd

To show the DHCP configuration, use the **show running-config dhcpd** command in privileged EXEC or global configuration mode.

show running-config dhcpd

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from the **show dhcpd** command to the **show running-config dhcpd** command.

Usage Guidelines

The **show running-config dhcpd** command displays the DHCP commands entered in the running configuration. To see DHCP binding, state, and statistical information, use the **show dhcpd** command.

Examples

The following is sample output from the **show running-config dhcpd** command:

```
hostname# show running-config dhcpd

dhcpd address 10.0.1.100-10.0.1.108 inside
dhcpd lease 3600
dhcpd ping_timeout 750
dhcpd dns 209.165.201.2 209.165.202.129
dhcpd enable inside
```

Related Commands

Command	Description
clear configure dhcpd	Removes all DHCP server settings.
debug dhcpd	Displays debug information for the DHCP server.
show dhcpd	Displays DHCP binding, statistic, or state information.

show running-config dhcprelay

To view the current DHCP relay agent configuration, use the **show running-config dhcprelay** command in privileged EXEC mode.

show running-config dhcprelay [**global | interface** [*ifc*]]

Syntax Description

global	Shows the global DHCP relay agent configuration.
ifc	Shows the DHCP relay agent configuration on a specified interface.
interface	Shows all of the DHCP relay agent configurations on all interfaces.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.1.(2)	The **global**, **interface**, and *ifc* options were added.

Usage Guidelines

The **show running-config dhcprelay** command displays the current DHCP relay agent configuration. To show DHCP relay agent packet statistics, use the **show dhcprelay statistics** command.

The vlan option for Catalyst 6500 VLANs is available when you show the DHCP relay configuration on a per-interface basis. You can show the DHCP relay configuration on a per-interface basis by including the interface name (*ifc* option).

Examples

The following is sample output from the **show running-config dhcprelay** command:

```
hostname(config)# show running-config dhcprelay

dhcprelay server 10.1.1.1
dhcprelay enable inside
dhcprelay timeout 90
```

The following is sample output from the **show running-config dhcprelay global** command:

```
hostname(config)# show running-config dhcprelay global
dhcprelay enable vlan391
dhcp timeout 60
```

```
dhcprelay information trust-all
```

The following is sample output from the **show running-config dhcprelay interface** command:

```
hostname(config)# show running-config dhcprelay interface

interface vlan391
nameif vlan391
dhcprelay server 198.16.48.1

interface vlan392
nameif vlan392
dhcprelay information trusted

interface vlan393
nameif vlan393
dhcprelay serv er 198.16.52.3
```

The following is sample output from the **show running-config dhcprelay interface** *ifc* command:

```
hostname(config)# show running-config dhcprelay interface vlan392

interface vlan392
nameif vlan392
dhcprelay information trusted
```

Related Commands

Command	Description
clear configure dhcprelay	Removes all DHCP relay agent settings.
clear dhcprelay statistics	Clears the DHCP relay agent statistic counters.
debug dhcprelay	Displays debugging information for the DHCP relay agent.
show dhcprelay statistics	Displays DHCP relay agent statistics.

show running-config dns

To show the DNS configuration in the running configuration, use the **show running-config dns** command in privileged EXEC mode.

show running-config dns

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show running-config dns** command:

```
hostname# show running-config dns
dns domain-lookup inside
dns name-server
dns retries 2
dns timeout 15
dns name-server 10.1.1.1
```

Related Commands

Command	Description
dns domain-lookup	Enables the ASA to perform a name lookup.
dns name-server	Configures a DNS server address.
dns retries	Specifies the number of times to retry the list of DNS servers when the ASA does not receive a response.
dns timeout	Specifies the amount of time to wait before trying the next DNS server.
show dns-hosts	Shows the DNS cache.

show running-config dns server-group

To show the DNS configuration in the running configuration, use the **show running-config dns** command in privileged EXEC mode.

show [**all**] **running-config dns server-group** [*name*]

Syntax Description

all	Displays the default and explicitly configured configuration information for one or all dns-server-groups.
name	Specifies the name of the dns server group for which you want to show the configuration information.

Defaults

If you omit the DNS server group name, this command displays all the existing DNS server group configurations.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.1 (1)	This command was introduced.

Examples

The following is sample output from the **show running-config dns server-group** command:

```
hostname# show running-config dns server-group
dns domain-lookup inside
dns server-group DefaultDNS
 name-server 90.1.1.22
 domain-name frqa.cisco.com
dns server-group writers1
 retries 10
 timeout 3
 name-server 10.86.194.61
 domain-name doc-group
hostname#
```

Related Commands

Command	Description
clear configure dns	Removes all DNS commands.
dns server-group	Enters DNS server group mode, in which you can configure a DNS server group.

show running-config domain-name

To show the domain name configuration in the running configuration, use the **show running-config domain-name** command in privileged EXEC mode.

show running-config domain-name

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was changed from **show domain-name**.

Examples

The following is sample output from the **show running-config domain-name** command:

```
hostname# show running-config domain-name
example.com
```

Related Commands

Command	Description
domain-name	Sets the default domain name.
hostname	Sets the ASA hostname.

show running-config dynamic-access-policy-record

To display the running configuration for all DAP records, or for the named DAP record, use the **show running-config dynamic-access-policy-record** command in privileged EXEC mode.

show running-config dynamic-access-policy-record [*name*]

Syntax DescriptionE

name	Specifies the name of the DAP record. The name can be up to 64 characters long and cannot contain spaces.

Defaults

All attributes display.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC mode	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Examples

This example shows the use of the **show running-config dynamic-access-policy-record** command to display statistics for the DAP record named Finance:

```
hostname(config)#show running-config dynamic-access-policy-record Finance
dynamic-access-policy-record Finance
description value "Finance users from trusted device"
network-acl FinanceFirewallAcl
user-message "Limit access to the Finance network"
priority 2
webvpn
  appl-acl FinanceWebvpnAcl
  url-list value FinanceLinks,StockLinks
  port-forward enable FinanceApps
  file-browsing enable
  file-entry enablehostname#
```

Related Commands

Command	Description
clear config dynamic-access-policy-record [*name*]	Removes all DAP records or the named DAP record.
dynamic-access-policy-record	Creates a DAP record.

show running-config dynamic-filter

To show the Botnet Traffic Filter configuration, use the **show running-config dynamic-filter** command in privileged EXEC mode.

show running-config [**all**] **dynamic-filter**

Syntax Description

all	(Optional) Shows the running configuration, including default configuration values.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
8.2(1)	This command was introduced.

Examples

The following is sample output from the **show running-config dynamic-filter** command:

```
hostname# show running-config dynamic-filter

dynamic-filter updater-client enable
dynamic-filter use-database
dynamic-filter enable interface outside
dynamic-filter enable interface inside classify-list test_l4tm
dynamic-filter enable interface publicl4tm
dynamic-filter enable interface publictftp
dynamic-filter enable interface mgmt
dynamic-filter whitelist
   name www.example.com
dynamic-filter blacklist
   name cisco.invalid
```

Related Commands

Command	Description
address	Adds an IP address to the blacklist or whitelist.
clear configure dynamic-filter	Clears the running Botnet Traffic Filter configuration.
clear dynamic-filter dns-snoop	Clears Botnet Traffic Filter DNS snooping data.

Command	Description
clear dynamic-filter reports	Clears Botnet Traffic filter report data.
clear dynamic-filter statistics	Clears Botnet Traffic filter statistics.
dns domain-lookup	Enables the ASA to send DNS requests to a DNS server to perform a name lookup for supported commands.
dns server-group	Identifies a DNS server for the ASA.
dynamic-filter ambiguous-is-black	Treats greylisted traffic as blacklisted traffic for action purposes.
dynamic-filter blacklist	Edits the Botnet Traffic Filter blacklist.
dynamic-filter database fetch	Manually retrieves the Botnet Traffic Filter dynamic database.
dynamic-filter database find	Searches the dynamic database for a domain name or IP address.
dynamic-filter database purge	Manually deletes the Botnet Traffic Filter dynamic database.
dynamic-filter drop blacklist	Automatically drops blacklisted traffic.
dynamic-filter enable	Enables the Botnet Traffic Filter for a class of traffic or for all traffic if you do not specify an access list.
dynamic-filter updater-client enable	Enables downloading of the dynamic database.
dynamic-filter use-database	Enables use of the dynamic database.
dynamic-filter whitelist	Edits the Botnet Traffic Filter whitelist.
inspect dns dynamic-filter-snoop	Enables DNS inspection with Botnet Traffic Filter snooping.
name	Adds a name to the blacklist or whitelist.
show asp table dynamic-filter	Shows the Botnet Traffic Filter rules that are installed in the accelerated security path.
show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
show dynamic-filter dns-snoop	Shows the Botnet Traffic Filter DNS snooping summary, or with the **detail** keyword, the actual IP addresses and names.
show dynamic-filter reports	Generates reports of the top 10 botnet sites, ports, and infected hosts.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.

show running-config enable

To show the encrypted enable passwords, use the **show running-config enable** command in privileged EXEC mode.

show running-config enable

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was changed from the **show enable** command.

Usage Guidelines

The password is saved to the configuration in encrypted form, so you cannot view the original password after you enter it. The password displays with the **encrypted** keyword to indicate that the password is encrypted.

Examples

The following is sample output from the **show running-config enable** command:

```
hostname# show running-config enable
enable password 2AfK9Kjr3BE2/J2r level 10 encrypted
enable password 8Ry2YjIyt7RRXU24 encrypted
```

Related Commands

Command	Description
disable	Exits privileged EXEC mode.
enable	Enters privileged EXEC mode.
enable password	Sets the enable password.

show running-config established

To display the allowed inbound connections that are based on established connections, use the **show running-config established** command in privileged EXEC mode.

show running-config established

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	The keyword **running-config** was added.

Usage Guidelines

This command has no usage guidelines.

Examples

This example shows how to display inbound connections that are based on established connections:

```
hostname# show running-config established
```

Related Commands

Command	Description
established	Permits return connections on ports that are based on an established connection.
clear configure established	Removes all established commands.

show running-config failover

To display the **failover** commands in the configuration, use the **show running-config failover** command in privileged EXEC mode.

show running-config [**all**] **failover**

Syntax Description

all	(Optional) Shows all failover commands, including the commands you have not changed from the default.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show running-config failover** command displays the **failover** commands in the running configuration. It does not display the **monitor-interface** or **join-failover-group** commands.

Examples

The following example shows the default failover configuration before failover has been configured:

```
hostname# show running-config all failover
no failover
failover lan unit secondary
failover polltime unit 15 holdtime 45
failover polltime interface 15
failover interface policy 1
```

Related Commands

Command	Description
show failover	Displays failover state and statistics.

show running-config filter

To show the filtering configuration, use the **show running-config filter** command in privileged EXEC mode.

show running-config filter

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show running-config filter** command displays the filtering configuration for the ASA.

Examples

The following is sample output from the **show running-config filter** command, and shows the filtering configuration for the ASA:

```
hostname# show running-config filter
!
filter activex 80 10.86.194.170 255.255.255.255 10.1.1.0 255.255.255.224
!
```

This example shows ActiveX filtering is enabled on port80 for the address 10.86.194.170.

Related Commands

Commands	Description
filter activex	Removes ActiveX objects from HTTP traffic passing through the ASA.
filter ftp	Identifies the FTP traffic to be filtered by a URL filtering server.
filter https	Identifies the HTTPS traffic to be filtered by a Websense server.
filter java	Removes Java applets from HTTP traffic passing through the ASA.
filter url	Directs traffic to a URL filtering server.

show running-config fips

To display the FIPS configuration that is running on the security appliance, use the **show running-config fips** command.

show running-config fips

Syntax Description

fips	Shows FIPS-2 compliance information

Defaults

This command has no default settings.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(4)	This command was introduced.

Usage Guidelines

The **show running-config fips** command allows you to display the current running fips configuration. You use the **running-config** keyword only in the **show running-config fips** command. You cannot use this keyword with no or clear, or as a standalone command as it is not supported. When you enter the **?**, **no ?**, or **clear ?** keywords, a **running-config** keyword is not listed in the command list.

Examples

```
hostname(config)# show running-config fips
```

Related Commands

Command	Description
clear configure fips	Clears the system or module FIPS configuration information stored in NVRAM.
crashinfo console disable	Disables the reading, writing and configuration of crash write info to flash.
fips enable	Enables or disablea policy-checking to enforce FIPS compliance on the system or module.
show crashinfo console	Reads, writes, and configures crash write to flash.

show running-config flow-export

To display the configured NetFlow commands, use the **show running-config flow-export** command in privileged EXEC mode.

show running-config flow-export [**active** | **delay** | **destination** | **template**]

Syntax Description

active	Shows the flow-export active configuration.
delay	Shows the flow-export delay configuration.
destination	Shows the flow-export destination configuration.
template	Shows the flow-export template configuration.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.1(2)	This command was introduced.
8.4(5)	The **active** keyword was added.

Usage Guidelines

The additional keywords are provided to filter the commands that are to be displayed.

Examples

The following is sample output from the **show running-config flow-export active** command:

```
hostname# show running-config flow-export active
flow-export active refresh-interval 2
```

The following is sample output from the **show running-config flow-export delay** command:

```
hostname(config)# show running-config flow-export delay
flow-export delay flow-create 30
```

The following is sample output from the **show running-config flow-export destination** command:

```
hostname(config)# show running-config flow-export destination
flow-export destination inside 192.68.10.70 9996
```

The following is sample output from the **show running-config flow-export template** command:

```
hostname(config)# show running-config flow-export template
flow-export template timeout-rate 1
```

Related Commands

Command	Description
clear configure flow-export	Removes all the NetFlow flow-export configurations.
flow-export active refresh-interval	Changes the time interval at which periodic flow-update events are sent to the NetFlow collector.
flow-export delay flow-create	Delays export of the flow-create event.
flow-export destination	Configures a collector to which NetFlow packets are sent.
flow-export template timeout-rate	Controls the interval at which the template information is sent to NetFlow collectors.

show running-config fragment

To display the current configuration of the fragment databases, use the **show running-config fragment** command in privileged EXEC mode.

show running-config fragment [*interface*]

Syntax Description

interface	(Optional) Specifies the ASA interface.

Defaults

If an interface is not specified, the command applies to all interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show running-config fragment** command displays the current configuration of the fragment databases. If you specify an interface name, only information for the database residing at the specified interface displays. If you do not specify an interface name, the command applies to all interfaces.

Use the **show running-config fragment** command to display this information:

- Size—Maximum number of packets set by the **size** keyword. This value is the maximum number of fragments that are allowed on the interface.
- Chain—Maximum number of fragments for a single packet set by the **chain** keyword.
- Timeout—Maximum number of seconds set by the **timeout** keyword. This is the maximum number of seconds to wait for an entire fragmented packet to arrive. The timer starts after the first fragment of a packet arrives. If all fragments of the packet do not arrive by the number of seconds specified, all fragments of the packet that were already received will be discarded.

Examples

The following example shows how to display the states of the fragment databases on all interfaces:

```
hostname# show running-config fragment
fragment size 200 inside
fragment chain 24 inside
fragment timeout 5 inside
fragment size 200 outside1
fragment chain 24 outside1
fragment timeout 5 outside1
```

```
fragment size 200 outside2
fragment chain 24 outside2
fragment timeout 5 outside2
fragment size 200 outside3
fragment chain 24 outside3
fragment timeout 5 outside3
```

The following example shows how to display the states of the fragment databases on interfaces that start with the name “outside”:

Note In this example, the interfaces named “outside1”, “outside2”, and “outside3” display.

```
hostname# show running-config fragment outside
fragment size 200 outside1
fragment chain 24 outside1
fragment timeout 5 outside1
fragment size 200 outside2
fragment chain 24 outside2
fragment timeout 5 outside2
fragment size 200 outside3
fragment chain 24 outside3
fragment timeout 5 outside3
```

The following example shows how to display the states of the fragment databases on the interfaces named “outside1” only:

```
hostname# show running-config fragment outside1
fragment size 200 outside1
fragment chain 24 outside1
fragment timeout 5 outside1
```

Related Commands

Command	Description
clear configure fragment	Resets all the IP fragment reassembly configurations to defaults.
clear fragment	Clears the operational data of the IP fragment reassembly module.
fragment	Provides additional management of packet fragmentation and improves compatibility with NFS.
show fragment	Displays the operational data of the IP fragment reassembly module.

show running-config ftp mode

To show the client mode configured for FTP, use the **show running-config ftp mode** command in privileged EXEC mode.

show running-config ftp mode

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show running-config ftp mode** command displays the client mode that is used by the ASA when accessing an FTP server.

Examples

The following is sample output from the **show running-config ftp-mode** command:

```
hostname# show running-config ftp-mode
!
ftp-mode passive
!
```

Related Commands

Commands	Description
copy	Uploads or downloads image files or configuration files to or from an FTP server.
debug ftp client	Displays detailed information about FTP client activity.
ftp mode passive	Sets the FTP client mode used by the ASA when accessing an FTP server.

show running-config global

To display the **global** commands in the configuration, use the **show running-config global** command in privileged EXEC mode.

show running-config global

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	Added keyword **running-config**.

Examples

The following is sample output from the **show running-config global** command:

```
hostname# show running-config global
global (outside1) 10 interface
```

Related Commands

Command	Description
clear configure global	Removes **global** commands from the configuration.
global	Creates entries from a pool of global addresses.

show running-config group-delimiter

To display the current delimiter to be used when parsing group names from the user names that are received when tunnels are being negotiated, use the **show running-config group-delimiter** command in global configuration mode or in tunnel-group ipsec-attributes configuration mode.

show running-config group-delimiter

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	—	—	•
Tunnel-group ipsec-attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.1(1)	Added tunnel-group ipsec-attributes configuration mode.

Usage Guidelines

Use this command to display the currently configured group-delimiter.

Examples

This example shows a **show running-config group-delimiter** command and its output:

```
hostname(config)# show running-config group-delimiter
group-delimiter @
```

Related Commands

Command	Description
group-delimiter	Enables group-name parsing and specifies the delimiter to be used when parsing group names from the user names that are received when tunnels are being negotiated.

show running-config group-policy

To display the running configuration for a particular group policy, use the **show running-config group-policy** command in privileged EXEC mode and append the name of the group policy. To display the running configuration for all group policies, use this command without naming a specific group policy. To have either display include the default configuration, use the **all** keyword.

show running-config [all] group-policy [*name*]

Syntax Description

all	(Optional) Displays the running configuration including default values.
name	(Optional) Specifies the name of the group policy.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	—	—
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to display the running configuration, including default values, for the group policy named FirstGroup:

```
hostname# show running-config all group-policy FirstGroup
```

Related Commands

Command	Description
group-policy	Creates, edits, or removes a group policy.
group-policy attributes	Enters group-policy attributes mode, which lets you configure AVPs for a specified group policy.
clear config group-policy	Removes the configuration for a particular group policy or for all group policies.

show running-config hpm

To display the hpm configuration, use the **show running-config hpm** command in privileged EXEC mode.

show running-config [all] hpm

Syntax Description

all	(Optional) Shows all commands, including the commands you have not changed from the default.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Examples

The following is sample output from the **show running-config hpm** command:

```
hostname# show running-config hpm
hpm topn enable
```

Related Commands

Command	Description
clear configure hpm	Clears the hpm configuration.
hpm topn enable	Enables top hosts reporting in ASDM.

show running-config http

To display the current set of configured http commands, use the **show running-config http** command in privileged EXEC mode.

show running-config http

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following sample output shows how to use the **show running-config http** command:

```
hostname# show running-config http
http server enabled
0.0.0.0 0.0.0.0 inside
```

Related Commands

Command	Description
clear http	Remove the HTTP configuration: disable the HTTP server and remove hosts that can access the HTTP server.
http	Specifies hosts that can access the HTTP server by IP address and subnet mask. Specifies the ASA interface through which the host accesses the HTTP server.
http authentication-certificate	Requires authentication via certificate from users who are establishing HTTPS connections to the ASA.
http redirect	Specifies that the ASA redirect HTTP connections to HTTPS.
http server enable	Enables the HTTP server.

show running-config icmp

To show the access rules configured for ICMP traffic, use the **show running-config icmp** command in privileged EXEC mode.

show running-config icmp *map_name*

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show running-config icmp** command displays the access rules configured for ICMP traffic.

Examples

The following is sample output from the **show running-config icmp** command:

```
hostname# show running-config icmp
!
icmp permit host 172.16.2.15 echo-reply outside
icmp permit 172.22.1.0 255.255.0.0 echo-reply outside
icmp permit any unreachable outside
!
```

Related Commands

Commands	Description
clear configure icmp	Clears the ICMP configuration.
debug icmp	Enables the display of debug information for ICMP.
show icmp	Displays ICMP configuration.
timeout icmp	Configures the idle timeout for ICMP.

show running-config imap4s

To display the running configuration for IMAP4S, use the s**how running-config imap4s** command in privileged EXEC mode.

show running-config [all] imap4s

Syntax Description

all	(Optional) Displays the running configuration including default values.

Defaults

No default behavior or values.

Command History

Release	Modification
7.0(1)	This command was introduced.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—
Global configuration	•	—	•	—	—
Webvpn	•	—	•	—	—

Examples

The following is sample output from the **show running-config imap4s** command:

```
hostname# show running-config imap4s

imap4s
 server 10.160.105.2
 authentication-server-group KerbSvr
 authentication aaa

hostname# show running-config all imap4s

imap4s
 port 993
 server 10.160.105.2
 outstanding 20
 name-separator :
 server-separator @
 authentication-server-group KerbSvr
 no authorization-server-group
 no accounting-server-group
 no default-group-policy
 authentication aaa
```

Related Commands

Command	Description
clear configure imap4s	Removes the IMAP4S configuration.
imap4s	Creates or edits an IMAP4S e-mail proxy configuration.

show running-config interface

To show the interface configuration in the running configuration, use the s**how running-config interface** command in privileged EXEC mode.

show running-config [**all**] **interface** [*physical_interface*[**.***subinterface*] | *mapped_name* | *interface_name*]

Syntax Description

all	(Optional) Shows all **interface** commands, including the commands you have not changed from the default.
interface_name	(Optional) Identifies the interface name set with the **nameif** command.
mapped_name	(Optional) In multiple context mode, identifies the mapped name if it was assigned using the **allocate-interface** command.
physical_interface	(Optional) Identifies the interface ID, such as **gigabitethernet0/1**. See the **interface** command for accepted values.
subinterface	(Optional) Identifies an integer between 1 and 4294967293 designating a logical subinterface.

Defaults

If you do not specify an interface, this command shows the configuration for all interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You cannot use the interface name in the system execution space, because the **nameif** command is only available within a context. Similarly, if you mapped the interface ID to a mapped name using the **allocate-interface** command, you can only use the mapped name in a context.

Examples

The following is sample output from the **show running-config interface** command. The following example shows the running configuration for all interfaces. The GigabitEthernet0/2 and 0/3 interfaces have not been configured yet, and show the default configuration. The Management0/0 interface also shows the default settings.

```
hostname# show running-config interface
!
interface GigabitEthernet0/0
```

```
 no shutdown
 nameif inside
 security-level 100
 ip address 10.86.194.60 255.255.254.0
 webvpn enable
!
interface GigabitEthernet0/1
 no shutdown
 nameif test
 security-level 0
 ip address 10.10.4.200 255.255.0.0
!
interface GigabitEthernet0/1.1
 vlan 101
 no shutdown
 nameif dmz
 security-level 50
 ip address 10.50.1.1 255.255.255.0
 mac-address 000C.F142.4CDE standby 020C.F142.4CDE
!
interface GigabitEthernet0/2
 shutdown
 no nameif
 security-level 0
 no ip address
!
interface GigabitEthernet0/3
 shutdown
 no nameif
 security-level 0
 no ip address
!
interface Management0/0
 shutdown
 no nameif
 security-level 0
 no ip address
```

Related CommandsI

Command	Description
allocate-interface	Assigns interfaces and subinterfaces to a security context.
clear configure interface	Clears the interface configuration.
interface	Configures an interface and enters interface configuration mode.
nameif	Sets the interface name.
show interface	Displays the runtime status and statistics of interfaces.

show running-config interface bvi

To view the bridge virtual interface configuration in the running configuration, use the **show running-config interface bvi** command in privileged EXEC mode.

show running-config [**all**] **interface bvi** *bridge_group_number*

Syntax Description

all	(Optional) Shows all commands, including the commands you have not changed from the default.
bridge_group_number	Specifies the bridge group number as an integer between 1 and 100.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	—	•	•	•	—

Command History

Release	Modification
8.4(1)	We introduced this command.

Examples

The following is sample output from the show running-config interface bvi command:

```
hostname# show running-config interface bvi 1

interface BVI1
```

Related Commands

Command	Description
bridge-group	Groups transparent firewall interfaces into a bridge group.
clear configure interface bvi	Clears the bridge group interface configuration.
interface	Configures an interface.
interface bvi	Creates a bridge virtual interface.
ip address	Sets the management IP address for a bridge group.
show bridge-group	Shows bridge group information, including member interfaces and IP addresses.

show running-config ip address

To show the IP address configuration in the running configuration, use the s**how running-config ip address** command in privileged EXEC mode.

show running-config ip address [*physical_interface*[**.***subinterface*] | *mapped_name* | *interface_name*]

Syntax Description

interface_name	(Optional) Identifies the interface name set with the **nameif** command.
mapped_name	(Optional) In multiple context mode, identifies the mapped name if it was assigned using the **allocate-interface** command.
physical_interface	(Optional) Identifies the interface ID, such as **gigabitethernet0/1**. See the **interface** command for accepted values.
subinterface	(Optional) Identifies an integer between 1 and 4294967293 designating a logical subinterface.

Defaults

If you do not specify an interface, this command shows the IP address configuration for all interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

In multiple context mode, if you mapped the interface ID in the **allocate-interface** command, you can only specify the mapped name or the interface name in a context.

In transparent firewall mode, do not specify an interface because this command shows only the management IP address; the transparent firewall does not have IP addresses associated with interfaces.

This display also shows the **nameif** command and **security-level** command configuration.

Examples

The following is sample output from the **show running-config ip address** command:

```
hostname# show running-config ip address
!
interface GigabitEthernet0/0
 nameif inside
 security-level 100
```

```
 ip address 10.86.194.60 255.255.254.0
!
interface GigabitEthernet0/1
 nameif test
 security-level 0
 ip address 10.10.4.200 255.255.0.0
!
```

Related Commands

Command	Description
clear configure interface	Clears the interface configuration.
interface	Configures an interface and enters interface configuration mode.
ip address	Sets the IP address for the interface or sets the management IP address for a transparent firewall.
nameif	Sets the interface name.
security-level	Sets the security level for the interface.

show running-config ip audit attack

To show the **ip audit attack** configuration in the running configuration, use the **show running-config ip audit attack** command in privileged EXEC mode.

show running-config ip audit attack

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from **show ip audit attack**.

Examples

The following is sample output from the **show running-config ip audit attack** command:

```
hostname# show running-config ip audit attack
ip audit attack action drop
```

Related Commands

Command	Description
ip audit attack	Sets the default actions for packets that match an attack signature.
ip audit info	Sets the default actions for packets that match an informational signature.
ip audit interface	Assigns an audit policy to an interface.
ip audit name	Creates a named audit policy that identifies the actions to take when a packet matches an attack signature or an informational signature.
ip audit signature	Disables a signature.

show running-config ip audit info

To show the **ip audit info** configuration in the running configuration, use the **show running-config ip audit info** command in privileged EXEC mode.

show running-config ip audit info

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from **show ip audit info**.

Examples

The following is sample output from the **show running-config ip audit info** command:

```
hostname# show running-config ip audit info
ip audit info action drop
```

Related Commands

Command	Description
ip audit attack	Sets the default actions for packets that match an attack signature.
ip audit info	Sets the default actions for packets that match an informational signature.
ip audit interface	Assigns an audit policy to an interface.
ip audit name	Creates a named audit policy that identifies the actions to take when a packet matches an attack signature or an informational signature.
ip audit signature	Disables a signature.

show running-config ip audit interface

To show the **ip audit interface** configuration in the running configuration, use the **show running-config ip audit interface** command in privileged EXEC mode.

show running-config ip audit interface [*interface_name*]

Syntax Description

interface_name	(Optional) Specifies the interface name.

Defaults

If you do not specify an interface name, this command shows the configuration for all interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from **show ip audit interface**.

Examples

The following is sample output from the **show running-config ip audit interface** command:

```
hostname# show running-config ip audit interface
ip audit interface inside insidepolicy
ip audit interface outside outsidepolicy
```

Related Commands

Command	Description
ip audit attack	Sets the default actions for packets that match an attack signature.
ip audit info	Sets the default actions for packets that match an informational signature.
ip audit interface	Assigns an audit policy to an interface.
ip audit name	Creates a named audit policy that identifies the actions to take when a packet matches an attack signature or an informational signature.
ip audit signature	Disables a signature.

show running-config ip audit name

To show the **ip audit name** configuration in the running configuration, use the **show running-config ip audit name** command in privileged EXEC mode.

show running-config ip audit name [*name* [**info** | **attack**]]

Syntax Description

attack	(Optional) Shows the named audit policy configuration for attack signatures.
info	(Optional) Shows the named audit policy configuration for informational signatures.
name	(Optional) Shows the configuration for the audit policy name created using the **ip audit name** command.

Defaults

If you do not specify a name, this command shows the configuration for all audit policies.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from **show ip audit name**.

Examples

The following is sample output from the **show running-config ip audit name** command:

```
hostname# show running-config ip audit name
ip audit name insidepolicy1 attack action alarm
ip audit name insidepolicy2 info action alarm
ip audit name outsidepolicy1 attack action reset
ip audit name outsidepolicy2 info action alarm
```

Related Commands

Command	Description
ip audit attack	Sets the default actions for packets that match an attack signature.
ip audit info	Sets the default actions for packets that match an informational signature.
ip audit interface	Assigns an audit policy to an interface.
ip audit name	Creates a named audit policy that identifies the actions to take when a packet matches an attack signature or an informational signature.
ip audit signature	Disables a signature.

show running-config ip audit signature

To show the **ip audit signature** configuration in the running configuration, use the **show running-config ip audit signature** command in privileged EXEC mode.

show running-config ip audit signature [*signature_number*]

Syntax Description

signature_number	(Optional) Shows the configuration for the signature number, if present. See the **ip audit signature** command for a list of supported signatures.

Defaults

If you do not specify a number, this command shows the configuration for all signatures.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from **show ip audit signature**.

Examples

The following is sample output from the **show running-config ip audit signature** command:

```
hostname# show running-config ip audit signature
ip audit signature 1000 disable
```

Related Commands

Command	Description
ip audit attack	Sets the default actions for packets that match an attack signature.
ip audit info	Sets the default actions for packets that match an informational signature.
ip audit interface	Assigns an audit policy to an interface.
ip audit name	Creates a named audit policy that identifies the actions to take when a packet matches an attack signature or an informational signature.
ip audit signature	Disables a signature.

show running-config ip local pool

To display IP address pools, use the **show running-config ip local pool** command in privileged EXEC mode.

show running-config ip local pool [*poolname*]

Syntax Description

poolname	(Optional) Specifies the name of the IP address pool.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show running-config ip local pool** command:

```
hostname(config)# show running-config ip local pool firstpool

Pool            Begin           End             Mask            Free    In use
firstpool               10.20.30.40     10.20.30.50     255.255.255.0      11
    0
Available Addresses:
10.20.30.40
10.20.30.41
10.20.30.42
10.20.30.43
10.20.30.44
10.20.30.45
10.20.30.46
10.20.30.47
10.20.30.48
10.20.30.49
10.20.30.50
```

Related Commands

Command	Description
clear configure ip local pool	Removes all ip local pools
ip local pool	Configures an IP address pool.

show running-config ip verify reverse-path

To show the **ip verify reverse-path** configuration in the running configuration, use the **show running-config ip verify reverse-path** command in privileged EXEC mode.

show running-config ip verify reverse-path [interface *interface_name*]

Syntax Description

interface *interface_name*	(Optional) Shows the configuration for the specified interface.

Defaults

This command shows the configuration for all interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from **show ip verify reverse-path**.

Examples

The following is sample output from the **show ip verify statistics** command:

```
hostname# show running-config ip verify reverse-path
ip verify reverse-path interface inside
ip verify reverse-path interface outside
ip verify reverse-path interface dmz
```

Related Commands

Command	Description
clear configure ip verify reverse-path	Clears the **ip verify reverse-path** configuration.
clear ip verify statistics	Clears the Unicast RPF statistics.
ip verify reverse-path	Enables the Unicast Reverse Path Forwarding feature to prevent IP spoofing.
show ip verify statistics	Shows the Unicast RPF statistics.

show running-config ipv6

To display the IPv6 commands in the running configuration, use the **show running-config ipv6** command in privileged EXEC mode.

show running-config [**all**] **ipv6**

Syntax Description

all	(Optional) Shows all **ipv6** commands, including the commands you have not changed from the default, in the running configuration.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show running-config ipv6** command:

```
hostname# show running-config ipv6
ipv6 unicast-routing
ipv6 route vlan101 ::/0 fec0::65:0:0:a0a:6575
ipv6 access-list outside_inbound_ipv6 permit ip any any
ipv6 access-list vlan101_inbound_ipv6 permit ip any any
hostname#
```

Related Commands

Command	Description
debug ipv6	Displays IPv6 debugging messages.
show ipv6 access-list	Displays the IPv6 access list.
show ipv6 interface	Displays the status of the IPv6 interfaces.
show ipv6 route	Displays the contents of the IPv6 routing table.
show ipv6 traffic	Displays IPv6 traffic statistics.

show running-config ipv6 router

To display the running configuration of OSPFv3 for IPv6, use the **show running-config ipv6 router** command in user EXEC or privileged EXEC mode.

show running-config ipv6 router {**ospf**}

Syntax Description

ospf	Shows the running configuration for OSPFv3 processes.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—
User EXEC	•	—	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Examples

The following is sample output from the **show running-config ipv6 router** command:

```
hostname# show running-config ipv6 router
ipv6 unicast-routing
ipv6 route vlan101 ::/0 fec0::65:0:0:a0a:6575
```

Related Commands

Command	Description
clear ipv6 ospf	Deletes all IPv6 settings in the OSPFv3 routing process.
debug ospfv3	Provides debugging information for troubleshooting OSPFv3 routing processes.

show running-config isakmp

To display the complete ISAKMP configuration, use the **show running-config isakmp** command in global configuration or privileged EXEC mode.

show running-config isakmp

Syntax Description

This command has no default behavior or values.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	The **show running-config isakmp** command was introduced.
7.2(1)	This command was deprecated. The **show running-config crypto isakmp** command replaces it.

Examples

The following example issued in global configuration mode, displays information about the ISKAKMP configuration:

```
hostname(config)# show running-config isakmp
isakmp enable inside
isakmp policy 1 authentication pre-share
isakmp policy 1 encryption 3des
isakmp policy 1 hash md5
isakmp policy 1 group 2
isakmp policy 1 lifetime 86400
hostname(config)#
```

Related Commands

Command	Description
clear configure isakmp	Clears all the ISAKMP configuration.
clear configure isakmp policy	Clears all ISAKMP policy configuration.
clear isakmp sa	Clears the IKE runtime SA database.

Command	Description
isakmp enable	Enables ISAKMP negotiation on the interface on which the IPsec peer communicates with the ASA.
show isakmp sa	Displays IKE runtime SA database with additional information.

CHAPTER 56

show running-config ldap through show running-config router Commands

show running-config ldap

To display the LDAP attribute name and value mappings in running LDAP attribute maps, use the **show running-config ldap** command in privileged EXEC mode.

show running-config [**all**] **ldap attribute-map** *name*

Syntax Description

all	Displays all LDAP attribute maps.
name	Specifies an individual LDAP attribute map for display.

Defaults

By default, all attribute maps, mapped names, and mapped values display.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Use this command to display the LDAP attribute name and value mappings contained in attribute maps running on your ASA. You can display all the attribute maps using the **all** option, or you can display a single attribute map by specifying the map name. If you enter neither the **all** option nor an LDAP attribute map name, all attribute maps, mapped names, and mapped values display.

Examples

The following example, entered in privileged EXEC mode, displays the attribute name and value mappings for a specific running attribute map, “myldapmap”:

```
hostname# show running-config ldap attribute-map myldapmap
map-name Hours cVPN3000-Access-Hours
map-value Hours workDay Daytime
```

The following command displays all attribute name and value mappings within all running attribute maps:

```
hostname# show running-config all ldap attribute-map
```

Related Commands

Command	Description
ldap attribute-map (global config mode)	Creates and names an LDAP attribute map for mapping user-defined attribute names to Cisco LDAP attribute names.
ldap-attribute-map (aaa-server host mode)	Binds an LDAP attribute map to an LDAP server.
map-name	Maps a user-defined LDAP attribute name with a Cisco LDAP attribute name.
map-value	Maps a user-defined attribute value to a Cisco attribute.
clear configure ldap attribute-map	Removes all LDAP attribute maps.

show running-config license-server

To show the license server configuration, use the **show running-config license-server** command in privileged EXEC mode.

show running-config [**all**] **license-server**

Syntax Description

all	(Optional) Shows the running configuration, including default configuration values.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Examples

The following is sample output from the **show running-config all license-server** command:

```
hostname# show running-config all license-server

license-server backup 10.1.1.2 backup-id JMX0916L0Z4 ha-backup-id JMX1378N0W3
license-server secret ********
license-server refresh-interval 30
license-server port 50554
license-server enable inside
```

Related Commands

Command	Description
activation-key	Enters a license activation key.
clear configure license-server	Clears the shared licensing server configuration.
clear shared license	Clears shared license statistics.
license-server address	Identifies the shared licensing server IP address and shared secret for a participant.
license-server backup address	Identifies the shared licensing backup server for a participant.
license-server backup backup-id	Identifies the backup server IP address and serial number for the main shared licensing server.

Command	Description
license-server backup enable	Enables a unit to be the shared licensing backup server.
license-server enable	Enables a unit to be the shared licensing server.
license-server port	Sets the port on which the server listens for SSL connections from participants.
license-server refresh-interval	Sets the refresh interval provided to participants to set how often they should communicate with the server.
license-server secret	Sets the shared secret on the shared licensing server.
show activation-key	Shows the current licenses installed.
show shared license	Shows shared license statistics.
show vpn-sessiondb	Shows license information about VPN sessions.

show running-config logging

To display all currently running logging configurations, use the **show runnig-config logging** command in privileged EXEC mode.

show running-config [all] logging [level | disabled]

Syntax Description

all	(Optional) Displays the logging configuration, including commands whose settings you have not changed from default values.
disabled	(Optional) Displays only the disabled syslog message configuration.
level	(Optional) Displays only the configuration for syslog messages with a non-default severity level.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was changed from the **show logging** command.

Examples

The following shows sample output from the **show running-config logging disabled** command:

```
hostname# show running-config logging disabled

no logging message 720067
```

Related Commands

Command	Description
logging message	Configures logging.
show logging	Shows the log buffer and other logging settings.

show running-config mac-address

To show the **mac-address auto** configuration in the running configuration, use the s**how running-config mac-address** command in privileged EXEC mode.

show running-config mac-address

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	—	•

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following is sample output from the **show running-config mac-address** command:

```
hostname# show running-config mac-address
no mac-address auto
```

Related Commands

Command	Description
failover mac address	Sets the active and standby MAC address of a physical interface for Active/Standby failover.
mac address	Sets the active and standby MAC address of a physical interface for Active/Active failover.
mac-address	Manually sets the MAC address (active and standby) for a physical interface or subinterface. In multiple context mode, you can set different MAC addresses in each context for the same interface.
mac-address auto	Auto-generates MAC addresses (active and standby) for shared interfaces in multiple context mode.
show interface	Shows the interface characteristics, including the MAC address.

show running-config mac-address-table

To view the **mac-address-table static** and **mac-address-table aging-time** configuration in the running configuration, use the **show running-config mac-address-table** command in privileged EXEC mode.

show running-config mac-address-table

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	—	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show running-config mac-learn** command:

```
hostname# show running-config mac-address-table
mac-address-table aging-time 50
mac-address-table static inside1 0010.7cbe.6101
```

Related Commands

Command	Description
firewall transparent	Sets the firewall mode to transparent.
mac-address-table aging-time	Sets the timeout for dynamic MAC address entries.
mac-address-table static	Adds static MAC address entries to the MAC address table.
mac-learn	Disables MAC address learning.
show mac-address-table	Shows the MAC address table, including dynamic and static entries.

show running-config mac-learn

To view the **mac-learn** configuration in the running configuration, use the **show running-config mac-learn** command in privileged EXEC mode.

show running-config mac-learn

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	—	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show running-config mac-learn** command:

```
hostname# show running-config mac-learn
mac-learn disable
```

Related Commands

Command	Description
firewall transparent	Sets the firewall mode to transparent.
mac-address-table static	Adds static MAC address entries to the MAC address table.
mac-learn	Disables MAC address learning.
show mac-address-table	Shows the MAC address table, including dynamic and static entries.

show running-config mac-list

To display a list of MAC addresses previously specified in a **mac-list** command with the indicated MAC list number, use the **show running-config mac-list** command in privileged EXEC mode.

show running-config mac-list *id*

Syntax Description

id	A hexadecimal MAC address list number.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was modified to conform to CLI guidelines.

Usage Guidelines

The **show running-config aaa** command displays the **mac-list** command statements as part of the AAA configuration.

Examples

The following example shows how to display a MAC address list with the *id* equal to adc:

```
hostname(config)# show running-config mac-list adc
mac-list adc permit 00a0.cp5d.0282 ffff.ffff.ffff
mac-list adc deny 00a1.cp5d.0282 ffff.ffff.ffff
mac-list ac permit 0050.54ff.0000 ffff.ffff.0000
mac-list ac deny 0061.54ff.b440 ffff.ffff.ffff
mac-list ac deny 0072.54ff.b440 ffff.ffff.ffff
```

Related Commands

Command	Description
mac-list	Add a list of MAC addresses using a first-match search.
clear configure mac-list	Remove the indicated **mac-list** command statements.
show running-config aaa	Display the running AAA configuration values.

show running-config management-access

To display the name of the internal interface configured for management access, use the **show running-config management-access** command in privileged EXEC mode.

show running-config management-access

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **management-access** command lets you define an internal management interface using the IP address of the firewall interface specified in *mgmt_if*. (The interface names are defined by the **nameif** command and displayed in quotes, " ", in the output of the **show interface** command.)

Examples

The following example shows how to configure a firewall interface named "inside" as the management access interface and display the result:

```
hostname# management-access inside
hostname# show running-config management-access
management-access inside
```

Related Commands

Command	Description
clear configure management-access	Removes the configuration of an internal interface for management access of the ASA.
management-access	Configures an internal interface for management access.

show running-config monitor-interface

To display all **monitor-interface** commands in the running configuration, use the **show running-config monitor-interface** command in privileged EXEC mode.

show running-config [all] monitor-interface

Syntax Description

all	(Optional) Shows all **monitor-interface** commands, including the commands you have not changed from the default.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **monitor-interface** command is enabled on all physical interfaces by default. You need to use the **all** keyword with this command to view this default configuration.

Examples

The following is sample output from the **show running-config monitor-interface** command. The first time the command is entered without the **all** keyword, so only the interface that has monitoring enabled appears in the output. The second time the command is entered with the **all** keyword, so the default **monitor-interface** configuration is also show.

```
hostname# show running-config monitor-interface
no monitor-interface outside
hostname#
hostname# show running-config all monitor-interface
monitor-interface inside
no monitor-interface outside
hostname#
```

Related Commands

Command	Description
monitor-interface	Enables health monitoring of a designated interface for failover purposes.
clear configure monitor-interface	Removes the **no monitor-interface** commands in the running configuration and restores the default interface health monitoring stance.

show running-config mroute

To display the static multicast route table in the configuration use the **show running-config mroute** command in privileged EXEC mode.

show running-config mroute [*dst* [*src*]]

Syntax Description

dst	The Class D address of the multicast group.
src	The IP address of the multicast source.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	Added keyword **running-config**.

Examples

The following is sample output from the **show running-config mroute** command:

```
hostname# show running-config mroute
```

Related Commands

Command	Description
mroute	Configures a static multicast route.

show running-config mtu

To display the current maximum transmission unit block size, use the **show running-config mtu** command in privileged EXEC mode.

show running-config mtu [*interface_name*]

Syntax Description

interface_name	(Optional) Internal or external network interface name.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	—	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show running-config mtu** command:

```
hostname# show running-config mtu
mtu outside 1500
mtu inside 1500
mtu dmz 1500
hostname# show running-config mtu outside
mtu outside 1500
```

Related Commands

Command	Description
clear configure mtu	Clears the configured maximum transmission unit values on all interfaces.
mtu	Specifies the maximum transmission unit for an interface.

show running-config multicast-routing

To display the **multicast-routing** command, if present, in the running configuration, use the **show running-config multicast-routing** command in privileged EXEC mode.

show running-config multicast-routing

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show running-config multicast-routing** command displays the **multicast-routing** command in the running configuration. Enter the **clear configure multicast-routing** command to remove the **multicast-routing** command from the running configuration.

Examples

The following is sample output from the **show running-config multicast-routing** command:

```
hostname# show running-config multicast-routing

multicast-routing
```

Related Commands

Command	Description
clear configure multicast-routing	Removes the **multicast-routing** command from the running configuration.
multicast-routing	Enables multicast routing on the ASA.

show running-config nac-policy

To show the configuration of each NAC policy on the ASA, use the **show running-config nac-policy** command in privileged EXEC mode.

show running-config [all] nac-policy [*nac-policy-name*]

Syntax Description

all	Displays the entire operating configuration of the NAC policy, including default settings.
nac-policy-name	Name of the NAC policy present in the configuration of the ASA.

Defaults

By default, the CLI displays the name and configuration of each NAC policy if you do not specify the *nac-policy-name.*

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	—	—	•

Command History

Release	Modification
8.0(2)	This command was introduced.

Examples

The following example shows the configuration of NAC policies named nacapp1 and nacapp2:

```
hostname# show running-config nac-policy
nac-policy framework nac-framework
 default-acl acl-1
 reval-period 36000
 sq-period 300
 exempt-list os "Windows XP" filter acl-2
nac-policy nacapp1 nacapp
 auth-vlan 1
 cas 209.165.202.129
 cam outside 209.165.201.22 community secretword
timeout 10
hostname#
```

The first line of each NAC policy indicates its name and type. The types are as follows:

- nacapp uses a Cisco NAC Appliance to provide a network access policy for remote hosts. Table 56-1 explains the nacapp attributes displayed in response to the **show running-config nac-policy** command.

- nac-framework uses a Cisco Access Control Server to provide a network access policy for remote hosts. Table 56-2 explains the nac-framework attributes displayed in response to the **show running-config nac-policy** command.

Table 56-1 show running-config nac-policy Command Fields for nacapp policies

Field	Description
auth-vlan	Authentication VLAN that provides the user with limited access while posture validation is in progress. Upon completion of the tunnel, the ASA copies the value of the auth-vlan to the vlan attribute assigned to the session. Following a successful posture validation, the ASA overwrites the value of the vlan attribute with the value of the access VLAN obtained from the NAC Appliance.
cam	This line shows the following values: • Interface on the ASA through which to communicate with the Clean Access Manager. • IP address or hostname of the CAM. • SNMP community string on the CAM.
cas	IP address or hostname of the Clean Access Server.
timeout	Maximum number of minutes a user session can be assigned to an authentication VLAN.

Table 56-2 show running-config nac-policy Command Fields for nac-framework policies

Field	Description
default-acl	NAC default ACL applied before posture validation. Following posture validation, the security appliance replaces the default ACL with the one obtained from the Access Control Server for the remote host. It retains the default ACL if posture validation fails.
reval-period	Number of seconds between each successful posture validation in a NAC Framework session.
sq-period	Number of seconds between each successful posture validation in a NAC Framework session and the next query for changes in the host posture
exempt-list	Operating system names that are exempt from posture validation. Also shows an optional ACL to filter the traffic if the remote computer's operating system matches the name.
authentication-server-group	name of the of authentication server group to be used for NAC posture validation.

Related Commands

nac-policy	Creates and accesses a Cisco NAC policy, and specifies its type.
clear configure nac-policy	Removes all NAC policies from the running configuration except for those that are assigned to group policies.
show nac-policy	Displays NAC policy usage statistics on the ASA.
show vpn-session_summary.db	Displays the number IPSec, Cisco AnyConnect, and NAC sessions, including VLAN mapping session data.
show vpn-session.db	Displays information about VPN sessions, including VLAN mapping and NAC results.

show running-config name

To display a list of names associated with IP addresses (configured with the **name** command), use the **show running-config name** command in privileged EXEC mode.

show running-config name

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

This example shows how to display a list of names associated with IP addresses:

```
hostname# show running-config name
name 192.168.42.3 sa_inside
name 209.165.201.3 sa_outside
```

Related Commands

Command	Description
clear configure name	Clears the list of names from the configuration.
name	Associates a name with an IP address.

show running-config nameif

To show the interface name configuration in the running configuration, use the s**how running-config nameif** command in privileged EXEC mode.

show running-config nameif [*physical_interface*[**.***subinterface*] | *mapped_name*]

Syntax Description

mapped_name	(Optional) In multiple context mode, identifies the mapped name if it was assigned using the **allocate-interface** command.
physical_interface	(Optional) Identifies the interface ID, such as **gigabitethernet0/1**. See the **interface** command for accepted values.
subinterface	(Optional) Identifies an integer between 1 and 4294967293 designating a logical subinterface.

Defaults

If you do not specify an interface, this command shows the interface name configuration for all interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from **show nameif**.

Usage Guidelines

In multiple context mode, if you mapped the interface ID in the **allocate-interface** command, you can only specify the mapped name in a context.

This display also shows the **security-level** command configuration.

Examples

The following is sample output from the **show running-config nameif** command:

```
hostname# show running-config nameif
!
interface GigabitEthernet0/0
 nameif inside
 security-level 100
!
interface GigabitEthernet0/1
 nameif test
 security-level 0
!
```

Related Commands

Command	Description
allocate-interface	Assigns interfaces and subinterfaces to a security context.
clear configure interface	Clears the interface configuration.
interface	Configures an interface and enters interface configuration mode.
nameif	Sets the interface name.
security-level	Sets the security level for the interface.

show running-config names

To display the IP address-to-name conversions, use the **show running-config names** command in privileged EXEC mode.

show running-config names

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use with the **names** command.

Examples

The following example shows how to display the IP address-to-name conversion:

```
hostname# show running-config names
name 192.168.42.3 sa_inside
name 209.165.201.3 sa_outside
```

Related Commands

Command	Description
clear configure name	Clears the list of names from the configuration.
name	Associates a name with an IP address.
names	Enables IP address-to-name conversions that you can configured with the **name** command.
show running-config name	Displays a list of names associated with IP addresses.

show running-config nat

To display the NAT configuration, use the **show running-config nat** command in privileged EXEC mode.

show running-config nat

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was changed to support the new NAT implementation.
7.0(1)	Added keyword **running-config**.

Usage Guidelines

Use this command to view the twice NAT and network object NAT configuration.

Note You cannot view the NAT configuration using the **show running-config object** command. You cannot reference objects or object groups that have not yet been created in **nat** commands. To avoid forward or circular references in **show** command output, the **show running-config** command shows the **object** command two times: first, where the IP address(es) are defined; and later, where the **nat** command is defined. This command output guarantees that objects are defined first, then object groups, and finally NAT.

Examples

The following example shows the twice NAT and network object NAT configuration:

```
hostname# show running-config nat

object network obj1
    range 192.168.49.1 192.150.49.100
object network obj2
    object 192.168.49.100
object network network-1
    subnet <network-1>
object network network-2
```

```
    subnet <network-2>
object-group network pool
    network-object object obj1
    network-object object obj2
!
object network network-1
    nat (inside,outside) dynamic pool
object network network-2
    nat (inside,outside) dynamic pool
```

Related Commands

Command	Description
clear configure nat	Removes the NAT configuration.
nat	Configures NAT.

show running-config ntp

To show the NTP configuration in the running configuration, use the **show running-config ntp** command in privileged EXEC mode.

show running-config ntp

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show running-config ntp** command:

```
hostname# show running-config ntp
ntp authentication-key 1 md5 test2
ntp authentication-key 2 md5 test
ntp trusted-key 1
ntp trusted-key 2
ntp server 10.1.1.1 key 1
ntp server 10.2.1.1 key 2 prefer
```

Related Commands

Command	Description
ntp authenticate	Enables NTP authentication.
ntp authentication-key	Sets an encrypted authentication key to synchronize with an NTP server.
ntp server	Identifies an NTP server.
ntp trusted-key	Provides a key ID for the ASA to use in packets for authentication with an NTP server.
show ntp status	Shows the status of the NTP association.

show running-config object

To display the current objects in the configuration, use the **show running-config object** command in privileged EXEC mode.

show running-config object

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

You cannot view the NAT configuration within an object using the **show running-config object** command; you must use the **show running-config nat** command. Also, you cannot reference objects or object groups that have not yet been created in **nat** commands. The reason is that **nat** commands can contain objects within them for mapped addresses, so you must define an object before you use it within a **nat** command. Without this separation, you could potentially have a configuration with a circular or forward reference problem. See the **nat** commands for more information.

Examples

The following is sample output from the **show running-config object** command:

```
hostname# show running-config object
object network obj1
    range 192.168.41.1 192.150.49.100
object network obj2
    object 192.168.49.100
object network network-1
    subnet <network-1>
object network network-2
    subnet <network-2>
object-group network pool
    network-object object obj1
    network-object object obj2
```

Related Commands

Command	Description
clear configure object	Removes all unused objects from the configuration.
group-object	Adds network object groups.
network-object	Adds a network object to a network object group.
object-group	Defines object groups to optimize your configuration.
port-object	Adds a port object to a service object group.
service-object	Adds a service object to a service object group.

show running-config object-group

To display the current object groups, use the **show running-config object-group** command in privileged EXEC mode.

show running-config [**all**] **object-group** [**protocol** | **service** | **network** | **icmp-type** | **security-group** | **id** *obj_grp_id*]

Syntax Description

icmp-type	(Optional) Displays ICMP type object groups.
id obj_grp_id	(Optional) Displays the specified object group.
network	(Optional) Displays network object groups.
protocol	(Optional) Displays protocol object groups.
security-group	(Optional) Displays security object groups.
service	(Optional) Displays service object groups.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show running-config object-group** command:

```
hostname# show running-config object-group
object-group protocol proto_grp_1
    protocol-object udp
    protocol-object tcp
object-group service eng_service tcp
    port-object eq smtp
    port-object eq telnet
object-group icmp-type icmp-allowed
    icmp-object echo
    icmp-object time-exceeded
```

Related Commands

Command	Description
clear configure object-group	Removes all the **object group** commands from the configuration.
group-object	Adds network object groups.
network-object	Adds a network object to a network object group.
object-group	Defines object groups to optimize your configuration.
port-object	Adds a port object to a service object group.

show running config object-group-search

To display the object-group-search configuration, use the **show running-config object-group-search** command in privileged EXEC mode.

show running-config object-group-search [all]

Syntax Description

all	(Optional) Shows all commands, including the commands you have not changed from the default.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Examples

The following is sample output from the **show running-config object-group-search** command:

```
hostname# show running-config object-group-search
```

Related Commands

Command	Description
clear config object-group-search	Clears the object-group-search configuration.
show running-config object-group	Displays the current object groups.
show running-config object-group-search	Shows the object-group-search configuration in the running configuration.

show running-config pager

To show the number of lines on a page set to displayin a Telnet session before the "---More---" prompt appears in the running configuration, use the **show running-config pager** command in privileged EXEC mode.

show running-config pager

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show running-config pager** commandshows the number of lines on a page set to displayin a Telnet session before the "---More---" prompt appears in the running configuration in global configuration mode.

Examples

The following is sample output from the **show running-config pager** command:

```
hostname# show running-config pager

pager lines 24
```

Related Commands

Command	Description
clear configure pager	Removes the number of lines set to display in a Telnet session before the "---More---" prompt appears from the running configuration.

Command	Description
show pager	Displays the default number of lines set to display in a Telnet session before the "---More---" prompt appears.
terminal pager	Sets the number of lines to display in a Telnet session before the "---More---" prompt appears. This command is not saved to the running configuration.

show running-config passwd

To show the encrypted login passwords, use the **show running-config passwd** command in privileged EXEC mode.

show running-config {**passwd** | **password**}

Syntax Description

passwd | **password**	You can enter either command; they are aliased to each other.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was changed from the **show passwd** command.

Usage Guidelines

The password is saved to the configuration in encrypted form, so you cannot view the original password after you enter it. The password displays with the **encrypted** keyword to indicate that the password is encrypted.

Examples

The following is sample output from the **show running-config passwd** command:

```
hostname# show running-config passwd
passwd 2AfK9Kjr3BE2/J2r encrypted
```

Related Commands

Command	Description
clear configure passwd	Clears the login password.
enable	Enters privileged EXEC mode.
enable password	Sets the enable password.
passwd	Sets the login password.
show curpriv	Shows the currently logged in username and the user privilege level.

show running-config password-policy

To show the password policy for the current context, use the **show running-config password-policy** command in privileged EXEC mode.

show running-config [**all**] **password-policy**

Syntax Description

all	Displays all policy attributes; otherwise, only attributes with non-default values appear.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
9.1(2)	This command was introduced.

Usage Guidelines

This command shows only the password policy from the current context unless you use the **all** keyword.

Examples

The following is sample output from the **show running-config password-policy** command:

```
hostname# show running-config password-policy
password-policy minimum-length 10
password-policy minimum-changes 3
password-policy minimum-lowercase 2
password-policy minimum-uppercase 1
password-policy minimum-numeric 0
password-policy minimum-special 1
password-policy lifetime 1000
password-policy authenticate-enable
```

Related Commands

Command	Description
clear configure password-policy	Clears the password policy for the current context to the default value.
change-password	Allows users to change their own account password.

show running-config phone-proxy

To show Phone Proxy specific information, use the **show running-config phone-proxy** command in privileged EXEC mode.

show running-config [**all**] **phone-proxy** [*phone_proxy_name*]

Syntax Description

phone_proxy_name	(Optional) Specifies the name of the Phone Proxy instance.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Examples

The following example shows the use of the **show running-config phone-proxy** command to show Phone Proxy specific information:

```
hostname# show running-config all phone proxy asa_phone_proxy
```

Related Commands

Command	Description
phone-proxy	Configures the Phone Proxy instance.

show running-config pim

To display the PIM commands in the running configuration, use the **show running-config pim** command in privileged EXEC mode.

show running-config pim

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show running-config pim** command displays the **pim** commands entered in global configuration mode. It does not show the **pim** commands entered in interface configuration mode. To see the **pim** commands entered in interface configuration mode, enter the **show running-config interface** command.

Examples

The following is sample output from the **show running-config pim** command:

```
hostname# show running-config pim

pim old-register-checksum
pim spt-threshold infinity
```

Related Commands

Command	Description
clear configure pim	Removes the **pim** commands from the running configuration.
show running-config interface	Displays interface configuration commands entered in interface configuration mode.

show running-config policy-map

To display all the policy-map configurations or the default policy-map configuration, use the **show running-config policy-map** command in privileged EXEC mode.

show running-config [all] policy-map [*policy_map_name* | **type inspect** [*protocol*]]

Syntax Description

all	(Optional) Shows all commands, including the commands you have not changed from the default.
policy_map_name	(Optional) Shows the running configuration for a policy map name.
protocol	(Optional) Specifies the type of inspection policy map you want to show. Available types include: • **dcerpc** • **dns** • **esmtp** • **ftp** • **gtp** • **h323** • **http** • **im** • **mgcp** • **netbios** • **p2p** • **radius-accounting** • **sip** • **skinny** • **snmp**
type inspect	(Optional) Shows inspection policy maps.

Defaults

Omitting the **all** keyword displays only the explicitly configured policy-map configuration.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Specifying the **all** keyword displays the default policy-map configuration as well as the explicitly configured policy-map configuration.

Examples

The following is sample output from the **show running-config policy-map** command:

```
hostname# show running-config policy-map
!
policy-map localmap1
    description this is a test.
    class firstclass
    priority
    ids promiscuous fail0close
    set connection random-seq# enable
    class class-default
!
```

Related Commands

Command	Description
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
clear configure policy-map	Removes the entire policy configuration.

show running-config pop3s

To display the running configuration for POP3S, use the s**how running-config pop3s** command in privileged EXEC mode. To have the display include the default configuration, use the **all** keyword.

show running-config [all] pop3s

Syntax Description

all	Displays the running configuration including default values.

Defaults

No default behavior or values.

Command History

Release	Modification
7.0(1)	This command was introduced.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—
Global configuration	•	—	•	—	—
Webvpn	•	—	•	—	—

Examples

The following is sample output from the **show running-config pop3s** command:

```
hostname# show running-config pop3s

pop3s
 server 10.160.102.188
 authentication-server-group KerbSvr
 authentication aaa

hostname# show running-config all pop3s

pop3s
 port 995
 server 10.160.102.188
 outstanding 20
 name-separator :
 server-separator @
 authentication-server-group KerbSvr
 no authorization-server-group
 no accounting-server-group
 no default-group-policy
 authentication aaa
```

Related Commands

Command	Description
clear configure pop3s	Removes the POP3S configuration.
pop3s	Creates or edits a POP3S e-mail proxy configuration.

show running-config prefix-list

To display the **prefix-list** command in the running configuration, use the **show running-config prefix-list** command in privileged EXEC mode.

show running-config prefix-list

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from the **show prefix-list** command to the **show running-config prefix-list** command.
9.0(1)	Multiple context modde is supported.

Usage Guidelines

The **prefix-list description** commands always appear before their associated **prefix-list** commands in the running configuration. It does not matter what order you entered them.

Examples

The following is sample output from the **show running-config prefix-list** command:

```
hostname# show running-config prefix-list

!
prefix-list abc description A sample prefix list
prefix-list abc seq 5 permit 192.168.0.0/8 le 24
prefix-list abc seq 10 deny 10.0.0.0/8 le 32
!
```

Related Commands

Command	Description
clear configure prefix-list	Clears the **prefix-list** commands from the running configuration.

show running-config priority-queue

To display the priority queue configuration details for an interface, use the **show running-config priority-queue** command in privileged EXEC mode.

show running-config priority-queue *interface-name*

Syntax Description

interface-name	Specifies the name of the interface for which you want to show the priority queue details

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

This example shows the use of the show running-config priority-queue command for the interface named test, and the command output:

```
hostname# show running-config priority-queue test
priority-queue test
  queue-limit   50
  tx-ring-limit 10
hostname#
```

Related Commands

Command	Description
clear configure priority-queue	Removes the priority-queue configuration from the named interface.
priority-queue	Configures priority queueing on an interface.
show priority-queue statistics	Shows the statistics for the priority queue configured on the named interface.

show running-config privilege

To display the privileges for a command or a set of commands, use the **show running-config privilege** command in privileged EXEC mode.

show running-config [all] privilege [**all | command** *command* **| level** *level*]

Syntax Description

all	(Optional) First occurrence -- Displays the default privilege level.
all	(Optional) Second occurrence -- Displays the privilege level for all commands.
command *command*	(Optional) Displays the privilege level for a specific command.
level *level*	(Optional) Displays the commands that are configured with the specified level; valid values are from 0 to 15.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was modified for this release to conform to CLI guidelines.

Usage Guidelines

Use the **show running-config privilege** command to view the current privilege level.

Examples

```
hostname(config)# show running-config privilege level 0
privilege show level 0 command checksum
privilege show level 0 command curpriv
privilege configure level 0 mode enable command enable
privilege show level 0 command history
privilege configure level 0 command login
privilege configure level 0 command logout
privilege show level 0 command pager
privilege clear level 0 command pager
privilege configure level 0 command pager
privilege configure level 0 command quit
privilege show level 0 command version
```

Related Commands

Command	Description
clear configure privilege	Remove privilege command statements from the configuration.
privilege	Configure the command privilege levels.
show curpriv	Display current privilege level.
show running-config privilege	Display privilege levels for commands.

show running-config quota management-session

To show the current value of the management session quota, use the **show running-config quota management-session** command in privileged EXEC mode.

show running-config [**all**] **quota management-session**

Syntax Description

all	Displays the current value of the management session quota.

Defaults

The default is 0.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
8.4(4.1)	This command was introduced.

Usage Guidelines

The current value of the quota management session does not appear if it is set to the default value of 0.

Examples

The following is sample output from the **show running-config quota management-session** command:

```
hostname# show running-config quota management-session
quota management-session 250
```

Related Commands

Command	Description
show quota management-session	Shows statistics for the management session.
quota management-session	Sets the number of simultaneous ASDM, SSH, and Telnet sessions allowed on the device.

show running-config regex

To display all regular expressions configured with the **regex** command, use the **show running-config regex** command in privileged EXEC mode.

show running-config regex

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output of the **show running-config regex** command, which shows all regular expressions:

```
hostname# show running-config regex
regex test "string"
```

Related Commands

Command	Description
class-map type regex	Creates a regular expression class map.
clear configure regex	Clears all regular expressions.
regex	Creates a regular expression.
test regex	Tests a regular expression.

show running-config route

To display the route configuration that is running on the ASA, use the **show running-config route** command in privileged EXEC mode.

show running-config [**all**] **route**

Syntax Description

No default behavior or values.

Defaults

This command has no arguments or keywords.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	Added keyword **running-config**.

Examples

The following is sample output from the **show running-config route** command:

```
hostname# show running-config route
route outside 10.30.10.0 255.255.255.0 1
```

Related Commands

Command	Description
clear configure route	Removes the **route** commands from the configuration that do not contain the **connect** keyword.
route	Specifies a static or default route for the an interface.
show route	Displays route information.

show running-config route-map

To display the information about the route map configuration, use the **show running-config route-map** command in privileged EXEC mode.

show running-config route-map [*map_tag*]

Syntax Description

map_tag	(Optional) Text for the route-map tag.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(1)	Added keyword **running-config**.

Usage Guidelines

To show all route-maps defined in the configuration, use the **show running-config route-map** command. To show individual route-maps by name, use the **show running-config route-map** *map_tag* command, where *map_tag* is the name of the route-map. Multiple route maps may share the same map tag name.

Examples

The following is sample output from the **show running-config route-map** command:

```
hostname# show running-config route-map
route-map maptag1 permit sequence 10
    set metric 5
    match metric 3
route-map maptag1 permit sequence 12
    set metric 5
    match interface backup
    match metric 3
route-map maptag2 deny sequence 10
    match interface dmz
```

Related Commands

Command	Description
clear configure route-map	Removes the conditions for redistributing the routes from one routing protocol into another routing protocol.
route-map	Defines the conditions for redistributing routes from one routing protocol into another.

show running-config router

To display the global configuration commands for the specified routing protocol, use the **show running-config router** command in privileged EXEC mode.

show running-config [all] **router** [**ospf** [*process_id*] | **rip** | **eigrp** [*as-number*]]

Syntax Description

all	Shows all router commands, including the commands you have not changed from the default.
as-number	(Optional) Displays the router configuration commands for the specified EIGRP autonomous system number. If not specified, the router configuration commands for all EIGRP routing processes are displayed. Because only one EIGRP routing process is supported on the ASA, including the optional *as-number* argument has the same effect as omitting it.
eigrp	(Optional) Displays the EIGRP router configuration commands.
ospf	(Optional) Displays the OSPF router configuration commands.
process_id	(Optional) Displays the commands for the selected OSPF process.
rip	(Optional) Displays the RIP router configuration commands.

Defaults

If a routing protocol is not specified, the router configuration commands for all configured routing protocols are displayed.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was changed from the **show router** command to the **show running-config router** command.
8.0(2)	This command was modified to include the **eigrp** keyword.

Examples

The following is sample output from the **show running-config router ospf** command:

```
hostname# show running-config router ospf 1

router ospf 1
  log-adj-changes detail
  ignore lsa mospf
  no compatible rfc1583
```

```
  distance ospf external 200
  timers spf 10 20
  timers lsa-group-pacing 60
```

The following is sample output from the **show running-config router rip** command:

```
hostname# show running-config router rip

router rip
    network 10.0.0.0
    version 2
    no auto-summary
```

Related Commands

Command	Description
clear configure router	Clears all router commands from the running configuration.
router eigrp	Enables an EIGRP routing process and enters router configuration mode for that process.
router ospf	Enables an OSPF routing process and enters router configuration mode for that process.
router rip	Enables a RIP routing process and enters router configuration mode for that process.

CHAPTER 57

show running-config same-security-traffic through show running-config xlate Commands

show running-config same-security-traffic

To display the same-security interface communication, use the **show running-config same-security-traffic** command in privileged EXEC mode.

show running-config same-security-traffic

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show running-config same-security-traffic** command:

```
hostname# show running-config same-security-traffic
```

Related Commands

Command	Description
same-security-traffic	Permits communication between interfaces with equal security levels.

show running-config service

To display the system services, use the **show running-config service** command in privileged EXEC mode.

show running-config service

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	The keyword **running-config** was added.

Examples

This command shows how to display the system services:

```
hostname# show running-config service
service resetoutside
```

Related Commands

Command	Description
service	Enables system services.

show running-config service-policy

To display all currently running service policy configurations, use the **show runnig-config service-policy** command in privileged EXEC mode.

show running-config [all] service-policy

Syntax Description

all	(Optional) Shows all service policy commands, including the commands you have not changed from the default.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output of the **show running-config service-policy** command:

```
hostname# show running-config service-policy
```

Related Commands

Command	Description
show service-policy	Displays the service policy.
service-policy	Configures service policies.
clear service-policy	Clears service policy configurations.
clear configure service-policy	Clears service policy configurations.

show running-config sla monitor

To display the SLA operation commands in the running configuration, use the **show running-config sla monitor** command in privileged EXEC mode.

show running-config sla monitor [*sla-id*]

Syntax Description

sla_id	Specifies the SLA ID for the **sla monitor** commands being displayed. Valid values are from 1 to 2147483647.

Defaults

If the *sla-id* is not specified, the **sla monitor** commands for all SLA operations are displayed.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command displays the **sla monitor** commands, associated SLA monitor configuration mode commands, and the associated **sla monitor** schedule command, if present. It does not display the **track rtr** commands in the configuration.

Examples

The following is sample output from the **show running-config sla monitor 5** command. It displays the SLA monitor configuration for the SLA operation with the SLA ID of 5:

```
hostname# show running-config sla monitor 5

sla monitor 124
 type echo protocol ipIcmpEcho 10.1.1.1 interface outside
 timeout 1000
 frequency 3
sla monitor schedule 124 life forever start-time now
```

Related Commands

Command	Description
clear configure sla monitor	Removes the **sla monitor**, and associated commands, from the running configuration.
show sla monitor configuration	Displays configuration values for the specified SLA operation.

show running-config smtps

To display the running configuration for SMPTS, use the s**how running-config smtps** command in privileged EXEC mode. To have the display include the default configuration, use the **all** keyword.

show running-config [all] smtps

Syntax Description

all	Displays the running configuration including default values.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show running-config smtps** command:

```
hostname# show running-config smtps

smtps
server 10.1.1.21
 authentication-server-group KerbSvr
 authentication aaa

hostname# show running-config all smtps

smtps
 port 995
 server 10.1.1.21
 outstanding 20
 name-separator :
 server-separator @
 authentication-server-group KerbSvr
 no authorization-server-group
 no accounting-server-group
 no default-group-policy
 authentication aaa
hostname#
```

show running-config snmp-map

To show the SNMP maps that have been configured, use the **show running-config snmp-map** command in privileged EXEC mode.

show running-config snmp-map *map_name*

Syntax Description.

map_name	Displays the configuration for the specified SNMP map.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show running-config snmp-map** command displays the SNMP maps that have been configured.

Examples

The following is sample output from the **show running-config snmp-map** command:

```
hostname# show running-config snmp-map snmp-policy
!
snmp-map snmp-policy
deny version 1
!
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
deny version	Disallows traffic using a specific version of SNMP.
inspect snmp	Enables SNMP application inspection.
snmp-map	Defines an SNMP map and enables SNMP map configuration mode.

show running-config snmp-server

To display all currently running SNMP server configurations, use the **show runnig-config snmp-server** command in global configuration mode.

show running-config snmp-server [**default**] [**group** | **host** | **user**]

Syntax Description

default	Displays the default SNMP server configuration.
group	Displays the SNMP group configurations.
host	Displays the SNMP host configurations.
user	Displays the SNMP user configurations.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command does not display output for the **snmp-server trap** commands for the default traps; output is displayed only for the enabled, non-default traps. The **no snmp-server trap** command is also displayed for the disabled default traps.

The following is sample output from the **show running-config snmp-server** command:

```
hostname# show running-config snmp-server
snmp-server host inside 10.21.104.209 community asa1
no snmp-server location
no snmp-server contact
snmp-server enable traps snmp authentication linkup linkdown coldstart
```

Related Commands

Command	Description
snmp-server	Configures the SNMP server.
clear configure snmp-server	Clears the SNMP server configuration.
show snmp-server statistics	Displays the SNMP server configuration.

show running-config ssh

To show the SSH commands in the current configuration, use the **show running-config ssh** command in privileged EXEC mode.

show running-config [**default**] **ssh** [**timeout** | **version**]

show run [**default**] **ssh** [**timeout**]

Syntax Description

default	(Optional) Displays the default SSH configuration values along with the configured values.
timeout	(Optional) Displays the current SSH session timeout value.
version	(Optional) Displays the version of SSH currently being supported.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	The command was changed from the **show ssh** command to the **show running-config ssh** command.

Usage Guidelines

This command shows the current ssh configuration. To display only the SSH session timeout value, use the **timeout** option. To see a list of active SSH sessions, use the **show ssh sessions** command.

Examples

The following example displays the SSH session timeout:

```
hostname# show running-config timeout
ssh timeout 5 minutes
hostname#
```

Related Commands

Command	Description
clear configure ssh	Clears all SSH commands from the running configuration.
ssh	Allows SSH connectivity to the ASA from the specified client or network.

Command	Description
ssh scopy enable	Enables a secure copy server on the ASA.
ssh timeout	Sets the timeout value for idle SSH sessions.
ssh version	Restricts the ASA to using either SSH Version 1 or SSH Version 2.

show running-config ssh key-exchange

To show which (Diffie-Hellman) key-exchange method can be used for SSH sessions, use the **show running-config ssh key-exchange** command in privileged EXEC mode.

show running-config ssh key-exchange

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(5)	This command was introduced.

Usage Guidelines

This command shows the current SSH key exchange configuration.

Examples

The following example displays the SSH key exchange configuration:

```
hostname# show running-config ssh key-exchange
ssh key-exchange group dh-group14-sha1
hostname#
```

Related Commands

Command	Description
clear configure ssh	Clears all SSH commands from the running configuration.
ssh	Allows SSH connectivity to the ASA from the specified client or network.
ssh scopy enable	Enables a secure copy server on the ASA.
ssh timeout	Sets the timeout value for idle SSH sessions.
ssh version	Restricts the ASA to using either SSH Version 1 or SSH Version 2.

show running-config ssl

To display the current set of configured ssl commands, use the **show running-config ssl** command in privileged EXEC mode.

show running-config ssl

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show running-config ssl** command:

```
hostname# show running-config ssl
ssl server-version  tlsv1
ssl client-version tlsv1-only
ssl encryption 3des-sha1
ssl trust-point Firstcert
```

Related Commands

Command	Description
clear config ssl	Removes all ssl commands from the configuration, reverting to the default values.
ssl client-version	Specifies the SSL/TLS protocol version the ASA uses when acting as a client.
ssl server-version	Specifies the SSL/TLS protocol version the ASA uses when acting as a server
ssl trust-point	Specifies the certificate trust point that represents the SSL certificate for an interface.

show running-config static

To display all **static** commands in the configuration, use the **show running-config static** command in privileged EXEC mode.

show running-config static

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	The keyword **running-config** was added.

Usage Guidelines

This command displays the maximum connections value for the UDP protocol. If the UDP maximum connections value is “0” or not set, the limit enforcement is disabled.

Examples

This example shows how to display all static commands in the configuration:

```
hostname# show running-config static
static (inside,outside) 192.150.49.91 10.1.1.91 netmask 255.255.255.255
static (inside,outside) 192.150.49.200 10.1.1.200 netmask 255.255.255.255 tcp 255 0
```

Note No UDP value connection limit is shown.

Related Commands

Command	Description
clear configure static	Removes all the **static** commands from the configuration.
static	Configures a persistent one-to-one address translation rule by mapping a local IP address to a global IP address.

show running-config sunrpc-server

To display the information about the SunRPC configuration, use the **show running-config sunrpc-server** command in privileged EXEC mode.

show running-config sunrpc-server *interface_name ip_addr mask* **service** *service_type* **protocol** [**TCP** | **UDP**] **port** *port* [**-** *port*] **timeout** *hh:mm:ss*

Syntax Description

interface_name	Server interface.
ip_addr	Server IP address.
mask	Network mask.
port *port* **-** *port*	SunRPC protocol port range and optionally, a second port.
protocol	SunRPC transport protocol.
service	Specifies a service.
service_type	Sets the SunRPC service program type.
timeout *hh:mm:ss*	Specifies the timeout idle time after which the access for the SunRPC service traffic is closed.
TCP	(Optional) Specifies TCP.
UDP	(Optional) Specifies UDP.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The *service_type* is specified in the **sunrpcinfo** command.

Examples

The following is sample output from the **show running-config sunrpc-server** command:

```
hostname# show running-config sunrpc-server
inside 30.26.0.23 255.255.0.0 service 2147483647 protocol TCP port 2222 timeout 0:03:00
```

Related Commands

Command	Description
clear configure sunrpc-server	Clears the SunRPC services from the ASA.
debug sunrpc	Enables debug information for SunRPC.
show conn	Displays the connection state for different connection types, including SunRPC.
sunrpc-server	Creates the SunRPC services table.
timeout	Sets the maximum idle time duration for different protocols and session types, including SunRPC.

show running-config sysopt

To show the **sysopt** command configuration in the running configuration, use the **show running-config sysopt** command in privileged EXEC mode.

show running-config sysopt

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from the **show sysopt** command.

Examples

The following is sample output from the **show running-config sysopt** command:

```
hostname# show running-config sysopt
no sysopt connection timewait
sysopt connection tcpmss 1200
sysopt connection tcpmss minimum 400
no sysopt nodnsalias inbound
no sysopt nodnsalias outbound
no sysopt radius ignore-secret
sysopt connection permit-ipsec
```

Related Commands

Command	Description
clear configure sysopt	Clears the **sysopt** command configuration.
sysopt connection permit-ipsec	Permits any packets that come from an IPSec tunnel without checking any ACLs for interfaces.
sysopt connection tcpmss	Overrides the maximum TCP segment size or ensures that the maximum is not less than a specified size.
sysopt connection timewait	Forces each TCP connection to linger in a shortened TIME_WAIT state after the final normal TCP close-down sequence.
sysopt nodnsalias	Disables alteration of the DNS A record address when you use the **alias** command.

show running-config tcp-map

To display the information about the TCP map configuration, use the **show running-config tcp-map** command in privileged EXEC mode.

show running-config tcp-map [*tcp_map_name*]

Syntax Description

tcp_map_name	(Optional) Text for the TCP map name; the text can be up to 58 characters in length.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show running-config tcp-map** command:

```
hostname# show running-config tcp-map
tcp-map localmap
```

Related Commands

Command	Description
tcp-map	Creates a TCP map and allows access to tcp-map configuration mode.
clear configure tcp-map	Clears the TCP map configuration.

show running-config telnet

To display the current list of IP addresses that are authorized to use Telnet connections to the ASA, use the **show running-config telnet** command in privileged EXEC mode. You can also use this command to display the number of minutes that a Telnet session can remain idle before being closed by the ASA.

show running-config telnet [**timeout**]

Syntax Description

timeout	(Optional) Displays the number of minutes that a Telnet session can be idle before being closed by the ASA.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	The keyword **running-config** was added.

Examples

This example shows how to display the current list of IP addresses that are authorized for use by Telnet connections to the ASA:

```
hostname# show running-config telnet
2003 Jul 15 14:49:36 %MGMT-5-LOGIN_FAIL:User  failed to
log in from 128.107.183.22 through Telnet
2003 Jul 15 14:50:27 %MGMT-5-LOGIN_FAIL:User  failed to log in from 128.107.183.
22 through Telnet
```

Related Commands

Command	Description
clear configure telnet	Removes the Telnet connection from the configuration.
telnet	Adds Telnet access to the console and sets the idle timeout.

show running-config terminal

To display the current terminal settings, use the **show running-config terminal** command in privileged EXEC mode.

show running-config terminal

Syntax Description

This command has no arguments or keywords.

Defaults

The default display width is 80 columns.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example clears the page length setting:

```
hostname# show running-config terminal

Width = 80, no monitor
```

Related Commands

Command	Description
clear configure terminal	Clears the terminal display width setting.
terminal	Sets the terminal line parameters.
terminal width	Sets the terminal display width.

show running-config tftp-server

To display the default TFTP server address and directory, use the **show running-config tftp-server** command in global configuration mode.

show running-config tftp-server

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	The **running-config** keyword was added.

Examples

This example shows how to display the IP/IPv6 address of the default TFTP server and the directory of the configuration file:

```
hostname(config)# show running-config tftp-server
tftp-server inside 10.1.1.42 /temp/config/test_config
```

Related Commands

Command	Description
configure net	Loads the configuration from the TFTP server and path you specify.
tftp-server	Configures the default TFTP server address and the directory of the configuration file.

show running-config threat-detection

To view the threat detection configuration, use the **show running-config threat-detection** command in privileged EXEC mode.

show running-config [**all**] **threat-detection** [**basic-threat** | **rate** | **scanning-threat** | **statistics** [**tcp-intercept**]]

Syntax Description

all	(Optional) Shows all threat detection commands, including the commands you have not changed from the default. For example, you can view the default rate limits for the **threat-detection basic-threat** command.
basic-threat	(Optional) Shows the basic threat configuration.
rate	(Optional) Shows the rate configuration.
scanning-threat	(Optional) Shows the scanning threat configuration.
statistics	(Optional) Shows the statistics configuration.
tcp-intercept	(Optional) Shows the statistics configuration for TCP Intercept.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.
8.0(4)	The **tcp-intercept** keyword was added.

Examples

The following is sample output from the **show running-config all threat-detection** command, which shows the default rate limits for the **threat-detection basic-threat** command:

```
hostname# show running-config all threat-detection
threat-detection basic-threat
threat-detection rate dos-drop rate-interval 600 average-rate 100 burst-rate 400
threat-detection rate dos-drop rate-interval 3600 average-rate 100 burst-rate 400
threat-detection rate bad-packet-drop rate-interval 600 average-rate 100 burst-rate 400
threat-detection rate bad-packet-drop rate-interval 3600 average-rate 100 burst-rate 400
threat-detection rate acl-drop rate-interval 600 average-rate 400 burst-rate 800
threat-detection rate acl-drop rate-interval 3600 average-rate 400 burst-rate 800
threat-detection rate conn-limit-drop rate-interval 600 average-rate 100 burst-rate 400
threat-detection rate conn-limit-drop rate-interval 3600 average-rate 100 burst-rate 400
threat-detection rate icmp-drop rate-interval 600 average-rate 100 burst-rate 400
```

```
threat-detection rate icmp-drop rate-interval 3600 average-rate 100 burst-rate 400
threat-detection rate scanning-drop rate-interval 600 average-rate 5 burst-rate 10
threat-detection rate scanning-drop rate-interval 3600 average-rate 5 burst-rate 10
threat-detection rate syn-attack rate-interval 600 average-rate 100 burst-rate 200
threat-detection rate syn-attack rate-interval 3600 average-rate 100 burst-rate 200
threat-detection rate fw-drop rate-interval 600 average-rate 400 burst-rate 1600
threat-detection rate fw-drop rate-interval 3600 average-rate 400 burst-rate 1600
threat-detection rate inspect-drop rate-interval 600 average-rate 400 burst-rate 1600
threat-detection rate inspect-drop rate-interval 3600 average-rate 400 burst-rate 1600
threat-detection rate interface-drop rate-interval 600 average-rate 2000 burst-rate 8000
threat-detection rate interface-drop rate-interval 3600 average-rate 2000 burst-rate 8000
threat-detection scanning-threat shun duration 3600
threat-detection statistics
threat-detection statistics tcp-intercept rate-interval 30 burst-rate 400 average-rate 200
```

Related Commands

Command	Description
clear threat-detection rate	Clears basic threat detection statistics.
show threat-detection rate	Shows basic threat detection statistics.
threat-detection basic-threat	Enables basic threat detection.
threat-detection rate	Sets the threat detection rate limits per event type.
threat-detection scanning-threat	Enables scanning threat detection.

show running-config timeout

To display the timeout value of all protocols, or just a specific one, use the **show running-config timeout** command in privileged EXEC mode.

show running-config timeout *protocol*

Syntax Description

protocol	(Optional) Displays the timeout value of the specified protocol. Supported protocols are: **xlate**, **conn, udp**, **icmp**, **rpc**, **h323**, **h225**, **mgcp**, **mgcp-pat**, **sip**, **sip_media**, and **uauth**.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	The **running-config** and **mgcp-pat** keywords were added.

Examples

This example shows how to display the timeout values for the system:

```
hostname(config)# show timeout
timeout xlate 3:00:00
timeout conn 1:00:00 half-closed 0:10:00 udp 0:02:00 icmp 0:00:02 rpc 0:10:00 h3
23 0:05:00 h225 1:00:00 mgcp 0:05:00 mgcp-pat 0:05:00 sip 0:30:00 sip_media 0:02
:00
timeout uauth 0:00:00 absolute
```

Related Commands

Command	Description
clear configure timeout	Restores the default idle time durations.
timeout	Sets the maximum idle time duration.

show running-config tls-proxy

To display all currently running TLS proxy configurations, use the **show running-config tls-proxy** command in privileged EXEC mode.

show running-config [**all**] **tls-proxy** [*proxy_name*]

Syntax Description

all	Shows all TLS proxy commands, including the commands you have not changed from the default.
proxy_name	Specifies the name of the TLS proxy to show.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Examples

The following is sample output of the **show running-config all tls-proxy** command:

```
hostname# show running-config tls-proxy
tls-proxy proxy
    server trust-point local_ccm
    client ldc issuer ldc_signer
    client ldc key-pair phone_common
    no client cipher-suite
```

Related Commands

Command	Description
client	Defines a cipher suite and sets the local dynamic certificate issuer or keypair.
ctl-provider	Defines a CTL provider instance and enters provider configuration mode.
show tls-proxy	Shows all TLS proxies.
tls-proxy	Defines a TLS proxy instance and sets the maximum sessions.

show running-config track

To display **track rtr** commands in the running configuration, use the **show running-config track** command in privileged EXEC mode.

show running-config track [*track-id*]

Syntax Description

track-id	(Optional) Limits the display to the **track rtr** command with the specified tracking object ID.

Defaults

If the *track-id* is not specified, all **track rtr** commands in the running configuration are shown.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following is sample output from the **show running-config track** command:

```
hostname# show running-config track 5

track 5 rtr 124 reachability
```

Related Commands

Command	Description
clear configure track	Removes the **track rtr** commands from the running configuration.
show track	Displays information about the objects being tracked.
track rtr	Creates a tracking entry to poll the SLA.

show running-config tunnel-group

To display tunnel group information about all or a specified tunnel group and tunnel-group attributes, use the **show running-config tunnel-group** command in global configuration or privileged EXEC mode.

show running-config [**all**] **tunnel-group** [*name* [**general-attributes | ipsec-attributes | ppp-attributes**]]

Syntax Description

all	[Optional] Displays all tunnel-group commands, including the commands you have not changed from the default.
general-attributes	Displays configuration information for general attributes.
ipsec-attributes	Displays configuration information for IPSec attributes.
name	Specifies the name of the tunnel group.
ppp-attributes	Displays configuration information for PPP attributes.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•		•		
Privileged EXEC	•		•		

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example entered in global configuration mode, displays the current configuration for all tunnel groups:

```
hostname(config)# show running-config tunnel-group
tunnel-group 209.165.200.225 type IPSec_L2L
tunnel-group 209.165.200.225 ipsec-attributes
    pre-shared-key xyzx
hostname(config)#
```

Related Commands

Command	Description
clear configure tunnel-group	Removes tunnel-group configuration
tunnel-group general-attributes	Enters subconfiguration mode for specifying general attributes for specified tunnel group.
tunnel-group ipsec-attributes	Enters subconfiguration mode for specifying IPSec attributes for specified tunnel group.
tunnel-group	Enters tunnel-group subconfiguration mode for the specified type.

show running-config url-block

To show the configuration for buffers and memory allocation used by URL filtering, use the **show running-config url-block** command in privileged EXEC mode.

show running-config url-block [**block** | **url-mempool** | **url-size**]

Syntax Description

block	Displays the configuration for the maximum number of blocks that will be buffered.
url-mempool	Displays the configuration for the maximum allow URL size (in KB).
url-size	Displays the configuration for the memory resource (in KB) allocated for the long URL buffer.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show running-config url-block** command displays the configuration for buffers and memory allocation used by URL filtering.

Examples

The following is sample output from the **show running-config url-block** command:

```
hostname# show running-config url-block
!
url-block block 56
!
```

Related Commands

Commands	Description
clear url-block block statistics	Clears the block buffer usage counters.
show url-block	Displays information about the URL cache, which is used for buffering URLs while waiting for responses from an N2H2 or Websense filtering server.
url-block	Manage the URL buffers used for web server responses.
url-cache	Enables URL caching while pending responses from an N2H2 or Websense server and sets the size of the cache.
url-server	Identifies an N2H2 or Websense server for use with the **filter** command.

show running-config url-cache

To show the cache configuration used by URL filtering, use the **show running-config url-cache** command in privileged EXEC mode.

show running-config url-cache

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show running-config url-cache** command displays the cache configuration used by URL filtering.

Examples

The following is sample output from the **show running-config url-cache** command:

```
hostname# show running-config url-cache
!
url-cache src_dst 128
!
```

Related Commands

Commands	Description
clear url-cache statistics	Removes **url-cache** command statements from the configuration.
filter url	Directs traffic to a URL filtering server.
show url-cache statistics	Displays information about the URL cache, which is used for buffering URLs while waiting for responses from an N2H2 or Websense filtering server.
url-cache	Enables URL caching while pending responses from an N2H2 or Websense server and sets the size of the cache.
url-server	Identifies an N2H2 or Websense server for use with the **filter** command.

show running-config url-server

To show the URL filtering server configuration, use the **show running-config url-server** command in privileged EXEC mode.

show running-config url-server

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show running-config url-server** command displays the URL filtering server configuration.

Examples

The following is sample output from the **show running-config url-server** command:

```
hostname# show running-config url-server
!
url-server (perimeter) vendor websense host 10.0.1.1
!
```

Related Commands

Commands	Description
clear url-server	Clears the URL filtering server statistics.
show url-server	Displays information about the URL cache, which is used for buffering URLs while waiting for responses from an N2H2 or Websense filtering server.
url-block	Manages the URL buffers used for web server responses while waiting for a filtering decision from the filtering server.
url-cache	Enables URL caching while pending responses from an N2H2 or Websense server and sets the size of the cache.
url-server	Identifies an N2H2 or Websense server for use with the **filter** command.

show running-config user-identity

To display the configuration for the Identity Firewall, use the **user-identity poll-import-user-group-timer** command in global configuration mode. To remove the timer, use the **no** form of this command.

show running-config user-identity [**ad-agent** | **logout-probe** | **action** | **default-domain** | **domain** *domain_nickname*]

Syntax Description

action	Displays the configuration for the following Identity Firewall actions configured by the following commands: • **user-identity action ad-agent-down** • **user-identity action domain-controller-down** • **user-identity action mac-address-mismatch** • **user-identity action netbios-response-fail**
ad-agent	Displays all configuration for the Active Directory Agent configured for the Identity Firewall.
domain_nickname	Displays the configuration for the domain specified by the *domain_nickname* argument.
default-domain	Specifies the configuration for the Identity Firewall default domain. You configure the default domain by entering the **user-identity default-domain** command.
domain	Displays all domains configured for the Identity Firewall.
logout-probe	Displays all configuration for the logout probe configured for the Identity Firewall. When NetBIOS probing is enabled for the Identity Firewall, the ASA probes the user client IP address to determine whether the client is still active. By default, NetBIOS probing is disabled.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Examples

The following example displays the configuration for the Active Directory Agent configured for the Identity Firewall:

```
hostname(config)# show running-config user-identity ad-agent
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.

show running-config username

To display the running configuration for a particular user, use the **show running-config username** command in privileged EXEC mode with the username appended. To display the running configuration for all users, use this command without a username.

show running-config [**all**] **username** [*name*] [**attributes**]]

Syntax Description

attributes	Displays the specific AVPs for the user(s)
all	(Optional) Displays all username commands, including the commands that you have not changed from the default settings.
name	Provides the name of the user.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	—	—
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.4.4(1)	The output for the **show running-config all username** command was updated to add password date information.

Examples

The following is sample output from the **show the running-config username** command for a user named anyuser:

```
hostname# show running-config username anyuser
username anyuser password .8T1d6ik58/lzXS5 encrypted privilege 3
username anyuser attributes
vpn-group-policy DefaultGroupPolicy
vpn-idle-timeout 10
vpn-session-timeout 120
vpn-tunnel-protocol IPSec
```

Related Commands

Command	Description
clear config username	Clears the username database.
username	Adds a user to the ASA database.
username attributes	Lets you configure attributes for specific users.

show running-config virtual

To display the IP address of the ASA virtual server, use the **show running-config virtual** command in privileged EXEC mode.

show running-config [**all**] **virtual**

Syntax Description

all	Display the virtual server IP address of all virtual servers.

Defaults

Omitting the **all** keyword displays the explicitly configured IP address of the current virtual server or servers.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was modified to conform to CLI guidelines.

Usage Guidelines

You must be in privileged EXEC mode to use this command.

Examples

This example displays the **show running-config virtual** command output for a situation in which there is a previously configured HTTP virtual server:

```
hostname(config)# show running-config virtual
virtual http 192.168.201.1
```

Related Commands

Command	Description
clear configure virtual	Removes **virtual** command statements from the configuration.
virtual	Displays the address for authentication virtual servers.

show running-config vpn load-balancing

To display the current VPN load-balancing virtual cluster configuration, use the **show running-config vpn-load-balancing** command in global configuration, privileged EXEC or VPN load-balancing mode.

show running-config [**all**] **vpn load-balancing**

Syntax Description

all	Display both the default and the explicitly configured VPN load-balancing configuration.

Defaults

Omitting the **all** keyword displays the explicitly configured VPN load-balancing configuration.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	—	—
Privileged EXEC	•	—	•	—	—
Vpn load-balancing	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show running-config vpn load-balancing** command also displays configuration information for the following related commands: **cluster encryption**, **cluster ip address**, **cluster key**, **cluster port**, **nat**, **participate**, and **priority**.

Examples

This example displays **show running-config vpn load-balancing** command and its output, with the **all** option enabled:

```
hostname(config)# show running-config all vpn load-balancing
vpn load-balancing
 no nat
 priority 9
 interface lbpublic test
 interface lbprivate inside
 no cluster ip address
 no cluster encryption
 cluster port 9023
 no participate
```

Related Commands

Command	Description
clear configure vpn load-balancing	Removes **vpn load-balancing** command statements from the configuration.
show vpn load-balancing	Displays the VPN load-balancing runtime statistics.
vpn load-balancing	Enters vpn load-balancing mode.

show running-config webvpn

To display the running configuration for webvpn, use the s**how running-config webvpn** command in privileged EXEC mode. To have the display include the default configuration, use the **all** keyword.

show running-config [all] webvpn [apcf | auto-signon | cache | proxy-bypass | rewrite | sso-server | url-list]

Syntax Description

all	(Optional) Displays the running configuration including default values.
apcf	(Optional) Displays the running configuration for SSL VPN APCF.
auto-signon	(Optional) Displays the running configuration for SSL VPN auto sign-on.
cache	(Optional) Displays the running configuration for SSL VPN caching.
proxy-bypass	(Optional) Displays the running configuration for SSL VPN proxy bypass.
rewrite	(Optional) Displays the running configuration for SSL VPN content transformation.
sso-server	(Optional) Displays the running configuration for single sign-on.
url-list	(Optional) Displays the running configuration for SSL VPN access to URLs.

Defaults

No default behavior or values.

Command History

Release	Modification
7.0(1)	This command was introduced.
7.1(1)	This command was revised.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—
Global configuration	•	—	•	—	—
Webvpn	•	—	•	—	—

Examples

The following is sample output from the **show running-config webvpn** command:

```
hostname# show running-configuration webvpn
webvpn
 title WebVPN Services for ASA-4
 title-color green
 default-idle-timeout 0
 nbns-server 10.148.1.28 master timeout 2 retry 2
```

```
 accounting-server-group RadiusACS1
 authentication-server-group RadiusACS2
 authorization-dn-attributes CN
```

The following is sample output from the **show running-config all webvpn** command:

```
hostname#(config-webvpn)# show running-config all webvpn

webvpn
 title WebVPN Services for ASA-4
 username-prompt Username
 password-prompt Password
 login-message Please enter your username and password
 logout-message Goodbye
 no logo
 title-color green
 secondary-color #CCCCFF
 text-color white
 secondary-text-color black
 default-idle-timeout 0
 no http-proxy
 no https-proxy
 nbns-server 10.148.1.28 master timeout 2 retry 2
 accounting-server-group RadiusACS1
 authentication-server-group RadiusACS2
 no authorization-server-group
 default-group-policy DfltGrpPolicy
 authentication aaa
 no authorization-required
 authorization-dn-attributes CN
hostname#
```

The following is sample output from the **show running-config webvpn sso-server** command:

```
hostname#(config-webvpn)# show running-config webvpn sso-server
sso-server
sso-server bxbsvr type siteminder
web-agent-url http://bxb-netegrity.demo.com/vpnauth/
policy-server-secret cisco1234
sso-server policysvr type siteminder
web-agent-url http://webagent1.mysiteminder.com/ciscoauth/
policy-server-secret Cisco1234
max-retry-attempts 4
request-timeout 10
hostname#(config-webvpn)#
```

Related Commands

Command	Description
clear configure webvpn	Removes all nondefault SSL VPN configuration attributes.
debug webvpn	Displays debug information about SSL VPN sessions.
show webvpn	Displays statistics about SSL VPN sessions.

show running-config webvpn auto-signon

To display all WebVPN auto-signon assignments in the running configuration, use the **show running-config webvpn auto-signon** command in global configuration mode.

show running-config webvpn auto-signon

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Examples

The following is sample output from the **show running-config webvpn auto-signon**:

```
hostname(config)# webvpn
hostname(config-webvpn)# auto-signon allow ip 10.1.1.0 255.255.255.0 auth-type ntlm
hostname(config-webvpn)# auto-signon allow uri *.example.com/* auth-type basic
hostname(config-webvpn)# show running-config webvpn auto-signon
auto-signon allow ip 10.1.1.0 255.255.255.0 auth-type ntlm
auto-signon allow uri *.example.com/* auth-type basic
```

Related Commands

auto-signon	Configures the ASA to automatically pass WebVPN login credentials to internal servers.

show running-config zonelabs-integrity

To display the Zone Labs Integrity Server configuration, use the **show running-config zonelabs-integrity** command in privileged EXEC mode.

show running-config [**all**] **zonelabs-integrity**

Syntax Description

all	(Optional) Shows the running configuration including default configuration values.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	—	•

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Use this command to display the addresses of all Zone Labs Integrity Servers and the configured values for the active Zone Labs Integrity Server. Use the **all** parameter to display the default as well as the explicitly configured values.

Examples

The following is sample output from the **show running-config zonelabs-integrity** command:

```
hostname# show running-config zonelabs-integrity
zonelabs-integrity server-address 10.0.9.1 10.0.9.2
zonelabs-integrity port 300
hostname#
```

The following is sample output from the **show running-config all zonelabs-integrity** command:

```
hostname# show running-config all zonelabs-integrity
zonelabs-integrity server-address 10.0.9.1 10.0.9.2
zonelabs-integrity port 300
zonelabs-integrity interface none
zonelabs-integrity fail-open
zonelabs-integrity fail-timeout 10
zonelabs-integrity ssl-client-authentication disable
zonelabs-integrity ssl-certificate-port 80
hostname#
```

Related Commands

Command	Description
clear configure zonelabs-integrity	Clears the Zone Labs Integrity Server configuration.

show running-config vpdn

To display the VPDN configuration used for PPPoE connections, use the **show running-config vpdn** command in privileged EXEC mode:

show running-config vpdn

Syntax Description

This command has no arguments or keywords.

Defaults

This command has no default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

Thie following is sample output from the **show running-config vpdn** command:

```
hostname# show running-config vpdn
vpdn group telecommuters ppp authentication mschap
vpdn username tomm password ********* store-local
```

Related Commands

Command	Description
show running-config vpdn group	Shows the current configuration for the VPDN group.
show running-config vpdn username	Shows the current configuration for vpdn usernames.

show running-configuration vpn-sessiondb

To display the current set of configured vpnsessiondb commands, use the **show running-configuration vpn-sessiondb** command in privileged EXEC mode.

show running-configuration [all] vpn-sessiondb

Syntax Description

all	(Optional) Displays all **vpn-sessionddb** commands, including the commands you have not changed from the default

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

As of Release 7.0, this command displays only the VPN maximum sessions limit, if configured.

Examples

The following is sample output for the **show running-configuration vpn-sessiondb** command:

```
hostname# show running-configuration vpn-sessiondb
```

Related Commands

Command	Description
show vpn-sessiondb	Displays sessions with or without extended details, optionally filtered and sorted by criteria you specify.
show vpn-sessiondb summary	Displays a session summary, including total current session, current sessions of each type, peak and total cumulative, maximum concurrent sessions

show running-config wccp

To show the WCCP configuration in the running configuration, use the **show running-config wccp** command in privileged EXEC mode.

show [**all**] **running-config wccp**

Syntax Description

all	Displays the default and explicitly configured configuration information for one or all WCCP commands.

Defaults

This command has no arguments or keywords.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following is sample output from the **show running-config wccp** command:

```
hostname# show running-config wccp
wccp web-cache redirect-list wooster group-list jeeves password whatho
hostname#
```

Related Commands

Command	Description
wccp	Enables support of WCCP.
wccp redirect	Enters support of WCCP redirection.

show running-config xlate

To show the **xlate per-session** rules, use the **show running-config xlate** command in global configuration mode.

show running-config [**all**] **xlate**

Syntax Description

all	(Optional) Shows the running configuration, including default configuration values.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

Use the **clear configure xlate** command to clear the **xlate per-session** configuration.

Examples

The following is sample output from the **show running-config xlate** and **show running-config all xlate** commands:

```
hostname(config)# show running-config xlate
hostname(config)# show running-config all xlate
xlate per-session permit tcp any4 any4
xlate per-session permit tcp any4 any6
xlate per-session permit tcp any6 any4
xlate per-session permit tcp any6 any6
xlate per-session permit udp any4 any4 eq domain
xlate per-session permit udp any4 any6 eq domain
xlate per-session permit udp any6 any4 eq domain
xlate per-session permit udp any6 any6 eq domain
```

Related Commands

Command	Description
clear configure xlate	Clears the **xlate per-session** rules.
nat (global)	Adds a twice NAT rule.

Command	Description
nat (object)	Adds an object NAT rule.
xlate per-session	Adds a per-session PAT rule.

CHAPTER 58

show scansafe through show switch vlan Commands

show scansafe server

To show the status of the Cloud Web Security proxy servers, use the **show scansafe server** command in privileged EXEC mode.

show scansafe server

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

This command shows the status of the server, whether it is the current active server, the backup server, or unreachable.

Examples

The following is sample output from the **show scansafe server** command:

```
hostname# show scansafe server
hostname# Primary: proxy197.scansafe.net (72.37.244.115) (REACHABLE)*
hostname# Backup: proxy137.scansafe.net (80.254.152.99)
```

Related Commands

Command	Description
class-map type inspect scansafe	Creates an inspection class map for whitelisted users and groups.
default user group	Specifies the default username and/or group if the ASA cannot determine the identity of the user coming into the ASA.
http[**s**] (parameters)	Specifies the service type for the inspection policy map, either HTTP or HTTPS.
inspect scansafe	Enables Cloud Web Security inspection on the traffic in a class.

Command	Description
license	Configures the authentication key that the ASA sends to the Cloud Web Security proxy servers to indicate from which organization the request comes.
match user group	Matches a user or group for a whitelist.
policy-map type inspect scansafe	Creates an inspection policy map so you can configure essential parameters for the rule and also optionally identify the whitelist.
retry-count	Enters the retry counter value, which is the amount of time that the ASA waits before polling the Cloud Web Security proxy server to check its availability.
scansafe	In multiple context mode, allows Cloud Web Security per context.
scansafe general-options	Configures general Cloud Web Security server options.
server {**primary** | **backup**}	Configures the fully qualified domain name or IP address of the primary or backup Cloud Web Security proxy servers.
show conn scansafe	Shows all Cloud Web Security connections, as noted by the capitol Z flag.
show scansafe statistics	Shows total and current http connections.
user-identity monitor	Downloads the specified user or group information from the AD agent.
whitelist	Performs the whitelist action on the class of traffic.

show scansafe statistics

To show information about Cloud Web Security activity, use the **show scansafe statistics** command in privileged EXEC mode.

show scansafe statistics

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

The **show scansafe statistics** command shows information about Cloud Web Security activity, such as the number of connections redirected to the proxy server, the number of current connections being redirected, and the number of whitelisted connections.

Examples

The following is sample output from the **show scansafe statistics** command:

```
hostname# show scansafe statistics
Current HTTP sessions : 0
Current HTTPS sessions : 0
Total HTTP Sessions : 0
Total HTTPS Sessions : 0
Total Fail HTTP sessions : 0
Total Fail HTTPS sessions : 0
Total Bytes In : 0 Bytes
Total Bytes Out : 0 Bytes
HTTP session Connect Latency in ms(min/max/avg) : 0/0/0
HTTPS session Connect Latency in ms(min/max/avg) : 0/0/0
```

Related Commands

Command	Description
class-map type inspect scansafe	Creates an inspection class map for whitelisted users and groups.
default user group	Specifies the default username and/or group if the ASA cannot determine the identity of the user coming into the ASA.
http[**s**] (parameters)	Specifies the service type for the inspection policy map, either HTTP or HTTPS.
inspect scansafe	Enables Cloud Web Security inspection on the traffic in a class.
license	Configures the authentication key that the ASA sends to the Cloud Web Security proxy servers to indicate from which organization the request comes.
match user group	Matches a user or group for a whitelist.
policy-map type inspect scansafe	Creates an inspection policy map so you can configure essential parameters for the rule and also optionally identify the whitelist.
retry-count	Enters the retry counter value, which is the amount of time that the ASA waits before polling the Cloud Web Security proxy server to check its availability.
scansafe	In multiple context mode, allows Cloud Web Security per context.
scansafe general-options	Configures general Cloud Web Security server options.
server {**primary** | **backup**}	Configures the fully qualified domain name or IP address of the primary or backup Cloud Web Security proxy servers.
show conn scansafe	Shows all Cloud Web Security connections, as noted by the capitol Z flag.
show scansafe server	Shows the status of the server, whether it's the current active server, the backup server, or unreachable.
user-identity monitor	Downloads the specified user or group information from the AD agent.
whitelist	Performs the whitelist action on the class of traffic.

show service-policy

To display the service policy statistics, use the **show service-policy** command in privileged EXEC mode.

show service-policy [**global** | **interface** *intf*] [**csc** | **cxsc** | **inspect** *inspection* [*arguments*] | **ips** | **police** | **priority** | **set connection** [**details**] | **shape** | **user-statistics**]

show service-policy [**global** | **interface** *intf*] [**flow** *protocol* {**host** *src_host* | *src_ip src_mask*} [**eq** *src_port*] {**host** *dest_host* | *dest_ip dest_mask*} [**eq** *dest_port*] [*icmp_number* | *icmp_control_message*]]

Syntax Description

csc	(Optional) Shows detailed information about policies that include the **csc** command.
cxsc	(Optional) Shows detailed information about policies that include the **cxsc** command.
dest_ip dest_mask	For the **flow** keyword, the destination IP address and netmask of the traffic flow.
details	(Optional) For the **set connection** keyword, displays per-client connection information, if a per-client connection limit is enabled.
eq *dest_port*	(Optional) For the **flow** keyword, equals the destination port for the flow.
eq *src_port*	(Optional) For the **flow** keyword, equals the source port for the flow.
flow *protocol*	(Optional) Shows policies that match a particular flow identified by the 5-tuple (protocol, source IP address, source port, destination IP address, destination port). You can use this command to check that your service policy configuration will provide the services you want for specific connections. Because the flow is described as a 5-tuple, not all policies are supported. See the following supported policy matches: • **match access-list** • **match port** • **match rtp** • **match default-inspection-traffic**
global	(Optional) Limits output to the global policy.
host *dest_host*	For the **flow** keyword, the host destination IP address of the traffic flow.
host *src_host*	For the **flow** keyword, the host source IP address of the traffic flow.
icmp_control_message	(Optional) For the **flow** keyword when you specify ICMP as the protocol, specifies an ICMP control message of the traffic flow.
icmp_number	(Optional) For the **flow** keyword when you specify ICMP as the protocol, specifies the ICMP protocol number of the traffic flow.
inspect *inspection* [*arguments*]	(Optional) Shows detailed information about policies that include an **inspect** command. Not all **inspect** commands are supported for detailed output. To see all inspections, use the **show service-policy** command without any arguments. The arguments available for each inspection vary; see the CLI help for more information.

interface *intf*	(Optional) Displays policies applied to the interface specified by the *intf* argument, where *intf* is the interface name given by the **nameif** command.
ips	(Optional) Shows detailed information about policies that include the **ips** command.
police	(Optional) Shows detailed information about policies that include the **police** command.
priority	(Optional) Shows detailed information about policies that include the **priority** command.
set connection	(Optional) Shows detailed information about policies that include the **set connection** command.
shape	(Optional) Shows detailed information about policies that include the **shape** command.
src_ip src_mask	For the **flow** keyword, the source IP address and netmask used in the traffic flow.
user-statistics	(Optional) Shows detailed information about policies that include the **user-statistics** command. This command displays user statistics for the Identify Firewall, including sent packet count, sent drop count, received packet count, and send drop count for selected users.

Defaults

If you do not specify any arguments, this command shows all global and interface policies.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.1(1)	The **csc** keyword was added.
7.2(4)/8.0(4)	The **shape** keyword was added.
8.4(2)	We added support for the **user-statistics** keyword for the Identity Firewall.
8.4(4.1)	We added support for the **cxsc** keyword for the ASA CX module.

Usage Guidelines

The number of embryonic connections displayed in the **show service-policy** command output indicates the current number of embryonic connections to an interface for traffic matching that defined by the **class-map** command. The “embryonic-conn-max” field shows the maximum embryonic limit configured for the traffic class using the Modular Policy Framework. If the current embryonic connections displayed equals or exceeds the maximum, TCP intercept is applied to new TCP connections that match the traffic type defined by the **class-map** command.

When you make service policy changes to the configuration, all *new* connections use the new service policy. Existing connections continue to use the policy that was configured at the time of the connection establishment. **show** command output will not include data about the old connections. For example, if you remove a QoS service policy from an interface, then re-add a modified version, then the **show service-policy** command only displays QoS counters associated with new connections that match the new service policy; existing connections on the old policy no longer show in the command output. To ensure that all connections use the new policy, you need to disconnect the current connections so they can reconnect using the new policy. See the **clear conn** or **clear local-host** commands.

Note For an **inspect icmp** and **inspect icmp error** policies, the packet counts only include the echo request and reply packets.

Examples

The following is sample output from the **show service-policy global** command:

```
hostname# show service-policy global

Global policy:
  Service-policy: inbound_policy
    Class-map: ftp-port
      Inspect: ftp strict inbound_ftp, packet 0, drop 0, reset-drop 0
```

The following is sample output from the **show service-policy priority** command:

```
hostname# show service-policy priority

Interface outside:

Global policy:
  Service-policy: sa_global_fw_policy

Interface outside:
  Service-policy: ramap
    Class-map: clientmap
      Priority:
        Interface outside: aggregate drop 0, aggregate transmit 5207048
    Class-map: udpmap
      Priority:
        Interface outside: aggregate drop 0,  aggregate transmit 5207048
    Class-map: cmap
```

The following is sample output from the **show service-policy flow** command:

```
hostname# show service-policy flow udp host 209.165.200.229 host 209.165.202.158 eq 5060

Global policy:
  Service-policy: f1_global_fw_policy
    Class-map: inspection_default
      Match: default-inspection-traffic
      Action:
        Input flow:  inspect sip

Interface outside:
  Service-policy: test
    Class-map: test
      Match: access-list test
        Access rule: permit ip 209.165.200.229 255.255.255.224 209.165.202.158
255.255.255.224
      Action:
        Input flow:  ids inline
```

```
        Input flow:  set connection conn-max 10 embryonic-conn-max 20
```

The following is sample output from the **show service-policy inspect http** command. This example shows the statistics of each match command in a match-any class map.

```
hostname# show service-policy inspect http

Global policy:
  Service-policy: global_policy
    Class-map: inspection_default
      Inspect: http http, packet 1916, drop 0, reset-drop 0
        protocol violations
          packet 0
        class http_any (match-any)
          Match: request method get, 638 packets
          Match: request method put, 10 packets
          Match: request method post, 0 packets
          Match: request method connect, 0 packets
          log, packet 648
```

The following is sample output from the **show service-policy inspect waas** command. This example shows the waas statistics.

```
hostname# show service-policy inspect waas

Global policy:
  Service-policy: global_policy
    Class-map: WAAS
      Inspect: waas, packet 12, drop 0, reset-drop 0
        SYN with WAAS option 4
        SYN-ACK with WAAS option 4
        Confirmed WAAS connections 4
        Invalid ACKs seen on WAAS connections 0
        Data exceeding window size on WAAS connections 0
```

The following is sample output from the **show gtp requests** command:

```
hostname# show gtp requests
0 in use, 0 most used, 200 maximum allowed
```

You can use the vertical bar | to filter the display, as in the following example:

```
hostname# show service-policy gtp statistics | grep gsn
```

This example shows the GTP statistics with the word gsn in the output.

The following command shows the statistics for GTP inspection:

```
hostname# show service-policy inspect gtp statistics
GPRS GTP Statistics:
  version_not_support | 0 | msg_too_short | 0
  unknown_msg | 0 | unexpected_sig_msg | 0
  unexpected_data_msg | 0 | ie_duplicated | 0
  mandatory_ie_missing | 0 | mandatory_ie_incorrect | 0
  optional_ie_incorrect | 0 | ie_unknown | 0
  ie_out_of_order | 0 | ie_unexpected | 0
  total_forwarded | 0 | total_dropped | 0
  signalling_msg_dropped | 0 | data_msg_dropped | 0
  signalling_msg_forwarded | 0 | data_msg_forwarded | 0
  total created_pdp | 0 | total deleted_pdp | 0
  total created_pdpmcb | 0 | total deleted_pdpmcb | 0
  pdp_non_existent | 0
```

Table 58-1 describes each column of the output from the **show service-policy inspect gtp statistics** command.

Table 58-1 GPRS GTP Statistics

Column Heading	Description
version_not_support	Displays packets with an unsupported GTP version field.
msg_too_short	Displays packets less than 8 bytes in length.
unknown_msg	Displays unknown type messages.
unexpected_data_msg	Displays unexpected data messages.
mandatory_ie_missing	Displays messages missing a mandatory Information Element (IE).
mandatory_ie_incorrect	Displays messages with an incorrectly formatted mandatory Information Element (IE).
optional_ie_incorrect	Displays messages with an incorrectly formatted optional Information Element (IE).
ie_unknown	Displays messages with an unknown Information Element (IE).
ie_out_of_order	Displays messages with out-of-sequence Information Elements (IEs).
ie_unexpected	Displays messages with an unexpected Information Element (IE).
total_forwarded	Displays the total messages forwarded.
total_dropped	Displays the total messages dropped.
signalling_msg_dropped	Displays the signaling messages dropped.
data_msg_dropped	Displays the data messages dropped.
signalling_msg_forwarded	Displays the signaling messages forwarded.
data_msg_forwarded	Displays the data messages forwarded.
total created_pdp	Displays the total Packet Data Protocol (PDP) contexts created.
total deleted_pdp	Displays the total Packet Data Protocol (PDP) contexts deleted.
total created_pdpmcb	Displays the total PDPMCB sessions created.
total deleted_pdpmcb	Displays the total PDPMCB sessions deleted.
pdp_non_existent	Displays the messages received for a non-existent PDP context.

The following command displays information about the PDP contexts:

```
hostname# show service-policy inspect gtp pdp-context
1 in use, 1 most used, timeout 0:00:00

Version TID | MS Addr | SGSN Addr | Idle | APN
v1 | 1234567890123425 | 1.1.1.1 | 11.0.0.2 0:00:13  gprs.cisco.com
```

```
| user_name (IMSI): 214365870921435 | MS address: | 1.1.1.1
| primary pdp: Y | nsapi: 2
| sgsn_addr_signal: | 11.0.0.2 | sgsn_addr_data: | 11.0.0.2
| ggsn_addr_signal: | 9.9.9.9 | ggsn_addr_data: | 9.9.9.9
| sgsn control teid: | 0x000001d1 | sgsn data teid: | 0x000001d3
| ggsn control teid: | 0x6306ffa0 | ggsn data teid: | 0x6305f9fc
| seq_tpdu_up: | 0 | seq_tpdu_down: | 0
| signal_sequence: | 0
| upstream_signal_flow: | 0 | upstream_data_flow: | 0
| downstream_signal_flow: | 0 | downstream_data_flow: | 0
| RAupdate_flow: | 0
```

Table 58-2 describes each column of the output from the **show service-policy inspect gtp pdp-context** command.

Table 58-2 PDP Contexts

Column Heading	Description
Version	Displays the version of GTP.
TID	Displays the tunnel identifier.
MS Addr	Displays the mobile station address.
SGSN Addr	Displays the serving gateway service node.
Idle	Displays the time for which the PDP context has not been in use.
APN	Displays the access point name.

Related Commands

Command	Description
clear configure service-policy	Clears service policy configurations.
clear service-policy	Clears all service policy configurations.
service-policy	Configures the service policy.
show running-config service-policy	Displays the service policies configured in the running configuration.

show shared license

To show shared license statistics, use the **show shared license** command in privileged EXEC mode. Optional keywords are available only for the licensing server.

show shared license [**detail** | **client** [*hostname*] | **backup**]

Syntax Description

backup	(Optional) Shows information about the backup server.
client	(Optional) Limits the display to participants.
detail	(Optional) Shows all statistics, including per participant.
hostname	(Optional) Limits the display to a particular participant.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•		—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

To clear the statistics, enter the **clear shared license** command.

Examples

The following is sample output from the **show shared license** command on the license participant:

```
hostname# show shared license
Primary License Server : 10.3.32.20
  Version              : 1
  Status               : Inactive

Shared license utilization:
  SSLVPN:
    Total for network :     5000
    Available         :     5000
    Utilized          :        0
  This device:
    Platform limit    :      250
    Current usage     :        0
    High usage        :        0
  Messages Tx/Rx/Error:
    Registration    : 0 / 0 / 0
```

```
    Get             : 0 / 0 / 0
    Release         : 0 / 0 / 0
    Transfer        : 0 / 0 / 0

Client ID           Usage   Hostname
  ASA0926K04D         0       5510-B
```

Table 58-3 describes the output from the **show shared license** command.

Table 58-3 show shared license Description

Field	Description
Primary License Server	The IP address of the primary server.
Version	The shared license version.
Status	If the command is issued on the backup server, “Active” means that this device has taken on the role as a Primary Shared Licensing server. “Inactive” means that the device is ready in standby mode, and the device is communicating with the primary server. If failover is configured on the primary licensing server, the backup server may become “Active” for a brief moment during a failover but should return to “Inactive” after communications have synced up again.
Shared license utilization	
SSLVPN	
Total for network	Displays the total number of shared sessions available.
Available	Displays the remaining shared sessions available.
Utilized	Displays the shared sessions obtained for the active license server.
This device	
Platform limit	Displays the total number of SSL VPN sessions for this device according to the installed license.
Current usage	Displays the number of shared SSL VPN session currently owned by this device from the shared pool.
High usage	Displays the highest number of shared SSL VPN sessions ever owned by this device.
Messages Tx/Rx/Error	
Registration Get Release Transfer	Shows the Transmit, Received, and Error packets of each type of connection.
Client ID	A unique client ID.
Usage	Displays the number of sessions in use.
Hostname	Displays the hostname for this device.

The following is sample output from the **show shared license detail** command on the license server:

```
hostname# show shared license detail
Backup License Server Info:
```

```
Device ID           : ABCD
Address             : 10.1.1.2
Registered          : NO
HA peer ID          : EFGH
Registered          : NO
  Messages Tx/Rx/Error:
    Hello           : 0 / 0 / 0
    Sync            : 0 / 0 / 0
    Update          : 0 / 0 / 0

Shared license utilization:
  SSLVPN:
    Total for network :      500
    Available         :      500
    Utilized          :        0
  This device:
    Platform limit    :      250
    Current usage     :        0
    High usage        :        0
  Messages Tx/Rx/Error:
    Registration    : 0 / 0 / 0
    Get             : 0 / 0 / 0
    Release         : 0 / 0 / 0
    Transfer        : 0 / 0 / 0

Client Info:

  Hostname          : 5540-A
  Device ID         : XXXXXXXXXXX
  SSLVPN:
    Current usage   : 0
    High            : 0
  Messages Tx/Rx/Error:

```

Related Commands

Command	Description
activation-key	Enters a license activation key.
clear configure license-server	Clears the shared licensing server configuration.
clear shared license	Clears shared license statistics.
license-server address	Identifies the shared licensing server IP address and shared secret for a participant.
license-server backup address	Identifies the shared licensing backup server for a participant.
license-server backup backup-id	Identifies the backup server IP address and serial number for the main shared licensing server.
license-server backup enable	Enables a unit to be the shared licensing backup server.
license-server enable	Enables a unit to be the shared licensing server.
license-server port	Sets the port on which the server listens for SSL connections from participants.
license-server refresh-interval	Sets the refresh interval provided to participants to set how often they should communicate with the server.

Command	Description
license-server secret	Sets the shared secret on the shared licensing server.
show activation-key	Shows the current licenses installed.
show running-config license-server	Shows the shared licensing server configuration.
show vpn-sessiondb	Shows license information about VPN sessions.

show shun

To display shun information, use the **show shun** command in privileged EXEC mode.

show shun [*src_ip* | *statistics*]

Syntax Description

src_ip	(Optional) Displays the information for that address.
statistics	(Optional) Displays the interface counters only.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.2(2)	For threat events, the severity level was changed from a warning to a notification. Threat events can be triggered every five minutes.

Examples

The following is sample output from the **show shun** command:

```
hostname# show shun
shun (outside) 10.1.1.27 10.2.2.89 555 666 6
shun (inside1) 10.1.1.27 10.2.2.89 555 666 6
```

Related Commands

Command	Description
clear shun	Disables all the shuns that are currently enabled and clears the shun statistics.
shun	Enables a dynamic response to an attacking host by preventing new connections and disallowing packets from any existing connection.

show sip

To display SIP sessions, use the **show sip** command in privileged EXEC mode.

show sip

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show sip** command assists in troubleshooting SIP inspection engine issues and is described with the **inspect protocol sip udp 5060** command. The **show timeout sip** command displays the timeout value of the designated protocol.

The **show sip** command displays information for SIP sessions established across the ASA. Along with the **debug sip** and **show local-host** commands, this command is used for troubleshooting SIP inspection engine issues.

Note We recommend that you configure the **pager** command before using the **show sip** command. If there are a lot of SIP session records and the **pager** command is not configured, it will take a while for the **show sip** command output to reach its end.

Examples

The following is sample output from the **show sip** command:

```
hostname# show sip
Total: 2
call-id c3943000-960ca-2e43-228f@10.130.56.44
 state Call init, idle 0:00:01
call-id c3943000-860ca-7e1f-11f7@10.130.56.45
 state Active, idle 0:00:06
```

This sample shows two active SIP sessions on the ASA (as shown in the `Total` field). Each `call-id` represents a call.

The first session, with the `call-id c3943000-960ca-2e43-228f@10.130.56.44,` is in the state `Call Init`, which means the session is still in call setup. Call setup is complete only when the ACK is seen. This session has been idle for 1 second.

The second session is in the state `Active`, in which call setup is complete and the endpoints are exchanging media. This session has been idle for 6 seconds.

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
debug sip	Enables debug information for SIP.
inspect sip	Enables SIP application inspection.
show conn	Displays the connection state for different connection types.
timeout	Sets the maximum idle time duration for different protocols and session types.

show skinny

To troubleshoot SCCP (Skinny) inspection engine issues, use the **show skinny** command in privileged EXEC mode.

show skinny

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show skinny** command assists in troubleshooting SCCP (Skinny) inspection engine issues.

Examples

The following is sample output from the **show skinny** command under the following conditions. There are two active Skinny sessions set up across the ASA. The first one is established between an internal Cisco IP Phone at local address 10.0.0.11 and an external Cisco CallManager at 172.18.1.33. TCP port 2000 is the CallManager. The second one is established between another internal Cisco IP Phone at local address 10.0.0.22 and the same Cisco CallManager.

```
hostname# show skinny

        LOCAL                   FOREIGN                 STATE

-----------------------------------------------------------------

1       10.0.0.11/52238         172.18.1.33/2000                1

  MEDIA 10.0.0.11/22948         172.18.1.22/20798

2       10.0.0.22/52232         172.18.1.33/2000                1

  MEDIA 10.0.0.22/20798         172.18.1.11/22948
```

The output indicates a call has been established between both internal Cisco IP Phones. The RTP listening ports of the first and second phones are UDP 22948 and 20798 respectively.

The following is the xlate information for these Skinny connections:

```
hostname# show xlate debug
2 in use, 2 most used
Flags: D|DNS, d|dump, I|identity, i|inside, n|no random,
|o|outside, r|portmap, s|static
NAT from inside:10.0.0.11 to outside:172.18.1.11 flags si idle 0:00:16 timeout 0:05:00
NAT from inside:10.0.0.22 to outside:172.18.1.22 flags si idle 0:00:14 timeout 0:05:00
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
debug skinny	Enables SCCP debug information.
inspect skinny	Enables SCCP application inspection.
show conn	Displays the connection state for different connection types.
timeout	Sets the maximum idle time duration for different protocols and session types.

show sla monitor configuration

To display the configuration values, including the defaults, for SLA operations, use the **show sla monitor configuration** command in user EXEC mode.

show sla monitor configuration [*sla-id*]

Syntax Description

sla-id	(Optional) The ID number of the SLA operation. Valid values are from 1 to 2147483647.

Defaults

If the *sla-id* is not specified, the configuration values for all SLA operations are shown.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Use the **show running config sla monitor** command to see the SLA operation commands in the running configuration.

Examples

The following is sample output from the **show sla monitor** command. It displays the configuration values for SLA operation 123. Following the output of the **show sla monitor** command is the output of the **show running-config sla monitor** command for the same SLA operation.

```
hostname> show sla monitor 124

SA Agent, Infrastructure Engine-II
Entry number: 124
Owner:
Tag:
Type of operation to perform: echo
Target address: 10.1.1.1
Interface: outside
Number of packets: 1
Request size (ARR data portion): 28
Operation timeout (milliseconds): 1000
Type Of Service parameters: 0x0
Verify data: No
Operation frequency (seconds): 3
Next Scheduled Start Time: Start Time already passed
```

```
Group Scheduled : FALSE
Life (seconds): Forever
Entry Ageout (seconds): never
Recurring (Starting Everyday): FALSE
Status of entry (SNMP RowStatus): Active
Enhanced History:

hostname# show running-config sla monitor 124

sla monitor 124
 type echo protocol ipIcmpEcho 10.1.1.1 interface outside
 timeout 1000
 frequency 3
sla monitor schedule 124 life forever start-time now
```

Related Commands

Command	Description
show running-config sla monitor	Displays the SLA operation configuration commands in the running configuration.
sla monitor	Defines an SLA monitoring operation.

show sla monitor operational-state

To display the operational state of SLA operations, use the **show sla monitor operational-state** command in user EXEC mode.

show sla monitor operational-state [*sla-id*]

Syntax Description

sla-id	(Optional) The ID number of the SLA operation. Valid values are from 1 to 2147483647.

Defaults

If the *sla-id* is not specified, statistics for all SLA operations are displayed.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Use the **show running-config sla monitor** command to display the SLA operation commands in the running configuration.

Examples

The following is sample output from the **show sla monitor operational-state** command:

```
hostname> show sla monitor operationl-state

Entry number: 124
Modification time: 14:42:23.607 EST Wed Mar 22 2006
Number of Octets Used by this Entry: 1480
Number of operations attempted: 4043
Number of operations skipped: 0
Current seconds left in Life: Forever
Operational state of entry: Active
Last time this entry was reset: Never
Connection loss occurred: FALSE
Timeout occurred: TRUE
Over thresholds occurred: FALSE
Latest RTT (milliseconds): NoConnection/Busy/Timeout
Latest operation start time: 18:04:26.609 EST Wed Mar 22 2006
Latest operation return code: Timeout
RTT Values:
RTTAvg: 0       RTTMin: 0       RTTMax: 0
```

```
NumOfRTT: 0      RTTSum: 0        RTTSum2: 0
```

Related Commands

Command	Description
show running-config sla monitor	Displays the SLA operation configuration commands in the running configuration.
sla monitor	Defines an SLA monitoring operation.

show snmp-server engineid

To display the identification of the SNMP engine that has been configured on the ASA, use the **show snmp-server engineid** command in privileged EXEC mode.

show snmp-server engineid

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Examples

The following is sample output from the **show snmp-server engineid** command:

```
hostname# show snmp-server engineid
Local SNMP engineID: 80000009fe85f8fd882920834a3af7e4ca79a0a1220fe10685
```

Usage Guidelines

An SNMP engine is a copy of SNMP that can reside on a local device. The engine ID is a unique value that is assigned for each SNMP agent for each ASA context. The engine ID is not configurable on the ASA. The engine ID is 25 bytes long, and is used to generate encrypted passwords. The encrypted passwords are then stored in flash memory. The engine ID can be cached. In a failover pair, the engine ID is synchronized with the peer.

Related Commands

Command	Description
clear configure snmp-server	Clears the SNMP server configuration.
show running-config snmp-server	Displays the SNMP server configuration.
snmp-server	Configures the SNMP server.

show snmp-server group

To display the names of configured SNMP groups, the security model being used, the status of different views, and the storage type of each group, use the **show snmp-server group** command in privileged EXEC mode.

show snmp-server group

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Examples

The following is sample output from the **show snmp-server group** command:

```
hostname# show snmp-server group
groupname: public                           security model:v1
readview : <no readview specified>          writeview: <no writeview specified>
notifyview: <no readview specified>
row status: active

groupname: public                           security model:v2c
readview : <no readview specified>          writeview: <no writeview specified>
notifyview: *<no readview specified>
row status: active

groupname: privgroup                    security model:v3 priv
readview : def_read_view                writeview: <no writeview specified>
notifyview: def_notify_view
row status: active
```

Usage Guidelines

SNMP users and groups are used according to the View-based Access Control Model (VACM) for SNMP. The SNMP group determines the security model to be used. The SNMP user should match the security model of the SNMP group. Each SNMP group name and security level pair must be unique.

Related Commands

Command	Description
clear configure snmp-server	Clears the SNMP server configuration.
show running-config snmp-server	Displays the SNMP server configuration.
snmp-server	Configures the SNMP server.

show snmp-server statistics

To display SNMP server statistics, use the **show snmp-server statistics** command in privileged EXEC mode.

show snmp-server statistics

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show snmp-server statistics** command:

```
hostname# show snmp-server statistics
0 SNMP packets input
    0 Bad SNMP version errors
    0 Unknown community name
    0 Illegal operation for community name supplied
    0 Encoding errors
    0 Number of requested variables
    0 Number of altered variables
    0 Get-request PDUs
    0 Get-next PDUs
    0 Get-bulk PDUs
    0 Set-request PDUs (Not supported)
0 SNMP packets output
    0 Too big errors (Maximum packet size 512)
    0 No such name errors
    0 Bad values errors
    0 General errors
    0 Response PDUs
    0 Trap PDUs
```

Related Commands

Command	Description
clear configure snmp-server	Clears the SNMP server configuration.
clear snmp-server statistics	Clears the SNMP packet input and output counters.
show running-config snmp-server	Displays the SNMP server configuration.
snmp-server	Configures the SNMP server.

show snmp-server user

To display information about the configured characteristics of SNMP users, use the **show snmp-server user** command in privileged EXEC mode.

show snmp-server user [*username*]

Syntax Description

username	(Optional) Identifies a specific user or users about which to display SNMP information.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Examples

The following is sample output from the **show snmp-server user** command:

```
hostname# show snmp-server user authuser
User name: authuser
Engine ID: 000000090200000000C025808
storage-type: nonvolatile       active access-list: N/A
Rowstatus: active
Authentication Protocol: MD5
Privacy protocol: DES
Group name: VacmGroupName
```

The output provides the following information:

- The username, which is a string that identifies the name of the SNMP user.
- The engine ID, which is a string that identifies the copy of SNMP on the ASA.
- The storage-type, which indicates whether or not the settings have been set in volatile or temporary memory on the ASA, or in nonvolatile or persistent memory, in which settings remain after the ASA has been turned off and on again.
- The active access list, which is the standard IP access list associated with the SNMP user.
- The Rowstatus, which indicates whether or not it is active or inactive.
- The authentication protocol, which identifies which authentication protocol is being used. Options are MD5, SHA, or none. If authentication is not supported in your software image, this field does not appear.

- The privacy protocol, which indicates whether or not DES packet encryption is enabled. If privacy is not supported in your software image, this field does not appear.
- The group name, which indicates to which SNMP group the user belongs. SNMP groups are defined according to the View-based Access Control Model (VACM).

Usage Guidelines

An SNMP user must be part of an SNMP group. If you do not enter the *username* argument, the **show snmp-server user** command displays information about all configured users. If you enter the *username* argument and the user exists, the information about that user appears.

Related Commands

Command	Description
clear configure snmp-server	Clears the SNMP server configuration.
show running-config snmp-server	Displays the SNMP server configuration.
snmp-server	Configures the SNMP server.

show software authenticity file

To display digital signature information related to software authentication for a specific image file, use the **show software authenticity file** command in privileged EXEC mode.

show software authenticity[*filename*]

Syntax Description

filename	(Optional) Identifies a specific image file.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
9.1(3)	This command was introduced.

Examples

The following is sample output from the **show software authenticity file** command:

```
hostname# show software authenticity file asa913.SSA
File Name                     : disk0:/asa913.SSA
Image type                    : Development
    Signer Information
        Common Name           : Cisco
        Organization Unit     : ASA5585-X
        Organization Name     : Engineering
    Certificate Serial Number : abcd1234efgh5678
    Hash Algorithm            : SHA512
    Signature Algorithm       : 2048-bit RSA
    Key Version               : A
```

The output provides the following information:

- The filename, which is the name of the filename in memory.
- The image type, which is the type of image being shown.
- The signer information specifies the signature information, which includes the following:
  - The common name, which is the name of the software manufacturer.
  - The organization unit, which indicates the hardware that the software image is deployed on.
  - The organization name, which is the owner of the software image.
- The certificate serial number, which is the certificate serial number for the digital signature.

- The hash algorithm, which indicates the type of hash algorithm used in digital signature verification.
- The signature algorithm, which identifies the type of signature algorithm used in digital signature verification.
- The key version, which indicates the key version used for verification.

Related Commands

Command	Description
show version	Displays the software version, hardware configuration, license key, and related uptime data.

show ssh sessions

To display information about the active SSH sessions on the ASA, use the **show ssh sessions** command in privileged EXEC mode.

show ssh sessions [**hostname** or **A.B.C.D**] [**hostname** or **X:X:X:X::X**] [**detail**]

Syntax Description

hostname or **A.B.C.D**	(Optional) Displays SSH session information for only the specified SSH client IPv4 address.
hostname or **X:X:X:X::X**	(Optional) Displays SSH session information for only the specified SSH client IPv6 address.
detail	Displays detailed SSH session information.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.1(2)	The **detail** option was added.

Usage Guidelines

The SID is a unique number that identifies the SSH session. The Client IP is the IP address of the system running an SSH client. The Version is the protocol version number that the SSH client supports. If the SSH only supports SSH version 1, then the Version column displays 1.5. If the SSH client supports both SSH version 1 and SSH version 2, then the Version column displays 1.99. If the SSH client only supports SSH version 2, then the Version column displays 2.0. The Encryption column shows the type of encryption that the SSH client is using. The State column shows the progress that the client is making as it interacts with the ASA. The Username column lists the login username that has been authenticated for the session. The Mode column describes the direction of the SSH data streams.

For SSH version 2, which can use the same or different encryption algorithms, the Mode field displays in and out. For SSH version 1, which uses the same encryption in both directions, the Mode field displays nil (‘-’) and allows only one entry per connection.

Examples

The following is sample output from the **show ssh sessions** command:

```
hostname# show ssh sessions
SID Client IP       Version Mode Encryption Hmac     State           Username
0   172.69.39.39    1.99    IN   aes128-cbc md5      SessionStarted  pat
                            OUT  aes128-cbc md5      SessionStarted  pat
1   172.23.56.236   1.5     -    3DES       -        SessionStarted  pat
2   172.69.39.29    1.99    IN   3des-cbc   sha1     SessionStarted  pat
                            OUT  3des-cbc   sha1     SessionStarted  pat
```

The following is sample output from the **show ssh sessions detail** command:

```
hostname# show ssh sessions detail
SSH Session ID             : 0
>   Client IP              : 161.44.66.200
>   Username               : root
>   SSH Version            : 2.0
>   State                  : SessionStarted
>   Inbound Statistics
>    Encryption            : aes256-cbc
>    HMAC                  : sha1
>    Bytes Received        : 2224
>   Outbound Statistics
>    Encryption            : aes256-cbc
>    HMAC                  : sha1
>    Bytes Transmitted     : 2856
>   Rekey Information
>    Time Remaining (sec)  : 3297
>    Data Remaining (bytes): 996145356
>    Last Rekey            : 16:17:19.732 EST Wed Jan 2 2013
>    Data-Based Rekeys     : 0
>    Time-Based Rekeys     : 0
```

Related Commands

Command	Description
ssh disconnect	Disconnects an active SSH session.
ssh timeout	Sets the timeout value for idle SSH sessions.

show ssl

To display information about the active SSL sessions on the ASA, use the **show ssl** command in privileged EXEC mode.

show ssl [**cache | errors | mib | objects | detail**]

Syntax Description

cache	(Optional) Displays SSL session cache statistics.
errors	(Optional) Displays SSL errors.
mib	(Optional) Displays SSL MIB statistics.
objects	(Optional) Displays SSL object statistics.
detail	Displays detailed SSH session information.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(1)	This command was introduced.
9.1(2)	The **detail** option was added.

Usage Guidelines

This command shows information about the current SSLv2 and SSLv3 sessions, including the enabled cipher order, which ciphers are disabled, SSL trustpoints being used, and whether or not certificate authentication is enabled.

Examples

The following is sample output from the **show ssl** command:

```
hostname# show ssl

Accept connections using SSLv2, SSLv3 or TLSv1 and negotiate to SSLv3 or TLSv1
Start connections using SSLv3 and negotiate to SSLv3 or TLSv1
Enabled cipher order: rc4-sha1 dhe-aes128-sha1 dhe-aes256-sha1 aes128-sha1 aes256-sha1
3des-sha1
Disabled ciphers: des-sha1 rc4-md5 null-sha1
SSL trust-points:
  inside interface: interfaceA
  outside interface: interfaceB
Certificate authentication is not enabled
```

The following is sample output from the **show ssh sessions detail** command:

```
hostname# show ssh sessions detail
SSH Session ID             : 0
>   Client IP              : 161.44.66.200
>   Username               : root
>   SSH Version            : 2.0
>   State                  : SessionStarted
>   Inbound Statistics
>    Encryption            : aes256-cbc
>    HMAC                  : sha1
>    Bytes Received        : 2224
>   Outbound Statistics
>    Encryption            : aes256-cbc
>    HMAC                  : sha1
>    Bytes Transmitted     : 2856
>   Rekey Information
>    Time Remaining (sec)  : 3297
>    Data Remaining (bytes): 996145356
>    Last Rekey            : 16:17:19.732 EST Wed Jan 2 2013
>    Data-Based Rekeys     : 0
>    Time-Based Rekeys     : 0
```

Related Commands

Command	Description
license-server port	Sets the port on which the server listens for SSL connections from participants.

show startup-config

To show the startup configuration or to show any errors when the startup configuration loaded, use the **show startup-config** command in privileged EXEC mode.

show startup-config [**errors**]

Syntax Description

errors	(Optional) Shows any errors that were generated when the ASA loaded the startup configuration.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System[1]
Privileged EXEC	•	•	•	•	•

1. The **errors** keyword is only available in single mode and the system execution space,

Command History

Release	Modification
7.0(1)	The **errors** keyword was added.
8.3(1)	The command output displays encrypted paswords.

Usage Guidelines

In multiple context mode, the **show startup-config** command shows the startup configuration for your current execution space: the system configuration or the security context.

The **show startup-config** command output displays encrypted, masked, or clear text passwords when password encryptionis either enabled or disabled.

To clear the startup errors from memory, use the **clear startup-config errors** command.

Examples

The following is sample output from the **show startup-config** command:

```
hostname# show startup-config

Related Commands

Command	Description
clear startup-config errors	Clears the startup errors from memory.
show running-config	Shows the running configuration.

show sunrpc-server active

To display the pinholes open for Sun RPC services, use the **show sunrpc-server active** command in privileged EXEC mode.

show sunrpc-server active

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the **show sunrpc-server active** command to display the pinholes open for Sun RPC services, such as NFS and NIS.

Examples

To display the pinholes open for Sun RPC services, enter the **show sunrpc-server active** command. The following is sample output from the **show sunrpc-server active** command:

```
hostname# show sunrpc-server active
        LOCAL           FOREIGN                 SERVICE TIMEOUT
        -----------------------------------------------
        192.168.100.2/0 209.165.200.5/32780     100005 00:10:00
```

Related Commands

Command	Description
clear configure sunrpc-server	Clears the Sun remote processor call services from the ASA.
clear sunrpc-server active	Clears the pinholes opened for Sun RPC services, such as NFS or NIS.
inspect sunrpc	Enables or disables Sun RPC application inspection and configures the port used.
show running-config sunrpc-server	Displays information about the SunRPC services configuration.

show switch mac-address-table

For models with a built-in switch, such as the ASA 5505 adaptive security appliance, use the **show switch mac-address-table** command in privileged EXEC mode to view the switch MAC address table.

show switch mac-address-table

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command is for models with built-in switches only. The switch MAC address table maintains the MAC address-to-switch port mapping for traffic within each VLAN in the switch hardware. If you are in transparent firewall mode, use the **show mac-address-table** command to view the bridge MAC address table in the ASA software. The bridge MAC address table maintains the MAC address-to-VLAN interface mapping for traffic that passes between VLANs.

MAC address entries age out in 5 minutes.

Examples

The following is sample output from the **show switch mac-address-table** command.

```
hostname# show switch mac-address-table
Legend: Age - entry expiration time in seconds

   Mac Address  | VLAN |       Type       | Age | Port
-----------------------------------------------------
 000e.0c4e.2aa4 | 0001 |     dynamic      | 287 | Et0/0
 0012.d927.fb03 | 0001 |     dynamic      | 287 | Et0/0
 0013.c4ca.8a8c | 0001 |     dynamic      | 287 | Et0/0
 00b0.6486.0c14 | 0001 |     dynamic      | 287 | Et0/0
 00d0.2bff.449f | 0001 |     static       |  -  | In0/1
 0100.5e00.000d | 0001 | static multicast |  -  | In0/1,Et0/0-7
Total Entries: 6
```

Table 58-4 shows each field description:

Table 58-4 show switch mac-address-table Fields

Field	Description
Mac Address	Shows the MAC address.
VLAN	Shows the VLAN associated with the MAC address.
Type	Shows if the MAC address was learned dynamically, as a static multicast address, or statically. The only static entry is for the internal backplane interface.
Age	Shows the age of a dynamic entry in the MAC address table.
Port	Shows the switch port through which the host with the MAC address can be reached.

Related Commands

Command	Description
show mac-address-table	Shows the MAC address table for models that do not have a built-in switch.
show switch vlan	Shows the VLAN and physical MAC address association.

show switch vlan

For models with a built-in switch, such as the ASA 5505 adaptive security appliance, use the **show switch vlan** command in privileged EXEC mode to view the VLANs and the associated switch ports.

show switch vlan

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
	Routed	Transparent	Single	Multiple	
				Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command is for models with built-in switches only. For other models, use the **show vlan** command.

Examples

The following is sample output from the **show switch vlan** command.

```
hostname# show switch vlan

VLAN Name                            Status    Ports
---- ------------------------------- --------- -------------
100  inside                          up        Et0/0, Et0/1
200  outside                         up        Et0/7
300  -                               down      Et0/1, Et0/2
400  backup                          down      Et0/3
```

Table 58-4 shows each field description:

Table 58-5 show switch vlan Fields

Field	Description
VLAN	Shows the VLAN number.
Name	Shows the name of the VLAN interface. If no name is set using the **nameif** command, or if there is no **interface vlan** command, the display shows a dash (-).

Table 58-5 show switch vlan Fields (continued)

Field	Description
Status	Shows the status, up or down, to receive and send traffic to and from the VLAN in the switch. At least one switch port in the VLAN needs to be in an up state for the VLAN state to be up.
Ports	Shows the switch ports assigned to each VLAN. If a switch port is listed for multiple VLANs, it is a trunk port. The above sample output shows Ethernet 0/1 is a trunk port that carries VLAN 100 and 300.

Related Commands

Command	Description
clear interface	Clears counters for the **show interface** command.
interface vlan	Creates a VLAN interface and enters interface configuration mode.
show interface	Displays the runtime status and statistics of interfaces.
show vlan	Shows the VLANs for models that do not have built-in switches.
switchport mode	Sets the mode of the switch port to access or trunk mode.

CHAPTER 59

show tcpstat through show traffic Commands

show tcpstat

To display the status of the ASA TCP stack and the TCP connections that are terminated on the ASA (for debugging), use the **show tcpstat** command in privileged EXEC mode. This command supports IPv4 and IPv6 addresses.

show tcpstat

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show tcpstat** command allows you to display the status of the TCP stack and TCP connections that are terminated on the ASA. The TCP statistics displayed are described in Table 28.

Table 59-1 TCP Statistics in the show tcpstat Command

Statistic	Description
tcb_cnt	Number of TCP users.
proxy_cnt	Number of TCP proxies. TCP proxies are used by user authorization.
tcp_xmt pkts	Number of packets that were transmitted by the TCP stack.
tcp_rcv good pkts	Number of good packets that were received by the TCP stack.
tcp_rcv drop pkts	Number of received packets that the TCP stack dropped.
tcp bad chksum	Number of received packets that had a bad checksum.
tcp user hash add	Number of TCP users that were added to the hash table.
tcp user hash add dup	Number of times a TCP user was already in the hash table when trying to add a new user.
tcp user srch hash hit	Number of times a TCP user was found in the hash table when searching.

Table 59-1 TCP Statistics in the show tcpstat Command (continued)

Statistic	Description
tcp user srch hash miss	Number of times a TCP user was not found in the hash table when searching.
tcp user hash delete	Number of times that a TCP user was deleted from the hash table.
tcp user hash delete miss	Number of times that a TCP user was not found in the hash table when trying to delete the user.
lip	Local IP address of the TCP user.
fip	Foreign IP address of the TCP user.
lp	Local port of the TCP user.
fp	Foreign port of the TCP user.
st	State (see RFC 793) of the TCP user. The possible values are as follows: 1 CLOSED 2 LISTEN 3 SYN_SENT 4 SYN_RCVD 5 ESTABLISHED 6 FIN_WAIT_1 7 FIN_WAIT_2 8 CLOSE_WAIT 9 CLOSING 10 LAST_ACK 11 TIME_WAIT
rexqlen	Length of the retransmit queue of the TCP user.
inqlen	Length of the input queue of the TCP user.
tw_timer	Value of the time_wait timer (in milliseconds) of the TCP user.
to_timer	Value of the inactivity timeout timer (in milliseconds) of the TCP user.
cl_timer	Value of the close request timer (in milliseconds) of the TCP user.
per_timer	Value of the persist timer (in milliseconds) of the TCP user.
rt_timer	Value of the retransmit timer (in milliseconds) of the TCP user.
tries	Retransmit count of the TCP user.

Examples

This example shows how to display the status of the TCP stack on the ASA:

```
hostname# show tcpstat
                CURRENT MAX      TOTAL
tcb_cnt         2       12       320
proxy_cnt       0       0        160

tcp_xmt pkts = 540591
tcp_rcv good pkts = 6583
tcp_rcv drop pkts = 2
```

```
tcp bad chksum = 0
tcp user hash add = 2028
tcp user hash add dup = 0
tcp user srch hash hit = 316753
tcp user srch hash miss = 6663
tcp user hash delete = 2027
tcp user hash delete miss = 0

lip = 172.23.59.230 fip = 10.21.96.254 lp = 443 fp = 2567 st = 4 rexqlen = 0
in0
  tw_timer = 0 to_timer = 179000 cl_timer = 0 per_timer = 0
rt_timer = 0
tries 0
```

Related Commands

Command	Description
show conn	Displays the connections used and those that are available.

show tech-support

To display the information that is used for diagnosis by technical support analysts, use the **show tech-support** command in privileged EXEC mode.

show tech-support [**detail** | **file** | **no-config**]

Syntax Description

detail	(Optional) Lists detailed information.
file	(Optional) Writes the output of the command to a file.
no-config	(Optional) Excludes the output of the running configuration.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	The **detail** and **file** keywords were added.
7.2(1)	The output was enhanced to display more detailed information about processes that hog the CPU.
9.1(2)	The output was enhanced to include information from the **show environment** command.
9.1(3)	The output was enhanced to include information from the **show memory detail, show memory top-usage,** and **show vlan** commands.

Usage Guidelines

The **show tech-suppor**t command lets you list information that technical support analysts need to help you diagnose problems. This command combines the output from the **show** commands that provide the most information to a technical support analyst.

Examples

The following example shows how to display information that is used for technical support analysis. The output was shortened to begin with output from the **show module** command.

```
hostname# show tech-support | beg show module

Related Commands

Command	Description
show clock	Displays the clock for use with the Syslog Server (PFSS) and the Public Key Infrastructure (PKI) protocol.
show conn count	Displays the connections used and available.
show cpu	Display the CPU utilization information.
show failover	Displays the status of a connection and which ASA is active
show memory	Displays a summary of the maximum physical memory and current free memory that is available to the operating system.
show perfmon	Displays information about the performance of the ASA
show processes	Displays a list of the processes that are running.
show running-config	Displays the configuration that is currently running on the ASA.
show xlate	Displays information about the translation slot.

show threat-detection memory

To show the memory used by advanced threat detection statistics, which are enabled by the **threat-detection statistics** command, use the **show threat-detection memory** command in privileged EXEC mode.

show threat-detection memory

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

Some statistics can use a lot of memory and can affect ASA performance. This command lets you monitor memory usage so you can adjust your configuration if necessary.

Examples

The following is sample output from the **show threat-detection memory** command:

```
hostname# show threat-detection memory
Cached chunks:
       CACHE TYPE             BYTES USED
TD Host                         70245888
TD Port                             2724
TD Protocol                         1476
TD ACE                               728
TD Shared counters                 14256
============================
Subtotal TD Chunks              70265072

Regular memory                BYTES USED
TD Port                             33824
TD Control block                   162064
============================
Subtotal Regular Memory            195888
```

```
Total TD memory:                70460960
```

Related Commands

Command	Description
show threat-detection statistics host	Shows the host statistics.
show threat-detection statistics port	Shows the port statistics.
show threat-detection statistics protocol	Shows the protocol statistics.
show threat-detection statistics top	Shows the top 10 statistics.
threat-detection statistics	Enables advanced threat-detection statistics.

show threat-detection rate

When you enable basic threat detection using the **threat-detection basic-threat** command, you can view statistics using the **show threat-detection rate** command in privileged EXEC mode.

show threat-detection rate [**min-display-rate** *min_display_rate*] [**acl-drop** | **bad-packet-drop** | **conn-limit-drop** | **dos-drop** | **fw-drop** | **icmp-drop** | **inspect-drop** | **interface-drop** | **scanning-threat** | **syn-attack**]

Syntax Description

acl-drop	(Optional) Shows the rate for dropped packets caused by denial by access lists.
min-display-rate *min_display_rate*	(Optional) Limits the display to statistics that exceed the minimum display rate in events per second. You can set the *min_display_rate* between 0 and 2147483647.
bad-packet-drop	(Optional) Shows the rate for dropped packets caused by denial by a bad packet format (such as invalid-ip-header or invalid-tcp-hdr-length).
conn-limit-drop	(Optional) Shows the rate for dropped packets caused by the connection limits being exceeded (both system-wide resource limits, and limits set in the configuration).
dos-drop	(Optional) Shows the rate for dropped packets caused by a detected DoS attack (such as an invalid SPI, Stateful Firewall check failure).
fw-drop	(Optional) Shows the rate for dropped packets caused by basic firewall check failure. This option is a combined rate that includes all firewall-related packet drops in this command. It does not include non-firewall-related drops such as **interface-drop**, **inspect-drop**, and **scanning-threat**.
icmp-drop	(Optional) Shows the rate for dropped packets caused by denial by suspicious ICMP packets detected.
inspect-drop	(Optional) Shows the rate limit for dropped packets caused by packets failing application inspection.
interface-drop	(Optional) Shows the rate limit for dropped packets caused by an interface overload.
scanning-threat	(Optional) Shows the rate for dropped packets caused by a scanning attack detected. This option monitors scanning attacks; for example, the first TCP packet is not a SYN packet, or the TCP connection failed the 3-way handshake. Full scanning threat detection (see the **threat-detection scanning-threat** command) takes this scanning attack rate information and acts on it by classifying hosts as attackers and automatically shunning them, for example.
syn-attack	(Optional) Shows the rate for dropped packets caused by an incomplete session, such as TCP SYN attack or no data UDP session attack.

Defaults

If you do not specify an event type, all events are shown.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
	Routed	Transparent	Single	Multiple Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.
8.2(1)	The burst rate interval changed from 1/60th to 1/30th of the average rate.
8.2(2)	For threat events, the severity level was changed from a warning to a notification. Threat events can be triggered every five minutes.

Usage Guidelines

The display output shows the following:

- The average rate in events/sec over fixed time periods
- The current burst rate in events/sec over the last completed burst interval, which is 1/30th of the average rate interval or 10 seconds, whichever is larger
- The number of times the rates were exceeded
- The total number of events over the fixed time periods.

The ASA computes the event counts 30 times over the average rate interval; in other words, the ASA checks the rate at the end of each burst period, for a total of 30 completed burst intervals. The unfinshed burst interval presently occurring is not included in the average rate. For example, if the average rate interval is 10 minutes, then the burst interval is 10 seconds. If the last burst interval was from 3:00:00 to 3:00:10, and you use the **show** command at 3:00:15, then the last 5 seconds are not included in the output.

The only exception to this rule is if the number of events in the unfinished burst interval already exceeds the number of events in the oldest burst interval (#1 of 30) when calculating the total events. In that case, the ASA calculates the total events as the last 59 complete intervals, plus the events so far in the unfinished burst interval. This exception lets you monitor a large increase in events in real time.

Examples

The following is sample output from the **show threat-detection rate** command:

```
hostname# show threat-detection rate

                      Average(eps)    Current(eps) Trigger         Total events

threat-detection scanning-threat	Enables scanning threat detection.

show threat-detection shun

If you enable scanning threat detection with the **threat-detection scanning-threat** command, and you automatically shun attacking hosts, then view the currently shunned hosts using the **show threat-detection shun** command in privileged EXEC mode.

show threat-detection shun

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.
8.2(2)	For threat events, the severity level was changed from a warning to a notification. Threat events can be triggered every five minutes.

Usage Guidelines

To release a host from being shunned, use the **clear threat-detection shun** command.

Examples

The following is sample output from the **show threat-detection shun** command:

```
hostname# show threat-detection shun
Shunned Host List:
10.1.1.6
198.1.6.7
```

Related Commands

Command	Description
clear threat-detection shun	Releases hosts from being shunned.
show threat-detection statistics host	Shows the host statistics.
show threat-detection statistics protocol	Shows the protocol statistics.
show threat-detection statistics top	Shows the top 10 statistics.
threat-detection scanning-threat	Enables scanning threat detection.

show threat-detection statistics host

After you enable threat statistics with the **threat-detection statistics host** command, view host statistics using the **show threat-detection statistics host** command in privileged EXEC mode. Threat detection statistics show both allowed and dropped traffic rates.

show threat-detection statistics [**min-display-rate** *min_display_rate*] **host** [*ip_address* [*mask*]]

Syntax Description

ip_address	(Optional) Shows statistics for a particular host.
mask	(Optional) Sets the subnet mask for the host IP address.
min-display-rate *min_display_rate*	(Optional) Limits the display to statistics that exceed the minimum display rate in events per second. You can set the *min_display_rate* between 0 and 2147483647.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.
8.2(1)	The burst rate interval changed from 1/60th to 1/30th of the average rate.
8.2(2)	For threat events, the severity level was changed from a warning to a notification. Threat events can be triggered every five minutes.

Usage Guidelines

The display output shows the following:

- The average rate in events/sec over fixed time periods.
- The current burst rate in events/sec over the last completed burst interval, which is 1/30th of the average rate interval or 10 seconds, whichever is larger
- The number of times the rates were exceeded (for dropped traffic statistics only)
- The total number of events over the fixed time periods.

The ASA computes the event counts 30 times over the average rate interval; in other words, the ASA checks the rate at the end of each burst period, for a total of 30 completed burst intervals. The unfinished burst interval presently occurring is not included in the average rate. For example, if the average rate

interval is 20 minutes, then the burst interval is 20 seconds. If the last burst interval was from 3:00:00 to 3:00:20, and you use the **show** command at 3:00:25, then the last 5 seconds are not included in the output.

The only exception to this rule is if the number of events in the unfinished burst interval already exceeds the number of events in the oldest burst interval (#1 of 30) when calculating the total events. In that case, the ASA calculates the total events as the last 29 complete intervals, plus the events so far in the unfinished burst interval. This exception lets you monitor a large increase in events in real time.

Examples

The following is sample output from the **show threat-detection statistics host** command:

```
hostname# show threat-detection statistics host

                        Average(eps)    Current(eps) Trigger         Total events

 24-hour Recv byte:                  0               0       0                   706
  1-hour Recv pkts:                  0               0       0                     7
```

Table 59-2 shows each field description.

Table 59-2 show threat-detection statistics host Fields

Field	Description
Host	Shows the host IP address.
tot-ses	Shows the total number of sessions for this host since it was added to the database.
act-ses	Shows the total number of active sessions that the host is currently involved in.

Table 59-2 show threat-detection statistics host Fields (continued)

Field	Description
fw-drop	Shows the number of firewall drops. Firewall drops is a combined rate that includes all firewall-related packet drops tracked in basic threat detection, including access list denials, bad packets, exceeded connection limits, DoS attack packets, suspicious ICMP packets, TCP SYN attack packets, and no data UDP attack packets. It does not include non-firewall-related drops such as interface overload, packets failed at application inspection, and scanning attack detected.
insp-drop	Shows the number of packets dropped because they failed application inspection.
null-ses	Shows the number of null sessions, which are TCP SYN sessions that did not complete within the 30-second timeout, and UDP sessions that did not have any data sent by its server 3 seconds after the session starts.
bad-acc	Shows the number of bad access attempts to host ports that are in a closed state. When a port is determined to be in a null session (see above), the port state of the host is set to HOST_PORT_CLOSE. Any client accessing the port of the host is immediately classified as a bad access without the need to wait for a timeout.
Average(eps)	Shows the average rate in events/sec over each time period. The security appliance stores the count at the end of each burst period, for a total of 30 completed burst intervals. The unfinished burst interval presently occurring is not included in the average rate. For example, if the average rate interval is 20 minutes, then the burst interval is 20 seconds. If the last burst interval was from 3:00:00 to 3:00:20, and you use the **show** command at 3:00:25, then the last 5 seconds are not included in the output. The only exception to this rule is if the number of events in the unfinished burst interval already exceeds the number of events in the oldest burst interval (#1 of 30) when calculating the total events. In that case, the ASA calculates the total events as the last 29 complete intervals, plus the events so far in the unfinished burst interval. This exception lets you monitor a large increase in events in real time.
Current(eps)	Shows the current burst rate in events/sec over the last completed burst interval, which is 1/30th of the average rate interval or 10 seconds, whichever is larger. For the example specified in the Average(eps) description, the current rate is the rate from 3:19:30 to 3:20:00
Trigger	Shows the number of times the dropped packet rate limits were exceeded. For valid traffic identified in the sent and received bytes and packets rows, this value is always 0, because there are no rate limits to trigger for valid traffic.
Total events	Shows the total number of events over each rate interval. The unfinished burst interval presently occurring is not included in the total events. The only exception to this rule is if the number of events in the unfinished burst interval already exceeds the number of events in the oldest burst interval (#1 of 30) when calculating the total events. In that case, the ASA calculates the total events as the last 29 complete intervals, plus the events so far in the unfinished burst interval. This exception lets you monitor a large increase in events in real time.

Table 59-2 show threat-detection statistics host Fields (continued)

Field	Description
20-min, 1-hour, 8-hour, and 24-hour	By default, there are three rate intervals shown. You can reduce the number of rate intervals using the **threat-detection statistics host number-of-rate** command. Because host statistics use a lot of memory, reducing the number of rate intervals from the default of 3 reduces the memory usage. If you set this keyword to 1, then only the shortest rate interval statistics are maintained. If you set the value to 2, then the two shortest intervals are maintained.
Sent byte	Shows the number of successful bytes sent from the host.
Sent pkts	Shows the number of successful packets sent from the host.
Sent drop	Shows the number of packets sent from the host that were dropped because they were part of a scanning attack.
Recv byte	Shows the number of successful bytes received by the host.
Recv pkts	Shows the number of successful packets received by the host.
Recv drop	Shows the number of packets received by the host that were dropped because they were part of a scanning attack.

Related Commands

Command	Description
threat-detection scanning-threat	Enables scanning threat detection.
show threat-detection statistics top	Shows the top 10 statistics.
show threat-detection statistics port	Shows the port statistics.
show threat-detection statistics protocol	Shows the protocol statistics.
threat-detection statistics	Enables threat statistics.

show threat-detection statistics port

After you enable threat statistics with the **threat-detection statistics port** command, view TCP and UDP port statistics using the **show threat-detection statistics port** command in privileged EXEC mode. Threat detection statistics show both allowed and dropped traffic rates.

show threat-detection statistics [**min-display-rate** *min_display_rate*] **port** [*start_port*[**-***end_port*]]

Syntax Description

start_port[**-***end_port*]	(Optional) Shows statistics for a particular port or range of ports, between 0 and 65535.
min-display-rate *min_display_rate*	(Optional) Limits the display to statistics that exceed the minimum display rate in events per second. You can set the *min_display_rate* between 0 and 2147483647.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.
8.2(1)	The burst rate interval changed from 1/60th to 1/30th of the average rate.
8.2(2)	For threat events, the severity level was changed from a warning to a notification. Threat events can be triggered every five minutes.

Usage Guidelines

The display output shows the following:

- The average rate in events/sec over fixed time periods.
- The current burst rate in events/sec over the last completed burst interval, which is 1/30th of the average rate interval or 10 seconds, whichever is larger
- The number of times the rates were exceeded (for dropped traffic statistics only)
- The total number of events over the fixed time periods.

The ASA computes the event counts 30 times over the average rate interval; in other words, the ASA checks the rate at the end of each burst period, for a total of 30 completed burst intervals. The unfinished burst interval presently occurring is not included in the average rate. For example, if the average rate

interval is 20 minutes, then the burst interval is 20 seconds. If the last burst interval was from 3:00:00 to 3:00:20, and you use the **show** command at 3:00:25, then the last 5 seconds are not included in the output.

The only exception to this rule is if the number of events in the unfinished burst interval already exceeds the number of events in the oldest burst interval (#1 of 30) when calculating the total events. In that case, the ASA calculates the total events as the last 29 complete intervals, plus the events so far in the unfinished burst interval. This exception lets you monitor a large increase in events in real time.

Examples

The following is sample output from the **show threat-detection statistics port** command:

```
hostname# show threat-detection statistics port

show threat-detection statistics top	Shows the top 10 statistics.
show threat-detection statistics host	Shows the host statistics.
show threat-detection statistics protocol	Shows the protocol statistics.
threat-detection statistics	Enables threat statistics.

show threat-detection statistics protocol

After you enable threat statistics with the **threat-detection statistics protocol** command, view IP protocol statistics using the **show threat-detection statistics protocol** command in privileged EXEC mode. Threat detection statistics show both allowed and dropped traffic rates.

show threat-detection statistics [**min-display-rate** *min_display_rate*] **protocol** [*protocol_number* | *protocol_name*]

Syntax Description

protocol_number	(Optional) Shows statistics for a specific protocol number, between 0 and 255.
min-display-rate *min_display_rate*	(Optional) Limits the display to statistics that exceed the minimum display rate in events per second. You can set the *min_display_rate* between 0 and 2147483647.
protocol_name	(Optional) Shows statistics for a specific protocol name: • **ah** • **eigrp** • **esp** • **gre** • **icmp** • **igmp** • **igrp** • **ip** • **ipinip** • **ipsec** • **nos** • **ospf** • **pcp** • **pim** • **pptp** • **snp** • **tcp** • **udp**

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.
8.2(1)	The burst rate interval changed from 1/60th to 1/30th of the average rate.
8.2(2)	For threat events, the severity level was changed from a warning to a notification. Threat events can be triggered every five minutes.

Usage Guidelines

The display output shows the following:

- The average rate in events/sec over fixed time periods.
- The current burst rate in events/sec over the last completed burst interval, which is 1/30th of the average rate interval or 10 seconds, whichever is larger
- The number of times the rates were exceeded (for dropped traffic statistics only)
- The total number of events over the fixed time periods.

The ASA computes the event counts 30 times over the average rate interval; in other words, the ASA checks the rate at the end of each burst period, for a total of 30 completed burst intervals. The unfinished burst interval presently occurring is not included in the average rate. For example, if the average rate interval is 20 minutes, then the burst interval is 20 seconds. If the last burst interval was from 3:00:00 to 3:00:20, and you use the **show** command at 3:00:25, then the last 5 seconds are not included in the output.

The only exception to this rule is if the number of events in the unfinished burst interval already exceeds the number of events in the oldest burst interval (#1 of 30) when calculating the total events. In that case, the ASA calculates the total events as the last 29 complete intervals, plus the events so far in the unfinished burst interval. This exception lets you monitor a large increase in events in real time.

Examples

The following is sample output from the **show threat-detection statistics protocol** command:

```
hostname# show threat-detection statistics protocol

                           Average(eps)    Current(eps) Trigger         Total events
ICMP: tot-ses:0 act-ses:0
  1-hour Sent byte:                   0               0       0                 1000
  8-hour Sent byte:                   0               2       0                 1000

  8-hour Sent pkts:                   0               0       0                   10
 24-hour Sent pkts:                   0               0       0                   10
```

Table 59-2 shows each field description.

Table 59-4 show threat-detection statistics protocol Fields

Field	Description
Average(eps)	Shows the average rate in events/sec over each time period. The security appliance stores the count at the end of each burst period, for a total of 30 completed burst intervals. The unfinished burst interval presently occurring is not included in the average rate. For example, if the average rate interval is 20 minutes, then the burst interval is 20 seconds. If the last burst interval was from 3:00:00 to 3:00:20, and you use the **show** command at 3:00:25, then the last 5 seconds are not included in the output. The only exception to this rule is if the number of events in the unfinished burst interval already exceeds the number of events in the oldest burst interval (#1 of 30) when calculating the total events. In that case, the ASA calculates the total events as the last 29 complete intervals, plus the events so far in the unfinished burst interval. This exception lets you monitor a large increase in events in real time.
Current(eps)	Shows the current burst rate in events/sec over the last completed burst interval, which is 1/30th of the average rate interval or 10 seconds, whichever is larger. For the example specified in the Average(eps) description, the current rate is the rate from 3:19:30 to 3:20:00
Trigger	Shows the number of times the dropped packet rate limits were exceeded. For valid traffic identified in the sent and received bytes and packets rows, this value is always 0, because there are no rate limits to trigger for valid traffic.
Total events	Shows the total number of events over each rate interval. The unfinished burst interval presently occurring is not included in the total events. The only exception to this rule is if the number of events in the unfinished burst interval already exceeds the number of events in the oldest burst interval (#1 of 30) when calculating the total events. In that case, the ASA calculates the total events as the last 29 complete intervals, plus the events so far in the unfinished burst interval. This exception lets you monitor a large increase in events in real time.
protocol_number/ *protocol_name*	Shows the protocol number and name where the packet or byte was sent, received, or droppped.
tot-ses	Not currently used.
act-ses	Not currently used.
20-min, 1-hour, 8-hour, and 24-hour	Shows statistics for these fixed rate intervals.
Sent byte	Shows the number of successful bytes sent from the protocol.
Sent pkts	Shows the number of successful packets sent from the protocol.
Sent drop	Shows the number of packets sent from the protocol that were dropped because they were part of a scanning attack.
Recv byte	Shows the number of successful bytes received by the protocol.

Table 59-4 show threat-detection statistics protocol Fields (continued)

Field	Description
Recv pkts	Shows the number of successful packets received by the protocol.
Recv drop	Shows the number of packets received by the protocol that were dropped because they were part of a scanning attack.

Related Commands

Command	Description
threat-detection scanning-threat	Enables scanning threat detection.
show threat-detection statistics top	Shows the top 10 statistics.
show threat-detection statistics port	Shows the port statistics.
show threat-detection statistics host	Shows the host statistics.
threat-detection statistics	Enables threat statistics.

show threat-detection statistics top

After you enable threat statistics with the **threat-detection statistics** command, view the top 10 statistics using the **show threat-detection statistics top** command in privileged EXEC mode. If you did not enable the threat detection statistics for a particular type, then you cannot view those statistics with this command. Threat detection statistics show both allowed and dropped traffic rates.

show threat-detection statistics [**min-display-rate** *min_display_rate*] **top** [[**access-list** | **host** | **port-protocol**] [**rate-1** | **rate-2** | **rate-3**] | **tcp-intercept** [**all**] [**detail**] [**long**]]

Syntax Description

access-list	(Optional) Shows the top 10 ACEs that that match packets, including both permit and deny ACEs. Permitted and denied traffic are not differentiated in this display. If you enable basic threat detection using the **threat-detection basic-threat** command, you can track access list denies using the **show threat-detection rate access-list** command.
all	(Optional) For TCP Intercept, shows the history data of all the traced servers.
detail	(Optional) For TCP Intercept, shows history sampling data.
host	(Optional) Shows the top 10 host statistics for each fixed time period. **Note** Due to the threat detection algorithm, an interface used for a failover link or state link could appear as one of the top 10 hosts. This occurrence is more likely when you use one interface for both the failover and state link. This is expected behavior, and you can ignore this IP address in the display.
long	(Optional) Shows the statistical history in a long format, with the real IP address and the untranslated IP address of the server.
min-display-rate *min_display_rate*	(Optional) Limits the display to statistics that exceed the minimum display rate in events per second. You can set the *min_display_rate* between 0 and 2147483647.
port-protocol	(Optional) Shows the top 10 combined statistics of TCP/UDP port and IP protocol types. TCP (protocol 6) and UDP (protocol 17) are not included in the display for IP protocols; TCP and UDP ports are, however, included in the display for ports. If you only enable statistics for one of these types, port or protocol, then you will only view the enabled statistics.
rate-1	(Optional) Shows the statistics for the smallest fixed rate intervals available in the display. For example, if the display shows statistics for the last 1 hour, 8 hours, and 24 hours, then when you use the **rate-1** keyword, the ASA shows only the 1 hour time interval.
rate-2	(Optional) Shows the statistics for the middle fixed rate intervals available in the display. For example, if the display shows statistics for the last 1 hour, 8 hours, and 24 hours, then when you use the **rate-2** keyword, the ASA shows only the 8 hour time interval.
rate-3	(Optional) Shows the statistics for the largest fixed rate intervals available in the display. For example, if the display shows statistics for the last 1 hour, 8 hours, and 24 hours, then when you use the **rate-3** keyword, the ASA shows only the 24 hour time interval.
tcp-intercept	Shows TCP Intercept statistics. The display includes the top 10 protected servers under attack.

Defaults

If you do not specify an event type, all events are shown.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.
8.0(4)	The **tcp-intercept** keyword was added.
8.2(1)	The burst rate interval changed from 1/60th to 1/30th of the average rate.
8.2(2)	The **long** keyword was added for **tcp-intercept**. For threat events, the severity level was changed from a warning to a notification. Threat events can be triggered every five minutes.

Usage Guidelines

The display output shows the following:

- The average rate in events/sec over fixed time periods.
- The current burst rate in events/sec over the last completed burst interval, which is 1/30th of the average rate interval or 10 seconds, whichever is larger
- The number of times the rates were exceeded (for dropped traffic statistics only)
- The total number of events over the fixed time periods.

The ASA computes the event counts 30 times over the average rate interval; in other words, the ASA checks the rate at the end of each burst period, for a total of 30 completed burst intervals. The unfinished burst interval presently occurring is not included in the average rate. For example, if the average rate interval is 20 minutes, then the burst interval is 20 seconds. If the last burst interval was from 3:00:00 to 3:00:20, and you use the **show** command at 3:00:25, then the last 5 seconds are not included in the output.

The only exception to this rule is if the number of events in the unfinished burst interval already exceeds the number of events in the oldest burst interval (#1 of 30) when calculating the total events. In that case, the ASA calculates the total events as the last 29 complete intervals, plus the events so far in the unfinished burst interval. This exception lets you monitor a large increase in events in real time.

Examples

The following is sample output from the **show threat-detection statistics top access-list** command:

```
hostname# show threat-detection statistics top access-list

                    Top     Average(eps)     Current(eps) Trigger         Total events
  1-hour ACL hits:
              100/3[0]              173                0       0               623488
              200/2[1]               43                0       0               156786
              100/1[2]               43                0       0               156786
```

```
8-hour ACL hits:
            100/3[0]              21            1298        0              623488
            200/2[1]               5             326        0              156786
            100/1[2]               5             326        0              156786
```

Table 59-2 shows each field description.

Table 59-5 show threat-detection statistics top access-list Fields

Field	Description
Top	Shows the ranking of the ACE within the time period, from [0] (highest count) to [9] (lowest count). You might not have enough statistics for all 10 positions, so less then 10 ACEs might be listed.
Average(eps)	Shows the average rate in events/sec over each time period. The security appliance stores the count at the end of each burst period, for a total of 30 completed burst intervals. The unfinished burst interval presently occurring is not included in the average rate. For example, if the average rate interval is 20 minutes, then the burst interval is 20 seconds. If the last burst interval was from 3:00:00 to 3:00:20, and you use the **show** command at 3:00:25, then the last 5 seconds are not included in the output. The only exception to this rule is if the number of events in the unfinished burst interval already exceeds the number of events in the oldest burst interval (#1 of 30) when calculating the total events. In that case, the ASA calculates the total events as the last 29 complete intervals, plus the events so far in the unfinished burst interval. This exception lets you monitor a large increase in events in real time.
Current(eps)	Shows the current burst rate in events/sec over the last completed burst interval, which is 1/30th of the average rate interval or 10 seconds, whichever is larger. For the example specified in the Average(eps) description, the current rate is the rate from 3:19:30 to 3:20:00.
Trigger	This column is always 0, because there are no rate limits triggered by access list traffic; denied and permitted traffic are not differentiated in this display. If you enable basic threat detection using the **threat-detection basic-threat** command, you can track access list denies using the **show threat-detection rate access-list** command.
Total events	Shows the total number of events over each rate interval. The unfinished burst interval presently occurring is not included in the total events. The only exception to this rule is if the number of events in the unfinished burst interval already exceeds the number of events in the oldest burst interval (#1 of 30) when calculating the total events. In that case, the ASA calculates the total events as the last 29 complete intervals, plus the events so far in the unfinished burst interval. This exception lets you monitor a large increase in events in real time.
1-hour, 8-hour	Shows statistics for these fixed rate intervals.
acl_name/line_number	Shows the access list name and line number of the ACE that caused the denies.

The following is sample output from the **show threat-detection statistics top access-list rate-1** command:

```
hostname# show threat-detection statistics top access-list rate-1
```

```
                  Top     Average(eps)     Current(eps) Trigger          Total events
  1-hour ACL hits:
              100/3[0]              173                0       0                623488
              200/2[1]               43                0       0                156786
              100/1[2]               43                0       0                156786
```

The following is sample output from the **show threat-detection statistics top port-protocol** command:

```
hostname# show threat-detection statistics top port-protocol

```

Table 59-6 shows each field description.

Table 59-6 show threat-detection statistics top port-protocol Fields

Field	Description
Top	Shows the ranking of the port or protocol within the time period/type of statistic, from [0] (highest count) to [9] (lowest count). You might not have enough statistics for all 10 positions, so less then 10 ports/protocols might be listed.
Name	Shows the port/protocol name.
Id	Shows the port/protocol ID number. The asterisk (*) means the ID is an IP protocol number.
Average(eps)	See the description in Table 59-2.
Current(eps)	See the description in Table 59-2.
Trigger	Shows the number of times the dropped packet rate limits were exceeded. For valid traffic identified in the sent and received bytes and packets rows, this value is always 0, because there are no rate limits to trigger for valid traffic.

Table 59-6 show threat-detection statistics top port-protocol Fields (continued)

Field	Description
Total events	See the description in Table 59-2.
Time_interval Sent byte	Shows the number of successful bytes sent from the listed ports and protocols for each time period.
Time_interval Sent packet	Shows the number of successful packets sent from the listed ports and protocols for each time period.
Time_interval Sent drop	Shows the number of packets sent for each time period from the listed ports and protocols that were dropped because they were part of a scanning attack.
Time_interval Recv byte	Shows the number of successful bytes received by the listed ports and protocols for each time period.
Time_interval Recv packet	Shows the number of successful packets received by the listed ports and protocols for each time period.
Time_interval Recv drop	Shows the number of packets received for each time period by the listed ports and protocols that were dropped because they were part of a scanning attack.
port_number/ *port_name*	Shows the port number and name where the packet or byte was sent, received, or droppped.
protocol_number/ *protocol_name*	Shows the protocol number and name where the packet or byte was sent, received, or droppped.

The following is sample output from the **show threat-detection statistics top host** command:

```
hostname# show threat-detection statistics top host

                  Top    Average(eps)    Current(eps) Trigger         Total events

```

Table 59-8 shows each field description.

Table 59-8 show threat-detection statistics top tcp-intercept Fields

Field	Description
Monitoring window size:	Shows the period of time over which the ASA samples data for statistics. The default is 30 minutes. You can change this setting using the **threat-detection statistics tcp-intercept rate-interval** command. The ASA samples data 30 times during this interval.
Sampling interval:	Shows the interval between samples. This value is always the rate interval divided by 30.
rank	Shows the ranking, 1 through 10, where 1 is the most attacked server, and 10 is the least attacked server.
server_ip:port	Shows the server IP address and the port on which it is being attacked.
interface	Shows the inerface through which the server is being attacked.
avg_rate	Shows the average rate of attack, in attacks per second over the sampling period
current_rate	Shows the current attack rate, in attacks per second.
total	Shows the total number of attacks.
attacker_ip	Shows the attacker IP address.
(*last_attack_time* ago)	Shows when the last attack occurred.

The following is sample output from the **show threat-detection statistics top tcp-intercept long** command with the real source IP address in parentheses:

```
hostname# show threat-detection statistics top tcp-intercept long

Top 10 protected servers under attack (sorted by average rate)
Monitoring window size: 30 mins    Sampling interval: 30 secs
<Rank> <Server IP:Port (Real IP:Real Port)> <Interface> <Ave Rate> <Cur Rate> <Total>
<Source IP (Last Attack Time)>
--------------------------------------------------------------------------------

Table 59-9 shows each field description.

Table 59-9 show threat-detection statistics top tcp-intercept detail Fields

Field	Description
Monitoring window size:	Shows the period of time over which the ASA samples data for statistics. The default is 30 minutes. You can change this setting using the **threat-detection statistics tcp-intercept rate-interval** command. The ASA samples data 30 times during this interval.
Sampling interval:	Shows the interval between samples. This value is always the rate interval divided by 30.
rank	Shows the ranking, 1 through 10, where 1 is the most attacked server, and 10 is the least attacked server.
server_ip:port	Shows the server IP address and the port on which it is being attacked.
interface	Shows the inerface through which the server is being attacked.
avg_rate	Shows the average rate of attack, in attacks per second over the rate interval set by the **threat-detection statistics tcp-intercept rate-interval** command (by default, the rate interval is 30 minutes). The ASA samples the data every 30 seconds over the rate interval.
current_rate	Shows the current attack rate, in attacks per second.
total	Shows the total number of attacks.
attacker_ip or <various> Last: *attacker_ip*	Shows the attacker IP address. If there is more than one attacker, then "<various>" displays followed by the last attacker IP address.
(*last_attack_time* ago)	Shows when the last attack occurred.
sampling data	Shows all 30 sampling data values, which show the number of attacks at each inerval.

Related Commands

Command	Description
threat-detection scanning-threat	Enables scanning threat detection.
show threat-detection statistics host	Shows the host statistics.
show threat-detection statistics port	Shows the port statistics.
show threat-detection statistics protocol	Shows the protocol statistics.
threat-detection statistics	Enables threat statistics.

show tls-proxy

To display TLS proxy and session information, use the **show tls-proxy** command in global configuration mode.

show tls-proxy *tls_name* [**session** [**host** *host_addr* | **detail** [**cert-dump** | **count**] [**statistics**]]

Syntax Description

cert-dump	Dumps the local dynamic certificate. Output is a hex dump of the LDC.
count	Shows only the session counters.
detail	Shows detailed TLS proxy information including the cipher for each SSL leg and the LDC.
host *host_addr*	Specifies a particular host to show the sessions associated with.
session	Shows active TLS proxy sessions.
statistics	Shows statistics for monitoring and managing TLS sessions.
tls_name	Name of the TLS proxy to show.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC mode	•	•	•	•	•

Command History

Release	Modification
8.0(2)	This command was introduced.
8.3(1)	The **statistics** keyword was added.

Examples

The following is sample output from the **show tls-proxy** command:

```
hostname# show tls-proxy
TLS-Proxy 'proxy': ref_cnt 1, seq#1
    Server proxy:
        Trust-point: local_ccm
    Client proxy:
        Local dynamic certificate issuer: ldc_signer
        Local dynamic certificate key-pair: phone_common
        Cipher-suite <unconfigured>
    Run-time proxies:
        Proxy 0x448b468: Class-map: skinny_ssl, Inspect: skinny
            Active sess 1, most sess 4, byte 3244
```

The following is sample output from the **show tls-proxy session** command:

```
hostname# show tls-proxy session
outside 133.9.0.211:51291 inside 195.168.2.200:2443 P:0x4491a60(proxy)
S:0x482e790 byte 3388
```

The following is sample output from the **show tls-proxy session detail** command:

```
hostname# show tls-proxy session detail
1 in use, 1 most used
outside 133.9.0.211:50433 inside 195.168.2.200:2443 P:0xcba60b60(proxy) S:0xcbc10748 byte
1831704
    Client: State SSLOK  Cipher AES128-SHA Ch 0xca55efc8 TxQSize 0 LastTxLeft 0 Flags 0x1
    Server: State SSLOK  Cipher AES128-SHA Ch 0xca55efa8 TxQSize 0 LastTxLeft 0 Flags 0x9
Local Dynamic Certificate
    Status: Available
    Certificate Serial Number: 29
    Certificate Usage: General Purpose
    Public Key Type: RSA (1024 bits)
    Issuer Name:
        cn=TLS-Proxy-Signer
    Subject Name:
        cn=SEP0002B9EB0AAD
        o=Cisco Systems Inc
        c=US
    Validity Date:
        start date: 00:47:12 PDT Feb 27 2007
        end   date: 00:47:12 PDT Feb 27 2008
    Associated Trustpoints:
```

The following is sample output from the **show tls-proxy session statistics** command:

```
hostname# show tls-proxy session stastics
    TLS Proxy Sessions (Established: 600)
        Mobility:                              200
        UC-IME:                                400

    Per-Session Licensed TLS Proxy Sessions
    (Established: 222, License Limit: 250)
        SIP:                                     2
        SCCP:                                   20
        Phone Proxy:                           200

    Total TLS Proxy Sessions
        Established:                           822
        Platform Limit:                       1000
```

Related Commands

Command	Description
client	Defines a cipher suite and sets the local dynamic certificate issuer or keypair.
ctl-provider	Defines a CTL provider instance and enters provider configuration mode.
show running-config tls-proxy	Shows running configuration of all or specified TLS proxies.
tls-proxy	Defines a TLS proxy instance and sets the maximum sessions.

show track

To display information about object tracked by the tracking process, use the **show track** command in user EXEC mode.

show track [*track-id*]

Syntax Description

track-id	A tracking entry object ID. Valid values are from 1 to 500.

Defaults

If the *track-id* is not provided, then information about all tracking objects is displayed.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following is sample output from the **show track** command:

```
hostname(config)# show track

Track 5
    Response Time Reporter 124 reachability
    Reachability is UP
    2 changes, last change 03:41:16
    Latest operation return code: OK
    Tracked by:
        STATIC-IP-ROUTING 0
```

Related Commands

Command	Description
show running-config track	Displays the **track rtr** commands in the running configuration.
track rtr	Creates a tracking entry to poll the SLA.

show traffic

To display interface transmit and receive activity, use the **show traffic** command in privileged EXEC mode.

show traffic

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.2(1)	Output for the ASA 5550 was added.

Usage Guidelines

The **show traffic** command lists the number of packets and bytes moving through each interface since the last **show traffic** command was entered or since the ASA came online. The number of seconds is the duration the ASA has been online since the last reboot, unless the **clear traffic** command was entered since the last reboot. If this is the case, then the number of seconds is the duration since that command was entered.

For the ASA 5550, the **show traffic** command also shows the aggregated throughput per slot. Because the ASA 5550 requires traffic to be evenly distributed across slots for maximum throughput, this output helps you determine if the traffic is distributed evenly.

Examples

The following is sample output from the **show traffic** command:

```
hostname# show traffic
outside:
        received (in 102.080 secs):
                2048 packets 204295 bytes
                20 pkts/sec 2001 bytes/sec
        transmitted (in 102.080 secs):
                2048 packets 204056 bytes
                20 pkts/sec 1998 bytes/sec

Ethernet0:
        received (in 102.080 secs):
                2049 packets 233027 bytes
```

```
                20 pkts/sec 2282 bytes/sec
        transmitted (in 102.080 secs):
                2048 packets 232750 bytes
                20 pkts/sec 2280 bytes/sec
```

For the ASA 5550, the following text is displayed at the end:

```
----------------------------------------
        Per Slot Throughput Profile
----------------------------------------
  Packets-per-second profile:
    Slot 0:       3148  50%|****************
    Slot 1:       3149  50%|****************

  Bytes-per-second profile:
    Slot 0:     427044  50%|****************
    Slot 1:     427094  50%|****************
```

Related Commands

Command	Description
clear traffic	Resets the counters for transmit and receive activity.

CHAPTER 60

show uauth through show xlate Commands

show uauth

To display one or all currently authenticated users, the host IP to which they are bound, and any cached IP and port authorization information, use the **show uauth** command in privileged EXEC mode.

show uauth [*username*]

Syntax Description

username	(Optional) Specifies, by username, the user authentication and authorization information to display.

Defaults

Omitting username displays the authorization information for all users.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show uauth** command displays the AAA authorization and authentication caches for one user or for all users.

This command is used with the **timeout** command.

Each user host IP address has an authorization cache attached to it. The cache allows up to 16 address and service pairs for each user host. If the user attempts to access a service that has been cached from the correct host, the ASA considers it preauthorized and immediately proxies the connection. Once you are authorized to access a website, for example, the authorization server is not contacted for each image as it is loaded (assuming the images come from the same IP address). This process significantly increases performance and reduces the load on the authorization server.

The output from the **show uauth** command displays the username that is provided to the authorization server for authentication and authorization purposes, the IP address to which the username is bound, and whether the user is authenticated only or has cached services.

Note When you enable Xauth, an entry is added to the uauth table (as shown by the **show uauth** command) for the IP address that is assigned to the client. However, when using Xauth with the Easy VPN Remote feature in Network Extension Mode, the IPsec tunnel is created from network to network, so that the users behind the firewall cannot be associated with a single IP address. For this reason, a uauth entry cannot be created upon completion of Xauth. If AAA authorization or accounting services are required, you can enable the AAA authentication proxy to authenticate users behind the firewall. For more information on AAA authentication proxies, see to the **aaa** commands.

Use the **timeout uauth** command to specify how long the cache should be kept after the user connections become idle. Use the **clear uauth** command to delete all the authorization caches for all the users, which will cause them to have to reauthenticate the next time that they create a connection.

Examples

This example shows sample output from the **show uauth** command when no users are authenticated and one user authentication is in progress:

```
hostname(config)# show uauth
                        Current    Most Seen
Authenticated Users       0          0
Authen In Progress        0          1
```

This example shows sample output from the **show uauth** command when three users are authenticated and authorized to use services through the ASA:

```
hostname(config)# show uauth
user 'pat' from 209.165.201.2 authenticated
user 'robin' from 209.165.201.4 authorized to:
   port 192.168.67.34/telnet    192.168.67.11/http     192.168.67.33/tcp/8001
        192.168.67.56/tcp/25    192.168.67.42/ftp
user 'terry' from 209.165.201.7 authorized to:
   port 192.168.1.50/http     209.165.201.8/http
```

Related Commands

Command	Description
clear uauth	Remove current user authentication and authorization information.
timeout	Set the maximum idle time duration.

show url-block

To display the number of packets held in the url-block buffer and the number (if any) dropped due to exceeding the buffer limit or retransmission, use the **show url-block** command in privileged EXEC mode.

show url-block [**block statistics**]

Syntax Description

block statistics	(Optional) Displays block buffer usage statistics.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show url-block block statistics** command displays the number of packets held in the url block buffer and the number (if any) dropped due to exceeding the buffer limit or retransmission.

Examples

The following is sample output from the **show url-block** command:

```
hostname# show url-block
|url-block url-mempool 128|url-block url-size 4|url-block block 128
```

This shows the configuration of the URL block buffer.

The following is sample output from the **show url-block block statistics** command:

```
hostname# show url-block block statistics

URL Pending Packet Buffer Stats with max block  128|
Cumulative number of packets held:|896
Maximum number of packets held (per URL):|3
Current number of packets held (global):|38
Packets dropped due to
|exceeding url-block buffer limit:|7546
|HTTP server retransmission:|10
Number of packets released back to client:|0
```

Related Commands

Commands	Description
clear url-block block statistics	Clears the block buffer usage counters.
filter url	Directs traffic to a URL filtering server.
url-block	Manage the URL buffers used for web server responses.
url-cache	Enables URL caching while pending responses from an N2H2 or Websense server and sets the size of the cache.
url-server	Identifies an N2H2 or Websense server for use with the **filter** command.

show url-cache statistics

To display information about the url-cache, which is used for URL responses received from an N2H2 or Websense filtering server, use the **show url-cache statistics** command in privileged EXEC mode.

show url-cache statistics

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show url-cache statistics** command displays the following entries:

- Size—The size of the cache in kilobytes, set with the **url-cache** *size* option.
- Entries—The maximum number of cache entries based on the cache size.
- In Use—The current number of entries in the cache.
- Lookups—The number of times the ASA has looked for a cache entry.
- Hits—The number of times the ASA has found an entry in the cache.

You can view additional information about N2H2 Sentian or Websense filtering activity with the **show perfmon** command.

Examples

The following is sample output from the **show url-cache statistics** command:

```
hostname# show url-cache statistics

URL Filter Cache Stats
----------------------
 Size :     1KB
 Entries :     36
  In Use :     30
 Lookups :     300
 Hits :     290
```

Related Commands

Commands	Description
clear url-cache statistics	Removes **url-cache** command statements from the configuration.
filter url	Directs traffic to a URL filtering server.
url-block	Manage the URL buffers used for web server responses.
url-cache	Enables URL caching for responses received from an N2H2 or Websense server and sets the size of the cache.
url-server	Identifies an N2H2 or Websense server for use with the **filter** command.

show url-server

To display information about the URL filtering server, use the **show url-server** command in privileged EXEC mode.

show url-server statistics

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **show url-server statistics** command displays the URL server vendor; number of URLs total, allowed, and denied; number of HTTPS connections total, allowed, and denied; number of TCP connections total, allowed, and denied; and the URL server status.

The **show url-server** command displays the following information:

- For N2H2, **url-server (***if_name***) vendor n2h2 host** *local_ip* **port** *number* **timeout** *seconds* **protocol** [{**TCP | UDP**}{**version 1 | 4**}]
- For Websense, **url-server (***if_name***) vendor websense host** *local_ip* **timeout** *seconds* **protocol** [{**TCP | UDP**}]

Examples

The following is sample output from the **show url-server statistics** command:

```
hostname## show url-server statistics
Global Statistics:
------------------

```

Related Commands

Commands	Description
clear url-server	Clears the URL filtering server statistics.
filter url	Directs traffic to a URL filtering server.
url-block	Manage the URL buffers used for web server responses.

url-cache	Enables URL caching while pending responses from an N2H2 or Websense server and sets the size of the cache.
url-server	Identifies an N2H2 or Websense server for use with the **filter** command.

show user-identity ad-agent

To display information about the AD Agent for the Identify Firewall, use the **show user-identity ad-agent** command in privileged EXEC mode.

show user-identity ad-agent [**statistics**]

Syntax Description

statistics	(Optional) Displays statistical information about the AD Agent.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

You can monitor the AD Agent component of the Identity Firewall.

Use the **show user-identity ad-agent** command to obtain troubleshooting information for the AD Agent. This command displays the following information about the primary and secondary AD Agents:

- Status of the AD Agents
- Status of the domains
- Statistics for the AD Agents

Table 60-1 Description of the Command Output

Type	Values	Description
Mode	Configuration mode	Specifies full download or on-demand download.
AD Agent IP Address	IP address	Displays the active AD Agent IP address.
Backup	IP address	Displays the backup AD Agent IP address.

Table 60-1 Description of the Command Output (continued)

Type	Values	Description
AD Agent Status	• Disabled • Down • Up (registered) • Probing	• The Identity Firewall is disabled. • The AD Agent is down. • The AD Agent is up and running. • The ASA is registered and the AD Agent is up and running. • The ASA is trying to connect to the AD Agent.
Authentication Port	udp/1645	Displays the AD Agent authentication port.
Accounting Port	udp/1646	Displays the AD Agent accounting port.
ASA Listening Port	udp/3799	Displays the ASA listening port.
Interface	Interface	Displays the interface that the ASA uses to contact the AD Agent.
IP Address	IP address	Displays the IP address that the ASA uses to contact the AD Agent.
Uptime	Time	Displays the AD Agent up time.
Average RTT	Milliseconds	Displays the average round trip time the ASA uses to contact the AD Agent.
Domain	Domain nickname Status: up Status: down	Displays the Microsoft Active Directory domain for the AD Agent.

Examples

This example shows how to display information for the AD Agent for the Identify Firewall:

```
hostname# show user-identity ad-agent
Primary AD Agent:
 Status                    up (registered)
 Mode:                     full-download
 IP address:               172.23.62.125
 Authentication port:      udp/1645
 Accounting port:          udp/1646
 ASA Listening port:       udp/3799
 Interface:                mgmt
 Up time:                  15 mins 41 secs
 Average RTT:              57 msec

Secondary AD Agent:
 Status                    up
 Mode:                     full-download
 IP address:               172.23.62.136
 Authentication port:      udp/1645
 Accounting port:          udp/1646
 ASA Listening port:       udp/3799
 Interface:                mgmt
 Up time:                  7 mins 56 secs
 Avg RTT:                  15 msec
```

Related Commands

Command	Description
clear user-identity ad-agent statistics	Clears the statistics data of AD Agents maintained by the ASA for the Identity Firewall.
user-identity enable	Creates the Cisco Identify Firewall instance.
show user-identity ad-group-members	Displays the group members in the domain of the AD Agent for the Identify Firewall.

show user-identity ad-group-members

To display the group members in the domain of the AD Agent for the Identify Firewall, use the **show user-identity ad-group-members** command in privileged EXEC mode.

show user-identity ad-group-members [*domain_nickname*\]*user_group_name* [**timeout seconds** *seconds*]

Syntax Description

domain_nickname	(Optional) Specifies the domain name for the Identity Firewall.
timeout seconds *seconds*	(Optional) Sets a timer for retrieving group member statistics and specifies the length of time for the timer.
user_group_name	(Optional) Specifies the group name from which to retrieve statistics.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

The **show user-identity ad-group-members** command displays the immediate members (the users and groups) of the specified user group.

Note This command does not display information for locally defined groups on the ASA configured with the **object-group user** command.

The ASA sends an LDAP query for the Active Directory groups configured on the Active Directory server. Running this command is equivalent to running an LDAP browser command that allows you to check members of a specified user group. ASA issues one level of LDAP query to retrieve the immediate members of the specified group in the distinguishedName format. Running this command does not update the ASA internal cache of imported user groups.

When you do not specify *domain_nickname*, the ASA displays information for the group that has *user_group_name* in the default domain. The argument *domain_nickname* can be the real domain nickname or LOCAL.

The group name is the AD group's unique sAMAccountName not the CN name. To display information for a specific group sAMAccountName, use the **show user-identity ad-groups filter** *filter_string* command to retrieve group's sAMAccountName.

Examples

This example shows how to display members of the group sample1 for the Identity Firewall:

```
hostname# show user-identity ad-group-member group.sample1
Domain:CSCO        AAA Server Group:  CISCO_AD_SERVER
Group Member List Retrieved Successfully
Number of Members in AD Group group.schiang: 12
dn: CN=user1,OU=Employees,OU=Cisco Users,DC=cisco,DC=com
dn: CN=user2,OU=Employees,OU=Cisco Users,DC=cisco,DC=com
...
```

Related Commands

Command	Description
user-identity enable	Creates the Cisco Identify Firewall instance.
show user-identity ad-groups	Displays information about the AD Agent for the Identify Firewall.

show user-identity ad-groups

To display information for a specific group for the Identify Firewall, use the **show user-identity ad-groups** command in privileged EXEC mode.

show user-identity ad-groups *domain_nickname* {**filter** *filter_string* | **import-user-group** [**count**]}

Syntax Description

count	(Optional) Displays the number of activated groups.
domain_nickname	Specifies the domain name for the Identity Firewall.
filter *filter_string*	Specifies to displays groups that contain the specified filter string in the CN attribute of the domain controller of the Microsoft Active Directory.
import-user-group	Displays only the activated groups for the Identity Firewall.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

When you run the **show user-identity ad-groups** command, the ASA sends an LDAP query to the Microsoft Active Directory to retrieve all user groups that are part of the specified domain nickname. The argument *domain_nickname* can be the real domain nickname or LOCAL. The ASA only retrieves groups that have the group objectclass attribute. The ASA displays the retrieved groups in distinguishedName format.

When you specify the **filter** *filter_string* keyword and argument, the ASA displays groups that contain the specified filter string in the CN attribute of the domain controller. Because the **access-list** and **object-group** commands only take sAMAccountName, you can run the **show user-identity ad-users filter** *filter_string* command to retrieve the sAMAccountName for a group. When you do not specify **filter** *filter_string*, the ASA displays all Active Directory groups.

When you specify the **import-user-group count** keywords, the ASA displays all Active Directory groups that are activated (because they are part an access-group, import-user-group, or service-policy configuration) and stored in the local database. The ASA only displays the sAMAccountName for the groups.

Examples

These examples show how to display user groups that are part of the specified domain nickname for the Identity Firewall:

```
hostname# show user-identity ad-groups CSCO filter sampleuser1
Domain: CSCO        AAA Server Group:       CISCO_AD_SERVER
Group list retrieved successfully
Number of Active Directory Groups       6
dn: CN=group.reg.sampleuser1,OU=Organizational,OU=Cisco Groups,DC=cisco,DC=com
sAMAccountName: group.reg.sampleuser1
dn: CN=group.temp.sampleuser1,OU=Organizational,OU=Cisco Groups,DC=cisco,DC=com
sAMAccountName: group.temp.sampleuser1
...

hostname# show user-identity ad-groups CSCO import-user-group count
Total AD groups in domain CSCO stored in local: 2

hostname# show user-identity ad-groups CSCO import-user-group
Domain: CSCO
Groups:
        group.SampleGroup1
        group.SampleGroup2
...
```

This example shows how to run the command to apply a filter string to the results from an access-list and object-group command. Running the **show user-identity ad-users CSCO filter SampleGroup1** command obtains the sAMAccountName of specified string:

```
hostname# show user-identity ad-users CSCO filter SampleGroup1
Domain:CSCO    AAA Server Group:  CISCO_AD_SERVER
User list retrieved successfully
Number of Active Directory Users: 2
dn: CN=SampleUser1,OU=Employees,OU=Cisco Users,DC=cisco,DC=com
sAMAccountName: SampleUser2
dn: CN=SAMPLEUSER2-WXP05,OU=Workstations,OU=Cisco Computers,DC=cisco,DC=com
sAMAccountName: SAMPLEUSER2-WXP05$
```

Related Commands

Command	Description
user-identity enable	Creates the Cisco Identify Firewall instance.

show user-identity ad-users

To display Microsoft Active Directory users for the Identify Firewall, use the **show user-identity ad-users** command in privileged EXEC mode.

show user-identity ad-users *domain_nickname* [**filter** *filter_string*]

Syntax Description

domain_nickname	Specifies the domain name for the Identity Firewall.
filter *filter_string*	(Optional) Specifies to displays users that contain the specified filter string in the CN attribute of the domain controller of the Microsoft Active Directory.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

When you run the **show user-identity ad-users** command, the ASA sends an LDAP query to the Microsoft Active Directory to retrieve all users that are part of the specified domain nickname. The argument *domain_nickname* can be the real domain nickname or LOCAL.

When you specify the **filter** *filter_string* keyword and argument, the ASA displays users that contain the specified filter string in the CN attribute of the domain controller. The ASA sends an LDAP query for the Active Directory groups configured on the Active Directory server.

The ASA only retrieves users that have the user objectclass attribute and the samAccountType attribute 805306368. Other objects, such as machine objects, can be included in the user objectclass; however, the samAccountType 805306368 filters out the non-user objects. When you do not specify a filter string, the ASA displays all Active Directory users.

The ASA displays the retrieved users in distinguishedName format.

Examples

This example shows how to display information about Active Directory users for the Identity Firewall:

```
hostname# show user-identity ad-users CSCO filter user
Domain: CSCO        AAA Server Group:  CISCO_AD_SERVER
User list retrieved successfully
```

```
Number of Active Directory Users: 10
dn: CN=sampleuser1,OU=Employees,OU=Cisco Users,DC=cisco,DC=com
sAMAccountName: sampleuser1
dn: CN=sampleuser2,OU=Employees,OU=Cisco Users,DC=cisco,DC=com
sAMAccountName: sampleuser2
dn: CN=user3,OU=Employees,OU=Cisco Users,DC=cisco,DC=com
sAMAccountName: user3
...
```

Related Commands

Command	Description
user-identity enable	Creates the Cisco Identify Firewall instance.

show user-identity group

To display the user groups configured for the Identify Firewall, use the **show user-identity group** command in privileged EXEC mode.

show user-identity group

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

Use the **show user-identity group** command to obtain troubleshooting information for the user groups configured for the Identity Firewall. The ASA sends an LDAP query for the Active Directory groups configured on the Active Directory server. This command displays the list of activated user groups in the following format:

domain\group_name

The ASA only displays top groups that are applied to a security policy. The maximum number of activated top groups is 256. Groups are activated when they are part an access-group, import-user-group, or service-policy configuration.

Examples

This example shows how to display the activated groups for the Identity Firewall:

```
hostname# show user-identity group
Group ID        Activated Group Name (Domain\\Group)
--------        ------------------------------------
       1        LOCAL\\og1
       2        LOCAL\\marketing
       3        CISCO\\group.sampleuser1
       4        IDFW\\grp1
...
```

Related Commands

Command	Description
user-identity enable	Creates the Cisco Identify Firewall instance.

show user-identity ip-of-user

To display the IP address for a specified user for the Identify Firewall, use the **show user-identity ip-of-user** command in privileged EXEC mode.

show user-identity ip-of-user [*domain_nickname*\]*user-name* [**detail**]

Syntax Description

detail	(Optional) Displays the detailed output about the user and IP address.
domain_nickname	(Optional) Specifies the domain name for the Identity Firewall.
user-name	Specifies the user for which to obtain an IP address.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

This command displays user information and the IP addresses for the specified user. Users can have more than one IP address associated with them.

When you do not specify the *domain_nickname* argument, the ASA displays information for the user with *user_name* in default domain. The argument *domain_nickname* can be the real domain nickname or LOCAL.

When you specify the **detail** keyword, the ASA displays the total number of active connections, the user-statistics period and the drops, and the input packets and output packets during the period over all IP addresses for the specified user. When you do not specify the **detail** option, the ASA displays only the domain nickname and status of each IP address.

Note The ASA displays detailed user statistics, such as received packets, sent packets and drops in the specified time period, only when you enable user-statistics scanning or accounting for the Identity Firewall. See the CLI configuration guide for information about configuring the Identity Firewall.

Examples

These examples show how to display IP addresses of specified users for the Identity Firewall:

```
hostname# show user-identity ip-of-user sampleuser1
```

```
CSCO\172.1.1.1 (Login)
CSCO\172.100.3.23 (Login)
CSCO\10.23.51.3 (Inactive)
```

```
hostname# show user-identity ip-of-user sampleuser1 detail
CSCO\172.1.1.1 (Login) Login time: 1440 mins;  Idle time: 10 mins; 2 active conns
CSCO\172.100.3.23 (Login) Login time: 20 mins;  Idle time: 10 mins; 10 active conns
CSCO\10.23.51.3 (Inactive) Login time: 3000 mins;  Idle time: 2040 mins; 8 active conns
Total number of active connections: 20
1-hour recv packets: 12560
1-hour sent packets: 32560
20-min drops: 560
```

```
hostname# show user-identity ip-of-user sampleuser2
ERROR: no such user
```

```
hostname# show user-identity ip-of-user sampleuser3
ERROR: no IP address, user not login now
```

IPv6 support

```
hostname# show user-identity ip-of-user sampleuser4
CSCO\172.1.1.1 (Login)
CSCO\8080:1:3::56 (Login)
CSCO\8080:2:3::34 (Inactive)
```

```
hostname# show user-identity ip-of-user sampleuser4 detail
CSCO\172.1.1.1 (Login) Login time: 1440 mins;  Idle time: 10 mins; 8 active conns
CSCO\8080:1:3::56 (Login) Login time: 20 mins;  Idle time: 10 mins; 12 active conns
CSCO\8080:2:3::34 (Inactive) Total number of active connections: 20
1-hour recv packets: 12560
1-hour sent packets: 32560
20-min drops: 560
```

Related Commands

Command	Description
user-identity enable	Creates the Cisco Identify Firewall instance.
show user-identity user-of-ip	Displays the user information associated with the specified IP address

show user-identity memory

To display the memory of various modules of the Identify Firewall, use the **show user-identity memory** command in privileged EXEC mode.

show user-identity memory

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

You can monitor the memory usage that the Identity Firewall consumes on the ASA. Running the s**how user-identity memory** command displays the memory for user records, group records, host records, and their associated hash table. The ASA also displays the memory used by the identity-based tmatch table.

The command displays the memory usage in bytes of various modules in the Identity Firewall:

- Users
- Groups
- User Statistics
- LDAP

The ASA sends an LDAP query for the Active Directory groups configured on the Active Directory server. The Active Directory server authenticates users and generates user logon security logs.

- AD Agent
- Miscellaneous
- Total Memory Usage

How you configure the Identity Firewall to retrieve user information from the AD Agent impacts the amount of memory used by the feature. You specify whether the ASA uses on demand retrieval or full download retrieval. Selecting On Demand has the benefit of using less memory as only users of received packets are queried and stored. See “Configuring Identity Options” in the CLI configuration guide for a description of these options.

Examples

This example shows how to display the memory status of the modules of the Identity Firewall:

```
hostname# show user-identity memory
Users:       22416048 bytes
Groups:           320 bytes
User stats:         0 bytes
LDAP:             300 bytes
AD agent:         500 bytes
Misc:           32428 bytes
Total:       22449596 bytes
Users:       22416048 bytes
```

Related Commands

Command	Description
user-identity enable	Creates the Cisco Identify Firewall instance.

show user-identity statistics

To display statistics for a user or user group for the Identify Firewall, use the **show user-identity statistics** command in privileged EXEC mode.

show user-identity statistics [**user** [*domain_nickname*\]*user_name* | **user-group** [*domain_nickname*\]*user_group_name*]

Syntax Description

domain_nickname	(Optional) Specifies the domain name for the Identity Firewall.
user *user_name*	(Optional) Specifies the user name from which to retrieve statistics.
user-group *domain_nickname*\ *user_group_name*	(Optional) Specifies the group name from which to retrieve statistics.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

Run the show **user-identity statistics** command to display the statistics for a user or user group.

When you do not specify the *domain_nickname* argument with the **user** keyword, the ASA displays information for the user with *user_name* in default domain.

When you do not specify *domain_nickname* with the **user-group** keyword, the ASA displays information for the group that has *user_group_name* in the default domain. The argument *domain_nickname* can be the real domain nickname or LOCAL.

Examples

These examples show how to display statistics about users for the Identity Firewall:

```
hostname# show user-identity statistics user
Current monitored users:11  Total not monitored users:0
                          Average(eps)    Current(eps) Trigger      Total events
User: CSCO\user1 tot-ses:4911 act-ses:1213 fw-drop:0 insp-drop:0 null-ses:4861 bad-acc:0

    1-hour Recv pkts:                  1              10        0             4901
User: CSCO\user2 tot-ses:2456 act-ses:607 fw-drop:0 insp-drop:0 null-ses:2431 bad-acc:0
```

```
  20-min Sent attack:                 4              10        4              4862
  1-hour Sent pkts:                     0              5         0              2451
...

hostname# show user-identity statistics user user1
Current                          Average(eps)    Current(eps) Trigger      Total events
User: -(user1-) tot-ses:4911 act-ses:1213 fw-drop:0 insp-drop:0 null-ses:4861 bad-acc:0
  20-min Recv attack:               4              10       14              4861
  1-hour Recv pkts:                  1              10       0              4901
```

Related Commands

Command	Description
user-identity enable	Creates the Cisco Identify Firewall instance.

show user-identity statistics top user

To display statistics for the top 10 users for the Identify Firewall, use the **show user-identity statistics top user** command in privileged EXEC mode.

show user-identity statistics top user

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

The **show user-identity statistics top user** command displays statistics for received EPS packets, sent EPS packets, and sent attacks for the top 10 users. For each user (displayed as *domain\user_name*), the ASA displays the average EPS packet, the current EPS packet, the trigger, and total events for that user.

Examples

This example shows how to display information about the top 10 users for the Identity Firewall:

```
hostname# show user-identity statistics top user
Top          Name   Id    Average(eps)    Current(eps) Trigger      Total events
  1-hour Recv pkts:
01    APAC\sampleuser1
                                  0               0       0               391
  1-hour Sent pkts:
01    APAC\sampleuser2
                                  0               0       0               196
02    CSCO\sampleuser3
                                  0               0       0               195
  10-min Sent attack:
01    CSCO\sampleuser4
                                  0               0       0               352
02    CSCO\sampleuser3
                                  0               0       0               350
```

Related Commands

Command	Description
user-identity enable	Creates the Cisco Identify Firewall instance.

show user-identity user active

To display the active users for the Identify Firewall, use the **show user-identity user active** command in privileged EXEC mode.

show user-identity user active [**domain** *domain_nickname* | **user-group** [*domain_nickname*\]*user_group_name* | **user** [*domain_nickname*\]*user_name*] [**list** [**detail**]]

Syntax Description

detail	(Optional) Displays the detailed output of the active user sessions.
domain *domain_nickname*	Displays statistics for the active users in a specified domain.
list	(Optional) Displays a list summarizing the active user statistics.
user *domain_nickname\user_name*	(Optional) Displays statistic for a specified user.
user-group *domain_nickname\user_group_name*	(Optional) Displays statistics for a specified user group.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

You can display information about all users contained in the IP-user mapping database used by the Identity Firewall.

The **show user-identity user active** command displays the following information for users:

- *domain\user_name*
- Active Connections
- Minutes Idle

The default domain name can be the real domain name, a special reserved word, or LOCAL. The Identity Firewall uses the LOCAL domain name for all locally defined user groups or locally defined users (users who log in and authenticate by using a VPN or web portal). When default domain is not specified, the default domain is LOCAL.

A user's name is appended with the number of minutes idle. The login time and idle time are stored on a per user basis instead of per the IP address of a user.

When the **user-group** keyword is specified, only the activated user-groups are displayed. Groups are activated when they are part an access-group, import-user-group, or service-policy configuration.

When you do not specify *domain_nickname* with the **user-group** keyword, the ASA displays information for the group that has *user_group_name* in the default domain.

Note When the **user-identity action domain-controller-down** is configured with the **disable-user-identity-rule** keyword and the specified domain is down, or when **user-identity action ad-agent-down** command is configured with the **disable-user-identity-rule** keyword and the AD agent is down, all the logged on users are displayed as disabled in the user statistics.

Note The ASA displays detailed user statistics, such as received packets, sent packets and drops in the specified time period, only when you enable user-statistics scanning or accounting for the Identity Firewall. See the CLI configuration guide for information about configuring the Identity Firewall.

Examples

The following examples show how to display information about active users for the Identity Firewall:

```
hostname# show user-identity user active
Total active users: 30  Total IP addresses: 35
  LOCAL: 0 users, 0 IP addresses
  cisco.com: 0 users, 0 IP addresses
  d1: 0 users, 0 IP addresses
  IDFW: 0 users, 0 IP addresses
  idfw.com: 0 users, 0 IP addresses
  IDFWTEST: 30 users, 35 IP addresses

hostname# show user-identity user active domain CSCO
Total active users: 48020 Total IP addresses:10000
  CSCO: 48020 users, 10000 IP addresses

hostname# show user-identity user active domain CSCO list
Total active users: 48020 Total IP addresses: 10000
  CSCO: 48020 users, 10000 IP addresses
   CSCO\sampleuser1: 20 active conns; idle 0 mins
   CSCO\member-1: 20 active conns; idle 5 mins
   CSCO\member-2: 20 active conns; idle 20 mins
   CSCO\member-3: 3 active conns; idle 101 mins
   …

hostname# show user-identity user active list
Total active users: 48032  Total IP addresses: 10000
   CSCO\sampleuser1: 20 active conns; idle 0 mins
   CSCO\member-1: 20 active conns; idle 6 mins
   APAC\sampleuser2: 20 active conns; idle 0 mins
   CSCO\member-2: 20 active conns; idle 1 mins
```

```
   CSCO\member-3: 20 active conns; idle 0 mins
   APAC\member-2: 20 active conns; idle 22 mins
   CSCO\member-4: 3 active conns; idle 101 mins
   …
hostname# show user-identity user active list detail
Total active users: 48032 Total IP addresses: 10010
  CSCO: 48020 users, 10000 IP addresses
  APAC: 12 users, 10 IP addresses
   CSCO\sampleuser1: 20 active conns; idle 0 mins
     172.1.1.1: login 360 mins, idle 0 mins, 15 active conns
     172.100.3.23: login 200 min, idle 15 mins , 5 active conns
     10.23.51.3: inactive
     1-hour recv packets: 12560
     1-hour sent packets: 32560
     20-min drops: 560
   CSCO\member-1: 4 active connections;  idle 350 mins
   …
  APAC\sampleuser12: 3 active conns; idle 101 mins
     172.1.1.1: login 360 mins, idle 101 mins, 1 active conns
     172.100.3.23: login 200 min, idle 150 mins, 2 active conns
     10.23.51.3: inactive
     1-hour recv packets: 12560
     1-hour sent packets: 32560
     20-min drops: 560

hostname# show user-identity user active list detail
Total users: 25  Total IP addresses: 5
   LOCAL\idfw: 0 active conns
    6.1.1.1: inactive
  cisco.com\sampleuser1: 0 active conns
  cisco.com\sampleuser2: 0 active conns
  cisco.com\sampleuser3: 0 active conns
    20.0.0.3: login 0 mins, idle 0 mins, 0 active conns (disabled)
  cisco.com\sampleuser4: 0 active conns; idle 0 mins
    20.0.0.2: login 0 mins, idle 0 mins, 0 active conns (disabled)
  cisco.com\sampleuser5: 0 active conns
  ...

hostname# show user-identity user active user sampleuser1 list detail
CSCO\sampleuser1: 20 active conns; idle 3 mins
     172.1.1.1: login 360 mins, idle 20 mins, 15 active conns
     172.100.3.23: login 200 mins, idle 3 mins, 5 active conns
     10.23.51.3: inactive
     1-hour recv packets: 12560
     1-hour sent packets: 32560
     20-min drops: 560

hostname# show user-identity user active user APAC\sampleuser2
APAC\sampleuser2: 20 active conns; idle 2 mins

hostname# show user-identity user active user-group APAC\\marketing list

   APAC\sampleuser1: 20 active conns; idle 2 mins
   APAC\member-1: 20 active conns; idle 0 mins
   APAC\member-2: 20 active conns; idle 0 mins
   APAC\member-3: 20 active conns; idle 6 mins

ERROR: group is not activated
```

Related Commands

Command	Description
clear user-identity active-user-database	Sets the status of a specified user, all users belong to a specified user group, or all users to logged out for the Identity Firewall.
user-identity enable	Creates the Cisco Identify Firewall instance.

show user-identity user all

To display statistics about users for the Identify Firewall, use the **show user-identity user all** command in privileged EXEC mode.

show user-identity user all [**list**] [**detail**]

Syntax Description

detail	(Optional) Displays the detailed output about all users for the Identity Firewall.
list	(Optional) Displays a list summarizing the statistics for all users for the Identity Firewall.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

Use the show user-identity all command to display information for all users contained in the IP-user mapping database used by the Identity Firewall.

When you include the detail keyword with this command and the command output shows an IP address is inactive, the IP address is not associated with the user. Searching for the user associated with that IP address will return an error.

Note When the **user-identity action domain-controller-down** is configured with the **disable-user-identity-rule** keyword and the specified domain is down, or when **user-identity action ad-agent-down** command is configured with the **disable-user-identity-rule** keyword and the AD agent is down, all the logged on users are displayed as disabled in the user statistics.

Note The ASA displays detailed user statistics, such as received packets, sent packets and drops in the specified time period, only when you enable user-statistics scanning or accounting for the Identity Firewall. See the CLI configuration guide for information about configuring the Identity Firewall.

Examples

The following examples show how to display statistics about all users for the Identity Firewall:

```
hostname# show user-identity user all list
Total inactive users: 1201  Total IP addresses: 100

hostname# show user-identity user all list
Total users: 7
  LOCAL\idfw: 0 active conns
  cisco.com\sampleuser1: 0 active conns
  cisco.com\sampleuser2: 0 active conns
  cisco.com\sampleuser3: 0 active conns
  cisco.com\sampleuser4: 0 active conns; idle 300 mins
  cisco.com\sampleuser5: 0 active conns
  cisco.com\sampleuser6: 0 active conns
  cisco.com\sampleuser7: 0 active conns

hostname# show user-identity user all list detail
Total users: 7 Total IP addresses: 3
  LOCAL\idfw: 0 active conns
    10.1.1.1: inactive
  cisco.com\sampleuser1: 0 active conns
  cisco.com\sampleuser2: 0 active conns
  cisco.com\sampleuser3: 0 active conns; idle 300 mins
    171.69.42.8: inactive
    10.0.0.2: login 300 mins, idle 300 mins, 5 active conns
  cisco.com\sampleuser4: 0 active conns
  cisco.com\sampleuser5: 0 active conns
  cisco.com\sampleuser6: 0 active conns
     1-hour recv packets: 12560
     1-hour sent packets: 32560
     20-min drops: 560
```

Related Commands

Command	Description
user-identity enable	Creates the Cisco Identify Firewall instance.

show user-identity user inactive

To display information about the inactive users for the Identify Firewall, use the **show user-identity user inactive** command in privileged EXEC mode.

show user-identity user inactive [**domain** *domain_nickname* | **user-group** [*domain_nickname*\]*user_group_name*]

Syntax Description

domain *domain_nickname*	(Optional) Displays statistics for the inactive users in the specified domain name for the Identity Firewall.
user-group *domain_nickname*\ *user_group_name*	(Optional) Displays statistics for the inactive users in the specified user group.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

Use the **show user-identity user inactive** command to display information about users who have no active traffic for longer than the value configured with the **user-identity inactive-user-timer** command.

When the **user-group** keyword is specified, only the activated user-groups are displayed. Groups are activated when they are part an access-group, import-user-group, or service-policy configuration.

When you do not specify *domain_nickname* with the **user-group** keyword, the ASA displays information for the group that has *user_group_name* in the default domain. The argument *domain_nickname* can be the real domain nickname or LOCAL.

Examples

These examples show how to display the status of inactive users for the Identity Firewall:

```
hostname# show user-identity user inactive
Total inactive users: 1201
   APAC\sampleuser1
   CSCO\sampleuser2
172.1.1.1: inactive     …
...
```

```
hostname# show user-identity user inactive domain CSCO
Total inactive users: 1101
    CSCO: 1101
   CSCO\sampleuser1
   CSCO\sampleuser2
   CSCO\sampleuser3
...

hostname# show user-identity user inactive user-group CSCO\\marketing
Total inactive users: 21
   CSCO\sampleuser1
   CSCO\sampleuser2
...
```

Related Commands

Command	Description
user-identity enable	Creates the Cisco Identify Firewall instance.
user-identity inactive-user-timer	Specifies the amount of time before a user is considered idle for the Cisco Identify Firewall instance.

show user-identity user-not-found

To display the IP addresses of the Active Directory users not found for the Identify Firewall, use the **show user-identity user-not-found** command in privileged EXEC mode.

show user-identity user-not-found

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

Use the **show user-identity user-not-found** command to display the IP addresses of the users who are not found in Microsoft Active Directory.

The ASA maintains a local user-not-found database of these IP addresses. The ASA keeps only the last 1024 packets (contiguous packets from the same source IP address are treated as one packet) of the user-not-found list and not the entire list in the database.

Examples

This example shows how to display information about not-found users for the Identity Firewall:

```
hostname# show user-identity user-not-found
172.13.1.2
171.1.45.5
169.1.1.2
172.13.12
…
```

Related Commands

Command	Description
clear user-identity user-not-found	Clears the ASA local user-not-found database for the Identity Firewall.

user-identity enable	Creates the Cisco Identify Firewall instance.
user-identity user-not-found	Enables user-not-found tracking for the Identify Firewall.

show user-identity user-of-group

To display the users of a specified user group for the Identify Firewall, use the **show user-identity user-of-group** command in privileged EXEC mode.

show user-identity user-of-group [*domain_nickname*\]*user_group_name*

Syntax Description

domain_nickname	Specifies the domain name for the Identity Firewall.
user_group_name	Specifies the user group for which to display statistics.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

Use the **show user-identity user-of-group** command to display users whose group ID matches the specified user group. (The ASA scans the IP-user hash list for this information and rather than sending an LDAP query to Active Directory. The AD Agent maintains a cache of user ID and IP address mappings and notifies the ASA of changes.)

The user group name you specify must be activated, meaning the group is an import user group (defined as a user group in an access list or service policy configuration) or a local user group (defined in an object-group user).

The group can have more than one user member. The members of the user group are all immediate members (including users and groups) of the specified group.

When you do not specify *domain_nickname* with the *user_group_name* argument, the ASA displays information for the group that has *user_group_name* in the default domain. The argument *domain_nickname* can be the real domain nickname or LOCAL.

When the command out put indicates a user's status is inactive, the user can be logged out or has never logged in.

Examples

These examples show how to display users of a specified user group for the Identity Firewall:

```
hostname# show user-identity user-of-group group.samplegroup1
```

```
Group: CSCO\\group.user1 Total users: 13
CSCO\user2 10.0.0.10(Login) 20.0.0.10(Inactive) …
CSCO\user3 10.0.0.11(Inactive)
CSCO\user4 10.0.0.12 (Login)
CSCO\user5 10.0.0.13 (Login)
CSCO\user6 10.0.0.14 (Inactive)
....
```

```
hostname# show user-identity user-of-group group.local1
Group: LOCAL\\group.local1    Total users: 2
CSCO\user1 10.0.4.12 (Login)
LOCAL\user2 10.0.3.13 (Login)
```

Related Commands

Command	Description
user-identity enable	Creates the Cisco Identify Firewall instance.

show user-identity user-of-ip

To display information about a user with a specific IP address for the Identify Firewall, use the **show user-identity user-of-ip** command in privileged EXEC mode.

show user-identity user-of-ip *ip_address* [**detail**]

Syntax Description

detail	(Optional) Displays the detailed output about user with the specified IP address.
ip_address	Indicates the IP address of the user for which to display information.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

Use the **show user-identity user-of-ip** command to display the user information associated with the specified IP address.

When you specify the **detail** keyword, the ASA displays user login time, idle time, the number of active connections, the user-statistics period and the drops, and the input packets and output packets during the period. When you do not specify the **detail** keyword, the ASA only displays the domain nickname, user name, and status.

When user status is inactive, the user can be logged out or has never logged in.

When you include the **detail** keyword with this command and the command output for an IP address displays an error, the IP address is inactive, meaning that the IP address is not associated with a user.

Note The ASA displays detailed user statistics, such as received packets, sent packets and drops in the specified time period, only when you enable user-statistics scanning or accounting for the Identity Firewall. See the CLI configuration guide for information about configuring the Identity Firewall.

Examples

These examples show how to display the status of the active users for the Identity Firewall:

```
hostname# show user-identity user-of-ip 172.1.1.1
```

```
CSCO\sampleuser1 (Login)
hostname# show user-identity user-of-ip 172.1.1.1 detail
CSCO\sampleuser1 (Login) Login time: 240 mins;  Idle time: 10 mins
Number of active connections: 20
1-hour sent packets: 3678
1-hour rcvd packets: 1256
20-min sent drops: 60

hostname# show user-identity user-of-ip 172.1.2.2 detail
CSCO\sampleuser2 (Login) Login time: 1440 mins; Idle time: 100 mins
Number of active connections: 0
1-hour sent packets: 3678
1-hour rcvd packets: 1256
20-min sent drops: 60

hostname# show user-identity user-of-ip 172.1.7.7
ERROR: no user with this IP address
```

IPv6 Support

```
hostname# show user-identity user-of-ip 8080:1:1::4
CSCO\sampleuser1 (Login)
hostname# show user-identity user-of-ip 8080:1:1::4 detail
CSCO\sampleuser1 (Login) Login time: 240 mins;  Idle time: 10 mins
Number of active connections: 20
1-hour sent packets: 3678
1-hour rcvd packets: 1256
20-min sent drops: 60

hostname# show user-identity user-of-ip 8080:1:1::6 detail
CSCO\sampleuser2 (Login) Login time: 1440 mins; Idle time: 100 mins
Number of active connections: 0
1-hour sent packets: 3678
1-hour rcvd packets: 1256
20-min sent drops: 60

hostname# show user-identity user-of-ip 8080:1:1::100
ERROR: no user with this IP address
```

Related Commands

Command	Description
user-identity enable	Creates the Cisco Identify Firewall instance.

show version

To display the software version, hardware configuration, license key, and related uptime data, use the **show version** command in user EXEC mode.

show version

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC	•	•	•	•	•

Command History

Release	Modification
7.2(1)	In stateful failover mode, an additional line showing cluster uptime is displayed.
8.3(1)	The output now includes whether a feature uses the permanent or time-based key, as well as the duration of the time-based key in use.
8.4(1)	Support for No Payload Encryption models (NPE) was added.

Usage Guidelines

The **show version** command allows you to display the software version, operating time since the last reboot, processor type, Flash partition type, interface boards, serial number (BIOS ID), activation key value, license type, and time stamp for when the configuration was last modified.

The serial number listed with the **show version** command is for the flash partition BIOS. This number is different from the serial number on the chassis. When you get a software upgrade, you will need the serial number that appears in the **show version** command, not the chassis number.

The failover cluster uptime value indicates how long a failover set has been running. If one unit stops running, the uptime value continues to increase as long as the active unit continues to operate. Therefore, it is possible for the failover cluster uptime to be greater than the individual unit uptime. If you temporarily disable failover, and then reenable it, the failover cluster uptime reports the time the unit was up before failover was disabled plus the time the unit was up while failover was disabled.

If you have a No Payload Encryption model, then when you view the license, VPN and Unified Communications licenses will not be listed.

For the Total VPN Peers on the ASA 5505, the total combined number of VPN sessions of all types depends on your licenses. If you enable AnyConnect Essentials, then the total is the model maximum of 25. If you enable AnyConnect Premium, then the total is the AnyConnect Premium value plus the Other

VPN value, not to exceed 25 sessions. Unlike other models, where the Other VPN value equals the model limit for all VPN sessions, the ASA 5505 has a lower Other VPN value than the model limit, so the total value can vary depending on the AnyConnect Premium license.

Examples

The following is sample output from the **show version** command, and shows the software version, hardware configuration, license key, and related uptime information. Note that in an environment where stateful failover is configured an additional line showing the failover cluster uptime is displayed. If failover is not configured, the line is not displayed. This display shows a warning message about minimum memory requirements.

Running Timebased Activation Key: 0xa821d549 0x35725fe4 0xc918b97b 0xce0b987b 0x47c7c285
Configuration register is 0x1
Configuration last modified by docs at 15:23:22.339 EDT Fri Oct 30 2012
```

The following message appears if you enter the **show version** command after the **eject** command has been executed, but the device has not been physically removed:

```
Slot 1: Compact Flash has been ejected!
It may be removed and a new device installed.
```

Related Commands

Command	Description
eject	Allows shutdown of external compact flash device before physical removal from the ASA.
show hardware	Displays detail hardware information.
show serial	Displays the hardware serial information.
show uptime	Displays how long the ASA has been up.

show vlan

To display all VLANs configured on the ASA, use the **show vlan** command in privileged EXEC mode.

show vlan

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example displays the configured VLANs:

```
hostname# show vlan
10-11,30,40,300
```

Related Commands

Command	Description
clear interface	Clears counters for the **show interface** command.
interface	Configures an interface and enters interface configuration mode.
show interface	Displays the runtime status and statistics of interfaces.

show vpn load-balancing

To display the runtime statistics for the VPN load-balancing virtual cluster configuration, use the **show vpn-load-balancing** command in global configuration, privileged EXEC, or VPN load-balancing mode.

show vpn load-balancing

Syntax Description

This command has no variables or arguments.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•		—
Privileged EXEC	•	—	•		—
Vpn load-balancing	•	—	•		—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.1(1)	Added separate IPsec and SSL columns for both Load (%) display and Session display in the output example.
8.4(0)	New information was added to the displayed output.

Usage Guidelines

The **show vpn load-balancing** command displays statistical information for the virtual VPN load-balancing cluster. If the local device is not participating in the VPN load-balancing cluster, this command indicates that VPN load balancing has not been configured for this device.

The asterisk (*) in the output indicates the IP address of the ASA to which you are connected.

Examples

This example displays **show vpn load-balancing** command and its output for a situation in which the local device is participating in the VPN load-balancing cluster:

```
hostname# sh vpn load-balancing
------------------------------------------------------------------------
    Status     Role   Failover   Encryption        Cluster IP   Peers
------------------------------------------------------------------------
   Enabled   Master        n/a     Disabled 192.0.2.255   0

Peers:
------------------------------------------------------------------------
```

```
       Public IP     Role  Pri             Model  Load-Balancing Version
-------------------------------------------------------------------------
        192.0.2.255    Master    5          ASA-5520            3

Total License Load:
-------------------------------------------------------------------------
       Public IP    AnyConnect Premium/Essentials          Other VPN
                   -------------------------------   ---------------------
                        Limit    Used   Load          Limit    Used   Load
-------------------------------------------------------------------------
     192.0.2.255       750       0     0%            750       1     0%

Licenses Used By Inactive Sessions :
-------------------------------------------------------------------------
       Public IP    AnyConnect Premium/Essentials     Inactive Load
-------------------------------------------------------------------------
     192.0.2.255                      0                0%
```

On the primary device, the Total License Load output includes information about the primary and backup device; however, the backup device only shows information about itself and not the primary device. Thus, the primary device knows about all licensed members, but the licensed members themselves only know about their own licenses.

The output also contains a License Used by Inactive Session section. When an AnyConnect session goes inactive, the ASA keeps that session as long as the session has not terminated by normal means. That way, AnyConnect sessions can reconnect using the same webvpn cookie and not have to re-authenticate. The inactive sessions will remain in that state until either the AnyConnect client resumes the session or an idle timeout occurs. The licenses for those sessions are maintained for these inactive sessions and are represented in this License Used by Inactive Session section.

If the local device is not participating in the VPN load-balancing cluster, the **show vpn load-balancing** command shows a different result:

```
hostname(config)# show vpn load-balancing
VPN Load Balancing has not been configured.
```

Related Commands

Command	Description
clear configure vpn load-balancing	Removes **vpn load-balancing** command statements from the configuration.
show running-config vpn load-balancing	Displays the the current VPN load-balancing virtual cluster configuration.
vpn load-balancing	Enters vpn load-balancing mode.

show vpn-sessiondb

To display information about VPN sessions, use the **show vpn-sessiondb** command in privileged EXEC mode.The command includes options for displaying information in full or in detail, lets you specify type of sessions to display, and provides options to filter and sort the information. The syntax table and usage notes organize the choices accordingly

show vpn-sessiondb [**detail**] [**ospfv3**] [**failover**] [**full**] [**summary**] [**ratio** {**encryption | protocol**}] [**license-summary**] {**anyconnect | email-proxy | index** *indexnumber* **| l2l | ra-ikev1-ipsec | vpn-lb | webvpn**} [**filter** {**name** *username* **| ipaddress** *IPaddr* **| a-ipaddress** *IPaddr* **| p-ipaddress** *IPaddr* **| tunnel-group** *groupname* **| protocol** *protocol-name* **| encryption** *encryption-algo* **| inactive**}] [**sort** {**name | ipaddress | a-ipaddress | p-ip address | tunnel-group | protocol | encryption | inactivity**}]

Syntax Description

anyconnect	Displays AnyConnect VPN client sessions, including OSPFv3 session information.
detail	(Optional) Displays extended details about a session. For example, using the **detail** option for an IPsec session displays additional details such as the IKE hashing algorithm, authentication mode, and rekey interval. If you choose **detail**, and the **full** option, the ASA displays the detailed output in a machine-readable format.
email-proxy	Displays email-proxy sessions.
encryption	Displays the ratio of encryption types as a ratio of the total number of sessions.
failover	Displays the session information for the failover IPsec tunnels.
filter *filter_criteria*	(Optional) Filters the output to display only the information you specify by using one or more of the filter options. For a list of *filter_criteria* options, see the "Usage Guidelines" section.
full	(Optional) Displays streamed, untruncated output. Output is delineated by | characters and a || string between records.
index *indexnumber*	Displays a single session by index number. Specify the index number for the session, 1 - 750.
l2l	Displays VPN LAN-to-LAN session information.
license-summary	Displays a summary of license information about the ASA.
ospfv3	Displays OSPFv3 session information.
protocol	Displays the ratio of protocol types as a ratio of the total number of sessions.
ra-ikev1-ipsec	Displays IPsec IKEv1 sessions.
ratio	Displays the ratio of encryption or protocol types, depending on the keyword you choose, as a ratio of the total number of sessions.
sort *sort_criteria*	(Optional) Sorts the output according to the sort option you specify. For a list of *sort_criteria* options, see the "Usage Guidelines" section.
summary	Displays VPN session summary information.
vpn-lb	Displays VPN Load Balancing management sessions.
webvpn	Displays clientless SSL VPN sessions, including OSPFv3 session information.

Defaults

There is no default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•		—

Command History

Release	Modification
7.2(1)	This command was introduced.
8.0(2)	Added VLAN field description.
8.0(5)	Added **inactive** as a **filter** option and **inactivity** as a **sort** option.
8.2(1)	License information was added to the output.
8.4(1)	The **svc** keyword was changed to **anyconnect**. The **remote** keyword was changed to **ra-ikev1-ipsec.** The **ratio** keyword was added.
9.0(1)	The **ospfv3** keyword was added, and the OSPFv3 session information is now included in the VPN session summary. The **fitler a-ipversion** and **filter p-ipversion** options were added to allow filtering on all AnyConnect, LAN-to-LAN, and Clientless SSL VPN sessions assigned IPv4 or IPv6 addresses.
9.1(2)	We added the failover tunnel type and **failover** keyword to support failover IPsec tunnels. See the **failover ipsec pre-shared-key** command.
9.1(4)	Output when using the **detail anyconnect** options has been updated to reflect the assigned IPv6 address and to indicate the GRE Transport Mode security association when doing IKEv2 dual traffic.

Usage Guidelines

You can use the following options to filter and to sort the session display:

Filter/Sort Option	Description
filter a-ipaddress *IPaddr*	Filters the output to display information for the specified assigned IP address or addresses only.
sort a-ipaddress	Sorts the display by assigned IP addresses.
filter a-ipversion {v4 | v6}	Filters the output to display information about all AnyConnect sessions assigned IPv4 or IPv6 addresses.
filter encryption *encryption-algo*	Filters the output to display information for sessions using the specified encryption algorithm(s) only.
sort encryption	Sorts the display by encryption algorithm. Encryption algorithms include: aes128, aes192, aes256, des, 3des, rc4

Filter/Sort Option	Description
filter inactive	Filters inactive sessions which have gone idle and have possibly lost connectivity (due to hibernation, mobile device disconnection, and so on). The number of inactive sessions increases when TCP keepalives are sent from the ASA without a response from the AnyConnect client. Each session is time stamped with the SSL tunnel drop time. If the session is actively passing traffic over the SSL tunnel, 00:00m:00s is displayed. **Note** The ASA does not send TCP keepalives to some devices (such as the iphone, ipad, and ipod) in order to save battery life, so the failure detection cannot distinguish between a disconnect and a sleep. For this reason, the inactivity counter remains as 00:00:00 by design.
sort inactivity	Sorts inactive sessions.
filter ipaddress *IPaddr*	Filters the output to display information for the specified inside IP address or addresses only.
sort ipaddress	Sorts the display by inside IP addresses.
filter name *username*	Filters the output to display sessions for the specified username(s).
sort name	Sorts the display by usernames in alphabetical order.
filter p-address *IPaddr*	Filters the output to display information for the specified outside IP address only.
sort p-address	Sorts the display by the specified outside IP address or addresses.
filter p-ipversion {v4 | v6}	Filters the output to display information about all AnyConnect sessions originating from endpoints with IPv4 or IPv6 addresses.
filter protocol *protocol-name*	Filters the output to display information for sessions using the specified protocol(s) only.
sort protocol	Sorts the display by protocol. Protocols include: IKE, IMAP4S, IPsec, IPsecLAN2LAN, IPsecLAN2LANOverNatT, IPsecOverNatT, IPsecoverTCP, IPsecOverUDP, SMTPS, userHTTPS, vcaLAN2LAN
filter tunnel-group *groupname*	Filters the output to display information for the specified tunnel group(s) only.
sort tunnel-group	Sorts the display by tunnel group.
|	Modifies the output, using the following arguments: {begin | include | exclude | grep | [-v]} {reg_exp}

Examples

The following is sample output from the **show vpn-sessiondb** command:

```
hostname# show vpn-sessiondb

--------------------------------------------------------------------------
VPN Session Summary
--------------------------------------------------------------------------

As shown in the examples, the fields displayed in response to the **show vpn-sessiondb** command vary, depending on the keywords you enter. Table 60-2 explains these fields.

Table 60-2 show vpn-sessiondb Command Fields

Field	Description
Auth Mode	Protocol or mode used to authenticate this session.
Bytes Rx	Total number of bytes received from the remote peer or client by the ASA.
Bytes Tx	Number of bytes transmitted to the remote peer or client by the ASA.
Client Type	Client software running on the remote peer, if available.
Client Ver	Version of the client software running on the remote peer.
Connection	Name of the connection or the private IP address.
D/H Group	Diffie-Hellman Group. The algorithm and key size used to generate IPsec SA encryption keys.
Duration	Elapsed time (HH:MM:SS) between the session login time and the last screen refresh.
EAPoUDP Session Age	Number of seconds since the last successful posture validation.
Encapsulation	Mode used to apply IPsec ESP (Encapsulation Security Payload protocol) encryption and authentication (that is, the part of the original IP packet that has ESP applied).
Encryption	Data encryption algorithm this session is using, if any.
EoU Age (T)	EAPoUDP Session Age. Number of seconds since the last successful posture validation.
Filter Name	Username specified to restrict the display of session information.
Hashing	Algorithm used to create a hash of the packet, which is used for IPsec data authentication.
Hold Left (T)	Hold-Off Time Remaining. 0 seconds if the last posture validation was successful. Otherwise, the number of seconds remaining before the next posture validation attempt.
Hold-Off Time Remaining	0 seconds if the last posture validation was successful. Otherwise, the number of seconds remaining before the next posture validation attempt.
IKE Neg Mode	IKE (IPsec Phase 1) mode for exchanging key information and setting up SAs: Aggressive or Main.
IKE Sessions	Number of IKE (IPsec Phase 1) sessions; usually 1. These sessions establish the tunnel for IPsec traffic.
Index	Unique identifier for this record.
IP Addr	Private IP address assigned to the remote client for this session. This is also known as the “inner” or “virtual” IP address. It lets the client appear to be a host on the private network.

Table 60-2 show vpn-sessiondb Command Fields (continued)

Field	Description
IPsec Sessions	Number of IPsec (Phase 2) sessions, which are data traffic sessions through the tunnel. Each IPsec remote-access session can have two IPsec sessions: one consisting of the tunnel endpoints, and one consisting of the private networks reachable through the tunnel.
License Information	Shows information about the shared SSL VPN license.
Local IP Addr	IP address assigned to the local endpoint of the tunnel (that is the interface on the ASA).
Login Time	Date and time (MMM DD HH:MM:SS) that the session logged in. Time is displayed in 24-hour notation.
NAC Result	State of Network Admission Control Posture Validation. It can be one of the following: • Accepted—The ACS successfully validated the posture of the remote host. • Rejected—The ACS could not successfully validate the posture of the remote host. • Exempted—The remote host is exempt from posture validation according to the Posture Validation Exception list configured on the ASA. • Non-Responsive—The remote host did not respond to the EAPoUDP Hello message. • Hold-off—The ASA lost EAPoUDP communication with the remote host after successful posture validation. • N/A—NAC is disabled for the remote host according to the VPN NAC group policy. • Unknown—Posture validation is in progress.
NAC Sessions	Number of Network Admission Control (EAPoUDP) sessions.
Packets Rx	Number of packets received from the remote peer by the ASA.
Packets Tx	Number of packets transmitted to the remote peer by the ASA.
PFS Group	Perfect Forward Secrecy group number.
Posture Token	Informational text string configurable on the Access Control Server. The ACS downloads the posture token to the ASA for informational purposes to aid in system monitoring, reporting, debugging, and logging. A typical posture token is Healthy, Checkup, Quarantine, Infected, or Unknown.
Protocol	Protocol the session is using.
Public IP	Publicly routable IP address assigned to the client.
Redirect URL	Following posture validation or clientless authentication, the ACS downloads the access policy for the session to the ASA. The Redirect URL is an optional part of the access policy payload. The ASA redirects all HTTP (port 80) and HTTPS (port 443) requests for the remote host to the Redirect URL if it is present. If the access policy does not contain a Redirect URL, the ASA does not redirect HTTP and HTTPS requests from the remote host. Redirect URLs remain in force until either the IPsec session ends or until posture revalidation, for which the ACS downloads a new access policy that can contain a different redirect URL or no redirect URL.

Table 60-2 show vpn-sessiondb Command Fields (continued)

Field	Description
Rekey Int (T)	Lifetime of the IPsec (IKE) SA encryption keys.
Rekey Left (T)	Lifetime remaining of the IPsec (IKE) SA encryption keys.
Rekey Time Interval	Lifetime of the IPsec (IKE) SA encryption keys.
Remote IP Addr	IP address assigned to the remote endpoint of the tunnel (that is the interface on the remote peer).
Reval Int (T)	Revalidation Time Interval. Interval in seconds required between each successful posture validation.
Reval Left (T)	Time Until Next Revalidation. 0 if the last posture validation attempt was unsuccessful. Otherwise, the difference between the Revalidation Time Interval and the number of seconds since the last successful posture validation.
Revalidation Time Interval	Interval in seconds required between each successful posture validation.
Session ID	Identifier for the session component (subsession). Each SA has its own identifier.
Session Type	Type of session: LAN-to-LAN or Remote
SQ Int (T)	Status Query Time Interval. Time in seconds allowed between each successful posture validation or status query response and the next status query response. A status query is a request made by the ASA to the remote host to indicate whether the host has experienced any changes in posture since the last posture validation.
Status Query Time Interval	Time in seconds allowed between each successful posture validation or status query response and the next status query response. A status query is a request made by the ASA to the remote host to indicate whether the host has experienced any changes in posture since the last posture validation.
Time Until Next Revalidation	0 if the last posture validation attempt was unsuccessful. Otherwise, the difference between the Revalidation Time Interval and the number of seconds since the last successful posture validation.
Tunnel Group	Name of the tunnel group referenced by this tunnel for attribute values.
UDP Dst Port or UDP Destination Port	Port number used by the remote peer for UDP.
UDP Src Port or UDP Source Port	Port number used by the ASA for UDP.
Username	User login name with which the session is established.
VLAN	Egress VLAN interface assigned to this session. The ASA forwards all traffic to that VLAN. One of the following elements specifies the value: • Group policy • Inherited group policy

Related Commands

Command	Description
show running-configuration vpn-sessiondb	Displays the VPN session database running configuration (max-other-vpn-limit, max-anyconnect-premium-or-essentials-limit).
show vpn-sessiondb ratio	Displays VPN session encryption or protocol ratios.
show vpn-sessiondb summary	Displays a summary of all VPN sessions.

show vpn-sessiondb license-summary

To display a summary of VPN license information for the ASA, use the **show vpn-sessiondb license-summary** command in privileged EXEC mode.

show vpn-sessiondb license-summary

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	•	•

Command History

Release	Modification
8.4(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Examples

The following is sample output for the **show vpn-sessiondb ratio** command, with **encryption** as the argument:

```
hostname(config)# show vpn-sessiondb license-summary

Related Commandss

Command	Description
show vpn-sessiondb	Displays sessions with or without extended details, optionally filtered and sorted by criteria you specify.
show vpn-sessiondb summary	Displays a session summary, including total current session, current sessions of each type, peak and total cumulative, maximum concurrent sessions

show vpn-sessiondb ratio

To display the ratio of current sessions as a percentage by protocol or encryption algorithm, use the **show vpn-sessiondb ratio** command in privileged EXEC mode.

show vpn-sessiondb ratio {protocol | encryption} [filter *groupname***]**

Syntax Description

encryption	Identifies the encryption protocols you want to display. Refers to phase 2 encryption. Encryption algorithms include:	
	aes128	des
	aes192	3des
	aes256	rc4
filter *groupname*	Filters the output to include session ratios only for the tunnel group you specify.	
protocol	Identifies the protocols you want to display. Protocols include:	
	IKEv1	L2TPOverIPsecOverNatT
	IKEv2	Clientless
	IPsec	Port-Forwarding
	IPsecLAN2LAN	IMAP4S
	IPsecLAN2LANOverNatT	POP3S
	IPsecOverNatT	SMTPS
	IPsecOverTCP	AnyConnect-Parent
	IPsecOverUDP	SSL-Tunnel
	L2TPOverIPsec	DTLS-Tunnel

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
8.4(1)	The output was enhanced to include IKEv2.
9.0(1)	Support for multiple context mode was added.

Examples

The following is sample output for the **show vpn-sessiondb ratio** command, with **encryption** as the argument:

```
hostname# show vpn-sessiondb ratio encryption
Filter Group         : All
Total Active Sessions: 5
Cumulative Sessions  : 9

Encryption               Sessions       Percent
none                     0               0%
DES                      1              20%
3DES                     0               0%
AES128                   4        80%
AES192                   0               0%
AES256                   0               0%
```

The following is sample output for the **show vpn-sessiondb ratio** command with **protocol** as the argument:

```
hostname# show vpn-sessiondb ratio protocol
Filter Group         : All
Total Active Sessions: 6
Cumulative Sessions  : 10

Protocol                 Sessions       Percent

```

Related Commandss

Command	Description
show vpn-sessiondb	Displays sessions with or without extended details, optionally filtered and sorted by criteria you specify.
show vpn-sessiondb summary	Displays a session summary, including total current session, current sessions of each type, peak and total cumulative, maximum concurrent sessions

show vpn-sessiondb summary

To display the number of IPsec, Cisco AnyConnect, and NAC sessions, use the **show vpn-sessiondb summary** command in privileged EXEC mode.

show vpn-sessiondb summary

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	•	•

Command History

Release	Modification
7.0(7)	This command was introduced.
8.0(2)	Added the VLAN Mapping Sessions table.
8.0(5)	Added new output for active, cumulative, peak concurrent, and inactive.
9.0(1)	Support for multiple context mode was added.

Examples

The following is sample output for the **show vpn-sessiondb summary** command with one IPsec IKEv1 and one clientless session:

Note A device in standby does not differentiate active from inactive sessions.

```
hostname# show vpn-sessiondb summary

VPN Session Summary
Sessions:
                         Active :Cumulative :Peak Concurrent :Inactive :

You can use the SSL output to determine the physical device resources in respect to the number of licenses. A single user session may occupy a license but could use multiple tunnels. For example, an AnyConnect user with DTLS often has the parent session, SSL tunnel, and DTLS tunnels associated with it.

Note The parent session represents when the client is not actively connected. It does not represent an encrypted tunnel. If the client shuts down, or sleeps, IPsec, IKE, TLS, and DLTLS tunnels are closed, but the parent session remains until the idle time or maximum connect time limit is reached. This enables the user to reconnect without reauthenticating.

With this example, you would see three tunnels allocated on the device, even if only one user is logged in. An IPsec LAN-to-LAN tunnel counts as one session, and it allows many host-to-host connections through the tunnel. An IPsec remote access session is one remote access tunnel that supports one user connection.

From the output you can see which sessions are active. If a session has no underlying tunnels associated to it, the status is *waiting to resume* mode (displayed as Clientless in the session output). This mode means that dead peer detection from the head-end device has started, and the head-end device can no longer communicate with the client. When you encounter this condition, you can hold the session to allow the user to roam networks, go to sleep, recover the session, and so on. These sessions count towards the actively connected sessions (from a license standpoint) and are cleared with a user idle timeout, a user logging out, or a resumption of the original session.

The Active SSL VPN With Client column shows the number of active connections passing data. The Cumulative SSL VPN With Client column shows the number of active sessions that have been established. It includes those that are inactive and increments only when a new session is added. The Peak Concurrent SSL VPN With Client column shows the peak number of concurrently active sessions that are passing data. The Inactive SSL VPN With Client column shows how long the AnyConnect client was disconnected. You can use this Inactivity timeout value to determine when licenses are expired. The ASA can then determine whether reconnection is possible. These are AnyConnect sessions without an active SSL tunnel associated with them.

Table 60-3 explains the fields in the Active Sessions and Session Information tables.

Table 60-3 show vpn-sessiondb summary Command: Active Sessions and Session Information Fields

Field	Description
Concurrent Limit	Maximum number of concurrently active sessions permitted on this ASA.
Cumulative Sessions	Number of sessions of all types since the ASA was last booted or reset.
LAN-to-LAN	Number of IPsec LAN-to-LAN sessions that are currently active.
Peak Concurrent	Highest number of sessions of all types that were concurrently active since the ASA was last booted or reset.
Percent Session Load	Percentage of the vpn session allocation in use. This value equals the Total Active Sessions divided by the maximum number of sessions available, displayed as a percentage. The maximum number of sessions available can be either of the following: • Maximum number of IPsec and SSL VPN sessions licensed • **vpn-sessiondb ?** (maximum number of sessions configured) • **max-anyconnect-premium-or-essentials-limit** (maximum AnyConnect Premium or Essentials session limit) • **max-other-vpn-limit** (maximum other VPN session limit)
Remote Access	ra-ikev1-ipsec—Number of IKEv1 IPsec remote-access user, L2TP over IPsec, and IPsec through NAT sessions that are currently active.
Total Active Sessions	Number of sessions of all types that are currently active.

The Active NAC Sessions table shows general statistics about remote peers that are subject to posture validation.

The Cumulative NAC Sessions table shows general statistics about remote peers that are or have been subject to posture validation.

Table 60-2 explains the fields in the Active NAC Sessions and Total Cumulative NAC Sessions tables.

Table 60-4 show vpn-sessiondb summary Command: Active NAC Sessions and Total Cumulative NAC Sessions Fields

Field	Description
Accepted	Number of peers that passed posture validation and have been granted an access policy by an Access Control Server.
Exempted	Number of peers that are not subject to posture validation because they match an entry in the Posture Validation Exception list configured on the ASA.
Hold-off	Number of peers for which the ASA lost EAPoUDP communications after a successful posture validation. The NAC Hold Timer attribute (Configuration > VPN > NAC) determines the delay between this type of event and the next posture validation attempt for each peer.
N/A	Number of peers for which NAC is disabled according to the VPN NAC group policy.

Table 60-4 show vpn-sessiondb summary Command: Active NAC Sessions and Total Cumulative NAC Sessions Fields (continued)

Field	Description
Non-responsive	Number of peers not responsive to Extensible Authentication Protocol (EAP) over UDP requests for posture validation. Peers on which no CTA is running do not respond to these requests. If the ASA configuration supports clientless hosts, the Access Control Server downloads the access policy associated with clientless hosts to the ASA for these peers. Otherwise, the ASA assigns the NAC default policy.
Rejected	Number of peers that failed posture validation or were not granted an access policy by an Access Control Server.

The Active VLAN Mapping Sessions table shows general statistics about remote peers that are subject to posture validation.

The Cumulative VLAN Mapping Sessions table shows general statistics about remote peers that are or have been subject to posture validation.

Table 60-5 explains the fields in the Active VLAN Mapping Sessions and Cumulative VLAN Mapping Sessions tables.

Table 60-5 show vpn-sessiondb summary Command: Active VLAN Mapping Sessions and Cumulative Active VLAN Mapping Sessions Fields

Field	Description
Access	Reserved for future use.
Auth	Reserved for future use.
Guest	Reserved for future use.
N/A	Reserved for future use.
Quarantine	Reserved for future use.
Static	This field shows the number of VPN sessions assigned to a pre-configured VLAN.

Related Commands

Command	Description
show vpn-sessiondb	Displays sessions with or without extended details, optionally filtered and sorted by criteria you specify.
show vpn-sessiondb ratio	Displays VPN session encryption or protocol ratios.

show wccp

To display global statistics related to Web Cache Communication Protocol (WCCP), use the **show wccp** command in privileged EXEC mode.

show wccp {**web-cache** | *service-number*}[*detail* | *view*]

Syntax Description

detail	(Optional) Displays information about the router and all web caches.
service-number	(Optional) Identification number of the web-cache service group being controlled by the cache. The number can be from 0 to 256. For web caches using Cisco Cache Engines, the reverse proxy service is indicated by a value of 99.
view	(Optional) Displays other members of a particular service group have or have not been detected.
web-cache	Specifies statistics for the web-cache service.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to display WCCP information:

```
hostname(config)# show wccp
Global WCCP information:
    Router information:
        Router Identifier:                   -not yet determined-
        Protocol Version:                    2.0

    Service Identifier: web-cache
        Number of Cache Engines:             0
        Number of routers:                   0
        Total Packets Redirected:            0
        Redirect access-list:                foo
        Total Connections Denied Redirect:   0
        Total Packets Unassigned:            0
        Group access-list:                   foobar
        Total Messages Denied to Group:      0
```

```
        Total Authentication failures:       0
        Total Bypassed Packets Received:     0
hostname(config)#
```

Related Commands

Commands	Description
wccp	Enables support of WCCP with service groups.
wccp redirect	Enables support of WCCP redirection.

show webvpn csd

To determine whether CSD is enabled, display the CSD version in the running configuration, determine what image is providing the Host Scan package, and to test a file to see if it is a valid CSD distribution package, use the **show webvpn csd** command in privileged EXEC mode.

show webvpn csd [**image** *filename*]

Syntax Description

filename	Specifies the name of a file to test for validity as a CSD distribution package. It must take the form **csd_n.n.n-k9.pkg**.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC mode	•	—	•		—

Command History

Release	Modification
7.1(1)	This command was introduced.

Examples

Use the **show webvpn csd** command to check the operational status of CSD. The CLI responds with a message indicating if CSD is installed and if it is enabled, if Host Scan is installed and if it is enabled, and which image is supplying the Host Scan package if there is both a CSD package and a Host Scan package installed.

```
hostname# show webvpn csd
```

These are the messages you could receive:

- `Secure Desktop is not installed`

  `Hostscan is not installed`

- `Secure Desktop version n.n.n.n is currently installed but not enabled`

  `Standalone Hostscan package is not installed (Hostscan is currently installed via the CSD package but not enabled)`

- `Secure Desktop version n.n.n.n is currently installed and enabled`

  `Standalone Hostscan package is not installed (Hostscan is currently installed and enabled via the CSD package)`

The message, "`Secure Desktop version n.n.n.n is currently installed ...`" means that the image is loaded on the ASA and in the running configuration. The image can be either **enabled** or **not enabled**. You can go to webvpn configuration mode and enter the **csd enable** command to enable CSD.

The messaage, "`(Hostscan is currently installed and enabled via the CSD package)`" means that the Host Scan package delivered with the CSD package is the Host Scan package in use.

- `Secure Desktop version n.n.n.n is currently installed and enabled`
  `Hostscan version n.n.n.n is currently installed and enabled`

  The message, "`Secure Desktop version n.n.n.n is currently installed and enabled Hostscan version n.n.n.n is currently installed and enabled`" means that both CSD and a Host Scan package, delivered either as a standalone package or as part of an AnyConnect image, are installed. If Host Scan is enabled and both CSD and an AnyConnect image with Host Scan, or a standalone Host Scan package, are installed and enabled, the Host Scan package delivered as a standalone package or as part of an AnyConnect image takes precedence over the one provided with a CSD package.

- `Secure Desktop version n.n.n.n is currently installed but not enabled`
  `Hostscan version n.n.n.n is currently installed but not enabled`

Use the **show webvpn csd image** ***filename*** command to test a file to determine if a CSD distribution package is valid.

hostname# **`show webvpn csd image csd_n.n.n-k9.pkg`**

The CLI responds with one of the following messages when you enter this command:

- `ERROR: This is not a valid Secure Desktop image file.`

  Make sure the filename is in the form the form **csd_n.n.n_k9.pkg**. If the csd package does not have this naming convention, replace the file with one obtained from the following website:

  http://www.cisco.com/cgi-bin/tablebuild.pl/securedesktop

  Then reenter the **show webvpn csd image** command. If the image is valid, use the **csd image** and **csd enable** commands in webvpn configuration mode to install and enable CSD.

- ```
  This is a valid Cisco Secure Desktop image:
  Version  : 3.6.172.0
  Hostscan Version  : 3.6.172.0
  Built on : Wed Feb 23 15:46:44 MST 2011
  ```

  Note that the CLI provides both the version and date stamp if the file is valid.

Related Commands

Command	Description
csd enable	Enables CSD for management and remote user access.
csd image	Copies the CSD image named in the command, from the flash drive specified in the path to the running configuration.
  ```

show webvpn group-alias

To display the aliases for a specific tunnel-group or for all tunnel groups, use the **group-alias** command in privileged EXEC mode.

show webvpn group-alias [*tunnel-group*]

Syntax Description

tunnel-group	(Optional) Specifies a particular tunnel group for which to show the group aliases.

Defaults

If you do not enter a tunnel-group name, this command displays all the aliases for all the tunnel groups.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•		—

Command History

Release	Modification
7.1	This command was introduced.

Usage Guidelines

WebVPN must be running when you enter the **show webvpn group-alias** command.

Each tunnel group can have multiple aliases or no alias.

Examples

The following example shows the **show webvpn group-alias** command that displays the aliases for the tunnel group “devtest” and the output of that command:

```
hostname# show webvpn group-alias devtest
QA
Fra-QA
```

Related Commands

Command	Description
group-alias	Specifies one or more URLs for the group.
tunnel-group webvpn-attributes	Enters the config-webvpn mode for configuring WebVPN tunnel-group attributes.

show webvpn group-url

To display the URLs for a specific tunnel-group or for all tunnel groups, use the **group-url** command in privileged EXEC mode.

show webvpn group-url [*tunnel-group*]

Syntax Description

tunnel-group	(Optional) Specifies a particular tunnel group for which to show the URLs.

Defaults

If you do not enter a tunnel-group name, this command displays all the URLs for all the tunnel groups.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•		—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

WebVPN must be running when you enter the **show webvpn group-url** command. Each group can have multiple URLs or no URL.

Examples

The following example shows the **show webvpn group-url** command that displays the URLs for the tunnel group "frn-eng1" and the output of that command:

```
hostname# show webvpn group-url
http://www.cisco.com
https://fra1.example.com
https://fra2.example.com
```

Related Commands

Command	Description
group-url	Specifies one or more URLs for the group.
tunnel-group webvpn-attributes	Enters the config-webvpn mode for configuring WebVPN tunnel-group attributes.

show webvpn kcd

Use the **show webvpn kcd** command in webvpn configuration mode to display the Domain Controller information and Domain join status on the ASA.

show webvpn kcd

Syntax Description

None.

Defaults

There are no defaults for this command.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
webvpn configuration	•	—	•		—

Command History

Release	Modification
8.4(1)	This command was introduced.

Usage Guidelines

The **show webvpn kcd** command in webvpn configuration mode displays the Domain Controller information and Domain join status on the ASA.

Examples

The following example shows important details to note from the **show webvpn kcd** command and the interpretation of the status message.

This example shows that the registration is under way and not finished:

```
hostname# show webvpn kcd
Kerberos Realm: CORP.TEST.INTERNAL
Domain Join: In-Progress
```

This example shows that a registration was successful and that the ASA has joined the domain:

```
hostname# show webvpn kcd
Kerberos Realm: CORP.TEST.INTERNAL
Domain Join: Complete
```

Related Commands

Command	Description
clear aaa kerberos	Clears all the Kerberos tickets cached on the ASA.
kcd-server	Allows the ASA to join an Active Directory domain.
show aaa kerberos	Displays all the Kerberos tickets cached on the ASA.

show webvpn sso-server

To display the operating statistics for Webvpn single sign-on servers, use the **show webvpn sso-server** command in privileged EXEC mode.

show webvpn sso-server [*name*]

Syntax Description

name	Optionally specifies the name of the SSO server. The server name must be between four and 31 characters in length.

Defaults

No default values or behavior.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Config-webvpn-sso-saml	•	—	•		—
Config-webvpn-sso-siteminder	•	—	•		—
Privileged EXEC	•	—	•		—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Single sign-on support, available only for WebVPN, lets users access different secure services on different servers without entering a username and password more than once. The **show webvpn sso-server** command displays operating statistics for any and all SSO servers configured on the security device.

If no SSO server name argument is entered, statistics for all SSO servers display.

Examples

The following example, entered in privileged EXEC mode, displays statistics for a SiteMinder-type SSO server named example:

```
hostname# show webvpn sso-server example
Name: example
Type: SiteMinder
Authentication Scheme Version: 1.0
Web Agent URL: http://www.example.com/webvpn
Number of pending requests:        0
Number of auth requests:           0
Number of retransmissions:         0
Number of accepts:                 0
```

```
Number of rejects:                 0
Number of timeouts:                0
Number of unrecognized responses:  0
hostname#
```

The following example of the command issued without a specific SSO server name, displays statistics for all configured SSO servers on the ASA:

```
hostname#(config-webvpn)# show webvpn sso-server
Name: high-security-server
Type: SAML-v1.1-POST
Assertion Consumer URL:
Issuer:
Number of pending requests:        0
Number of auth requests:           0
Number of retransmissions:         0
Number of accepts:                 0
Number of rejects:                 0
Number of timeouts:                0
Number of unrecognized responses:  0
Name: my-server
Type: SAML-v1.1-POST
Assertion Consumer URL:
Issuer:
Number of pending requests:        0
Number of auth requests:           0
Number of retransmissions:         0
Number of accepts:                 0
Number of rejects:                 0
Number of timeouts:                0
Number of unrecognized responses:  0
Name: server
Type: SiteMinder
Authentication Scheme Version: 1.0
Web Agent URL:
Number of pending requests:        0
Number of auth requests:           0
Number of retransmissions:         0
Number of accepts:                 0
Number of rejects:                 0
Number of timeouts:                0
Number of unrecognized responses:  0
asa1(config-webvpn)#
```

Related Commands

Command	Description
max-retry-attempts	Configures the number of times the ASA retries a failed SSO authentication attempt.
policy-server-secret	Creates a secret key used to encrypt authentication requests to a SiteMinder-type SSO server.
request-timeout	Specifies the number of seconds before a failed SSO authentication attempt times out.
sso-server	Creates a single sign-on server.
web-agent-url	Specifies the SSO server URL to which the ASA makes SiteMinder SSO authentication requests.

show webvpn anyconnect

To view information about SSL VPN client images installed on the ASA and loaded in cache memory, or to test a file to see if it is a valid client image, use the **show webvpn anyconnect** command from privileged EXEC mode.

show webvpn anyconnect [**image** *filename*]

Syntax Description

image *filename*	Specifies the name of a file to test as an SSL VPN client image file.

Defaults

This command has no default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•		—

Command History

Release	Modification
7.1(1)	This command was introduced.
8.4(1)	The **show webvpn anyconnect** form of the command replaced **show webvpn svc**.

Usage Guidelines

Use the **show webvpn anyconnect** command to view information about SSL VPN client images that are loaded in cache memory and available for download to remote PCs. Use the **image** *filename* keyword and argument to test a file to see if it is a valid image. If the file is not a valid image, the following message appears:

```
ERROR: This is not a valid SSL VPN Client image file.
```

Examples

The following example shows the output of the **show webvpn anyconnect** command for currently installed images:

```
hostname# show webvpn anyconnect
1. windows.pkg 1
SSL VPN Client
CISCO STC win2k+ 1.1.0
1,1,0,107
Thu 04/14/2005 09:27:54.43
2. window2.pkg 2
CISCO STC win2k+ 1.1.0
1,1,0,107
Thu 04/14/2005 09:27:54.43
```

The following example shows the output of the **show webvpn anyconnect image** *filename* command for a valid image:

```
hostname(config-webvpn)# show webvpn anyconnect image sslclient-win-1.0.2.127.pkg

This is a valid SSL VPN Client image:
  CISCO STC win2k+ 1.0.0
  1,0,2,127
  Fri 07/22/2005 12:14:45.43
```

Related Commands

Command	Description
anyconnect enable	Enables the ASA to download the SSL VPN client to remote PCs.
anyconnect image	Causes the security appliance to load SSL VPN client files from flash memory to cache memory, and specifies the order in which the security appliance downloads portions of the client image to the remote PC as it attempts to match the client image with the operating system.
vpn-tunnel-protocol	Enables specific VPN tunnel protocols for remote VPN users, including SSL used by an SSL VPN client.

show xlate

To display information about NAT sessions (xlates), use the **show xlate** command in privileged EXEC mode.

show xlate [**global** *ip1*[**-***ip2*] [**netmask** *mask*]] [**local** *ip1*[**-***ip2*] [**netmask** *mask*]] [**gport** *port1*[**-***port2*]] [**lport** *port1*[**-***port2*]] [**interface** *if_name*] [**type** *type*]

show xlate count

Syntax Description

count	Displays the translation count.
global *ip1*[**-***ip2*]	(Optional) Displays the active translations by mapped IP address or range of addresses.
gport *port1*[*-port2*]	Displays the active translations by the mapped port or range of ports.
interface *if_name*	(Optional) Displays the active translations by interface.
local *ip1*[**-***ip2*]	(Optional) Displays the active translations by real IP address or range of addresses.
lport *port1*[*-port2*]	Displays the active translations by real port or range of ports.
netmask *mask*	(Optional) Specifies the network mask to qualify the mapped or real IP addresses.
state *state*	(Optional) Displays the active translations by type. You can enter one or more of the following types: • **static** • **portmap** • **dynamic** • **twice-nat** When specifying more than one type, separate the types with a space.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was modified to support the new NAT implementation.
8.4(3)	The **e** flag was added to show use of extended PAT. In addition, the destination address to which the xlate is extended is shown.
9.0(1)	This command was modified to support IPv6.

Usage Guidelines

The **show xlate** command displays the contents of the translation slots.

When the **vpnclient** configuration is enabled and the inside host is sending out DNS requests, the **show xlate** command may list multiple xlates for a static translation.

In an ASA clustering environment, up to three xlates may be duplicated to different nodes in the cluster to handle a PAT session. One xlate is created on the unit that owns the connection. One xlate is created on a different unit to backup the PAT address. Finally, one xlate exists on the director that replicates the flow. In the case where the backup and director is the same unit, two instead of three xlates may be created.

Examples

The following is sample output from the **show xlate** command.

```
hostname# show xlate
5 in use, 5 most used
Flags: D - DNS, i - dynamic, r - portmap, s - static, I - identity, T - twice
       e - extended
NAT from any:10.90.67.2 to any:10.9.1.0/24
    flags idle 277:05:26 timeout 0:00:00
NAT from any:10.1.1.0/24 to any:172.16.1.0/24
    flags idle 277:05:26 timeout 0:00:00
NAT from any:10.90.67.2 to any:10.86.94.0
    flags idle 277:05:26 timeout 0:00:00
NAT from any:10.9.0.9, 10.9.0.10/31, 10.9.0.12/30,
    10.9.0.16/28, 10.9.0.32/29, 10.9.0.40/30,
    10.9.0.44/31 to any:0.0.0.0
    flags idle 277:05:26 timeout 0:00:00
NAT from any:10.1.1.0/24 to any:172.16.1.0/24
    flags idle 277:05:14 timeout 0:00:00
```

The following is sample output from the **show xlate** command showing use of the **e - extended** flag and the destination address to which the xlate is extended.

```
hostname# show xlate

```

Related Commands

Command	Description
clear xlate	Clears current translation and connection information.
show conn	Displays all active connections.
show local-host	Displays the local host network information.
show uauth	Displays the currently authenticated users.

CHAPTER 61

shun through snmp-server user Commands

shun

To block connections from an attacking host, use the **shun** command in privileged EXEC mode. To disable a shun, use the **no** form of this command.

shun *source_ip* [*dest_ip source_port dest_port* [*protocol*]] [**vlan** *vlan_id*]

no shun *source_ip* [**vlan** *vlan_id*]

Syntax Description

dest_port	(Optional) Specifies the destination port of a current connection that you want to drop when you place the shun on the source IP address.
dest_ip	(Optional) Specifies the destination address of a current connection that you want to drop when you place the shun on the source IP address.
protocol	(Optional) Specifies the IP protocol of a current connection that you want to drop when you place the shun on the source IP address, such as UDP or TCP. By default, the protocol is 0 (any protocol).
source_ip	Specifies the address of the attacking host. If you only specify the source IP address, all future connections from this address are dropped; current connections remain in place. To drop a current connection and also place the shun, specify the additional parameters of the connection. Note that the shun remains in place for all future connections from the source IP address, regardless of destination parameters.
source_port	(Optional) Specifies the source port of a current connection that you want to drop when you place the shun on the source IP address.
vlan_id	(Optional) Specifies the VLAN ID where the source host resides.

Defaults

The default protocol is 0 (any protocol).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **shun** command lets you block connections from an attacking host. All future connections from the source IP address are dropped and logged until the blocking function is removed manually or by the Cisco IPS sensor. The blocking function of the **shun** command is applied whether or not a connection with the specified host address is currently active.

If you specify the destination address, source and destination ports, and the protocol, then you drop the matching connection as well as placing a shun on all future connections from the source IP address; all future connections are shunned, not just those that match these specific connection parameters.

You can only have one **shun** command per source IP address.

Because the **shun** command is used to block attacks dynamically, it is not displayed in the ASA configuration.

Whenever an interface configuration is removed, all shuns that are attached to that interface are also removed. If you add a new interface or replace the same interface (using the same name), then you must add that interface to the IPS sensor if you want the IPS sensor to monitor that interface.

Examples

The following example shows that the offending host (10.1.1.27) makes a connection with the victim (10.2.2.89) with TCP. The connection in the ASA connection table reads as follows:

```
10.1.1.27, 555-> 10.2.2.89, 666 PROT TCP
```

Apply the **shun** command using the following options:

```
hostname# shun 10.1.1.27 10.2.2.89 555 666 tcp
```

The command deletes the specific current connection from the ASA connection table and also prevents all future packets from 10.1.1.27 from going through the ASA.

Related Commands

Command	Description
clear shun	Disables all the shuns that are currently enabled and clears the shun statistics.
show conn	Shows all active connections.
show shun	Displays the shun information.

shutdown

To disable an interface, use the **shutdown** command in interface configuration mode. To enable an interface, use the **no** form of this command.

shutdown

no shutdown

Syntax Description

This command has no arguments or keywords.

Defaults

All physical interfaces are shut down by default. Allocated interfaces in security contexts are not shut down in the configuration.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was moved from a keyword of the **interface** command to an interface configuration mode command.

Usage Guidelines

The default state of an interface depends on the type and the context mode.

In multiple context mode, all allocated interfaces are enabled by default, no matter what the state of the interface is in the system execution space. However, for traffic to pass through the interface, the interface also has to be enabled in the system execution space. If you shut down an interface in the system execution space, then that interface is down in all contexts that share it.

In single mode or in the system execution space, interfaces have the following default states:

- Physical interfaces—Disabled.
- Redundant Interfaces—Enabled. However, for traffic to pass through the redundant interface, the member physical interfaces must also be enabled.
- Subinterfaces—Enabled. However, for traffic to pass through the subinterface, the physical interface must also be enabled.

Note This command only disables the software interface. The physical link remains up, and the directly connected device is still recognized as being up even when the corresponding interface is configured with the **shutdown** command.

Examples

The following example enables a main interface:

```
hostname(config)# interface gigabitethernet0/2
hostname(config-if)# speed 1000
hostname(config-if)# duplex full
hostname(config-if)# nameif inside
hostname(config-if)# security-level 100
hostname(config-if)# ip address 10.1.1.1 255.255.255.0
hostname(config-if)# no shutdown
```

The following example enables a subinterface:

```
hostname(config)# interface gigabitethernet0/2.1
hostname(config-subif)# vlan 101
hostname(config-subif)# nameif dmz1
hostname(config-subif)# security-level 50
hostname(config-subif)# ip address 10.1.2.1 255.255.255.0
hostname(config-subif)# no shutdown
```

The following example shuts down the subinterface:

```
hostname(config)# interface gigabitethernet0/2.1
hostname(config-subif)# vlan 101
hostname(config-subif)# nameif dmz1
hostname(config-subif)# security-level 50
hostname(config-subif)# ip address 10.1.2.1 255.255.255.0
hostname(config-subif)# shutdown
```

Related Commands

Command	Description
clear xlate	Resets all translations for existing connections, causing the connections to be reset.
interface	Configures an interface and enters interface configuration mode.

shutdown (ca-server mode)

To disable the local Certificate Authority (CA) server and render the enrollment interface inaccessible to users, use the **shutdown** command in CA server configuration mode. To enable the CA server, lock down the configuration from changes, and to render the enrollment interface accessible, use the **no** form of this command.

[**no**] **shutdown**

Syntax Description

This command has no arguments or keywords.

Defaults

Initially, by default, the CA server is shut down.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca server configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

This command in CA server mode is similar to the **shutdown** command in interface mode. At setup time, the local CA server is shutdown by default and must be enabled using the **no shutdown** command. When you use the **no shutdown** command for the first time, you enable the CA server and generate the CA server certificate and keypair.

Note The CA configuration cannot be changed once you lock it and generate the CA certificate by issuing the **no shutdown** command.

To enable the CA server and lock down the current configuration with the **no shutdown** command, a 7-character password is required to encode and archive a PKCS12 file containing the CA certificate and keypair that is to be generated. The file is stored to the storage identified by a previously specified **database path** command.

Examples

The following example disables the local CA server and renders the enrollment interface inaccessible:

```
hostname(config)# crypto ca server
hostname(config-ca-server)# shutdown
hostname(config-ca-server)#
```

The following example enables the local CA server and makes the enrollment interface accessible:

```
hostname(config)# crypto ca server
hostname(config-ca-server)# no shutdown
hostname(config-ca-server)#

hostname(config-ca-server)# no shutdown

% Some server settings cannot be changed after CA certificate generation.
% Please enter a passphrase to protect the private key
% or type Return to exit

Password: caserver

Re-enter password: caserver

Keypair generation process begin. Please wait...

hostname(config-ca-server)#
```

Related Commands

Command	Description
crypto ca server	Provides access to the CA Server Configuration mode CLI command set, which allows you to configure and manage the local CA.
show crypto ca server	Displays the status of the CA configuration.

sla monitor

To create an SLA operation, use the **sla monitor** command in global configuration mode. To remove the SLA operation, use the **no** form of this command.

sla monitor *sla_id*

no sla monitor *sla_id*

Syntax Description

sla_id	Specifies the ID of the SLA being configured. If the SLA does not already exist, it is created. Valid values are from 1 to 2147483647.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The **sla monitor** command creates SLA operations and enters SLA Monitor configuration mode. Once you enter this command, the command prompt changes to `hostname(config-sla-monitor)#` to indicate that you are in SLA Monitor configuration mode. If the SLA operation already exists, and a type has already been defined for it, then the prompt appears as `hostname(config-sla-monitor-echo)#`. You can create a maximum of 2000 SLA operations. Only 32 SLA operations may be debugged at any time.

The **no sla monitor** command removes the specified SLA operation and the commands used to configure that operation.

After you configure an SLA operation, you must schedule the operation with the **sla monitor schedule** command. You cannot modify the configuration of the SLA operation after scheduling it. To modify the the configuration of a scheduled SLA operation, you must use the **no sla monitor** command to remove the selected SLA operation completely. Removing an SLA operation also removes the associated **sla monitor schedule** command. Then you can reenter the SLA operation configuration.

To display the current configuration settings of the operation, use the **show sla monitor configuration** command. To display operational statistics of the SLA operation, use the **show sla monitor operation-state command**. To see the SLA commands in the configuration, use the **show running-config sla monitor** command.

Examples

The following example configures an SLA operation with an ID of 123 and creates a tracking entry with the ID of 1 to track the reachability of the SLA:

```
hostname(config)# sla monitor 123
hostname(config-sla-monitor)# type echo protocol ipIcmpEcho 10.1.1.1 interface outside
hostname(config-sla-monitor-echo)# timeout 1000
hostname(config-sla-monitor-echo)# frequency 3
hostname(config)# sla monitor schedule 123 life forever start-time now
hostname(config)# track 1 rtr 123 reachability
```

Related Commands

Command	Description
frequency	Specifies the rate at which the SLA operation repeats.
show sla monitor configuration	Displays the SLA configuration settings.
sla monitor schedule	Schedules the SLA operation.
timeout	Sets the amount of time the SLA operation waits for a response.
track rtr	Creates a tracking entry to poll the SLA.

sla monitor schedule

To schedule an SLA operation, use the **sla monitor schedule** command in global configuration mode. To remove SLA operation schedule, and place the operation in the pending state, use the **no** form of this command.

sla monitor schedule *sla-id* [**life** {**forever** | *seconds*}] [**start-time** {*hh*:*mm*[:*ss*] [*month day* | *day month*] | **pending** | **now** | **after** *hh*:*mm*:*ss*}] [**ageout** *seconds*] [**recurring**]

no sla monitor schedule *sla-id*

Syntax Description

after *hh*:*mm*:*ss*	Indicates that the operation should start the specified number of hours, minutes, and seconds after the command was entered.
ageout *seconds*	(Optional) Specifies the number of seconds to keep the operation in memory when it is not actively collecting information. After an SLA operation ages out, it is removed from the running configuration.
day	Number of the day to start the operation on. Valid values are from 1 to 31. If a day is not specified, then the current day is used. If you specify a day you must also specify a month.
hh:*mm*[:*ss*]	Specifies an absolute start time in 24-hour notation. Seconds are optional. The next time the specified time occurs is implied unless you specify a *month* and a *day*.
life forever	(Optional) Schedules the operation to run indefinitely.
life *seconds*	(Optional) Sets the number of seconds the operation actively collects information.
month	(Optional) Name of the month to start the operation in. If a month is not specified, then the current month is used. I f you specify a month you must also specify a day. You can enter the full English name of the month or just the first three letters.
now	Indicates that the operation should start as soon as the command is entered.
pending	Indicates that no information is collected. This is the default state.
recurring	(Optional) Indicates that the operation will start automatically at the specified time and for the specified duration every day.
sla-id	The ID of the SLA operation being scheduled.
start-time	Sets the time when the SLA operation starts.

Defaults

The defaults are as follows:

- SLA operations are in the **pending** state until the scheduled time is met. This means that the operation is enabled but not actively collecting data.
- The default **ageout** time is 0 seconds (never ages out).
- The default **life** is 3600 seconds (one hour).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

When an SLA operation is in an active state, it immediately begins collecting information. The following time line shows the age-out process of the operation:

```
W---------------------X---------------------Y---------------------Z
```

- W is the time the SLA operation was configured with the **sla monitor** command.
- X is the start time of the SLA operation. This is when the operation became “active”.
- Y is the end of life as configured with the **sla monitor schedule** command (the **life** seconds have counted down to zero).
- Z is the age out of the operation.

The age out process, if used, starts counting down at W, is suspended between X and Y, and is reset to its configured size are starts counting down again at Y. When an SLA operation ages out, the SLA operation configuration is removed from the running configuration. It is possible for the operation to age out before it executes (that is, Z can occur before X). To ensure that this does not happen, the difference between the operation configuration time and start time (X and W) must be less than the age-out seconds.

The **recurring** keyword is only supported for scheduling single SLA operations. You cannot schedule multiple SLA operations using a single **sla monitor schedule** command. The **life** value for a recurring SLA operation should be less than one day. The **ageout** value for a recurring operation must be “never” (which is specified with the value 0), or the sum of the **life** and **ageout** values must be more than one day. If the recurring option is not specified, the operations are started in the existing normal scheduling mode.

You cannot modify the configuration of the SLA operation after scheduling it. To modify the configuration of a scheduled SLA operation, you must use the **no sla monitor** command to remove the selected SLA operation completely. Removing an SLA operation also removes the associated **sla monitor schedule** command. Then you can reenter the SLA operation configuration.

Examples

The following example shows SLA operation 25 scheduled to begin actively collecting data at 3:00 p.m. on April 5. This operation will age out after 12 hours of inactivity. When this SLA operation ages out, all configuration information for the SLA operation is removed from the running configuration.

```
hostname(config)# sla monitor schedule 25 life 43200 start-time 15:00 apr 5 ageout 43200
```

The following example shows SLA operation 1 schedule to begin collecting data after a 5-minute delay. The default life of one hour applies.

```
hostname(config)# sla monitor schedule 1 start after 00:05:00
```

The following example shows SLA operation 3 scheduled to begin collecting data immediately and is scheduled to run indefinitely:

```
hostname(config)# sla monitor schedule 3 life forever start-time now
```

The following example shows SLA operation 15 scheduled to begin automatically collecting data every day at 1:30 a.m.:

```
hostname(config)# sla monitor schedule 15 start-time 01:30:00 recurring
```

Related Commands

Command	Description
show sla monitor configuration	Displays the SLA configuration settings.
sla monitor	Defines an SLA monitoring operation.

smart-tunnel auto-signon enable

To enable smart tunnel auto sign-on in clientless (browser-based) SSL VPN sessions, use the **smart-tunnel auto-signon enable** command in group-policy webvpn configuration mode or username webvpn configuration mode.

To remove the **smart-tunnel auto-signon enable** command from the group policy or username and inherit it from the default group-policy, use the **no** form of this command.

no smart-tunnel auto-signon enable *list* [**domain** *domain*] [port *port*] [realm *realm string*]

Syntax Description

domain *domain*	(Optional). Name of the domain to be added to the username during authentication. If you enter a domain, enter the **use-domain** keyword in the list entries.
list	The name of a smart tunnel auto sign-on list already present in the ASA webvpn configuration. To view the smart tunnel auto sign-on list entries in the SSL VPN configuration, enter the **show running-config webvpn smart-tunnel** command in privileged EXEC mode.
port	Specifies which port performs auto sign-on.
realm	Configures a realm for the authentication.

Defaults

No defaults exist for this command.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group-policy webvpn configuration	•	—	•	—	—
Username webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.0(4)	This command was introduced.
8.4(1)	Optional *realm* and *port* arguments were introduced.

Usage Guidelines

The smart-tunnel auto sign-on feature supports only applications communicating HTTP and HTTPS using the Microsoft WININET library. For example, Microsoft Internet Explorer uses the WININET dynamic linked library to communicate with web servers.

You must use the **smart-tunnel auto-signon** *list* command to create a list of servers first. You can assign only one list to a group policy or username.

A realm string is associated with the protected area of the website and is passed back to the browser either in the authentication prompt or in the HTTP headers during authentication. If adminstrators do not know the corresponding realm, they should perform logon once and get the string from the prompt dialog.

Administrators can now optionally specify a port number for the corresponding hosts. For Firefox, if no port number is specified, auto sign-on is performed on HTTP and HTTPS, accessed by the default port numbers 80 and 443 respectively.

Examples

The following commands enable the smart tunnel auto sign-on list named HR:

```
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# smart-tunnel auto-signon enable HR
hostname(config-group-webvpn)
```

The following command enables the smart tunnel auto sign-on list named HR and adds the domain named CISCO to the username during authentication:

```
hostname(config-group-webvpn)# smart-tunnel auto-signon enable HR domain CISCO
```

The following command removes the smart tunnel auto sign-on list named HR from the group policy and inherits the smart tunnel auto sign-on list command from the default group policy:

```
hostname(config-group-webvpn)# no smart-tunnel auto-signon enable HR
```

Related Commands

Command	Description
smart-tunnel auto-signon *list*	Creates a list of servers for which to automate the submission of credentials in smart tunnel connections.
show running-config webvpn smart-tunnel	Displays the smart tunnel configuration on the ASA.
smart-tunnel auto-start	Starts smart tunnel access automatically upon user login.
smart-tunnel disable	Prevents smart tunnel access.
smart-tunnel *list*	Adds an entry to a list of applications that can use a Clientless SSL VPN session to connect to private sites.

smart-tunnel auto-signon list

To create a list of servers for which to automate the submission of credentials in smart tunnel connections, use the **smart-tunnel auto-signon list** command in webvpn configuration mode.Use this command for each server you want to add to a list.

To remove an entry from a list, use the **no** form of this command, specifying both the list and the IP address or hostname, as it appears in the ASA configuration.

no smart-tunnel auto-signon *list* [**use-domain**] {**ip** *ip-address* [*netmask*] | **host** *hostname-mask*}

To display the smart tunnel auto sign-on list entries, enter the **show running-config webvpn smart-tunnel** command in privileged EXEC mode.

To remove an entire list of servers from the ASA configuration, use the **no** form of the command, specifying only the list.

no smart-tunnel auto-signon *list*

Syntax Description

host	Server to be identified by its host name or wildcard mask.
hostname-mask	Host name or wildcard mask to auto-authenticate to.
ip	Server to be identified by its IP address and netmask.
ip-address [*netmask*]	Sub-network of hosts to auto-authenticate to.
list	Name of a list of remote servers. Use quotation marks around the name if it includes a space. The string can be up to 64 characters. The ASA creates the list if it is not present in the configuration. Otherwise, it adds the entry to the list.
use-domain	(Optional) Add the Windows domain to the username if authentication requires it. If you enter this keyword, be sure to specify the domain name when assigning the smart tunnel list to one or more group policies, or usernames.

Defaults

No defaults exist for this command.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
webvpn configuration mode	•	—	•	—	—

Command History

Release	Modification
8.0(4)	This command was introduced.

Usage Guidelines

The smart-tunnel auto sign-on feature supports only applications communicating HTTP and HTTPS using the Microsoft WININET library. For example, Microsoft Internet Explorer uses the WININET dynamic linked library to communicate with web servers.

Following the population of a smart tunnel auto sign-on list, use the **smart-tunnel auto-signon enable** *list* command in group policy webvpn or username webvpn mode to assign the list.

Examples

The following command adds all hosts in the subnet and adds the Windows domain to the username if authentication requires it:

```
asa2(config-webvpn)# smart-tunnel auto-signon HR use-domain ip 192.32.22.56 255.255.255.0
```

The following command removes that entry from the list:

```
asa2(config-webvpn)# no smart-tunnel auto-signon HR use-domain ip 192.32.22.56
255.255.255.0
```

The command shown above also removes the list named HR if the entry removed is the only entry in the list. Otherwise, the following command removes the entire list from the ASA configuration:

```
asa2(config-webvpn)# no smart-tunnel auto-signon HR
```

The following command adds all hosts in the domain to the smart tunnel auto sign-on list named intranet:

```
asa2(config-webvpn)# smart-tunnel auto-signon intranet host *.exampledomain.com
```

The following command removes that entry from the list:

```
asa2(config-webvpn)# no smart-tunnel auto-signon intranet host *.exampledomain.com
```

Related Commands

Command	Description
smart-tunnel auto-signon enable	Enables smart tunnel auto sign-on for the group policy or username specified in the command mode.
smart-tunnel auto-signon enable *list*	Assigns a smart tunnel auto sign-on list to a group policy or username
show running-config webvpn smart-tunnel	Displays the smart tunnel configuration.
smart-tunnel auto-start	Starts smart tunnel access automatically upon user login.
smart-tunnel enable	Enables smart tunnel access upon user login, but requires the user to start smart tunnel access manually, using the **Application Access > Start Smart Tunnels** button on the Clientless SSL VPN portal page.

smart-tunnel auto-start

To start smart tunnel access automatically upon user login in a clientless (browser-based) SSL VPN session, use the **smart-tunnel auto-start** command in group-policy webvpn configuration mode or username webvpn configuration mode.

smart-tunnel auto-start *list*

To remove the **smart-tunnel** command from the group policy or username and inherit the [**no**] **smart-tunnel** command from the default group-policy, use the **no** form of the command.

no smart-tunnel

Syntax Description

list	*list* is the name of a smart tunnel list already present in the ASA webvpn configuration. To view any smart tunnel list entries already present in the SSL VPN configuration, enter the **show running-config webvpn** command in privileged EXEC mode.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy webvpn configuration mode	•	—	•	—	—
Username webvpn configuration mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

This command requires that you use the **smart-tunnel list** command to create the list of applications first.

This option to start smart tunnel access upon user login applies only to Windows.

Examples

The following commands start smart tunnel access for a list of applications named apps1:

```
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# smart-tunnel auto-start apps1
hostname(config-group-webvpn)
```

The following commands remove the list named apps1 from the group policy and inherit the smart tunnel commands from the default group policy:

```
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# no smart-tunnel
hostname(config-group-webvpn)
```

Related Commands

Command	Description
show running-config webvpn	Displays the Clientless SSL VPN configuration, including all smart tunnel list entries.
smart-tunnel disable	Prevents smart tunnel access.
smart-tunnel enable	Enables smart tunnel access upon user login, but requires the user to start smart tunnel access manually, using the **Application Access > Start Smart Tunnels** button on the Clientless SSL VPN portal page.
smart-tunnel list	Adds an entry to a list of applications that can use a Clientless SSL VPN session to connect to private sites.

smart-tunnel disable

To prevent smart tunnel access through clientless (browser-based) SSL VPN sessions, use the **smart-tunnel disable** command in group-policy webvpn configuration mode or username webvpn configuration mode.

smart-tunnel disable

To remove a **smart-tunnel** command from the group policy or username and inherit the [**no**] **smart-tunnel** command from the default group-policy, use the **no** form of the command.

no smart-tunnel

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy webvpn configuration mode	•	—	•	—	—
Username webvpn configuration mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

By default, smart tunnels are not enabled, so the **smart-tunnel disable** command is necessary only if the (default) group policy or username configuration contains a **smart-tunnel auto-start** or **smart-tunnel enable** command that you do not want applied for the group policy or username in question.

Examples

The following commands prevent smart tunnel access:

```
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# smart-tunnel disable
hostname(config-group-webvpn)
```

Related Commands

Command	Description
smart-tunnel auto-start	Starts smart tunnel access automatically upon user login.
smart-tunnel enable	Enables smart tunnel access upon user login, but requires the user to start smart tunnel access manually, using the **Application Access** > **Start Smart Tunnels** button on the Clientless SSL VPN portal page.
smart-tunnel list	Adds an entry to a list of applications that can use a Clientless SSL VPN session to connect to private sites.

smart-tunnel enable

To enable smart tunnel access through clientless (browser-based) SSL VPN sessions, use the **smart-tunnel enable** command in group-policy webvpn configuration mode or username webvpn configuration mode.

smart-tunnel enable *list*

To remove the **smart-tunnel** command from the group policy or username and inherit the [**no**] **smart-tunnel** command from the default group-policy, use the **no** form of the command.

no smart-tunnel

Syntax Description

list	*list* is the name of a smart tunnel list already present in the ASA webvpn configuration. To view the smart tunnel list entries in the SSL VPN configuration, enter the **show running-config webvpn** command in privileged EXEC mode.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy webvpn configuration mode	•	—	•	—	—
Username webvpn configuration mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The **smart-tunnel enable** command assigns a list of applications eligible for smart tunnel access to a group policy or username. It requires the user to start smart tunnel access manually, using the **Application Access > Start Smart Tunnels** button on the clientless-SSL-VPN portal page. Alternatively, you can use the **smart-tunnel auto-start** command to start smart tunnel access automatically upon user login.

Both commands require that you use the **smart-tunnel list** command to create the list of applications first.

Examples

The following commands enable the smart tunnel list named apps1:

```
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# smart-tunnel enable apps1
hostname(config-group-webvpn)
```

The following commands remove the list named apps1 from the group policy and inherit the smart tunnel list from the default group policy:

```
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# no smart-tunnel
hostname(config-group-webvpn)
```

Related Commands

Command	Description
show running-config webvpn	Displays the Clientless SSL VPN configuration, including all smart tunnel list entries.
smart-tunnel auto-start	Starts smart tunnel access automatically upon user login.
smart-tunnel disable	Prevents smart tunnel access.
smart-tunnel list	Adds an entry to a list of applications that can use a Clientless SSL VPN session to connect to private sites.

smart-tunnel list

To populate a list of applications that can use a clientless (browser-based) SSL VPN session to connect to private sites, use the **smart-tunnel list** command in webvpn configuration mode. To remove an application from a list, use the **no** form of the command, specifying the entry. To remove an entire list of applications from the ASA configuration, use the **no** form of the command, specifying only the list.

[**no**] **smart-tunnel list** *list application path* [**platform** *OS*] [*hash*]

no smart-tunnel list *list*

Syntax Description

application	Name of the application to be granted smart tunnel access. The string can be up to 64 characters.
hash	(Optional and applicable only for Windows) To obtain this value, enter the checksum of the application (that is, the checksum of the executable file) into a utility that calculates a hash using the SHA-1 algorithm. One example of such a utility is the Microsoft File Checksum Integrity Verifier (FCIV), which is available at http://support.microsoft.com/kb/841290/. After installing FCIV, place a temporary copy of the application to be hashed on a path that contains no spaces (for example, c:/fciv.exe), then enter **fciv.exe -sha1** *application* at the command line (for example, **fciv.exe -sha1 c:\msimn.exe**) to display the SHA-1 hash. The SHA-1 hash is always 40 hexadecimal characters.
list	Name of a list of applications or programs. Use quotation marks around the name if it includes a space. The CLI creates the list if it is not present in the configuration. Otherwise, it adds the entry to the list.
path	For Mac OS, the full path to the application. For Windows, the filename of the application; or a full or partial path to the application, including its filename. The string can be up to 128 characters.
platform *OS*	(Optional if the OS is Microsoft Windows) Enter **windows or mac** to specify the host of the application.

Defaults

Windows is the default platform.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.
8.0(4)	Added **platform** *OS*.

Usage Guidelines

You can configure more than one smart tunnel list on an ASA, but you cannot assign more than one smart tunnel list to a given group policy or username. To populate a smart tunnel list, enter the **smart-tunnel list** command once for each application, entering the same *list* string, but specifying an *application* and *path* that is unique for the OS. Enter the command once for each *OS* you want the list to support.

The session ignores a list entry if the OS does not match the one indicated in the entry. It also ignores an entry if the path to the application is not present.

To view the smart tunnel list entries in the SSL VPN configuration, enter the **show running-config webvpn smart-tunnel** command in privileged EXEC mode.

The *path* must match the one on the computer, but it does not have to be complete. For example, the *path* can consist of nothing more than the executable file and its extension.

Smart tunnels have the following requirements:

- The remote host originating the smart tunnel connection must be running a 32-bit version of Microsoft Windows Vista, Windows XP, or Windows 2000; or Mac OS 10.4 or 10.5.
- Users of Microsoft Windows Vista who use smart tunnels or port forwarding must add the URL of the ASA to the Trusted Site zone. To access the Trusted Site zone, they must start Internet Explorer and choose the Tools > Internet Options > Security tab. Vista users can also disable Protected Mode to facilitate smart tunnel access; however, we recommend against this method because it increases the computer's vulnerability to attack.
- The browser must be enabled with Java, Microsoft ActiveX, or both.
- Smart tunnel support for Mac OS requires Safari 3.1.1 or later.

On Microsoft Windows, only Winsock 2, TCP-based applications are eligible for smart tunnel access.

On Mac OS, applications using TCP that are dynamically linked to the SSL library can work over a smart tunnel. The following types of applications do not work over a smart tunnel:

- Applications using dlopen or dlsym to locate libsocket calls
- Statically linked applications to locate libsocket calls
- Mac OS applications that use two-level name spaces.
- Mac OS, console-based applications, such as Telnet, SSH, and cURL.
- Mac OS, PowerPC-type applications. To determine the type of a Mac OS application, right-click its icon and select Get Info.

On Mac OS, only applications started from the portal page can establish smart tunnel sessions. This requirement includes smart tunnel support for Firefox. Using Firefox to start another instance of Firefox during the first use of a smart tunnel requires the user profile named csco_st. If this user profile is not present, the session prompts the user to create one.

The following limitations apply to smart tunnels:

- If the remote computer requires a proxy server to reach the ASA, the URL of the terminating end of the connection must be in the list of URLs excluded from proxy services. In this configuration, smart tunnels support only basic authentication.
- The smart tunnel auto sign-on feature supports only applications communicating HTTP and HTTPS using the Microsoft WININET library on a Microsoft Windows OS. For example, Microsoft Internet Explorer uses the WININET dynamic linked library to communicate with web servers.
- A group policy or local user policy supports no more than one list of applications eligible for smart tunnel access and one list of smart tunnel auto sign-on servers.
- A stateful failover does not retain smart tunnel connections. Users must reconnect following a failover.

Note A sudden problem with smart tunnel access may be an indication that a *path* value is not up-to-date with an application upgrade. For example, the default path to an application typically changes following the acquisition of the company that produces the application and the next upgrade.

Entering a hash provides a reasonable assurance that clientless SSL VPN does not qualify an illegitimate file that matches the string you specified in the *path*. Because the checksum varies with each version or patch of an application, the *hash* you enter can only match one version or patch on the remote host. To specify a *hash* for more than one version of an application, enter the **smart-tunnel list** command once for each version, entering the same *list* string, but specifying the unique *application* string and unique *hash* value in each command.

Note You must maintain the smart tunnel list in the future if you enter *hash* values and you want to support future versions or patches of an application with smart tunnel access. A sudden problem with smart tunnel access may be an indication that the application list containing *hash* values is not up-to-date with an application upgrade. You can avoid this problem by not entering a *hash*.

Following the configuration of a smart tunnel list, use the **smart-tunnel auto-start** or **smart-tunnel enable** command to assign the list to group policies or usernames.

Examples

The following command adds the Microsoft Windows application Connect to a smart tunnel list named apps1:

```
hostname(config-webvpn)# smart-tunnel list apps1 LotusSametime connect.exe
```

The following command adds the Windows application msimn.exe and requires that the hash of the application on the remote host match the last string entered to qualify for smart tunnel access:

```
hostname(config-webvpn)# smart-tunnel list apps1 OutlookExpress msimn.exe
4739647b255d3ea865554e27c3f96b9476e75061
```

The following command provides smart tunnel support for the Mac OS browser Safari:

```
hostname(config-webvpn)# smart-tunnel list apps1 Safari /Applications/Safari platform mac
```

Related Commands

Command	Description
show running-config webvpn smart-tunnel	Displays the smart tunnel configuration on the ASA.
smart-tunnel auto-start	Starts smart tunnel access automatically upon user login.
smart-tunnel disable	Prevents smart tunnel access.
smart-tunnel enable	Enables smart tunnel access upon user login, but requires the user to start smart tunnel access manually, using the **Application Access > Start Smart Tunnels** button on the Clientless SSL VPN portal page.

smart-tunnel network

To create a list of hosts to use for configuring smart tunnel tunnel policies, use the **smart-tunnel network** command in webvpn configuration mode. To disallow a list of hosts for smart tunnel tunnel policies, use the [no] form of this command.

smart-tunnel network

no smart-tunnel network

Syntax Description

host *host mask*	The hostname mask, such as *.cisco.com.
ip *ip address*	The IP address of a network.
netmask	The Netmask of a network.
network name	The name of the network to apply to tunnel policy.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Webvpn configuration	•	•	•		

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

When the smart tunnel is turned on, you can allow traffic outside of the tunnel with the **smart-tunnel network** command, which configures the network (a set of hosts), and the **smart-tunnel tunnel-policy** command, which uses the specified smart-tunnel network to enforce a policy on a user.

Examples

The following is a sample of how the **smart-tunnel network** command is used:

```
hostname(config-webvpn)# smart-tunnel network testnet ip 192.168.0.0 255.255.255
```

Related Commands

Command	Description
smart-tunnel tunnel-policy	Uses the specified smart-tunnel network to enforce a policy on a user.

smart-tunnel tunnel-policy

To apply smart tunnel tunnel policies to a particular group or user policy, use the **smart-tunnel tunnel-policy** command in configuration webvpn mode. To unapply smart tunnel tunnel policies to a particular group, use the [no] form of this command.

smart-tunnel tunnel-policy

no smart-tunnel tunnel-policy

Syntax Description

excludespecified	Tunnels only networks that are outside of the networks specified by network name.
network name	Lists networks to be tunneled.
tunnelall	Makes everything tunneled (encrypted).
tunnelspecified	Tunnels only networks specified by network name.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Webvpn configuration	•	•	•		

Command History

Release	Modification
8.3.1	This command was introduced.

Usage Guidelines

When the smart tunnel is turned on, you can allow traffic outside of the tunnel with the **smart-tunnel network** command, which configures the network (a set of hosts), and the **smart-tunnel tunnel-policy** command, which uses the specified smart-tunnel network to enforce a policy on a user.

Examples

The following is a sample of how the **smart-tunnel tunnel-policy**command is used:

```
hostname(config-username-webvpn)# smart-tunnel tunnel-policy tunnelspecified testnet
```

Related Commands

Command	Description
smart-tunnel network	Creates a list of hosts for configuring smart tunnel policies.

smtp from-address

To specify the e-mail address to use in the E-mail From: field for all e-mails generated by the local CA server (such as distribution of one-time passwords) use the **smtp from-address** command in CA server configuration mode. To reset the e-mail address to the default, use the **no** form of this command.

smtp from-address *e-mail_address*

no smtp from-address

Syntax Description

e-mail_address	Specifies the e-mail address appearing in the From: field of all e-mails generated by the CA server.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca server configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Examples

The following example specifies that the From: field of all e-mails from the local CA server include ca-admin@asa1-ca.example.com:

```
hostname(config)# crypto ca server
hostname(config-ca-server)# smtp from-address ca-admin@asa1-ca.example.com
hostname(config-ca-server)#
```

The following example resets the From: field of all e-mails from the local CA server to the default address admin@asa1-ca.example.com:

```
hostname(config)# crypto ca server
hostname(config-ca-server)# smtp from-address admin@asa1-ca.example.com
hostname(config-ca-server)#
```

Related Commands

Command	Description
crypto ca server	Provides access to CA Server Configuration mode CLI command set, which allows you to configure and manage a local CA.
smtp subject	Customizes the text to appear in the subject field of all e-mails generated by the local CA server.

smtp subject

To customize the text that appears in the subject field of all e-mails generated by the local Certificate Authority (CA) server (such as distribution of one-time passwords), use the **smtp subject** command in CA server configuration mode. To reset the text to the default, use the **no** form of this command.

smtp subject *subject-line*

no smtp subject

Syntax Description

subject-line	Specifies the text appearing in the Subj: field of all e-mails sent from the CA server. The maximum number of characters is 127.

Defaults

By default, the text in the Subj: field is "Certificate Enrollment Invitation".

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca server configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Examples

The following example specifies that the text *Action: Enroll for a certificate* appear in the Subj: field of all e-mails from the CA server:

```
hostname(config)# crypto ca server
hostname(config-ca-server)# smtp subject Action: Enroll for a certificate
hostname(config-ca-server)#
```

The following example resets the Subj: field text for all e-mails from the CA server to the default text "Certificate Enrollment Invitation":

```
hostname(config)# crypto ca server
hostname(config-ca-server)# no smtp subject
hostname(config-ca-server)#
```

Related Commands

Command	Description
crypto ca server	Provides access to CA Server Configuration mode CLI command set, which allows you to configure and manage a local CA.
smtp from-address	Specifies the e-mail address to use in the E-mail From: field for all e-mails generated by the local CA server.

smtps

To enter SMTPS configuration mode, use the **smtps** command in global configuration mode. To remove any commands entered in SMTPS command mode, use the **no** version of this command. SMTPS is a TCP/IP protocol that lets you to send e-mail over an SSL connection.

smtps

no smtps

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to enter SMTPS configuration mode:

```
hostname(config)# smtps
hostname(config-smtps)#
```

Related Commands

Command	Description
clear configure smtps	Removes the SMTPS configuration.
show running-config smtps	Displays the running configuration for SMTPS.

smtp-server

To configure an SMTP server, use the **smtp-server** command in global configuration mode. To remove the attribute from the configuration, use the **no** form of this command.

smtp-server {*primary_server*} [*backup_server*]

no smtp-server

Syntax Description

backup_server	Identifies a backup SMTP server to relay event messages if the primary SMTP server is unavailable. Use either an IP address or DNS name.
primary_server	Identifies the primary SMTP server. Use either an IP address or DNS name

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The ASA includes an internal SMTP client that the Events system can use to notify external entities that a certain event has occurred. You can configure SMTP servers to receive these event notices, and then forward them to specified e-mail addresses. The SMTP facility is active only when you enable E-mail events to the ASA.

Examples

The following example shows how to set an SMTP server with an IP address of 10.1.1.24, and a backup SMTP server with an IP address of 10.1.1.34:

```
hostname(config)# smtp-server 10.1.1.24 10.1.1.34
```

snmp cpu threshold rising

To configure the threshold value for a high CPU threshold and the threshold monitoring period, use the **snmp cpu threshold rising** command in global configuration mode. To not configure the threshold value and threshold monitoring period, use the **no** form of this command.

snmp cpu threshold rising *threshold_value monitoring_period*

no snmp cpu threshold rising *threshold_value monitoring_period*

Syntax Description

monitoring_period	Defines the monitoring period in minutes.
threshold_value	Defines the threshold level as a percentage of CPU usage.

Defaults

If the **snmp cpu threshold rising** command is not configured, the default for the high threshold level is set at over 70 percent of CPU usage, and the default for the critical threshold level isset at over 95 percent of CPU usage. The default monitoring period is set to one minute.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.4(1)	This command was introduced. Does not apply to the ASA Services Module.

Usage Guidelines

You cannot configure the critical CPU threshold level, which is maintained at a constant 95 percent. Valid threshold values range from 10 to 94 percent of CPU usage. Valid values for the monitoring period range from 1 to 60 minutes.

Examples

The following example shows how to configure the SNMP CPU threshold level to 75 percent of CPU usage and a monitoring period of 30 minutes:

```
hostname(config)# snmp cpu threshold 75% 30
```

Related Commands

Command	Description
snmp-server enable traps	Enables SNMP-related traps.
snmp link threshold	Defines the SNMP interface threshold value.
snmp-server enable	Enables SNMP on the ASA.
snmp-server host	Sets the SNMP host address.
snmp-server location	Sets the SNMP server location string.

snmp link threshold

To configure the threshold value for an SNMP physical interface and the threshold value for system memory usage, use the **snmp link threshold** command in global configuration mode. To clear the threshold value for an SNMP physical interface and the threshold value for system memory usage, use the **no** form of this command.

snmp link threshold *threshold_value*

no snmp link threshold *threshold_value*

Syntax Description

threshold_value	Defines the threshold value as a percentage of CPU usage.

Defaults

If you do not configure the **snmp link threshold** command, the default threshold value is 70 percent of CPU usage and system memory usage.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.4(1)	This command was introduced.

Usage Guidelines

Valid threshold values range from 30 to 99 percent of physical interfaces. The **snmp link threshold** command is available only in the admin context.

Examples

The following example shows how to configure the SNMP interface threshold value to 75 percent for all physical interfaces:

```
hostname(config)# snmp link threshold 75%
```

Related Commands

Command	Description
snmp-server enable traps	Enables SNMP-related traps.
snmp cpu threshold rising	Defines the SNMP CPU threshold value.
snmp-server enable	Enables SNMP on the ASA.

Command	Description
snmp-server host	Sets the SNMP host address.
snmp-server location	Sets the SNMP server location string.

snmp-map

To identify a specific map for defining the parameters for SNMP inspection, use the **snmp-map** command in global configuration mode. To remove the map, use the **no** form of this command.

snmp-map *map_name*

no snmp-map *map_name*

Syntax Description

map_name	The name of the SNMP map.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the **snmp-map** command to identify a specific map to use for defining the parameters for SNMP inspection. When you enter this command, the system enters the SNMP map configuration mode, which lets you enter the different commands used for defining the specific map. After defining the SNMP map, you use the **inspect snmp** command to enable the map. Then you use the **class-map**, **policy-map**, and **service-policy** commands to define a class of traffic, to apply the **inspect** command to the class, and to apply the policy to one or more interfaces.

Examples

The following example shows how to identify SNMP traffic, define a SNMP map, define a policy, and apply the policy to the outside interface.

```
hostname(config)# access-list snmp-acl permit tcp any any eq 161
hostname(config)# access-list snmp-acl permit tcp any any eq 162
hostname(config)# class-map snmp-port
hostname(config-cmap)# match access-list snmp-acl
hostname(config-cmap)# exit
hostname(config)# snmp-map inbound_snmp
hostname(config-snmp-map)# deny version 1
hostname(config-snmp-map)# exit
hostname(config)# policy-map inbound_policy
hostname(config-pmap)# class snmp-port
hostname(config-pmap-c)# inspect snmp inbound_snmp
```

```
hostname(config-pmap-c)#
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
deny version	Disallows traffic using a specific version of SNMP.
inspect snmp	Enables SNMP application inspection.
policy-map	Associates a class map with specific security actions.

snmp-server community

To set the SNMP community string, use the **snmp-server community** command in global configuration mode. To remove the SNMP community string, use the **no** form of this command.

snmp-server community [*0* | *8*] *community-string*

no snmp-server community [*0* | *8*] *community-string*

Syntax Description

0	(Optional) Specifies that an unencrypted (clear text) community string will follow.
8	Specifies that an encrypted community string will follow.
community-string	Sets the SNMP community string, which is the password in encrypted or unencrypted (clear text) format. The community string can have a maximum of 32 characters.

Defaults

The default community string is "public."

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.2(1)	The *text* argument was changed to the *community-string* argument.
8.3(1)	Support for encrypted passwords was added.

Usage Guidelines

The SNMP community string is a shared secret among the SNMP management station and the network nodes being managed. It is used only for Version 1 and 2c communication between the management station and the device. The ASA uses a key to determine whether or not the incoming SNMP request is valid.

For example, you could designate a site with a community string and then configure the routers, the ASA, and the management station with this same string. The ASA uses this string and does not respond to requests with an invalid community string.

After you have used an encrypted community string, only the encrypted form is visible to all systems (for example, CLI, ASDM, CSM, and so on). The clear text password is not visible.

The encrypted community string is always generated by the ASA; you normally enter the clear text form.

Note If you downgrade from version 8.3(1) to a lower version of the ASA software and have configured encrypted passwords, you must first revert the encrypted passwords to clear text using the **no key config-key password encryption** command, then save the results.

Examples

The following example sets the community string to ”onceuponatime”:

```
hostname(config)# snmp-server community onceuponatime
```

The following example sets an encrypted community string:

```
hostname(config)# snmp-server community 8 LvAu+JdFG+GjPmZYlKvAhXpb28E=
```

The following example sets an unencrypted community string:

```
hostname(config)# snmp-server community 0 cisco
```

Related Commands

Command	Description
clear configure snmp-server	Clears the SNMP counters.
snmp-server contact	Sets the SNMP contact name.
snmp-server enable	Enables SNMP on the ASA.
snmp-server host	Sets the SNMP host address.
snmp-server location	Sets the SNMP server location string.

snmp-server contact

To set the SNMP server contact name, use the **snmp-server contact** command in global configuration mode. To remove the SNMP contact name, use the **no** form of this command.

snmp-server contact *text*

no snmp-server contact [*text*]

Syntax Description

text	Specifies the name of the contact person or the ASA system administrator. The name is case sensitive and can be up to 127 characters. Spaces are accepted, but multiple spaces are shortened to a single space.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example sets the SNMP server contact to EmployeeA:

```
hostname(config)# snmp-server contact EmployeeA
```

Related Commands

Command	Description
snmp-server community	Sets the SNMP community string.
snmp-server enable	Enables SNMP on the ASA.
snmp-server enable traps	Enables SNMP traps.
snmp-server host	Sets the SNMP host address.
snmp-server location	Sets the SNMP server location string.

snmp-server enable

To enable the SNMP server on the ASA, use the **snmp-server enable** command in global configuration mode. To disable the SNMP server, use the **no** form of this command.

snmp-server enable

no snmp-server enable

Syntax Description

This command has no arguments or keywords.

Defaults

The SNMP server is enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can enable and disable SNMP easily, without configuring and reconfiguring SNMP traps or other configuration.

Examples

The following example enables SNMP, configures the SNMP host and traps, and then sends traps as syslog messages.

```
hostname(config)# snmp-server enable
hostname(config)# snmp-server community onceuponatime
hostname(config)# snmp-server location Building 42, Sector 54
hostname(config)# snmp-server contact EmployeeB
hostname(config)# snmp-server host perimeter 10.1.2.42
hostname(config)# snmp-server enable traps all
hostname(config)# logging history 7
hostname(config)# logging enable
```

Related Commands

Command	Description
snmp-server community	Sets the SNMP community string.
snmp-server contact	Sets the SNMP contact name.

Command	Description
snmp-server enable traps	Enables SNMP traps.
snmp-server host	Sets the SNMP host address.
snmp-server location	Sets the SNMP server location string.

snmp-server enable traps

To enable the ASA to send traps to the NMS, use the **snmp-server enable traps** command in global configuration mode. To disable traps, use the **no** form of this command.

snmp-server enable traps [**all** | **syslog** | **snmp** [*trap*] [...] | **entity** [*trap*] [...] | **ipsec** [*trap*] [...] | **ikev2** [*trap*] [...] | **remote-access** [*trap*] | **connection-limit-reached** | **cpu threshold rising** | **link-threshold** | **memory-threshold** | **nat** [*trap*]

no snmp-server enable traps [**all** | **syslog** | **snmp** [*trap*] [...] | **entity** [*trap*] [...] | **ipsec** [*trap*] [...] | **remote-access** [*trap*] | **connection-limit-reached** | **cpu threshold rising** | **link-threshold** | **memory-threshold** | **nat** [*trap*]

Syntax Description

all	Enables all traps.
connection-limit-reached	Enables connection limit reached traps.
cpu threshold rising	Enables CPU threshold rising traps.
entity [*trap*]	Enables entity traps. Traps for **entity** include the following: • **config-change** • **fru-insert** • **fru-remove** • **cpu-temperature** • **fan-failure** • **power-supply** • **power-supply-failure** • **power-supply-temperature** • **chassis-temperature** • **power-supply-presence** • **chassis-fan-failure**
ipsec [*trap*]	Enables IPsec traps. Traps for **ipsec** include the following: • **start** • **stop**
ikev2 [*trap*]	Enables IKEv2 IPsec traps. Traps for **ikev2** include: • **start** • **stop**
link-threshold	Enables link threshold reached traps.
memory-threshold	Enables memory threshold reached traps.
nat [*trap*]	Enables NAT-related traps. Traps for **nat** include the following: • **packet-discard**
remote-access [*trap*]	Enables remote access traps. Traps for **remote-access** include the following: • **session-threshold-exceeded**

snmp [*trap*]	Enables SNMP traps. By default, all SNMP traps are enabled. Traps for **snmp** include the following: • **authentication** • **linkup** • **linkdown** • **coldstart** • **warmstart**
syslog	Enables syslog message traps.

Defaults

The default configuration has all **snmp** traps enabled (**snmp-server enable traps snmp authentication linkup linkdown coldstart warmstart**). If you enter this command and do not specify a trap type, then the default is **syslog**. (The default **snmp** traps continue to be enabled along with the **syslog** trap.) All other traps are disabled by default.

You can disable these traps using the **no** form of this command with the **snmp** keyword. The **clear configure snmp-server** command restores the default enabling of SNMP traps.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.4(1)	The following traps have been added: **snmp warmstart**, **nat packet-discard**, **link-threshold**, **memory-threshold**, **entity power-supply**, **entity fan-failure**, **entity cpu-temperature**, **cpu threshold rising**, and **connection-limit-reached**. These traps do not apply to the ASASM.
8.6(1)	The following traps have been added to support the ASA 5512-X, 5515-X, 5525-X, 5545-X, and 5555-X: **entity power-supply-failure**, **entity chassis-fan-failure**, **entity power-supply-presence**, **entity chassis-temperature**, and **entity power-supply-temperature**.
9.0(1)	Support for multiple context mode was added for IKEv2 and IPsec.

Usage Guidelines

To enable individual traps or sets of traps, enter this command for each feature type. To enable all traps, enter the **all** keyword.

To send traps to the NMS, enter the **logging history** command, then enable logging using the **logging enable** command.

Traps generated in the admin context only include the following:

- **connection-limit-reached**

- **entity**
- **memory-threshold**

Traps generated through the admin context only for physically connected interfaces in the system context include the following:

- **interface-threshold**

All other traps are available in the admin and user contexts.

Note In multi-mode, the **fan-failure** trap, the **power-supply-failure** trap, and the **cpu-temperature** trap are generated only from the admin context, and not the user contexts (applies only to the ASA 5512-X, 5515-X, 5525-X, 5545-X, and 5555-X). These traps do not apply to the ASA 5505.

If the CPU usage is greater than the configured threshold value for the configured monitoring period, a **cpu threshold rising** trap is generated.

When the used system memory reaches 80 percent, the **memory-threshold** trap is generated.

Note SNMP does not monitor voltage sensors.

Examples

The following example enables SNMP, configures the SNMP host and traps, then sends traps as syslog messages:

```
hostname(config)# snmp-server enable
hostname(config)# snmp-server community onceuponatime
hostname(config)# snmp-server location Building 42, Sector 54
hostname(config)# snmp-server contact EmployeeB
hostname(config)# snmp-server host perimeter 10.1.2.42
hostname(config)# snmp-server enable traps all
hostname(config)# logging history 7
hostname(config)# logging enable
```

Related Commands

Command	Description
snmp-server community	Sets the SNMP community string.
snmp-server contact	Sets the SNMP contact name.
snmp-server enable	Enables SNMP on the ASA.
snmp-server host	Sets the SNMP host address.
snmp-server location	Sets the SNMP server location string.

snmp-server group

To configure a new SNMP group, use the **snmp-server group** command in global configuration mode. To remove a specified SNMP group, use the **no** form of this command.

snmp-server group *group-name* {**v3** {**auth** | **noauth** | **priv**}}

no snmp-server group *group-name* {**v3** {**auth** | **noauth** | **priv**}}

Syntax Description

auth	Specifies packet authentication without encryption.
group-name	Specifies the name of the group.
noauth	Specifies no packet authentication.
priv	Specifies packet authentication with encryption.
v3	Specifies that the group is using the SNMP Version 3 security model, which is the most secure of the supported security models. This version allows you to explicitly configure authentication characteristics.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.
8.3(1)	Support for password encryption was added.

Usage Guidelines

To use the Version 3 security model, you must first configure an SNMP group, then configure an SNMP user, and then configure an SNMP host. You must also specify Version 3 and a security level. When a community string is configured internally, two groups with the name “public” are automatically created—one for the Version 1 security model and one for the Version 2c security model. When you delete a community string, both configured groups are automatically deleted.

Note A user that is configured to belong to a certain group should have the same security model as the group.

During bootup or upgrade of the ASA, single-digit passwords and passwords starting with a digit followed by a whitespace are no longer supported. For example, 0 pass and 1 are invalid passwords.

Note If you downgrade from version 8.3(1) to a lower version of the ASA software and have configured encrypted passwords, you must first revert the encrypted passwords to clear text using the **no key config-key password encryption** command, then save the results.

Examples

The following example show how the ASA can receive SNMP requests using the SNMP Version 3 security model, which includes creating a group, creating a user, and creating a host:

```
hostname(config)# snmp-server group v3 vpn-group priv
hostname(config)# snmp-server user admin vpn group v3 auth sha letmein priv 3des cisco123
hostname(config)# snmp-server host mgmt 10.0.0.1 version 3 priv admin
```

Related Commands

Command	Description
clear configure snmp-server	Clears the SNMP configuration counters.
snmp-server host	Sets the SNMP host address.
snmp-server user	Creates a new SNMP user.

snmp-server host

To specify the NMS that can use SNMP on the ASA, use the **snmp-server host** command in global configuration mode. To disable the NMS, use the **no** form of this command.

snmp-server host {*interface* {*hostname* | *ip_address*}} [**trap** | **poll**] [**community** *0* | *8* *community-string*] [**version** {**1** | **2c** | **3** *username*}] [**udp-port** *port*]

no snmp-server host {*interface* {*hostname* | *ip_address*}} [**trap** | **poll**] [**community** *0* | *8* *community-string*] [**version** {**1** | **2c** | **3** *username*}] [**udp-port** *port*]

Syntax Description

0	(Optional) Specifies that an unencrypted (clear text) community string will follow.
8	Specifies that an encrypted community string will follow.
community	Specifies that a non-default string is required for requests from the NMS, or when generating traps sent to the NMS. Valid only for SNMP Version 1 or 2c.
community-string	Specifies the password-like community string that is sent with the notification or in a request from the NMS. The community string can have a maximum of 32 characters. Can be in encrypted or unencrypted (clear text) format.
hostname	Specifies the SNMP notification host, which is usually an NMS or SNMP manager.
interface	Specifies the interface name through which the NMS communicates with the ASA.
ip_address	Specifies the IP address of an NMS to which SNMP traps should be sent or from which the SNMP requests come. Supports *only* IPv4 addresses.
poll	(Optional) Specifies that the host is allowed to browse (poll), but no traps can be sent.
port	Sets the UDP port number of the NMS host.
trap	(Optional) Specifies that only traps can be sent, and that this host is not allowed to browse (poll).
udp-port	(Optional) Specifies that SNMP traps must be sent to an NMS host on a non-default port.
username	Specifies the username to embed in the trap PDU that is sent to the host. Valid only for SNMP Version 3.
version {**1** | **2c** | **3**}	(Optional) Sets the SNMP notification version to use for sending traps to Version 1, 2c, or 3.

Defaults

The default UDP port is 162.

The default version is 1.

SNMP traps are enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.2(1)	• SNMP Version 3 is supported. • The *username* argument was introduced. • The *text* argument was changed to the *community-string* argument. • The *interface_name* argument was changed to the *interface* argument.
8.3(1)	Support for encrypted passwords was added.

Usage Guidelines

If you configure the **snmp-server host** command on a port that is currently in use, the following message appears:

Warning **The UDP port *port* is in use by another feature. SNMP requests to the device will fail until the snmp-server listen-port command is configured to use a different port.**

The existing SNMP thread continues to poll every 60 seconds until the port is available, and issues syslog message %ASA-1-212001 if the port is still in use.

To use the Version 3 security model, you must configure an SNMP group first, then an SNMP user, and then an SNMP host. The username must already be configured on the device. When a device is configured as the standby unit of a failover pair, the SNMP engine ID and user configuration are replicated from the active unit. This action allows a transparent switchover from an SNMP Version 3 query perspective. No configuration changes are necessary in the NMS to accommodate a switchover event.

After you have used an encrypted community string, only the encrypted form is visible to all systems (for example, CLI, ASDM, CSM, and so on). The clear text password is not visible.

The encrypted community string is always generated by the ASA; you normally enter the clear text form.

During bootup or upgrade of the ASA, single-digit passwords and passwords starting with a digit followed by a whitespace are no longer supported. For example, 0 pass and 1 are invalid passwords.

Note If you downgrade from version 8.3(1) to a lower version of the ASA software and have configured encrypted passwords, you must first revert the encrypted passwords to clear text using the **no key config-key password encryption** command, then save the results.

Examples

The following example sets the host to 192.0.2.5, which is attached to the inside interface:

```
hostname(config)# snmp-server host inside 192.0.2.5
hostname(config)# snmp-server host inside 192.0.2.5 version 3 md5aes128 udp-port 190
```

The following example show how the ASA can receive SNMP requests using the SNMP Version 3 security model, which includes creating a group, creating a user, and creating a host:

```
hostname(config)# snmp-server group v3 vpn-group priv
hostname(config)# snmp-server user admin vpn group v3 auth sha letmein priv 3des cisco123
hostname(config)# snmp-server host mgmt 10.0.0.1 version 3 priv admin
```

The following example sets the host to use an encrypted community string:

```
hostname(config)# snmp-server host mgmt 1.2.3.4 community 8 LvAu+JdFG+GjPmZYlKvAhXpb28E=
```

The following example sets the host to use an unencrypted community string:

```
hostname(config)# snmp-server host mgmt 1.2.3.4 community 0 cisco
```

Related Commands

Command	Description
clear configure snmp-server	Clears SNMP configuration counters.
snmp-server enable	Enables SNMP on the ASA.
snmp-server group	Configures a new SNMP group.
snmp-server user	Configures a new SNMP user.

snmp-server listen-port

To set the listening port for SNMP requests, use the **snmp-server listen-port** command in global configuration mode. To restore the default port, use the **no** form of the command.

snmp-server listen-port *lport*

no snmp-server listen-port *lport*

Syntax Description

lport	The port on which incoming requests will be accepted[1].

1. The **snmp-server listen-port** command is only available in admin context, and is not available in the system context.

Defaults

The default port is 161.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If you configure the **snmp-server listen-port** command on a port that is currently in use, the following message appears:

Warning **The UDP port** *port* **is in use by another feature. SNMP requests to the device will fail until the snmp-server listen-port command is configured to use a different port.**

The existing SNMP thread continues to poll every 60 seconds until the port is available, and issues syslog message %ASA-1-212001 if the port is still in use.

Examples

The following example sets the listening port to 192:

```
hostname(config)# snmp-server listen-port 192
```

Related Commands

Command	Description
snmp-server community	Sets the SNMP community string.
snmp-server contact	Sets the SNMP contact name.
snmp-server enable	Enables SNMP on the ASA.
snmp-server enable traps	Enables SNMP traps.
snmp-server location	Sets the SNMP server location string.

snmp-server location

To set the ASA location for SNMP, use the **snmp-server location** command in global configuration mode. To remove the location, use the **no** form of this command.

snmp-server location *text*

no snmp-server location [*text*]

Syntax Description

location *text*	Specifies the security appliance location. The **location** *text* is case sensitive and can be up to 127 characters. Spaces are accepted, but multiple spaces are shortened to a single space.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example sets the ASA location for SNMP as Building 42, Sector 54:

```
hostname(config)# snmp-server location Building 42, Sector 54
```

Related Commands

Command	Description
snmp-server community	Sets the SNMP community string.
snmp-server contact	Sets the SNMP contact name.
snmp-server enable	Enables SNMP on the ASA.
snmp-server enable traps	Enables SNMP traps.
snmp-server host	Sets the SNMP host address.

snmp-server user

To configure a new SNMP user, use the **snmp-server user** command in global configuration mode. To remove a specified SNMP user, use the **no** form of this command.

snmp-server user *username group-name* {**v3** [encrypted] [auth {md5 | sha} *auth-password]*} [priv {**des** | **3des** | **aes** {**128** | **192** | **256**}} *priv-password*]

no snmp-server user *username group-name* {**v3** [encrypted] [auth {md5 | sha} *auth-password]*} [priv {**des** | **3des** | **aes** {**128** | **192** | **256**}} *priv-password*]

Syntax Description

128	(Optional) Specifies the use of the 128-bit AES algorithm for encryption.
192	(Optional) Specifies the use of the 192-bit AES algorithm for encryption.
256	(Optional) Specifies the use of the 256-bit AES algorithm for encryption.
3des	(Optional) Specifies the use of the 168-bit 3DES algorithm for encryption.
aes	(Optional) Specifies the use of the AES algorithm for encryption.
auth	(Optional) Specifies which authentication level should be used.
auth-password	(Optional) Specifies a string that enables the agent to receive packets from the host. The minimum length is one character; the recommended length is at least eight characters, and should include letters and numbers. The maximum length is 64 characters. You can specify a plain-text password or a localized MD5 digest. If you have the localized MD5 or SHA digest, you can specify that string instead of the plain-text password. The digest should be formatted as aa:bb:cc:dd, where aa, bb, and cc are hexadecimal values. The digest should be exactly 16 octets long.
des	(Optional) Specifies the use of the 56-bit DES algorithm for encryption.
encrypted	(Optional) Specifies whether or not the password appears in encrypted format. Encrypted passwords must be in hexadecimal format.
group-name	Specifies the name of the group to which the user belongs.
md5	(Optional) Specifies the HMAC-MD5-96 authentication level.
priv	Specifies packet authentication with encryption.
priv-password	(Optional) Specifies a string that indicates the privacy user password. The minimum length is one character; the recommended length is at least eight characters, and should include letters and numbers. The maximum length is 64 characters. You can specify a plain-text password or a localized MD5 digest. If you have the localized MD5 or SHA digest, you can specify that string instead of the plain-text password. The digest should be formatted as aa:bb:cc:dd, where aa, bb, and cc are hexadecimal values. The digest should be exactly 16 octets long.
sha	(Optional) Specifies the HMAC-SHA-96 authentication level.
username	Specifies the name of the user on the host that connects to the agent.
v3	Specifies that the SNMP Version 3 security model should be used. Allows the use of the **encrypted, priv,** or **auth** keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

An SNMP user must be part of an SNMP group. To use the Version 3 security model, you must first configure an SNMP group, then configure an SNMP user, and then configure an SNMP host.

Note If you forget a password, you cannot recover it, and must reconfigure the user.

When the snmp-server user configuration is displayed on the console or written to a file (for example, the startup-configuration file), the localized authentication and privacy digests always appear instead of a plain-text password. This usage is required by RFC 3414, Section 11.2.

Note You must have a 3DES or AES feature license to configure users with the 3DES or AES algorithm.

During bootup or upgrade of the ASA, single-digit passwords and passwords starting with a digit followed by a whitespace are no longer supported. For example, 0 pass and 1 are invalid passwords.

Examples

The following example shows how the ASA can receive SNMP requests using the SNMP Version 3 security model:

```
hostname(config)# snmp-server group engineering v3 auth
hostname(config)# snmp-server user engineering v3 auth sha mypassword
```

Related Commands

Command	Description
clear configure snmp-server	Clears the SNMP server configuration.
snmp-server enable	Enables SNMP on the ASA.
snmp-server group	Creates a new SNMP group.
snmp-server host	Sets the SNMP host address.

CHAPTER 62

software-version through storage-objects Commands

software-version

To identify the Server and User-Agent header fields, which expose the software version of either a server or an endpoint, use the **software-version** command in parameters configuration mode. Parameters configuration mode is accessible from policy map configuration mode. To disable this feature, use the **no** form of this command.

software-version action {**mask** | **log**} [**log**}

no software-version action {**mask** | **log**} [**log**}

Syntax Description

log	Specifies standalone or additional log in case of violation.
mask	Masks the software version in the SIP message.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to identify the software version in a SIP inspection policy map:

```
hostname(config)# policy-map type inspect sip sip_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# software-version action log
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

speed

To set the speed of a copper (RJ-45) Ethernet interface, use the **speed** command in interface configuration mode. To restore the speed setting to the default, use the **no** form of this command.

speed {**auto** | **10** | **100** | **1000** | **nonegotiate**}

no speed [**auto** | **10** | **100** | **1000** | **nonegotiate**]

Syntax Description

10	Sets the speed to 10BASE-T.
100	Sets the speed to 100BASE-T.
1000	Sets the speed to 1000BASE-T. For copper Gigabit Ethernet only.
auto	Auto detects the speed.
nonegotiate	For fiber interfaces, sets the speed to 1000 Mbps and does not negotiate link parameters. This command and the **no** form of this command are the only settings available for fiber interfaces. When you set the value to **no speed nonegotiate** (the default), the interface enables link negotiation, which exchanges flow-control parameters and remote fault information.

Defaults

For copper interfaces, the default is **speed auto**.

For fiber interfaces, the default is **no speed nonegotiate**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was moved from a keyword of the **interface** command to an interface configuration mode command.

Usage Guidelines

Set the speed on the physical interface only.

If your network does not support auto detection, set the speed to a specific value.

For RJ-45 interfaces on the ASA 5500 series, the default auto-negotiation setting also includes the Auto-MDI/MDIX feature. Auto-MDI/MDIX eliminates the need for crossover cabling by performing an internal crossover when a straight cable is detected during the auto-negotiation phase. Either the speed or duplex must be set to auto-negotiate to enable Auto-MDI/MDIX for the interface. If you explicitly set both the speed and duplex to a fixed value, thus disabling auto-negotiation for both settings, then Auto-MDI/MDIX is also disabled.

If you set the speed to anything other than **auto** on PoE ports, if available, then Cisco IP phones and Cisco wireless access points that do not support IEEE 802.3af will not be detected and supplied with power.

Note Do not set the **speed** command for an ASA 5500x series or an ASA 5585 with fiber interfaces. Doing so causes a link failure.

Examples

The following example sets the speed to 1000BASE-T:

```
hostname(config)# interface gigabitethernet0/1
hostname(config-if)# speed 1000
hostname(config-if)# duplex full
hostname(config-if)# nameif inside
hostname(config-if)# security-level 100
hostname(config-if)# ip address 10.1.1.1 255.255.255.0
hostname(config-if)# no shutdown
```

Related Commands

Command	Description
clear configure interface	Clears all configuration for an interface.
duplex	Sets the duplex mode.
interface	Configures an interface and enters interface configuration mode.
show interface	Displays the runtime status and statistics of interfaces.
show running-config interface	Shows the interface configuration.

split-dns

To enter a list of domains to be resolved through the split tunnel, use the **split-dns** command in group-policy configuration mode. To delete a list, use the **no** form of this command.

To delete all split tunneling domain lists, use the **no split-dns** command without arguments. This deletes all configured split tunneling domain lists, including a null list created by issuing the **split-dns none** command.

When there are no split tunneling domain lists, users inherit any that exist in the default group policy. To prevent users from inheriting such split tunneling domain lists, use the **split-dns none** command.

split-dns {**value** *domain-name1 domain-name2 domain-nameN* | **none**}

no split-dns [*domain-name domain-name2 domain-nameN*]

Syntax Description

value *domain-name*	Provides a domain name that the ASA resolves through the split tunnel.
none	Indicates that there is no split DNS list. Sets a split DNS list with a null value, thereby disallowing a split DNS list. Prevents inheriting a split DNS list from a default or specified group policy.

Defaults

Split DNS is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use a single space to separate each entry in the list of domains. There is no limit on the number of entries, but the entire string can be no longer than 255 characters. You can use only alphanumeric characters, hyphens (-), and periods (.).

The **no split-dns** command, when used without arguments, deletes all current values, including a null value created by issuing the **split-dns none** command.

Starting with version 3.0.4235, AnyConnect Secure Mobility Client supports true split DNS functionality for Windows platforms.

Examples

The following example shows how to configure the domains Domain1, Domain2, Domain3 and Domain4 to be resolved through split tunneling for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# split-dns value Domain1 Domain2 Domain3 Domain4
```

Related Commands

Command	Description
default-domain	Specifies a default domain name that the IPsec client uses the for DNS queries which omit the domain field.
split-dns	Provides a list of domains to be resolved through the split tunnel.
split-tunnel-network-list	Identifies the access list the ASA uses to distinguish which networks require tunneling.
split-tunnel-policy	Lets an IPsec client conditionally direct packets over an IPsec tunnel in encrypted form, or to a network interface in cleartext form

split-horizon

To reenable EIGRP split horizon, use the **split-horizon** command in interface configuration mode. To disable EIGRP split horizon, use the **no** form of this command.

split-horizon eigrp *as-number*

no split-horizon eigrp *as-number*

Syntax Description

as-number	The autonomous system number of the EIGRP routing process.

Defaults

The **split-horizon** command is enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

For networks that include links over X.25 packet-switched networks, you can use the **neighbor** command to defeat the split horizon feature. As an alternative, you can explicitly specify the **no split-horizon eigrp** command in your configuration. However, if you do so, you must similarly disable split horizon for all routers and access servers in any relevant multicast groups on that network.

In general, it is best that you not change the default state of split horizon unless you are certain that your application requires the change in order to properly advertise routes. If split horizon is disabled on a serial interface and that interface is attached to a packet-switched network, you must disable split horizon for all routers and access servers in any relevant multicast groups on that network.

Examples

The following example disables EIGRP split horizon on interface Ethernet0/0:

```
hostname(config)# interface Ethernet0/0
hostname(config-if)# no split-horizon eigrp 100
```

Related Commands

Command	Description
router eigrp	Creates an EIGRP routing process and enters configuration mode for that process.

split-tunnel-all-dns

To enable the AnyConnect Secure Mobility Client to the resolve all DNS addresses through the VPN tunnel, use the **split-tunnel-all-dns** command from group policy configuration mode.

To remove the command from the running configuration, use the **no** form of this command. This enables inheritance of the value from another group policy.

split-tunnel-all-dns {**disable | enable**}

no split-tunnel-all-dns [{**disable | enable**}]

Syntax Description

disable (default)	The AnyConnect client sends DNS queries over the tunnel according to the split tunnel policy—tunnel all networks, tunnel networks specified in a network list, or exclude networks specified in a network list.
enable	The AnyConnect client resolves all DNS addresses through the VPN tunnel.

Defaults

The default is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
8.2(5)	This command was introduced.

Usage Guidelines

The **split-tunnel-all-dns enable** command applies to VPN connections using the SSL or IPsec/IKEv2 protocol, and instructs the AnyConnect client to resolve all DNS addresses through the VPN tunnel. If DNS resolution fails, the address remains unresolved and the AnyConnect client does not try to resolve the address through public DNS servers.

By default, this feature is disabled. The client sends DNS queries over the tunnel according to the split tunnel policy—tunnel all networks, tunnel networks specified in a network list, or exclude networks specified in a network list.

Examples

The following example configures the ASA to enable the AnyConnect client to resolve all DNS queries through the VPN tunnel:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# split-tunnel-all-dns enable
```

Related Commands

Command	Description
default-domain	Specifies a default domain name that the legacy IPsec (IKEv1) VPN client or the AnyConnect VPN Client (SSL) uses for DNS queries that omit the domain field.
split-dns	Provides a list of domains to be resolved through the split tunnel.
split-tunnel-network-list	Identifies the access list the ASA uses to distinguish networks that require tunneling and those that do not.
split-tunnel-policy	Lets a legacy VPN client (IPsec/IKEv1) or the AnyConnect VPN client (SSL) conditionally direct packets over a tunnel in encrypted form, or to a network interface in clear text form

split-tunnel-network-list

To create a network list for split tunneling, use the **split-tunnel-network-list** command in group-policy configuration mode. To delete a network list, use the **no** form of this command.

To delete all split tunneling network lists, use the **no split-tunnel-network-list** command without arguments. This deletes all configured network lists, including a null list created by issuing the **split-tunnel-network-list none** command.

When there are no split tunneling network lists, users inherit any network lists that exist in the default or specified group policy. To prevent users from inheriting such network lists, use the **split-tunnel-network-list none** command.

Split tunneling network lists distinguish networks that require traffic to travel across the tunnel from those that do not require tunneling.

split-tunnel-network-list {value *access-list name* **| none}**

no split-tunnel-network-list value [*access-list name*]

Syntax Description

none	Indicates that there is no network list for split tunneling; the ASA tunnels all traffic. Sets a split tunneling network list with a null value, thereby disallowing split tunneling. Prevents inheriting a default split tunneling network list from a default or specified group policy.
value *access-list name*	Identifies an access list that enumerates the networks to tunnel or not tunnel.

Defaults

By default, there are no split tunneling network lists.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The ASA makes split tunneling decisions on the basis of a network list, which is a standard ACL that consists of a list of addresses on the private network.

The **no split-tunnel-network-list** command, when used without arguments, deletes all current network lists, including a null value created by issuing the **split-tunnel-network-list none** command.

Note The ASA provides supports for 200 split networks.

Examples

The following example shows how to set a network list called FirstList for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# split-tunnel-network-list FirstList
```

Related Commands

Command	Description
access-list	Creates an access list, or uses a downloadable access list.
default-domain	Specifies a default domain name that he IPsec client uses the for DNS queries that omit the domain field.
split-dns	Provides a list of domains to be resolved through the split tunnel.
split-tunnel-policy	Lets an IPsec client conditionally direct packets over an IPsec tunnel in encrypted form, or to a network interface in cleartext form.

split-tunnel-policy

To set a split tunneling policy, use the **split-tunnel-policy** command in group-policy configuration mode. To remove the split-tunnel-policy attribute from the running configuration, use the **no** form of this command. This enables inheritance of a value for split tunneling from another group policy.

Split tunneling lets a remote-access VPN client conditionally direct packets over an IPsec or SSL tunnel in encrypted form, or to a network interface in cleartext form. With split-tunneling enabled, packets not bound for destinations on the other side of the IPsec or SSL VPN tunnel endpoint do not have to be encrypted, sent across the tunnel, decrypted, and then routed to a final destination.

This command applies this split tunneling policy to a specific network.

split-tunnel-policy {tunnelall | tunnelspecified | excludespecified}

no split-tunnel-policy

Syntax Description

excludespecified	Defines a list of networks to which traffic goes in the clear. This feature is useful for remote users who want to access devices on their local network, such as printers, while they are connected to the corporate network through a tunnel.
split-tunnel-policy	Indicates that you are setting rules for tunneling traffic.
tunnelall	Specifies that no traffic goes in the clear or to any other destination than the ASA. Remote users reach internet networks through the corporate network and do not have access to local networks.
tunnelspecified	Tunnels all traffic from or to the specified networks. This option enables split tunneling. It lets you create a network list of addresses to tunnel. Data to all other addresses travels in the clear, and is routed by the remote user's internet service provider.

Defaults

Split tunneling is disabled by default, which is tunnelall.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Split tunneling is primarily a traffic management feature, not a security feature. In fact, for optimum security, we recommend that you not enable split tunneling.

Examples

The following example shows how to set a split tunneling policy of tunneling only specified networks for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# split-tunnel-policy tunnelspecified
```

Related Commands

Command	Description
default-domain	Specifies a default domain name that he IPsec client uses the for DNS queries that omit the domain field.
split-dns	Provides a list of domains to be resolved through the split tunnel.
split-tunnel-network-list none	Indicates that no access list exists for split tunneling. All traffic travels across the tunnel.
split-tunnel-network-list value	Identifies the access list the ASA uses to distinguish networks that require tunneling and those that do not.

spoof-server

To substitute a string for the server header field for HTTP protocol inspection, use the **spoof-server** command in parameters configuration mode. To disable this feature, use the **no** form of this command.

spoof-server *string*

no spoof-server *string*

Syntax Description

string	String to substitute for the server header field. 82 characters maximum.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

WebVPN streams are not subject to the **spoof-server** comand.

Examples

The following example shows how to substitute a string for the server header field in an HTTP inspection policy map:

```
hostname(config-pmap-p)# spoof-server string
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

sq-period

To specify the interval between each successful posture validation in a NAC Framework session and the next query for changes in the host posture, use the **sq-period** command in nac-policy-nac-framework configuration mode. To remove the command from the NAC policy, use the **no** form of this command.

sq-period *seconds*

no sq-period [*seconds*]

Syntax Description

seconds	Number of seconds between each successful posture validation. The range is 30 to 1800.

Defaults

The default value is 300.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Nac-policy-nac-framework configuration	•	—	•	—	—

Command History

Release	Modification
7.3(0)	"nac-" removed from command name. Command moved from group-policy configuration mode to nac-policy-nac-framework configuration mode.
7.2(1)	This command was introduced.

Usage Guidelines

The ASA starts the status query timer after each successful posture validation and status query response. The expiration of this timer triggers a query for changes in the host posture, referred to as a *status query.*

Examples

The following example changes the value of the status query timer to 1800 seconds:

```
hostname(config-nac-policy-nac-framework)# sq-period 1800
hostname(config-nac-policy-nac-framework)
```

The following example removes the status query timer from the NAC Framework policy:

```
hostname(config-nac-policy-nac-framework)# no sq-period
hostname(config-nac-policy-nac-framework)
```

Related Commands

Command	Description
nac-policy	Creates and accesses a Cisco NAC policy, and specifies its type.
nac-settings	Assigns a NAC policy to a group policy.
eou timeout	Changes the number of seconds to wait after sending an EAP over UDP message to the remote host in a NAC Framework configuration.
reval-period	Specifies the interval between each successful posture validation in a NAC Framework session.
debug eap	Enables logging of Extensible Authentication Protocol events to debug NAC Framework messaging.

ssh

To add SSH access to the ASA, use the **ssh** command in global configuration mode. To disable SSH access to the ASA, use the **no** form of this command.

ssh {*ip_address mask* | *ipv6_address/prefix*} *interface*

no ssh {*ip_address mask* | *ipv6_address/prefix*} *interface*

Syntax Description

interface	The ASA interface on which SSH is enabled. If not specified, SSH is enabled on all interfaces except the outside interface.
ip_address	IPv4 address of the host or network authorized to initiate an SSH connection to the ASA. For hosts, you can also enter a host name.
ipv6_address/prefix	The IPv6 address and prefix of the host or network authorized to initiate an SSH connection to the ASA.
mask	Network mask for *ip_address*.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command supports IPv4 and IPv6 addresses. The **ssh** *ip_address* command specifies hosts or networks that are authorized to initiate an SSH connection to the ASA. You can have multiple ssh commands in the configuration. The **no** form of the command removes a specific SSH command from the configuration. Use the **clear configure ssh** command to remove all SSH commands.

Before you can begin using SSH to the ASA, you must generate a default RSA key using the **crypto key generate rsa** command.

The following security algorithms and ciphers are supported on the ASA:

- 3DES and AES ciphers for data encryption
- HMAC-SHA and HMAC-MD5 algorithms for packet integrity
- RSA public key algorithm for host authentication

The following SSH Version 2 features are not supported on the ASA:

- X11 forwarding
- Port forwarding
- SFTP support
- Kerberos and AFS ticket passing
- Data compression

Examples

The following example shows how to configure the inside interface to accept SSH version 2 connections from a management console with the IP address 10.1.1.1. The idle session timeout is set to 60 minutes and SCP is enabled.

```
hostname(config)# ssh 10.1.1.1 255.255.255.0 inside
hostname(config)# ssh version 2
hostname(config)# ssh scopy enable
hostname(config)# ssh timeout 60
```

Related Commands

Command	Description
clear configure ssh	Clears all SSH commands from the running configuration.
crypto key generate rsa	Generates RSA key pairs for identity certificates.
debug ssh	Displays debugging information and error messages for SSH commands.
show running-config ssh	Displays the current SSH commands in the running configuration.
ssh scopy enable	Enables a secure copy server on the ASA.
ssh version	Restricts the ASA to using either SSH Version 1 or SSH Version 2.

ssh authentication

To enable public key authentication on a per-user basis, use the **ssh authentication** command in username attributes mode. To disable public key authentication on a per-user basis, use the **no** form of this command.

ssh authentication {**pkf** | **publickey** [**nointeractive**] *key* [**hashed**]}

no ssh authentication {**pkf** | **publickey** [**nointeractive**] *key* [**hashed**]}

Syntax Description

hashed	Hashed with SHA-256 and 32 bytes long, with each byte separated by a colon (for parsing purposes).
key	The value of the *key* argument can be one of the following: • When the *key* argument is supplied and the hashed tag is not specified, the value of the key must be a Base 64 encoded public key that is generated by SSH key generation software that can generate SSH-RSA raw keys (that is, with no certificates). After you submit the Base 64 encoded public key, that key is then hashed via SHA-256 and the corresponding 32-byte hash is used for all further comparisons. • When the *key* argument is supplied and the hashed tag is specified, the value of the key must have been previously hashed with SHA-256 and be 32 bytes long, with each byte separated by a colon (for parsing purposes).
nointeractive	The **nointeractive** option suppresses all prompts when importing an SSH public key file formatted key. This noninteractive data entry mode is only intended for ASDM use.
pkf	For a **pkf** key, you are prompted to paste in a PKF formatted key, up to 4096 bits. Use this format for keys that are too large to paste inline in Base64 format. For example, you can generate a 4096-bit key using ssh keygen, then convert it to PKF, and use the **pkf** keyword to be prompted for the key. **Note** You can use the **pkf** option with failover, but the PKF key is not automatically replicated to the standby system. You must enter the **write standby** command to synchronize the PKF key.
publickey	For a **publickey**, the *key* is a Base64-encoded public key. You can generate the key using any SSH key generation software (such as ssh keygen) that can generate SSH-RSA raw keys (with no certificates).

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
	Routed	Transparent	Single	Multiple Context	System
Username attributes	•	•	•	•	—

Command History

Release	Modification
9.1(2)	This command was introduced.

Usage Guidelines

You can specify a public key file (PKF) formatted key (the **pkf** keyword) or a Base64 key (the **publickey** keyword).

The *key* field and the **hashed** keyword are only available with the **publickey** option, and the **nointeractive** keyword is only available with the **pkf** option.

When you save the configuration, the hashed key value is saved to the configuration and used when the ASA is rebooted.

When you view the key on the ASA using the **show running-config username** command, the key is encrypted using a SHA-256 hash. Even if you entered the key as **pkf**, the ASA hashes the key, and shows it as a hashed **publickey**. If you need to copy the key from **show** output, specify the **publickey** type with the **hashed** keyword.

Examples

The following example shows how to authenticate using a PKF formatted key:

```
hostname(config-username)# ssh authentication pkf

Enter an SSH public key formatted file.
End with the word "quit" on a line by itself:
---- BEGIN SSH2 PUBLIC KEY ----
Comment: "4096-bit RSA, converted by xxx@xxx from OpenSSH"

Related Commands

Command	Description
clear configure ssh	Clears all SSH commands from the running configuration.
debug ssh	Displays debugging information and error messages for SSH commands.

Command	Description
show running-config ssh	Displays the current SSH commands in the running configuration.
ssh version	Restricts the ASA to using either SSH Version 1 or SSH Version 2.

ssh disconnect

To disconnect an active SSH session, use the **ssh disconnect** command in privileged EXEC mode.

ssh disconnect *session_id*

Syntax Description

session_id	Disconnects the SSH session specified by the ID number.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You must specify a session ID. Use the **show ssh sessions** command to obtain the ID of the SSH session you want to disconnect.

Examples

The following example shows an SSH session being disconnected:

```
hostname# show ssh sessions
SID Client IP       Version Mode Encryption Hmac     State           Username
0   172.69.39.39    1.99    IN   aes128-cbc md5      SessionStarted  pat
                            OUT  aes128-cbc md5      SessionStarted  pat
1   172.23.56.236   1.5     -    3DES       -        SessionStarted  pat
2   172.69.39.29    1.99    IN   3des-cbc   sha1     SessionStarted  pat
                            OUT  3des-cbc   sha1     SessionStarted  pat
hostname# ssh disconnect 2
hostname# show ssh sessions
SID Client IP       Version Mode Encryption Hmac     State           Username
0   172.69.39.29    1.99    IN   aes128-cbc md5      SessionStarted  pat
                            OUT  aes128-cbc md5      SessionStarted  pat
1   172.23.56.236   1.5     -    3DES       -        SessionStarted  pat
```

Related Commands

Command	Description
show ssh sessions	Displays information about active SSH sessions to the ASA.
ssh timeout	Sets the timeout value for idle SSH sessions.

ssh key-exchange

To exchange keys using either the Diffie-Hellman (DH) Group 1 or DH Group 14 key-exchange method, use the **ssh key-exchange** command in global configuration mode. To disable key exchange using either the DH Group 1 or DH Group 14 key-exchange method, use the **no** form of this command.

ssh key-exchange group {**dh-group1** | **dh-group14**} **sha1**

no ssh key-exchange group {**dh-group1** | **dh-group14**} **sha1**

Syntax Description

dh-group1	Indicates that the DH group 1 key-exchange method will follow and should be used when exchanging keys. DH group 2 is called DH group 1 for legacy reasons.
dh-group14	Indicates that the DH group 14 key-exchange method will follow and should be used when exchanging keys.
group	Indicates that either the DH group 1 key-exchange method or the DH group 14 key-exchange method will follow and should be used when exchanging keys.
key-exchange	Specifies that either the DH group 1 or DH group 14 key-exchange method will follow and should be used when exchanging keys.
sha-1	Specifies that the SHA-1 encryption algorithm should be used.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.4(4)	This command was introduced.
9.1(2)	This command was changed to **ssh key-exchange group dh-group1-sha1**.

Usage Guidelines

Before you can begin using SSH to the ASA, you must generate a default RSA key using the **crypto key generate rsa** command.

Both the DH Group 1 and Group 14 key-exchange methods for key exchange are supported on the ASA. If no DH group key-exchange method is specified, the DH group 1 key-exchange method is used. For more information about using DH key-exchange methods, see RFC 4253.

Note This command is not available in the 9.1(1) or 9.1.1(2) release.

Examples

The following example shows how to exchange keys using the DH Group 14 key-exchange method:

```
hostname(config)# ssh key-exchange dh-group-1-sha1
```

Related Commands

Command	Description
clear configure ssh	Clears all SSH commands from the running configuration.
crypto key generate rsa	Generates RSA key pairs for identity certificates.
debug ssh	Displays debugging information and error messages for SSH commands.
show running-config ssh	Displays the current SSH commands in the running configuration.
ssh scopy enable	Enables a secure copy server on the ASA.
ssh version	Restricts the ASA to using either SSH Version 1 or SSH Version 2.

ssh scopy enable

To enable Secure Copy (SCP) on the ASA, use the **ssh scopy enable** command in global configuration mode. To disable SCP, use the **no** form of this command.

ssh scopy enable

no ssh scopy enable

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

SCP is a server-only implementation; it will be able to accept and terminate connections for SCP but can not initiate them. The ASA has the following restrictions:

- There is no directory support in this implementation of SCP, limiting remote client access to the ASA internal files.
- There is no banner support when using SCP.
- SCP does not support wildcards.
- The ASA license must have the VPN-3DES-AES feature to support SSH version 2 connections.

Before initiating the file transfer, the ASA check available Flash memory. If there is not enough available space, the ASA terminates the SCP connection. If you are overwriting a file in Flash memory, you still need to have enough free space for the file being copied to the ASA. The SCP process copies the file to a temporary file first, then copies the temporary file over the file being replaced. If you do not have enough space in Flash to hold the file being copied and the file being overwritten, the ASA terminates the SCP connection.

Examples

The following example shows how to configure the inside interface to accept SSH Version 2 connections from a management console with the IP address 10.1.1.1. The idle session timeout is set to 60 minutes and SCP is enabled.

```
hostname(config)# ssh 10.1.1.1 255.255.255.0 inside
hostname(config)# ssh version 2
hostname(config)# ssh scopy enable
hostname(config)# ssh timeout 60
```

Related Commands

Command	Description
clear configure ssh	Clears all SSH commands from the running configuration.
debug ssh	Displays debug information and error messages for SSH commands.
show running-config ssh	Displays the current SSH commands in the running configuration.
ssh	Allows SSH connectivity to the ASA from the specified client or network.
ssh version	Restricts the ASA to using either SSH Version 1 or SSH Version 2.

ssh timeout

To change the default SSH session idle timeout value, use the **ssh timeout** command in global configuration mode. To restore the default timeout value, use the **no** form of this command.

ssh timeout *number*

no ssh timeout

Syntax Description

number	Specifies the duration in minutes that an SSH session can remain inactive before being disconnected. Valid values are from 1 to 60 minutes.

Defaults

The default session timeout value is 5 minutes.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
Preexisting	This command was preexisting.

Usage Guidelines

The **ssh timeout** command specifies the duration in minutes that a session can be idle before being disconnected. The default duration is 5 minutes.

Examples

The following example shows how to configure the inside interface to accept only SSH version 2 connections from a management console with the IP address 10.1.1.1. The idle session timeout is set to 60 minutes and SCP is enabled.

```
hostname(config)# ssh 10.1.1.1 255.255.255.0 inside
hostname(config)# ssh version 2
hostname(config)# ssh copy enable
hostname(config)# ssh timeout 60
```

Related Commands

Command	Description
clear configure ssh	Clears all SSH commands from the running configuration.
show running-config ssh	Displays the current SSH commands in the running configuration.

Command	Description
show ssh sessions	Displays information about active SSH sessions to the ASA.
ssh disconnect	Disconnects an active SSH session.

ssh version

To restrict the version of SSH accepted by the ASA, use the **ssh version** command in global configuration mode. To restore the default value, use the **no** form of this command. The default values permits SSH Version 1 and SSH Version 2 connections to the ASA.

ssh version {**1** | **2**}

no ssh version [**1** | **2**]

Syntax Description

1	Specifies that only SSH Version 1 connections are supported.
2	Specifies that only SSH Version 2 connections are supported.

Defaults

By default, both SSH Version 1 and SSH Version 2 are supported.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

1 and 2 specify which version of SSH the ASA is restricted to using. The **no** form of the command returns the ASA to the default stance, which is compatible mode (both version can be used).

Examples

The following example shows how to configure the inside interface to accept SSH Version 2 connections from a management console with the IP address 10.1.1.1. The idle session timeout is set to 60 minutes and SCP is enabled.

```
hostname(config)# ssh 10.1.1.1 255.255.255.0 inside
hostname(config)# ssh version 2
hostname(config)# ssh copy enable
hostname(config)# ssh timeout 60
```

Related Commands

Command	Description
clear configure ssh	Clears all SSH commands from the running configuration.
debug ssh	Displays debug information and error messages for SSH commands.

Command	Description
show running-config ssh	Displays the current SSH commands in the running configuration.
ssh	Allows SSH connectivity to the ASA from the specified client or network.

ssl certificate-authentication

To enable client certificate authentication for backwards compatibility for versions previous to 8.2(1), use the **ssl certificate-authentication** command in global configuration mode. To disable ssl certificate authentication, use the **no** version of this command.

ssl certificate-authentication interface *interface-name* **port** *port-number*

no ssl certificate-authentication interface *interface-name* **port** *port-numbe***r**

Syntax Description

interface-name	The name of the selected interface, such as inside, management, and outside.
port-number	The TCP port number, an integer in the range 1-65535.

Defaults

This feature is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
8.0(3)	This command was introduced.
8.2(1)	This command is no longer needed, but the ASA retains it for downgrading to previous versions.

Usage Guidelines

This command replaces the deprecated http authentication-certificate command.

Examples

The following example shows how to configure the ASA to use the SSL certificate authentication feature:

```
hostname(config)# ssl certificate-authentication interface inside port 330
```

Related Commands

Command	Description
show running-config ssl	Displays the current set of configured SSL commands.

ssl client-version

To specify the SSL/TLS protocol version the ASA uses when acting as a client, use the **ssl client-version** command in global configuration mode. To revert to the default, **any**, use the **no** version of this command. This command lets you restrict the versions of SSL/TLS that the ASA sends.

ssl client-version [*any* | *sslv3-only* | *tlsv1-only*]

no ssl client-version

Syntax Description

any	The ASA sends SSL version3 hellos, and negotiates either SSL version 3 or TLS version 1.
sslv3-only	The security appliance sends SSL version 3 hellos, and accepts only SSL version 3.
tlsv1-only	The security appliance sends TLSv1 client hellos, and accepts only TLS version 1.

Defaults

The default value is **any**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

TCP Port Forwarding does not work when a WebVPN user connects with some SSL versions, as follows:

Negotiate SSLv3	Java downloads
Negotiate SSLv3/TLSv1	Java downloads
Negotiate TLSv1	Java does NOT download
TLSv1Only	Java does NOT download
SSLv3Only	Java does NOT download

The issue is that JAVA only negotiates SSLv3 in the client Hello packet when you launch the Port Forwarding application.

Examples

The following example shows how to configure the ASA to communicate using only TLSv1 when acting as an SSL client:

```
hostname(config)# ssl client-version tlsv1-only
```

Related Commands

Command	Description
clear config ssl	Removes all SSL commands from the configuration, reverting to the default values.
ssl encryption	Specifies the encryption algorithms that the SSL/TLS protocol uses.
show running-config ssl	Displays the current set of configured SSL commands.
ssl server-version	Specifies the SSL/TLS protocol version the ASA uses when acting as a server.
ssl trust-point	Specifies the certificate trust point that represents the SSL certificate for an interface.

ssl encryption

To specify the encryption algorithms for the SSL DTLS and TLS protocols, use the **ssl encryption** command in global configuration mode**.** Issuing the command again overwrites the previous setting. To restore the default, which is the complete set of encryption algorithms, use the **no** version of the command.

ssl encryption [**3des-sha1**] [**aes128-sha1**] [**aes256-sha1**] [**des-sha1**] [**null-sha1**] [**rc4-md5**] [**rc4-sha1**] **[dhe-aes256-sha1] [dhe-aes128-sha1]**

no ssl encryption

Syntax Description

3des-sha1	Specifies triple DES 168-bit encryption with Secure Hash Algorithm 1 (FIPS-compliant).
aes128-sha1	Specifies triple AES 128-bit encryption with Secure Hash Algorithm 1 (FIPS-compliant).
aes256-sha1	Specifies triple AES 256-bit encryption with Secure Hash Algorithm 1 (FIPS-compliant).
dhe-aes128-sha1	Specifies AES 128-bit encryption ciphersuites for Transport Layer Security (TLS).
dhe-aes256-sha1	Specifies AES 256-bit encryption ciphersuites for Transport Layer Security (TLS).
des-sha1	Specifies DES 56-bit encryption with Secure Hash Algorithm 1.
null-sha1	Specifies null encryption with Secure Hash Algorithm 1. This setting enforces message integrity without confidentiality. ⚠ **Caution** If you specify **null-sha1**, data is not encrypted.
rc4-md5	Specifies RC4 128-bit encryption with an MD5 hash function.
rc4-sha1	Specifies RC4 128-bit encryption with Secure Hash Algorithm 1.

Defaults

By default, the SSL encryption list on the ASA contains these algorithms in the following order:

1. RC4-SHA1
2. AES128-SHA1 (FIPS-compliant)
3. AES256-SHA1 (FIPS-compliant)
4. 3DES-SHA1 (FIPS-compliant)
5. DHE-AES256-SHA1
6. DHE-AES128-SHA1

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
	Routed	Transparent	Single	Multiple Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
9.1(2)	Support for ssl encryption dhe-aes128-sha1 and dhe-aes256-sha1 was added.

Usage Guidelines

The ASDM License tab reflects the maximum encryption the license supports, not the value you configure.

The ordering of the algorithms determines preference for their use. You can add or remove algorithms to meet the needs of your environment.

For FIPS-compliant AnyConnect client SSL connections, you must ensure a FIPS-compliant cipher is the first one specified in the list of SSL encryptions.

Several applications do not support DHE, so include at least one other SSL encryption method to ensure a cipher suite common to both.

Cryptographic operations use symmetric-key algorithms as referenced in http://en.wikipedia.org/wiki/Symmetric-key_algorithm.

Examples

The following example shows how to configure the ASA to use the 3des-sha1 and des-sha1 encryption algorithms:

```
hostname(config)# ssl encryption 3des-sha1 des-sha1
```

Related Commands

Command	Description
clear config ssl	Removes all SSL commands from the configuration, reverting to the default values.
show running-config ssl	Displays the current set of configured SSL commands.
ssl client-version	Specifies the SSL/TLS protocol version the ASA uses when acting as a client.
ssl server-version	Specifies the SSL/TLS protocol version the ASA uses when acting as a server.
ssl trust-point	Specifies the certificate trust point that represents the SSL certificate for an interface.

ssl server-version

To specify the SSL/TLS protocol version the ASA uses when acting as a server, use the **ssl server-version** command in global configuration mode. To revert to the default, any, use the **no** version of this command. This command lets you restrict the versions of SSL/TSL that the ASA accepts.

ssl server-version [*any* | *sslv3* | *tlsv1* | *sslv3-only* | *tlsv1-only*]

no ssl server-version

Syntax Description

any	The ASA accepts SSL version 2 client hellos, and negotiates either SSL version 3 or TLS version 1.
sslv3	The ASA accepts SSL version 2 client hellos, and negotiates to SSL version 3.
sslv3-only	The security appliance accepts only SSL version 3 client hellos, and uses only SSL version 3.
tlsv1	The ASA accepts SSL version 2 client hellos, and negotiates to TLS version 1.
tlsv1-only	The security appliance accepts only TLSv1 client hellos, and uses only TLS version 1.

Defaults

The default value is **any**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

TCP Port Forwarding does not work when a WebVPN user connects with some SSL versions, as follows:

Negotiate SSLv3	Java downloads
Negotiate SSLv3/TLSv1	Java downloads
Negotiate TLSv1	Java does NOT download
TLSv1Only	Java does NOT download
SSLv3Only	Java does NOT download

If you configure e-mail proxy, do not set thhe SSL version to TLSv1 Only. Outlook and Outlook Express do not support TLS.

Remote endpoints with FIPS enabled cannot communicate when ssl-version is configured for sslv3 or sslv3-only. For that environment, set ssl server-version to tlsv1 or to any.

Examples

The following example shows how to configure the ASA to communicate using only TLSv1 when acting as an SSL server:

```
hostname(config)# ssl server-version tlsv1-only
```

Related Commands

Command	Description
clear config ssl	Removes all ssl commands from the configuration, reverting to the default values.
show running-config ssl	Displays the current set of configured ssl commands.
ssl client-version	Specifies the SSL/TLS protocol version the ASA uses when acting as a client.
ssl encryption	Specifies the encryption algorithms that the SSL/TLS protocol uses.
ssl trust-point	Specifies the certificate trust point that represents the SSL certificate for an interface.

ssl trust-point

To specify the certificate trustpoint that represents the SSL certificate for an interface, use the **ssl trust-point** command with the *interface* argument in global configuration mode. If you do not specify an interface, this command creates the fallback trustpoint for all interfaces that do not have a trustpoint configured. To remove an SSL trustpoint from the configuration that does not specify an interface, use the **no** version of this command. To remove an entry that does specify an interface, use the **no ssl trust-point {***trustpoint [interface]***}** version of the command.

ssl trust-point {*trustpoint [interface]***}**

no ssl trust-point

Syntax Description

interface	The name for the interface to which the trustpoint applies. The **nameif** command specifies the name of the interface.
trustpoint	The *name* of the CA trustpoint as configured in the **crypto ca trustpoint** {*name*} command.

Defaults

The default is no trustpoint association. The ASA uses the default self-generated RSA key-pair certificate.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Observe these guidelines when using this command:

- The value for *trustpoint* must be the name of the CA trustpoint as configured in the **crypto ca trustpoint {*name*}** command.
- The value for *interface* must be the *nameif* name of a previously configured interface.
- Removing a trustpoint also removes any **ssl trust-point** entries that reference that trustpoint.
- You can have one **ssl trustpoint** entry for each interface and one that specifies no interfaces.
- You can reuse the same trustpoint for multiple entries.

The following example explains how to use the **no** versions of this command:

The configuration includes these SSL trustpoints:

```
ssl trust-point tp1
ssl trust-point tp2 outside
```

Issue the command:

no ssl trust-point

Then show run ssl will have:

ssl trust-point tp2 outside

Examples

The following example shows how to configure an ssl trustpoint called FirstTrust for the inside interface, and a trustpoint called DefaultTrust with no associated interface.

```
hostname(config)# ssl trust-point FirstTrust inside
hostname(config)# ssl trust-point DefaultTrust
```

The next example shows how to use the **no** version of the command to delete a trustpoint that has no associated interface:

```
hostname(config)# show running-configuration ssl
ssl trust-point FirstTrust inside
ssl trust-point DefaultTrust
hostname(config)# no ssl trust-point
hostname(config)# show running-configuration ssl
ssl trust-point FirstTrust inside
```

The next example shows how to delete a trustpoint that does have an associated interface:

```
hostname(config)# show running-configuration ssl
ssl trust-point FirstTrust inside
ssl trust-point DefaultTrust
hostname(config)# no ssl trust-point FirstTrust inside
hostname(config)# show running-configuration ssl
ssl trust-point DefaultTrust
```

Related Commands

Command	Description
clear config ssl	Removes all SSL commands from the configuration, reverting to the default values.
show running-config ssl	Displays the current set of configured SSL commands.
ssl client-version	Specifies the SSL/TLS protocol version the ASA uses when acting as a client.
ssl encryption	Specifies the encryption algorithms that the SSL/TLS protocol uses.
ssl server-version	Specifies the SSL/TLS protocol version the ASA uses when acting as a server.

sso-server

To create a Single Sign-On (SSO) server for ASA user authentication, use the **sso-server** command in webvpn configuration mode. With this command, you must specify the SSO server type.

To remove an SSO server, use the **no** form of this command.

sso-server *name* **type** [*siteminder* | *saml-v1.1-post*]

no sso-server *name*

Note This command is required for SSO authentication.

Syntax Description

name	Specifies the name of the SSO server. Minimum of 4 characters and maximum of 31 characters.
saml-v1.1-post	Specifies that the ASA SSO server being configured is a SAML, Version 1.1, SSO server of the POST type.
siteminder	Specifies that the ASA SSO server being configured is a Computer Associates SiteMinder SSO server.
type	Specifies the type of SSO server. SiteMinder and SAML-V1.1-POST are the only types available.

Defaults

There is no default value or behavior.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Single sign-on support, available only for WebVPN, lets users access different secure services on different servers without entering a username and password more than once. The **sso-server** command lets you create an SSO server.

In the authentication, the ASA acts as a proxy for the WebVPN user to the SSO server. The ASA currently supports the SiteMinder SSO server (formerly Netegrity SiteMinder) and the SAML POST-type SSO server. Currently, the available arguments for the type option are restricted to *siteminder* or *saml-V1.1-post*.

Examples

The following example, entered in webvpn configuration mode, creates a SiteMinder-type SSO server named “example1”:

```
hostname(config)# webvpn
hostname(config-webvpn)# sso-server example1 type siteminder
hostname(config-webvpn-sso-siteminder)#
```

The following example, entered in webvpn configuration mode, creates a SAML, Version 1.1, POST-type SSO server named “example2”:

```
hostname(config)# webvpn
hostname(config-webvpn)# sso-server example2 type saml-v1.1-post
hostname(config-webvpn-sso-saml)#
```

Related Commands

Command	Description
assertion-consumer-url	Identifies the URL for the SAML-type SSO assertion consumer service.
issuer	Specifies the SAML-type SSO server’s security device name.
max-retry-attempts	Configures the number of times the ASA retries a failed SSO authentication attempt.
policy-server-secret	Creates a secret key used to encrypt authentication requests to a SiteMinder SSO server.
request-timeout	Specifies the number of seconds before a failed SSO authentication attempt times out.
show webvpn sso-server	Displays the operating statistics for an SSO server.
test sso-server	Tests an SSO server with a trial authentication request.
trustpoint	Specifies a trustpoint name that contains the certificate to use to sign the SAML-type browser assertion
web-agent-url	Specifies the SSO server URL to which the ASA makes SiteMinder SSO authentication requests.

sso-server value (group-policy webvpn)

To assign an SSO server to a group policy, use the **sso-server value** command in webvpn configuration mode available in group-policy configuration mode.

To remove the assignment and use the default policy, use the **no** form of this command.

To prevent inheriting the default policy, use the **sso-server none** command.

sso-server {**value** *name* | **none**}

[**no**] **sso-server value** *name*

Syntax Description

name	Specifies the name of the SSO server being assigned to the group policy.

Defaults

The default policy assigned to the group is DfltGrpPolicy.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The **sso-server value** command, when entered in group-policy webvpn mode, lets you assign an SSO server to a group policy.

Single sign-on support, available only for WebVPN, lets users access different secure services on different servers without entering a username and password more than once. The ASA currently supports the SiteMinder-type of SSO server and the SAML POST-type SSO server.

This command applies to both types of SSO Servers.

Note Enter the same command, **sso-server value**, in username-webvpn configuration mode to assign SSO servers to user policies.

Examples

The following example commands create the group policy my-sso-grp-pol and assigns it to the SSO server named example:

```
hostname(config)# group-policy my-sso-grp-pol internal
```

```
hostname(config)# group-policy my-sso-grp-pol attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# sso-server value example
hostname(config-group-webvpn)#
```

Related Commands

Command	Description
policy-server-secret	Creates a secret key used to encrypt authentication requests to a SiteMinder SSO server.
show webvpn sso-server	Displays the operating statistics for all SSO servers configured on the security device.
sso-server	Creates a single sign-on server.
sso-server value (**username webvpn**)	Assigns an SSO server to a user policy.
web-agent-url	Specifies the SSO server URL to which the ASA makes SiteMinder-type SSO authentication requests.

sso-server value (username webvpn)

To assign an SSO server to a user policy, use the **sso-server value** command in webvpn configuration mode available in username configuration mode.

To remove an SSO server assignment for a user, use the **no** form of this command.

When a user policy inherits an unwanted SSO server assignment from a group policy, use the **sso-server none** command to remove the assignment.

sso-server {**value** *name* | **none**}

[**no**] **sso-server value** *name*

Syntax Description

name	Specifies the name of the SSO server being assigned to the user policy.

Defaults

The default is for the user policy to use the SSO server assignment in the group policy.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Username webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Single sign-on support, available only for WebVPN, lets users access different secure services on different servers without entering a username and password more than once. The ASA currently supports the SiteMinder-type of SSO server and the SAML POST-type SSO server.

This command applies to both types of SSO Servers.

The **sso-server value** command lets you assign an SSO server to a user policy.

Note Enter the same command, **sso-server value**, in group-webvpn configuration mode to assign SSO servers to group policies.

Examples

The following example commands assign the SSO server named my-sso-server to the user policy for a WebVPN user named Anyuser:

```
hostname(config)# username Anyuser attributes
hostname(config-username)# webvpn
hostname(config-username-webvpn)# sso-server value my-sso-server
```

```
hostname(config-username-webvpn)#
```

Related Commands

Command	Description
policy-server-secret	Creates a secret key used to encrypt authentication requests to a SiteMinder SSO server.
show webvpn sso-server	Displays the operating statistics for all SSO servers configured on the security device.
sso-server	Creates a single sign-on server.
sso-server value (config-group-webvpn)	Assigns an SSO server to a group policy.
web-agent-url	Specifies the SSO server URL to which the ASA makes SiteMinder SSO authentication requests.

start-url

To enter the URL at which to retrieve an optional pre-login cookie, use the **start-url** command in aaa-server-host configuration mode. This is an SSO with HTTP Forms command.

start-url *string*

Note To configure SSO with the HTTP protocol correctly, you must have a thorough working knowledge of authentication and HTTP protocol exchanges.

Syntax Description

string	The URL for an SSO server. The maximum URL length is 1024 characters.

Defaults

There is no default value or behavior.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server-host configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The WebVPN server of the ASA can use an HTTP POST request to submit a single sign-on authentication request to an authenticating web server. The authenticating web server may execute a pre-login sequence by sending a Set-Cookie header along with the login page content. You can discover this by connecting directly to the authenticating web server's login page with your browser. If the web server sets a cookie when the login page loads and if this cookie is relevant for the following login session, you must use the **start-url** command to enter the URL at which the cookie is retrieved. The actual login sequence starts after the pre-login cookie sequence with the form submission to the authenticating web server.

Note The **start-url** command is only required in the presence of the pre-login cookie exchange.

Examples

The following example, entered in aaa-server host configuration mode, specifies a URL for retrieving the pre-login cookie of https://example.com/east/Area.do?Page-Grp1:

```
hostname(config)# aaa-server testgrp1 (inside) host example.com
hostname(config-aaa-server-host)# start-url https://example.com/east/Area.do?Page=Grp1
hostname(config-aaa-server-host)#
```

Related Commands

Command	Description
action-uri	Specifies a web server URI to receive a username and password for single sign-on authentication.
auth-cookie-name	Specifies a name for the authentication cookie.
hidden-parameter	Creates hidden parameters for exchange with the authenticating web server.
password-parameter	Specifies the name of the HTTP POST request parameter in which a user password must be submitted for SSO authentication.
user-parameter	Specifies the name of the HTTP POST request parameter in which a username must be submitted for SSO authentication.

state-checking

To enforce state checking for H.323, use the **state-checking** command in parameters configuration mode. To disable this feature, use the **no** form of this command.

state-checking [h225 | ras]

no state-checking [h225 | ras]

Syntax Description

h225	Enforces state checking for H.225.
ras	Enforces state checking for RAS.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to enforce state checking for RAS on an H.323 call:

```
hostname(config)# policy-map type inspect h323 h323_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# state-checking ras
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

strict-header-validation

To enable strict validation of the header fields in the SIP messages according to RFC 3261, use the **strict-header-validation** command in parameters configuration mode. Parameters configuration mode is accessible from policy map configuration mode. To disable this feature, use the **no** form of this command.

strict-header-validation action {**drop** | **drop-connection** | **reset** | **log**} [**log**]

no strict-header-validation action {**drop** | **drop-connection** | **reset** | **log**} [**log**]

Syntax Description

drop	Drops the packet if validation occurs.
drop-connection	Drops the connection of a violation occurs.
reset	Resets the connection of a violation occurs.
log	Specifies standalone or additional log in case of violation. It can be associated to any of the actions.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to enable strict validation of SIP header fields in a SIP inspection policy map:

```
hostname(config)# policy-map type inspect sip sip_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# strict-header-validation action log
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.

Command	Description
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

strict-http

To allow forwarding of non-compliant HTTP traffic, use the **strict-http** command in HTTP map configuration mode, which is accessible using the **http-map** command. To reset this feature to its default behavior, use the **no** form of the command.

strict-http action {**allow** | **reset** | **drop**} [**log**]

no **strict-http action** {**allow** | **reset** | **drop**} [**log**]

Syntax Description

action	The action taken when a message fails this command inspection.
allow	Allows the message.
drop	Closes the connection.
log	(Optional) Generate a syslog.
reset	Closes the connection with a TCP reset message to client and server.

Defaults

This command is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
HTTP map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Although strict HTTP inspection cannot be disabled, the **strict-http action allow** command causes the ASA to allow forwarding of non-compliant HTTP traffic. This command overrides the default behavior, which is to deny forwarding of non-compliant HTTP traffic.

Examples

The following example allows forwarding of non-compliant HTTP traffic:

```
hostname(config)# http-map inbound_http
hostname(config-http-map)# strict-http allow
hostname(config-http-map)#
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
debug appfw	Displays detailed information about traffic associated with enhanced HTTP inspection.
http-map	Defines an HTTP map for configuring enhanced HTTP inspection.
inspect http	Applies a specific HTTP map to use for application inspection.
policy-map	Associates a class map with specific security actions.

strip-group

This command applies only to usernames received in the form user@realm. A realm is an administrative domain appended to a username with the "@" delimiter (juser@abc).

To enable or disable strip-group processing, use the **strip-group** command in tunnel-group general-attributes mode. The ASA selects the tunnel group for IPsec connections by obtaining the group name from the username presented by the VPN client. When strip-group processing is enabled, the ASA sends only the user part of the username for authorization/authentication. Otherwise (if disabled), the ASA sends the entire username including the realm.

To disable strip-group processing, use the **no** form of this command.

strip-group

no strip-group

Syntax Description

This command has no arguments or keywords.

Defaults

The default setting for this command is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group general attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can apply this attribute only to the IPsec remote access tunnel-type.

Note Because of a limitation of MSCHAPv2, you cannot perform tunnel group switching when MSCHAPv2 is used for PPP authentication. The hash computation during MSCHAPv2 is bound to the username string (such as user + delimit + group).

Examples

The following example configures a remote access tunnel group named "remotegrp" for type IPsec remote access, then enters general configuration mode, sets the tunnel group named "remotegrp" as the default group policy, and then enables strip group for that tunnel group:

```
hostname(config)# tunnel-group remotegrp type IPsec_ra
```

```
hostname(config)# tunnel-group remotegrp general
hostname(config-tunnel-general)# default-group-policy remotegrp
hostname(config-tunnel-general)# strip-group
```

Related Commands

Command	Description
clear-configure tunnel-group	Clears all configured tunnel groups.
group-delimiter	Enables group-name parsing and specifies the delimiter to be used when parsing group names from the user names that are received when tunnels are being negotiated.
show running-config tunnel group	Shows the tunnel group configuration for all tunnel groups or for a particular tunnel group.
tunnel-group general-attributes	Specifies the general attributes for the named tunnel-group.

strip-realm

To enable or disable strip-realm processing, use the **strip-realm** command in tunnel-group general-attributes configuration mode. Strip-realm processing removes the realm from the username when sending the username to the authentication or authorization server. A realm is an administrative domain appended to a username with the @ delimiter (username@realm). If the command is enabled, the ASA sends only the user part of the username authorization/authentication. Otherwise, the ASA sends the entire username.

To disable strip-realm processing, use the **no** form of this command.

strip-realm

no strip-realm

Syntax Description

This command has no arguments or keywords.

Defaults

The default setting for this command is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group general attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.0.1	This command was introduced.

Usage Guidelines

You can apply this attribute only to the IPsec remote access tunnel-type.

Examples

The following example configures a remote access tunnel group named “remotegrp” for type IPsec remote access, then enters general configuration mode, sets the tunnel group named “remotegrp” as the default group policy, and then enables strip realm for that tunnel group:

```
hostname(config)# tunnel-group remotegrp type IPsec_ra
hostname(config)# tunnel-group remotegrp general
hostname(config-tunnel-general)# default-group-policy remotegrp
hostname(config-tunnel-general)# strip-real
```

storage-key

To specify a storage key to protect the date stored between sessions, use the **storage-key** command in group-policy webvpn configuration mode. To remove this command from the configuration, use the **no** version of this command.

storage- key { **none** | **value** *string*}

no storage-key

Syntax Description

string	Specifies a string to use as the value of the storage key. This string can be up to 64 characters long.

Defaults

The default is **none**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy webvpn configuration mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

While you can use any character except spaces in the storage key value, we recommend using only the standard alphanumeric character set: 0 through 9 and a through z.

Examples

The following example sets the storage key to the value abc123:

```
hostname(config)# group-policy test attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# storage-key value abc123
```

Related Commands

Command	Description
storage-objects	Configures storage objects for the data stored between sessions.

storage-objects

To specify which storage objects to use for the data stored between sessions, use the **storage-objects** command in group-policy webvpn configuration mode. To remove this command from the configuration, use the **no** version of this command.

storage- objects { **none** | **value** *string*}

no storage-objects

Syntax Description

string	Specifies the name of the storage objects. This string can be up to 64 characters long.

Defaults

The default is **none**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy webvpn configuration mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

While you can use any character except spaces and commas in the storage object name, we recommend using only the standard alphanumeric character set: 0 through 9 and a through z. Use a comma, with no space, to separate the names of storage objects in the string.

Examples

The following example sets the storage object names to cookies and xyz456:

```
hostname(config)# group-policy test attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# storage-object value cookies,xyz456
```

Related Commands

Command	Description
storage-key	Configures storage key to use for the data stored between sessions.
user-storage	Configures a location for storing user data between sessions

CHAPTER 63

subject-name through sysopt radius ignore-secret Commands

subject-name (crypto ca certificate map)

To indicate that rule entry is applied to the subject DN of the IPsec peer certificate, use the **subject-name** command in crypto ca certificate map configuration mode. To remove an subject-name, use the **no** form of the command.

subject-name [**attr** *tag* **eq | ne |co | nc** *string*]

no subject-name [**attr** *tag* **eq | ne |co | nc** *string*]

Syntax Description

attr *tag*	Indicates that only the specified attribute value from the certificate DN will be compared to the rule entry string. The tag values are as follows: DNQ = DN qualifier GENQ = Generational qualifier I = Initials GN = Given name N = Name SN = Surname IP = IP address SER = Serial number UNAME = Unstructured name EA = Email address T = Title O = Organization Name L = Locality SP = State/Province C = Country OU = Organizational unit CN = Common name
co	Specifies that the rule entry string must be a substring in the DN string or indicated attribute.
eq	Specifies that the DN string or indicated attribute must match the entire rule string.
nc	Specifies that the rule entry string must not be a substring in theDN string or indicated attribute.
ne	Specifies that the DN string or indicated attribute must not match the entire rule string.
string	Specifies the value to be matched.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Crypto ca certificate map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example enters the ca certificate map configuration mode for certificate map 1 and creates a rule entry indicating that the Organization attribute of the certificate subject name must be equal to Central:

```
hostname(config)# crypto ca certificate map 1
hostname(ca-certificate-map)# subject-name attr o eq central
hostname(ca-certificate-map)# exit
```

Related Commands

Command	Description
crypto ca certificate map	Enters ca certificate map configurationmode.
issuer-name	Identifies the DN from the CA certificate that is to be compared to the rule entry string.
tunnel-group-map	Associates the certificate map entries created using the **crypto ca certificate map** command with tunnel groups.

subject-name (crypto ca trustpoint)

To include the indicated subject DN in the certificate during enrollment, use the **subject-name** command in crypto ca trustpoint configuration mode. This is the person or system that uses the certificate. To restore the default setting, use the **no** form of the command.

subject-name *X.500_name*

no subject-name

Syntax Description

X.500_name	Defines the X.500 distinguished name. Use commas to separate attribute-value pairs. Insert quotation marks around any value that contains commas or spaces. For example: **cn=crl,ou=certs,o="cisco systems, inc.",c=US**. The maximum length is 500 characters.

Defaults

The default setting is not to include the subject name.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca trustpoint configuration	•	•	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example enters crypto ca trustpoint configuration mode for trustpoint central, and sets up automatic enrollment at the URL https//:frog.example.com and includes the subject DN OU certs in the enrollment request for trustpoint central:

```
hostname(config)# crypto ca trustpoint central
hostname(ca-trustpoint)# enrollment url http://frog.example.com/
hostname(ca-trustpoint)# subject-name ou=certs
hostname(ca-trustpoint)#
```

Related Commands

Command	Description
crypto ca trustpoint	Enters trustpoint configuration mode.
default enrollment	Returns enrollment parameters to their defaults.
enrollment url	Specifies the URL for enrolling with a CA.

subject-name-default

To specify a generic subject-name distinguished name (DN) to be appended to the username in all user certificates issued by the local CA server, use the **subject-name-default** command in CA server configuration mode. To reset the subject-name DN to the default value, use the **no** form of this command.

subject-name-default *dn*

no subject-name-default

Syntax Description

dn	Specifies the generic subject-name DN included with a username in all user certificates issued by the local CA server. Supported DN attributes are cn (common name), ou (organizational unit), ol (organization locality), st (state), ea (e-mail address), c (company), t (title), and sn (surname). Use commas to separate attribute-value pairs. Insert quotation marks around any value that contains a comma. The *dn* can be up to 500 characters.

Defaults

This command is not part of the default configuration. This command specifies the default DN in the certificate. The ASA ignores this command if the user entry has a DN.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
CA server configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The **subject-name-default** command specifies a common, generic DN to be used with a username to form a subject name for issued certificates. The *dn* value cn=username is sufficient for this purpose. This command eliminates the need to define a subject-name DN specifically for each user. The DN field is optional when a user is added using the **crypto ca server user-db add** dn *dn* command.

The ASA uses this command only when issuing certificates if a user entry does not specify a DN.

Examples

The following example specifies a DN:

```
hostname(config)# crypto ca server
hostname(config-ca-server)# subject-name-default cn=cisco,cn=example_corp,ou=eng,st=ma,
c="cisco systems, inc."
hostname(config-ca-server)#
```

Related Commands

Command	Description
crypto ca server	Provides access to CA Server Configuration mode CLI command set, which allows you to configure and manage a local CA.
issuer-name	Specifies the subject-name DN of the certificate authority certificate.
keysize	Specifies the size of the public and private keys generated at user certificate enrollment.
lifetime	Specifies the lifetime of the CA certificate, issued certificates, or the CRL.

subnet

To configure a subnet for a network object, use the **subnet** command in object configuration mode. Use the **no** form of this command to remove the object from the configuration.

subnet {*ipv4_net_addr net_mask* | *ipv6_prefix*/*mask*}

no subnet {*ipv4_net_addr net_mask* | *ipv6_prefix*/*mask*}

Syntax Description

ipv4_net_addr	Specifies the IPv4 network address.
net_mask	Specifies the subnet mask.
ipv6_prefix/*mask*	Specifies the IPv6 prefix and mask.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Object network configuration	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

If you configure an existing network object with a different IP address, the new configuration will replace the existing configuration.

Examples

The following example shows how to create a subnet network object:

```
hostname (config)# object network OBJECT_SUBNET
hostname (config-network-object)# subnet 10.1.1.0 255.255.255.0
```

Related Commands

Command	Description
clear configure object	Clears all objects created.
description	Adds a description to the network object.
fqdn	Specifies a fully-qualified domain name network object.
host	Specifies a host network object.

Command	Description
nat	Enables NAT for the network object.
object network	Creates a network object.
object-group network	Creates a network object group.
range	Specifies a range of addresses for the network object.
show running-config object network	Shows the network object configuration.

summary-address (EIGRP)

To configure a summary for EIGRP on a specific interface, use the **summary-address** command in interface configuration mode. To remove the summary address, use the **no** form of this command.

summary-address *as-number addr mask* [*admin-distance*]

no summary-address *as-number addr mask*

Syntax Description

as-number	The autonomous system number. This must be the same as the autonomous system number of your EIGRP routing process.
addr	The summary IP address.
mask	The subnet mask to apply to the IP address.
admin-distance	(Optional) The administrative distance of the summary route. Valid values are from 0 to 255. If not specified, the default value is 5.

Defaults

The defaults are as follows:

- EIGRP automatically summarizes routes to the network level, even for a single host route.
- The administrative distance of EIGRP summary routes is 5.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

By default, EIGRP summarizes subnet routes to the network level. Use the **no auto-summary** command to disable automatic route summarization. Using the **summary-address** command lets you manually define subnet route summaries on a per-interface basis.

Examples

The following example configures route summarization with a **tag** set to 3:

```
hostname(config-router)# summary-address 1.1.0.0 255.255.0.0
hostname(config-router)#
```

The following example shows how to use the **no** form of the **summary-address** command with an option to set that option back to the default value. In this example, the **tag** value, set to 3 in the previous example, is removed from the **summary-address** command.

```
hostname(config-router)# no summary-address 1.1.0.0 255.255.0.0
hostname(config-router)#
```

The following example removes the **summary-address** command from the configuration:

```
hostname(config-router)# no summary-address 1.1.0.0 255.255.0.0
hostname(config-router)#
```

Related Commands

Command	Description
auto-summary	Automatically creates summary addresses for the EIGRP routing process.

summary-address (OSPFv2)

To create aggregate addresses for OSPF, use the **summary-address** command in router configuration mode. To remove the summary address or specific summary address options, use the **no** form of this command.

summary-address *addr mask* [**not-advertise**] [**tag** *tag_value*]

no summary-address *addr mask* [**not-advertise**] [**tag** *tag_value*]

Syntax Description

addr	Value of the summary address that is designated for a range of addresses.
mask	IP subnet mask that is used for the summary route.
not-advertise	(Optional) Suppresses routes that match the specified prefix/mask pair.
tag *tag_value*	(Optional) A 32-bit decimal value attached to each external route. This value is not used by OSPF itself. It may be used to communicate information between ASBRs. If none is specified, then the remote autonomous system number is used for routes from BGP and EGP; for other protocols, zero (0) is used. Valid values range from 0 to 4294967295.

Defaults

The defaults are as follows:

- *tag_value* is 0.
- Routes that match the specified prefix/mask pair are not suppressed.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	•	—

Command History

Release	Modification
Preexisting	This command was preexisting.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

Routes learned from other routing protocols can be summarized. Using this command for OSPF causes an OSPF Autonomous System Boundary Router (ASBR) to advertise one external route as an aggregate for all redistributed routes that are covered by the address. This command summarizes only routes from other routing protocols that are being redistributed into OSPF. Use the **area range** command for route summarization between OSPF areas.

To remove a **summary-address** command from the configuration, use the no form of the command without specifying any of the optional keywords or arguments. To remove an option from a summary command in the configuration, use the **no** form of the command with the options that you want removed. See the "Examples" section for more information.

Examples

The following example configures route summarization with a **tag** set to 3:

```
hostname(config-router)# summary-address 1.1.0.0 255.255.0.0 tag 3
hostname(config-router)#
```

The following example shows how to use the **no** form of the **summary-address** command with an option to set that option back to the default value. In this example, the **tag** value, set to 3 in the previous example, is removed from the **summary-address** command.

```
hostname(config-router)# no summary-address 1.1.0.0 255.255.0.0 tag 3
hostname(config-router)#
```

The following example removes the **summary-address** command from the configuration:

```
hostname(config-router)# no summary-address 1.1.0.0 255.255.0.0
hostname(config-router)#
```

Related Commands

Command	Description
area range	Consolidates and summarizes routes at an area boundary.
router ospf	Enters router configuration mode.
show ospf summary-address	Displays the summary address settings for each OSPF routing process.

summary-prefix (OSPFv3)

To configure an IPv6 summary prefix, use the **summary-prefix** command in IPv6 router configuration mode. To restore the default, use the **no** form of this command.

summary-prefix *prefix* [**not-advertise**] [**tag** *tag_value*]

no summary-prefix *prefix* [**not-advertise**] [**tag** *tag_value*]

Syntax Description

not-advertise	(Optional) Suppresses routes that match the specified prefix and mask pair. This keyword applies to OSPFv3 only.
prefix	Specifies the IPv6 prefix for the destination.
tag *tag_value*	(Optional) Specifies the tag value that can be used as a match value for controlling redistribution by means of route maps. This keyword applies to OSPFv3 only.

Defaults

The defaults are as follows:

- *tag_value* is 0.
- Routes that match the specified prefix and mask pair are not suppressed.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
IPv6 router configuration	•	—	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to configure an IPv6 summary prefix.

Examples

In the following example, the summary prefix FECO::/24 includes addresses FECO::/1 through FECO::/24. Only the address FECO::/24 is advertised in an external LSA:

```
hostname(config-if)# ipv6 router ospf 1
hostname(config-router)# router-id 172.16.3.3
hostname(config-router)# summary-prefix FECO::/24
hostname(config-router)# redistribute static
```

Related Commands

Command	Description
ipv6 router ospf	Enters router configuration mode for OSPFv3.
redistribute	Redistributes IPv6 routes from one OSPFv3 routing domain into another OSPFv3 routing domain.

sunrpc-server

To create entries in the SunRPC services table, use the **sunrpc-server** command in global configuration mode. To remove SunRPC services table entries from the configuration, use the **no** form of this command.

sunrpc-server *ifc_name ip_addr mask* **service** *service_type* **protocol** [**tcp** | **udp**] **port** *port* **[-** *port* **]** **timeout** *hh:mm:ss*

no sunrpc-server *ifc_name ip_addr mask* **service** *service_type* **protocol** [**tcp** | **udp**] **port** *port* [*- port]* **timeout** *hh:mm:ss*

no sunrpc-server active service *service_type* **server** *ip_addr*

Syntax Description

ifc_name	Server interface name.
ip_addr	SunRPC server IP address.
mask	Network mask.
port *port* [- *port*]	Specifies the SunRPC protocol port range.
port- *port*	(Optional) Specifies the SunRPC protocol port range.
protocol tcp	Specifies the SunRPC transport protocol.
protocol udp	Specifies the SunRPC transport protocol.
service	Specifies a service.
service_type	Sets the SunRPC service program number as specified in the **sunrpcinfo** command.
timeout *hh:mm:ss*	Specifies the timeout idle time after which the access for the SunRPC service traffic is closed.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The SunRPC services table is used to allow SunRPC traffic through the ASA based on an established SunRPC session for the duration specified by the timeout.

Examples

The following example shows how to create an SunRPC services table:

```
hostname(config)# sunrpc-server outside 10.0.0.1 255.0.0.0 service 100003 protocol TCP
port 111 timeout 0:11:00
hostname(config)# sunrpc-server outside 10.0.0.1 255.0.0.0 service 100005 protocol TCP
port 111 timeout 0:11:00
```

Related Commands

Command	Description
clear configure sunrpc-server	Clears the Sun remote processor call services from the ASA.
show running-config sunrpc-server	Displays the information about the SunRPC configuration.

support-user-cert-validation

To validate a remote user certificate based on the current trustpoint, provided that this trustpoint is authenticated to the CA that issued the remote certificate, use the **support-user-cert-validation** command in crypto ca trustpoint configuration mode. To restore the default setting, use the **no** form of the command.

support-user-cert-validation

no support-user-cert-validation

Syntax Description

This command has no arguments or keywords.

Defaults

The default setting is to support user certificate validation.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca trustpoint configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The ASA can have two trustpoints with the same CA resulting in two different identity certificates from the same CA. This option is automatically disabled if the trustpoint is authenticated to a CA that is already associated with another trustpoint that has enabled this feature. This prevents ambiguity in the choice of path-validation parameters. If the user attempts to activate this feature on a trustpoint that has been authenticated to a CA already associated with another trustpoint that has enabled this feature, the action is not permitted. No two trustpoints can have this setting enabled and be authenticated to the same CA.

Examples

The following example enters crypto ca trustpoint configuration mode for trustpoint central, and enables the trustpoint central to accept user validation:

```
hostname(config)# crypto ca trustpoint central
hostname(ca-trustpoint)# support-user-cert-validation
hostname(ca-trustpoint)#
```

Related Commands

Command	Description
crypto ca trustpoint	Enters trustpoint configuration mode.
default enrollment	Returns enrollment parameters to their defaults.

sw-module module password-reset

To reset the password on the software module to the default value, "cisco," use the **sw-module module password-reset** command in privileged EXEC mode.

sw-module module *id* **password-reset**

Syntax Description

id	Specifies the module ID, either **cxsc** or **ips**.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.6(1)	This command was introduced.
9.1(1)	We added support for the ASA CX software module by adding the **cxsc** keyword.

Usage Guidelines

After resetting the password, you should change it to a unique value using the module application. Resetting the module password causes the module to reboot. Services are not available while the module is rebooting, which may take several minutes. You can run the **show module** command to monitor the module state.

The command always prompts for confirmation. If the command succeeds, no other output appears. If the command fails, an error message appears that explains why the failure occurred.

This command is only valid when the module is in the Up state.

The default password depends on the module:

- ASA IPS—The default password is **cisco** for user cisco.
- ASA CX—The default password is **Admin123** for user admin.

Examples

The following example resets a password on the IPS module:

```
hostname# sw-module module ips password-reset
Reset the password on module ips? [confirm] y
```

Related Commands

Command	Description
sw-module module recover	Recovers a module by loading a recovery image from disk.
sw-module module reload	Reloads the module software.
sw-module module reset	Shuts down and reloads the module.
sw-module module shutdown	Shuts down the module software in preparation for being powered off without losing configuration data.
show module	Shows module information.

sw-module module recover

To load a recovery software image from disk for a software module, or to configure the image location, use the **sw-module module recover** command in privileged EXEC mode. You might need to recover a module using this command if, for example, the module is unable to load the current image.

sw-module module *id* **recover** {**boot** | **stop** | **configure image** *path*}

Syntax Description

id	Specifies the module ID, either **cxsc** or **ips**.
boot	Initiates recovery of this module and downloads a recovery image according to the **configure** settings. The module then reboots from the new image.
configure image *path*	Configures the new image location on the local disk, for example, disk0:image2.
stop	Stops the recovery action. The module boots from the original image. You must enter this command within 30 seconds after starting recovery using the **sw-module module** *id* **recover boot** command. If you issue the **stop** command after this period, it might cause unexpected results, such as the module becoming unresponsive.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.6(1)	This command was introduced.
9.1(1)	We added support for the ASA CX software module by adding the **cxsc** keyword.

Usage Guidelines

If the module suffers a failure, and the module application image cannot run, you can reinstall a new image on the module from the local disk.

This command is only available when the module is in the Up, Down, Unresponsive, or Recovery state. See the **show module** command for state information. If the module is not in an Up state, the ASA will forcefully shutdown the module. A forced shutdown will destroy the old module disk image, including any configuration, and should only be used as a disaster recovery mechanism.

You can view the recovery configuration using the **show module** *id* **recover** command.

Note Do not use the **upgrade** command within the module software to install the image.

Examples

The following example sets the module to download an image from disk0:image2:

```
hostname# sw-module module ips recover configure image disk0:image2
```

The following example recovers the module:

```
hostname# sw-module module ips recover boot
The module in slot ips will be recovered.  This may
erase all configuration and all data on that device and
attempt to download a new image for it.
Recover module in slot ips? [confirm]
```

Related Commands

Command	Description
debug module-boot	Shows debug messages about the module booting process.
sw-module module reset	Shuts down a module and performs a reset.
sw-module module reload	Reloads the module software.
sw-module module shutdown	Shuts down the module software in preparation for being powered off without losing configuration data.
show module	Shows module information.

sw-module module reload

To reload module software for a software module, use the **sw-module module reload** command in privileged EXEC mode.

sw-module module *id* **reload**

Syntax Description

id	Specifies the module ID, either **cxsc** or **ips**.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.6(1)	This command was introduced.
9.1(1)	We added support for the ASA CX software module by adding the **cxsc** keyword.

Usage Guidelines

This command differs from the **sw-module module reset** command, which also performs a reset before reloading the module.

This command is only valid when the module status is Up. See the **show module** command for state information.

Examples

The following example reloads the IPS module:

```
hostname# sw-module module ips reload
Reload module in slot ips? [confirm] y
Reload issued for module in slot ips
%XXX-5-505002: Module in slot ips is reloading.  Please wait...
%XXX-5-505006: Module in slot ips is Up.
```

Related Commands

Command	Description
debug module-boot	Shows debug messages about the module booting process.
sw-module module recover	Recovers a module by loading a recovery image from disk.
sw-module module reset	Shuts down a module and performs a reset.
sw-module module shutdown	Shuts down the module software in preparation for being powered off without losing configuration data.
show module	Shows module information.

sw-module module reset

To reset the module and then reload the module software, use the **sw-module module reset** command in privileged EXEC mode.

sw-module module *id* **reset**

Syntax Description

id	Specifies the module ID, either **cxsc** or **ips**.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.6(1)	This command was introduced.
9.1(1)	We added support for the ASA CX software module by adding the **cxsc** keyword.

Usage Guidelines

When the module is in an Up state, the **sw-module module reset** command prompts you to shut down the software before resetting.

You can recover a module using the **sw-module module recover** command. If you enter the **sw-module module reset** command while the module is in a Recover state, the module does not interrupt the recovery process. The **sw-module module reset** command performs a reset of the module, and the module recovery continues after the reset. You might want to reset the module during recovery if the module hangs; a reset might resolve the issue.

This command differs from the **sw-module module reload** command, which only reloads the software and does not perform a reset.

This command is only valid when the module status is Up, Down, Unresponsive, or Recover. See the **show module** command for state information.

Examples

The following example resets an IPS module that is in the Up state:

```
hostname# sw-module module ips reset
The module in slot ips should be shut down before
resetting it or loss of configuration may occur.
Reset module in slot ips? [confirm] y
```

```
Reset issued for module in slot ips
%XXX-5-505001: Module in slot ips is shutting down.  Please wait...
%XXX-5-505004: Module in slot ips shutdown is complete.
%XXX-5-505003: Module in slot ips is resetting.  Please wait...
%XXX-5-505006: Module in slot ips is Up.
```

Related Commands

Command	Description
debug module-boot	Shows debug messages about the module booting process.
sw-module module recover	Recovers a module by loading a recovery image from disk.
sw-module module reload	Reloads the module software.
sw-module module shutdown	Shuts down the module software in preparation for being powered off without losing configuration data.
show module	Shows module information.

sw-module module shutdown

To shut down the module software, use the **sw-module module shutdown** command in privileged EXEC mode.

sw-module module *id* **shutdown**

Syntax Description

id	Specifies the module ID, either **cxsc** or **ips**.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.6(1)	This command was introduced.
9.1(1)	We added support for the ASA CX software module by adding the **cxsc** keyword.

Usage Guidelines

Shutting down the module software prepares the module to be safely powered off without losing configuration data.

This command is only valid when the module status is Up or Unresponsive. See the **show module** command for state information.

Examples

The following example shuts down an IPS module:

```
hostname# sw-module module ips shutdown
Shutdown module in slot ips? [confirm] y
Shutdown issued for module in slot ips
hostname#
%XXX-5-505001: Module in slot ips is shutting down.  Please wait...
%XXX-5-505004: Module in slot ips shutdown is complete.
```

Related Commands

Command	Description
debug module-boot	Shows debugging messages about the module booting process.
sw-module module recover	Recovers a module by loading a recovery image from disk.
sw-module module reload	Reloads the module software.
sw-module module reset	Shuts down a module and performs a reset.
show module	Shows module information.

sw-module module uninstall

To uninstall a software module image and associated configuration, use the **sw-module module uninstall** command in privileged EXEC mode.

sw-module module *id* **uninstall**

Syntax Description

id	Specifies the module ID, either **cxsc** or **ips**.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.6(1)	We introduced this command.
9.1(1)	We added support for the ASA CX software module by adding the **cxsc** keyword.

Usage Guidelines

This command permanently uninstalls the software module image and associated configuration.

Examples

The following example uninstalls the IPS module image and configuration:

```
hostname# sw-module module ips uninstall
Module ips will be uninstalled. This will completely remove the
disk image associated with the sw-module including any configuration
that existed within it.

Uninstall module <id>? [confirm]
```

sw-module module recover	Recovers a module by loading a recovery image from disk.
sw-module module reload	Reloads the module software.

Command	Description
sw-module module reset	Shuts down a module and performs a reset.
show module	Shows module information.

switchport access vlan

For models with a built-in switch, such as the ASA 5505 adaptive security appliance, use the **switchport access vlan** command in interface configuration mode to assign a switch port to a VLAN.

switchport access vlan *number*

no switchport access vlan *number*

Syntax Description

vlan *number*	Specifies the VLAN ID to which you want to assign this switch port. The VLAN ID is between 1 and 4090.

Defaults

By default, all switch ports are assigned to VLAN 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

In transparent firewall mode, you can configure two active VLANs in the ASA 5505 adaptive security appliance Base license and three active VLANs in the Security Plus license, one of which must be for failover.

In routed mode, you can configure up to three active VLANs in the ASA 5505 adaptive security appliance Base license, and up to 20 active VLANs with the Security Plus license.

An active VLAN is a VLAN with a **nameif** command configured.

You can assign one or more physical interfaces to each VLAN using the **switchport access vlan** command. By default, the VLAN mode of the interface is to be an access port (one VLAN associated with the interface). If you want to create a trunk port to pass multiple VLANs on the interface, use the **switchport mode access trunk** command to change the mode to trunk mode, and then use the **switchport trunk allowed vlan** command.

Examples

The following example assigns five physical interfaces to three VLAN interfaces:

```
hostname(config-if)# interface ethernet 0/0
hostname(config-if)# switchport access vlan 100
hostname(config-if)# no shutdown
```

```
hostname(config-if)# interface ethernet 0/1
hostname(config-if)# switchport access vlan 200
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/2
hostname(config-if)# switchport access vlan 200
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/3
hostname(config-if)# switchport access vlan 200
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/4
hostname(config-if)# switchport access vlan 300
hostname(config-if)# no shutdown

...
```

Related Commands

Command	Description
interface	Configures an interface and enters interface configuration mode.
show running-config interface	Shows the interface configuration in the running configuration.
switchport mode	Sets the VLAN mode to be access or trunk.
switchport protected	Prevents a switch port from communicating with other switch ports on the same VLAN for extra security.
switchport trunk allowed vlan	Assigns VLANs to a trunk port.

switchport mode

For models with a built-in switch, such as the ASA 5505 adaptive security appliance, use the **switchport mode** command in interface configuration mode to set the VLAN mode to either access (the default) or trunk.

switchport mode {**access** | **trunk**}

no switchport mode {**access** | **trunk**}

Syntax Description

access	Sets the switch port to access mode, which allows the switch port to pass traffic for only one VLAN. Packets exit the switch port without an 802.1Q VLAN tag. If a packet enters the switch port with a tag, the packet is dropped.
trunk	Sets the switch port to trunk mode, so it can pass traffic for multiple VLANs. Packets exit the switch port with an 802.1Q VLAN tag. If a packet enters the switch port without a tag, the packet is dropped.

Defaults

By default, the mode is access.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.
7.2(2)	You can now configure multiple trunk ports, rather than being limited to one trunk.

Usage Guidelines

By default, the VLAN mode of the switch port is to be an access port (one VLAN associated with the switch port). In access mode, assign a switch port to a VLAN using the **switchport access vlan** command. If you want to create a trunk port to pass multiple VLANs on the switch port, set the mode to trunk mode, and then use the **switchport trunk allowed vlan** command to assign multiple VLANs to the trunk. If you set the mode to trunk mode, and you have not yet configured the **switchport trunk allowed vlan** command, the switch port remains in "line protocol down" state and cannot participate in traffic forwarding. Trunk mode is available only with the Security Plus license.

The **switchport vlan access** command does not take effect unless the mode is set to access mode. The **switchport trunk allowed vlan** command does not take effect unless the mode is set to trunk mode.

Examples

The following example configures an access mode switch port assigned to VLAN 100, and a trunk mode switch port assigned to VLANs 200 and 300:

```
hostname(config-if)# interface ethernet 0/0
hostname(config-if)# switchport access vlan 100
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/1
hostname(config-if)# switchport mode trunk
hostname(config-if)# switchport trunk allowed vlan 200,300
hostname(config-if)# no shutdown

...
```

Related Commands

Command	Description
interface	Configures an interface and enters interface configuration mode.
show running-config interface	Shows the interface configuration in the running configuration.
switchport access vlan	Assigns the switch port to a VLAN.
switchport protected	Prevents a switch port from communicating with other switch port on the same VLAN for extra security.
switchport trunk allowed vlan	Assigns VLANs to a trunk port.

switchport monitor

For models with a built-in switch, such as the ASA 5505 adaptive security appliance, use the **switchport monitor** command in interface configuration mode to enable SPAN, also known as switch port monitoring. The port for which you enter this command (called the destination port) receives a copy of every packet transmitted or received on the specified source port. The SPAN feature lets you attach a sniffer to the destination port so you can monitor traffic. You can specify multiple source ports by entering this command multiple times. You can only enable SPAN for one destination port. To disable monitoring of a source port, use the **no** form of this command.

switchport monitor *source_port* [**tx** | **rx** | **both**]

no switchport monitor *source_port* [**tx** | **rx** | **both**]

Syntax Description

source_port	Specifies the port you want to monitor. You can specify any Ethernet port as well as the Internal-Data0/1 backplane port that passes traffic between VLAN interfaces. Because the Internal-Data0/1 port is a Gigabit Ethernet port, you might overload the Fast Ethernet destination port with traffic. Monitor the port Internal-Data0/1 with caution.
tx	(Optional) Specifies that only transmitted traffic is monitored.
rx	(Optional) Specifies that only received traffic is monitored.
both	(Optional) Specifies that both transmitted and received traffic is monitored. **both** is the default.

Defaults

The default type of traffic to monitor is **both**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

If you do not enable SPAN, then attaching a sniffer to one of the switch ports only captures traffic to or from that port. To capture traffic to or from multiple ports, you need to enable SPAN and identify the ports you want to monitor.

Use caution while connecting a SPAN destination port to another switch, as it could result in network loops.

Examples

The following example configures the Ethernet 0/1 port as the destination port which monitors the Ethernet 0/0 and Ethernet 0/2 ports:

```
hostname(config)# interface ethernet 0/1
hostname(config-if)# switchport monitor ethernet 0/0
hostname(config-if)# switchport monitor ethernet 0/2
```

Related Commands

Command	Description
interface	Configures an interface and enters interface configuration mode.
show running-config interface	Shows the interface configuration in the running configuration.
switchport access vlan	Assigns the switch port to a VLAN.
switchport protected	Prevents a switch port from communicating with other switch port on the same VLAN for extra security.

switchport protected

For models with a built-in switch, such as the ASA 5505 adaptive security appliance, use the **switchport protected** command in interface configuration mode to prevent the switch port from communicating with other protected switch ports on the same VLAN. This feature provides extra security to the other switch ports on a VLAN if one switch port becomes compromised.

switchport protected

no switchport protected

Syntax Description

This command has no arguments or keywords.

Defaults

By default, the interfaces are not protected.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

You might want to prevent switch ports from communicating with each other if the devices on those switch ports are primarily accessed from other VLANs, you do not need to allow intra-VLAN access, and you want to isolate the devices from each other in case of infection or other security breach. For example, if you have a DMZ that hosts three web servers, you can isolate the web servers from each other if you apply the **switchport protected** command to each switch port. The inside and outside networks can both communicate with all three web servers, and vice versa, but the web servers cannot communicate with each other.

Communication to and from unprotected ports is not restricted by this command.

Examples

The following example configures seven switch ports. The Ethernet 0/4, 0/5, and 0/6 are assigned to the DMZ network and are protected from each other.

```
hostname(config)# interface ethernet 0/0
hostname(config-if)# switchport access vlan 100
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/1
hostname(config-if)# switchport access vlan 200
```

```
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/2
hostname(config-if)# switchport access vlan 200
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/3
hostname(config-if)# switchport access vlan 200
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/4
hostname(config-if)# switchport access vlan 300
hostname(config-if)# switchport protected
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/5
hostname(config-if)# switchport access vlan 300
hostname(config-if)# switchport protected
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/6
hostname(config-if)# switchport access vlan 300
hostname(config-if)# switchport protected
hostname(config-if)# no shutdown

...
```

Related Commands

Command	Description
interface	Configures an interface and enters interface configuration mode.
show running-config interface	Shows the interface configuration in the running configuration.
switchport access vlan	Assigns the switch port to a VLAN.
switchport mode	Sets the VLAN mode to be access or trunk.
switchport trunk allowed vlan	Assigns VLANs to a trunk port.

switchport trunk

For models with a built-in switch, such as the ASA 5505 adaptive security appliance, use the **switchport trunk** command in interface configuration mode to assign VLANs to the trunk port. Use the **no** form of the command to remove a VLAN from the trunk.

switchport trunk {allowed vlans *vlan_range* **| native vlan** v*lan*}

no switchport trunk {allowed vlans *vlan_range* **| native vlan** v*lan*}

Syntax Description

allowed vlans *vlan_range*	Identifies one or more VLANs that you can assign to the trunk port. The VLAN ID is between 1 and 4090. The *vlan_range* can be identified in one of the following ways: • A single number (n) • A range (n-x) Separate numbers and ranges by commas, for example: 5,7-10,13,45-100 You can enter spaces instead of commas, but the command is saved to the configuration with commas. You can include the native VLAN in this command, but it is not required; the native VLAN is passed whether it is included in this command or not.
native vlan *vlan*	Assigns a native VLAN to the trunk. Packets on the native VLAN are not modified when sent over the trunk. For example, if a port has VLANs 2, 3 and 4 assigned to it, and VLAN 2 is the native VLAN, then packets on VLAN 2 that egress the port are not modified with an 802.1Q header. Frames that ingress (enter) this port and have no 802.1Q header are put into VLAN 2. Each port can only have one native VLAN, but every port can have either the same or a different native VLAN.

Defaults

By default, no VLANs are assigned to the trunk.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.
7.2(2)	This command was modified to allow more than 3 VLANs per switch port. Also, you can now configure multiple trunk ports, instead of being limited to only one. This command also uses commas instead of spaces to separate VLAN IDs.
7.2(4)/8.0(4)	Native VLAN support was introduced with the **native vlan** keywords.

Usage Guidelines

If you want to create a trunk port to pass multiple VLANs on the switch port, set the mode to trunk mode using the **switchport mode trunk** command, and then use the **switchport trunk** command to assign VLANs to the trunk. This switch port cannot pass traffic until you assign at least one VLAN to it. If you set the mode to trunk mode, and you have not yet configured the **switchport trunk allowed vlan** command, the switch port remains in "line protocol down" state and cannot participate in traffic forwarding. Trunk mode is available only with the Security Plus license. The **switchport trunk** command does not take effect unless the mode is set to trunk mode using the **switchport mode trunk** command.

Note This command is not downgrade-compatible to Version 7.2(1); the commas separating the VLANs are not recognized in 7.2(1). If you downgrade, be sure to separate the VLANs with spaces, and do not exceed the 3 VLAN limit.

Examples

The following example configures seven VLAN interfaces, including the failover interface which is configured using the **failover lan** command. VLANs 200, 201, and 202 are trunked on Ethernet 0/1.

```
hostname(config)# interface vlan 100
hostname(config-if)# nameif outside
hostname(config-if)# security-level 0
hostname(config-if)# ip address 10.1.1.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 200
hostname(config-if)# nameif inside
hostname(config-if)# security-level 100
hostname(config-if)# ip address 10.2.1.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 201
hostname(config-if)# nameif dept1
hostname(config-if)# security-level 90
hostname(config-if)# ip address 10.2.2.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 202
hostname(config-if)# nameif dept2
hostname(config-if)# security-level 90
hostname(config-if)# ip address 10.2.3.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 300
hostname(config-if)# nameif dmz
hostname(config-if)# security-level 50
hostname(config-if)# ip address 10.3.1.1 255.255.255.0
hostname(config-if)# no shutdown
```

```
hostname(config-if)# interface vlan 400
hostname(config-if)# nameif backup-isp
hostname(config-if)# security-level 50
hostname(config-if)# ip address 10.1.2.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# failover lan faillink vlan500
hostname(config)# failover interface ip faillink 10.4.1.1 255.255.255.0 standby 10.4.1.2
255.255.255.0

hostname(config)# interface ethernet 0/0
hostname(config-if)# switchport access vlan 100
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/1
hostname(config-if)# switchport mode trunk
hostname(config-if)# switchport trunk allowed vlan 200-202
hostname(config-if)# switchport trunk native vlan 5
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/2
hostname(config-if)# switchport access vlan 300
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/3
hostname(config-if)# switchport access vlan 400
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/4
hostname(config-if)# switchport access vlan 500
hostname(config-if)# no shutdown
```

Related Commands

Command	Description
interface	Configures an interface and enters interface configuration mode.
show running-config interface	Shows the interface configuration in the running configuration.
switchport access vlan	Assigns the switch port to a VLAN.
switchport mode	Sets the VLAN mode to be access or trunk.
switchport protected	Prevents a switch port from communicating with other switch ports on the same VLAN for extra security.

synack-data

To set the action for TCP SYNACK packets that contain data, use the **synack-data** command in tcp-map configuration mode. To set the value back to the default, use the **no** form of this command. This command is part of the TCP normalization policy enabled using the **set connection advanced-options** command.

synack-data {**allow** | **drop**}

no synack-data

Syntax Description

allow	Allows TCP SYNACK packets that contain data.
drop	Drops TCP SYNACK packets that contain data.

Defaults

The default action is to drop TCP SYNACK packets that contain data.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tcp-map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(4)/8.0(4)	This command was introduced.

Usage Guidelines

To enable TCP normalization, use the Modular Policy Framework:

1. **tcp-map**—Identifies the TCP normalization actions.
   a. **synack-data**—In tcp-map configuration mode, you can enter the **synack-data** command and many others.
2. **class-map**—Identify the traffic on which you want to perform TCP normalization.
3. **policy-map**—Identify the actions associated with each class map.
   a. **class**—Identify the class map on which you want to perform actions.
   b. **set connection advanced-options**—Identify the tcp-map you created.
4. **service-policy**—Assigns the policy map to an interface or globally.

Examples

The following example sets the ASA to allow TCP SYNACK packets that contain data:

```
hostname(config)# tcp-map tmap
```

```
hostname(config-tcp-map)# synack-data allow
hostname(config)# class-map cmap
hostname(config-cmap)# match any
hostname(config)# policy-map pmap
hostname(config-pmap)# class cmap
hostname(config-pmap)# set connection advanced-options tmap
hostname(config)# service-policy pmap global
hostname(config)#
```

Related Commands

Command	Description
class-map	Identifies traffic for a service policy.
policy-map	dentifies actions to apply to traffic in a service policy.
set connection advanced-options	Enables TCP normalization.
service-policy	Applies a service policy to interface(s).
show running-config tcp-map	Shows the TCP map configuration.
tcp-map	Creates a TCP map and allows access to tcp-map configuration mode.

syn-data

To allow or drop SYN packets with data, use the **syn-data** command in tcp-map configuration mode. To remove this specification, use the **no** form of this command.

syn-data {**allow** | **drop**}

no syn-data {**allow** | **drop**}

Syntax Description

allow	Allows SYN packets that contain data.
drop	Drops SYN packets that contain data.

Defaults

Packets with SYN data are allowed by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Tcp-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **tcp-map** command is used along with the Modular Policy Framework infrastructure. Define the class of traffic using the **class-map** command and customize the TCP inspection with **tcp-map** commands. Apply the new TCP map using the **policy-map** command. Activate TCP inspection with **service-policy** commands.

Use the **tcp-map** command to enter tcp-map configuration mode. Use the **syn-data** command in tcp-map configuration mode to drop packets with data in SYN packets.

According to the TCP specification, TCP implementations are required to accept data contained in a SYN packet. Because this is a subtle and obscure point, some implementations may not handle this correctly. To avoid any vulnerabilities to insertion attacks involving incorrect end-system implementations, you may choose to drop packets with data in SYN packets.

Examples

The following example shows how to drop SYN packets with data on all TCP flows:

```
hostname(config)# access-list TCP extended permit tcp any any
hostname(config)# tcp-map tmap
hostname(config-tcp-map)# syn-data drop
hostname(config)# class-map cmap
hostname(config-cmap)# match access-list TCP
```

```
hostname(config)# policy-map pmap
hostname(config-pmap)# class cmap
hostname(config-pmap)# set connection advanced-options tmap
hostname(config)# service-policy pmap global
hostname(config)#
```

Related Commands

Command	Description
class	Specifies a class map to use for traffic classification.
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
set connection	Configures connection values.
tcp-map	Creates a TCP map and allows access to tcp-map configuration mode.

sysopt connection permit-vpn

For traffic that enters the ASA through a VPN tunnel and is then decrypted, use the **sysopt connection permit-vpn** command in global configuration mode to allow the traffic to bypass interface access lists. Group policy and per-user authorization access lists still apply to the traffic. To disable this feature, use the **no** form of this command.

sysopt connection permit-vpn

no sysopt connection permit-vpn

Syntax Description

This command has no arguments or keywords.

Defaults

This feature is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command is now enabled by default. Also, only interface access lists are bypassed; group policy or per-user access lists remain in force.
7.1(1)	This command was changed from **sysopt connection permit-ipsec**.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

By default, the ASA allows VPN traffic to terminate on an ASA interface; you do not need to allow IKE or ESP (or other types of VPN packets) in an interface access list. By default, you also do not need an interface access list for local IP addresses of decrypted VPN packets. Because the VPN tunnel was terminated successfully using VPN security mechanisms, this feature simplifies configuration and maximizes the ASA performance without any security risks. (Group policy and per-user authorization access lists still apply to the traffic.)

You can require an interface access list to apply to the local IP addresses by entering the **no sysopt connection permit-vpn** command. See the **access-list** and **access-group** commands to create an access list and apply it to an interface. The access list applies to the local IP address, and not to the original client IP address used before the VPN packet was decrypted.

Examples

The following example requires decrypted VPN traffic to comply with interface access lists:

```
hostname(config)# no sysopt connection permit-vpn
```

Related Commands

Command	Description
clear configure sysopt	Clears the **sysopt** command configuration.
show running-config sysopt	Shows the **sysopt** command configuration.
sysopt connection tcpmss	Overrides the maximum TCP segment size or ensures that the maximum is not less than a specified size.
sysopt connection timewait	Forces each TCP connection to linger in a shortened TIME_WAIT state after the final normal TCP close-down sequence.

sysopt connection preserve-vpn-flows

To preserve and resume stateful (TCP) tunneled IPsec LAN-to-LAN traffic within the timeout period after the tunnel drops and recovers, use the **sysopt connection preserve-vpn-flows** command. To disable this feature, use the **no** form of this command.

sysopt connection preserve-vpn-flows

no sysopt connection preserve-vpn-flows

Syntax Description

This command has no arguments or keywords.

Defaults

This feature is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.0(4)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

With the persistent IPsec tunneled flows feature enabled, as long as the tunnel is recreated within the timeout window, data continues flowing successfully because the security appliance still has access to the state information in the original flow.

This command supports only IPsec LAN-to-LAN tunnels, including Network Extension Mode. It does not support AnyConnect/SSL VPN or IPsec remote-access tunnels.

Examples

The following example specifies that the state information for the tunnel will be preserved and the tunneled IPsec LAN-to-LAN VPN traffic will resume after the tunnel drops and is reestablished within the timeout period:

```
hostname(config)# no sysopt connection preserve-vpn-flows
```

To see whether this feature is enabled, enter the show run all command for sysopt:

```
hostname(config)# show run all sysopt
```

A sample result follows. For illustrative purposes, in this and all following examples, the preserve-vpn-flows item is bolded:

```
no sysopt connection timewait
sysopt connection tcpmss 1380
sysopt connection tcpmss minimum 0
no sysopt nodnsalias inbound
no sysopt nodnsalias outbound
no sysopt radius ignore-secret
sysopt connection permit-vpn
no sysopt connection reclassify-vpn
no sysopt connection preserve-vpn-flows
hostname(config)#
```

sysopt connection reclassify-vpn

To reclassify existing VPN flows, use the **sysopt connection reclassify-vpn** command in global configuration mode. To disable this feature, use the **no** form of this command.

sysopt connection reclassify-vpn

no sysopt connection reclassify-vpn

Syntax Description

This command has no arguments or keywords.

Defaults

This feature is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

When VPN tunnels come up, this command reclassifies existing VPN flows to make sure that flows that need encryption get torn down and recreated.

This command only applies for LAN-to-LAN and dynamic VPNs. This command has no effect on EZVPN or VPN client connections.

Examples

The following example enables VPN reclassification:

```
hostname(config)# sysopt connection reclassify-vpn
```

Related Commands

Command	Description
clear configure sysopt	Clears the **sysopt** command configuration.
show running-config sysopt	Shows the **sysopt** command configuration.
sysopt connection permit-vpn	Permits any packets that come from an IPsec tunnel without checking any acess lists for interfaces.

Command	Description
sysopt connection tcpmss	Overrides the maximum TCP segment size or ensures that the maximum is not less than a specified size.
sysopt connection timewait	Forces each TCP connection to linger in a shortened TIME_WAIT state after the final normal TCP close-down sequence.

sysopt connection tcpmss

To ensure that the maximum TCP segment size does not exceed the value you set and that the maximum is not less than a specified size, use the **sysopt connection tcpmss** command in global configuration mode. To restore the default setting, use the **no** form of this command.

sysopt connection tcpmss [**minimum**] *bytes*

no sysopt connection tcpmss [**minimum**] [*bytes*]

Syntax Description

bytes	Sets the maximum TCP segment size in bytes, between 48 and any maximum number. The default value is 1380 bytes. You can disable this feature by setting *bytes* to 0. For the **minimum** keyword, the *bytes* represent the smallest maximum value allowed.
minimum	Overrides the maximum segment size to be no less than *bytes*, between 48 and 65535 bytes. This feature is disabled by default (set to 0).

Defaults

The default maximum value is 1380 bytes. The minimum feature is disabled by default (set to 0).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
Preexisting	This command was preexisting.

Usage Guidelines

Both the host and the server can set the maximum segment size when they first establish a connection. If either maximum exceeds the value you set with the **sysopt connection tcpmss** command, then the ASA overrides the maximum and inserts the value you set. If either maximum is less than the value you set with the **sysopt connection tcpmss minimum** command, then the ASA overrides the maximum and inserts the "minimum" value you set (the minimum value is actually the smallest maximum allowed). For example, if you set a maximum size of 1200 bytes and a minimum size of 400 bytes, when a host requests a maximum size of 1300 bytes, then the ASA alters the packet to request 1200 bytes (the maximum). If another host requests a maximum value of 300 bytes, then the ASA alters the packet to request 400 bytes (the minimum).

The default of 1380 bytes allows room for header information so that the total packet size does not exceed 1500 bytes, which is the default MTU for Ethernet. See the following calculation:

1380 data + 20 TCP + 20 IP + 24 AH + 24 ESP_CIPHER + 12 ESP_AUTH + 20 IP = 1500 bytes

If the host or server does not request a maximum segment size, the ASA assumes that the RFC 793 default value of 536 bytes is in effect.

If you set the maximum size to be greater than 1380, packets might become fragmented, depending on the MTU size (which is 1500 by default). Large numbers of fragments can impact the performance of the ASA when it uses the Frag Guard feature. Setting the minimum size prevents the TCP server from sending many small TCP data packets to the client and impacting the performance of the server and the network.

Note Although not advised for normal use of this feature, if you encounter the syslog IPFRAG messages 209001 and 209002, you can raise the *bytes* value.

Examples

The following example sets the maximum size to 1200 and the minimum to 400:

```
hostname(config)# sysopt connection tcpmss 1200
hostname(config)# sysopt connection tcpmss minimum 400
```

Related Commands

Command	Description
clear configure sysopt	Clears the **sysopt** command configuration.
show running-config sysopt	Shows the **sysopt** command configuration.
sysopt connection permit-ipsec	Permits any packets that come from an IPsec tunnel without checking any ACLs for interfaces.
sysopt connection timewait	Forces each TCP connection to linger in a shortened TIME_WAIT state after the final normal TCP close-down sequence.

sysopt connection timewait

To force each TCP connection to linger in a shortened TIME_WAIT state of at least 15 seconds after the final normal TCP close-down sequence, use the **sysopt connection timewait** command in global configuration mode. To disable this feature, use the **no** form of this command. You might want to use this feature if an end host application default TCP terminating sequence is a simultaneous close.

sysopt connection timewait

no sysopt connection timewait

Note An RST packet (not a normal TCP close-down sequence) will also trigger the 15 second delay. The ASA holds on to the connection for 15 seconds after receiving the last packet (either FIN/ACK or RST) of the connection .

Syntax Description

This command has no arguments or keywords.

Defaults

This feature is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The default behavior of the ASA is to track the shutdown sequence and release the connection after two FINs and the ACK of the last FIN segment. This quick release heuristic enables the ASA to sustain a high connection rate, based on the most common closing sequence, known as the normal close sequence. However, in a simultaneous close, both ends of the transaction initiate the closing sequence, as opposed to the normal close sequence where one end closes and the other end acknowledges prior to initiating its own closing sequence (see RFC 793). Thus, in a simultaneous close, the quick release forces one side of the connection to linger in the CLOSING state. Having many sockets in the CLOSING state can degrade the performance of an end host. For example, some WinSock mainframe clients are known to exhibit this behavior and degrade the performance of the mainframe server. Using the **sysopt connection timewait** command creates a window for the simultaneous close down sequence to complete.

Examples

The following example enables the timewait feature:

```
hostname(config)# sysopt connection timewait
```

Related Commands

Command	Description
clear configure sysopt	Clears the **sysopt** command configuration.
show running-config sysopt	Shows the **sysopt** command configuration.
sysopt connection permit-ipsec	Permits any packets that come from an IPsec tunnel without checking any ACLs for interfaces.
sysopt connection tcpmss	Overrides the maximum TCP segment size or ensures that the maximum is not less than a specified size.

sysopt noproxyarp

To disable proxy ARP for NAT global addresses or VPN client addresses on an interface, use the **sysopt noproxyarp** command in global configuration mode. To reenable proxy ARP, use the **no** form of this command.

sysopt noproxyarp *interface_name*

no sysopt noproxyarp *interface_name*

Syntax Description

interface_name	The interface name for which you want to disable proxy ARP.

Defaults

Proxy ARP is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.0(3)	This command was extended to affect VPN proxy ARPs when the VPN client addresses overlap with an internal network.

Usage Guidelines

If you have a VPN client address pool that overlaps with an existing network, the ASA by default sends proxy ARPs on all interfaces. If you have another interface that is on the same Layer 2 domain, it will see the ARP requests and will answer with the MAC address of its interface. The result of this is that the return traffic of the VPN clients towards the internal hosts will go to the wrong interface and will get dropped. In this case, you need to enter the **sysopt noproxyarp** command for the interface where you do not want proxy ARPs.

In rare circumstances, you might want to disable proxy ARP for NAT global addresses.

When a host sends IP traffic to another device on the same Ethernet network, the host needs to know the MAC address of the device. ARP is a Layer 2 protocol that resolves an IP address to a MAC address. A host sends an ARP request asking “Who is this IP address?” The device owning the IP address replies, “I own that IP address; here is my MAC address.”

Proxy ARP is when a device responds to an ARP request with its own MAC address, even though the device does not own the IP address. The ASA uses proxy ARP when you configure NAT and specify a global address that is on the same network as the ASA interface. The only way traffic can reach the hosts is if the ASA uses proxy ARP to claim that the ASA MAC address is assigned to destination global addresses.

Examples

The following example disables proxy ARP on the inside interface:

```
hostname(config)# sysopt noproxyarp inside
```

Related Commands

Command	Description
alias	Translates an outside address and alters the DNS records to accommodate the translation.
clear configure sysopt	Clears the **sysopt** command configuration.
show running-config sysopt	Shows the **sysopt** command configuration.
sysopt nodnsalias	Disables alteration of the DNS A record address when you use the **alias** command.

sysopt radius ignore-secret

To ignore the authentication key in RADIUS accounting responses, use the **sysopt radius ignore-secret** command in global configuration mode. To disable this feature, use the **no** form of this command. You might need to ignore the key for compatibility with some RADIUS servers.

sysopt radius ignore-secret

no sysopt radius ignore-secret

Syntax Description

This command has no arguments or keywords.

Defaults

This feature is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Some RADIUS servers fail to include the key in the authenticator hash within the accounting acknowledgment response. This usage caveat can cause the ASA to continually retransmit the accounting request. Use the **sysopt radius ignore-secret** command to ignore the key in these acknowledgments, thus avoiding the retransmit problem. (The key identified here is the same one you set with the **aaa-server host** command.)

Examples

The following example ignores the authentication key in accounting responses:

```
hostname(config)# sysopt radius ignore-secret
```

Related Commands

Command	Description
aaa-server host	Identifies a AAA server.
clear configure sysopt	Clears the **sysopt** command configuration.
show running-config sysopt	Shows the **sysopt** command configuration.

CHAPTER 64

tcp-map through title Commands

tcp-map

To define a set of TCP normalization actions, use the **tcp-map** command in global configuration mode. The TCP normalization feature lets you specify criteria that identify abnormal packets, which the ASA drops when they are detected. To remove the TCP map, use the **no** form of this command.

tcp-map *map_name*

no tcp-map *map_name*

Syntax Description

map_name	Specifies the TCP map name.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(4)/8.0(4)	The **invalid-ack**, **seq-past-window**, and **synack-data** subcommands were added.

Usage Guidelines

This feature uses Modular Policy Framework. First define the TCP normalization actions you want to take using the **tcp-map** command. The **tcp-map** command enters tcp-map configuration mode, where you can enter one or more commands to define the TCP normalization actions. Then define the traffic to which you want to apply the TCP map using the **class-map** command. Enter the **policy-map** command to define the policy, and enter the **class** command to reference the class map. In class configuration mode, enter the **set connection advanced-options** command to reference the TCP map. Finally, apply the policy map to an interface using the **service-policy** command. For more information about how Modular Policy Framework works, see the CLI configuration guide.

The following commands are available in tcp-map configuration mode:

check-retransmission	Enables and disables the retransmit data checks.
checksum-verification	Enables and disable checksum verification.
exceed-mss	Allows or drops packets that exceed MSS set by peer.
invalid-ack	Sets the action for packets with an invalid ACK.

queue-limit	Configures the maximum number of out-of-order packets that can be queued for a TCP connection. This command is only available on the ASA 5500 series adaptive ASA. On the PIX 500 series ASA, the queue limit is 3 and cannot be changed.
reserved-bits	Sets the reserved flags policy in the ASA.
seq-past-window	Sets the action for packets that have past-window sequence numbers, namely the sequence number of a received TCP packet is greater than the right edge of the TCP receiving window.
synack-data	Sets the action for TCP SYNACK packets that contain data.
syn-data	Allows or drops SYN packets with data.
tcp-options	Allows or clears the selective-ack, timestamps, or window-scale TCP options.
ttl-evasion-protection	Enables or disables the TTL evasion protection offered by the ASA.
urgent-flag	Allows or clears the URG pointer through the ASA.
window-variation	Drops a connection that has changed its window size unexpectedly.

Examples

For example, to allow urgent flag and urgent offset packets for all traffic sent to the range of TCP ports between the well known FTP data port and the Telnet port, enter the following commands:

```
hostname(config)# tcp-map tmap
hostname(config-tcp-map)# urgent-flag allow

hostname(config-tcp-map)# class-map urg-class
hostname(config-cmap)# match port tcp range ftp-data telnet

hostname(config-cmap)# policy-map pmap
hostname(config-pmap)# class urg-class
hostname(config-pmap-c)# set connection advanced-options tmap

hostname(config-pmap-c)# service-policy pmap global
```

Related Commands

Command	Description
class (policy-map)	Specifies a class map to use for traffic classification.
clear configure tcp-map	Clears the TCP map configuration.
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
show running-config tcp-map	Displays the information about the TCP map configuration.
tcp-options	Allows or clears the selective-ack, timestamps, or window-scale TCP options.

tcp-options

To allow or clear the TCP options through the ASA, use the **tcp-options** command in tcp-map configuration mode. To remove this specification, use the **no** form of this command.

tcp-options {**selective-ack** | **timestamp** | **window-scale**} {**allow** | **clear**}

no tcp-options {**selective-ack** | **timestamp** | **window-scale**} {**allow** | **clear**}

tcp-options range *lower upper* {**allow** | **clear** | **drop**}

no tcp-options range *lower upper* {**allow** | **clear** | **drop**}

Syntax Description

allow	Allows the TCP options through the TCP normalizer.
clear	Clears the TCP options through the TCP normalizer and allows the packet.
drop	Drops the packet.
lower	Lower bound ranges (6-7) and (9-255).
selective-ack	Sets the selective acknowledgement mechanism (SACK) option. The default is to allow the SACK option.
timestamp	Sets the timestamp option. Clearing the timestamp option will disable PAWS and RTT. The default is to allow the timestamp option.
upper	Upper bound range (6-7) and (9-255).
window-scale	Sets the window scale mechanism option. The default is to allow the window scale mechanism option.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Tcp-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **tcp-map** command is used along with the Modular Policy Framework infrastructure. Define the class of traffic using the **class-map** command and customize the TCP inspection with **tcp-map** commands. Apply the new TCP map using the **policy-map** command. Activate TCP inspection with **service-policy** commands.

Use the **tcp-map** command to enter tcp-map configuration mode. Use the **tcp-options** command in tcp-map configuration mode to clear selective-acknowledgement, window-scale, and timestamp TCP options. You can also clear or drop packets with options that are not very well defined.

Examples

The following example shows how to drop all packets with TCP options in the ranges of 6-7 and 9-255:

```
hostname(config)# access-list TCP extended permit tcp any any
hostname(config)# tcp-map tmap
hostname(config-tcp-map)# tcp-options range 6 7 drop
hostname(config-tcp-map)# tcp-options range 9 255 drop
hostname(config)# class-map cmap
hostname(config-cmap)# match access-list TCP
hostname(config)# policy-map pmap
hostname(config-pmap)# class cmap
hostname(config-pmap)# set connection advanced-options tmap
hostname(config)# service-policy pmap global
```

Related Commands

Command	Description
class	Specifies a class map to use for traffic classification.
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
set connection	Configures connection values.
tcp-map	Creates a TCP map and allows access to tcp-map configuration mode.

telnet

To allow Telnet access to an interface, use the **telnet** command in global configuration mode. To remove Telnet access, use the **no** form of this command.

telnet {*ipv4_address mask* | *ipv6_address/prefix*} *interface_name*

no telnet {*ipv4_address mask* | *ipv6_address/prefix*} *interface_name*

Syntax Description

interface_name	Specifies the name of the interface on which to allow Telnet. You cannot enable Telnet on the lowest security interface unless you use Telnet in a VPN tunnel.
ipv4_address mask	Specifies the IPv4 address of a host or network authorized to Telnet to the ASA, and the subnet mask.
ipv6_address/prefix	Specifies the IPv6 address/prefix authorized to Telnet to the ASA.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(2), 9.1(2)	The default password, "cisco," has been removed; you must actively set a login password using the **password** command.

Usage Guidelines

The **telnet** command lets you specify which hosts can access the ASA CLI with Telnet. You can enable Telnet to the ASA on all interfaces. However, You cannot use Telnet to the lowest security interface unless you use Telnet inside a VPN tunnel.

Use the **password** command to set a password for Telnet access to the console. Use the **who** command to view which IP addresses are currently accessing the ASA console. Use the **kill** command to terminate an active Telnet console session.

If you use the **aaa authentication telnet console** command, Telnet console access must be authenticated with an authentication server.

Examples

This example shows how to permit hosts 192.168.1.3 and 192.168.1.4 to access the ASA CLI through Telnet. In addition, all the hosts on the 192.168.2.0 network are given access.

```
hostname(config)# telnet 192.168.1.3 255.255.255.255 inside
hostname(config)# telnet 192.168.1.4 255.255.255.255 inside
hostname(config)# telnet 192.168.2.0 255.255.255.0 inside
hostname(config)# show running-config telnet
192.168.1.3 255.255.255.255 inside
192.168.1.4 255.255.255.255 inside
192.168.2.0 255.255.255.0 inside
```

This example shows a Telnet console login session (the password does not display when entered):

```
hostname# passwd: cisco

Welcome to the XXX
…
Type help or '?' for a list of available commands.
hostname>
```

You can remove individual entries with the **no telnet** command or all telnet command statements with the **clear configure telnet** command:

```
hostname(config)# no telnet 192.168.1.3 255.255.255.255 inside
hostname(config)# show running-config telnet
192.168.1.4 255.255.255.255 inside
192.168.2.0 255.255.255.0 inside

hostname(config)# clear configure telnet
```

Related Commands

Command	Description
clear configure telnet	Removes a Telnet connection from the configuration.
kill	Terminates a Telnet session.
show running-config telnet	Displays the current list of IP addresses that are authorized to use Telnet connections to the ASA.
telnet timeout	Sets the Telnet timeout.
who	Displays active Telnet administration sessions on the ASA.

telnet timeout

To set the Telnet idle timeout, use the **telnet timeout** command in global configuration mode. To restore the default timeout, use the **no** form of this command.

telnet timeout *minutes*

no telnet timeout *minutes*

Syntax Description

minutes	Number of minutes that a Telnet session can be idle before being closed by the ASA. Valid values are from 1 to 1440 minutes. The default is 5 minutes.

Defaults

By default, Telnet sessions left idle for five minutes are closed by the ASA.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the **telnet timeout** command to set the maximum time that a console Telnet session can be idle before being logged off by the ASA.

Examples

This example shows how to change the maximum session idle duration:

```
hostname(config)# telnet timeout 10
hostname(config)# show running-config telnet timeout
telnet timeout 10 minutes
```

Related Commands

Command	Description
clear configure telnet	Removes a Telnet connection from the configuration.
kill	Terminates a Telnet session.
show running-config telnet	Displays the current list of IP addresses that are authorized to use Telnet connections to the ASA.

Command	Description
telnet	Enables Telnet access to the ASA.
who	Displays active Telnet administration sessions on the ASA.

terminal

To allow syslog messages to show in the current Telnet session, use the **terminal monitor** command in privileged EXEC mode. To disable syslog messages, use the **no** form of this command.

terminal {**monitor** | **no monitor**}

Syntax Description

monitor	Enables the display of syslog messages in the current Telnet session.
no monitor	Disables the display of syslog messages in the current Telnet session.

Defaults

Syslog messages are disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

This example shows how to display and disable syslog messages in the current session:

```
hostname# terminal monitor
hostname# terminal no monitor
```

Related Commands

Command	Description
clear configure terminal	Clears the terminal display width setting.
pager	Sets the number of lines to display in a Telnet session before the "---more---" prompt. This command is saved to the configuration.
show running-config terminal	Displays the current terminal settings.
terminal pager	Sets the number of lines to display in a Telnet session before the "---more---" prompt. This command is not saved to the configuration.
terminal width	Sets the terminal display width in global configuration mode.

terminal pager

To set the number of lines on a page before the "---More---" prompt appears for Telnet sessions, use the **terminal pager** command in privileged EXEC mode.

terminal pager [lines] *lines*

Syntax Description

[**lines**] *lines*	Sets the number of lines on a page before the "---More---" prompt appears. The default is 24 lines; 0 means no page limit. The range is 0 through 2147483647 lines. The **lines** keyword is optional, and the command is the same with or without it.

Defaults

The default is 24 lines.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command changes the pager line setting only for the current Telnet session. To save a new default pager setting to the configuration, use the **pager** command.

If you use Telnet to access the admin context, then the pager line setting follows your session when you change to other contexts, even if the **pager** command in a given context has a different setting. To change the current pager setting, enter the **terminal pager** command with a new setting, or you can enter the **pager** command in the current context. In addition to saving a new pager setting to the context configuration, the **pager** command applies the new setting to the current Telnet session.

Examples

The following example changes the number of lines displayed to 20:

```
hostname# terminal pager 20
```

Related Commands

Command	Description
clear configure terminal	Clears the terminal display width setting.
pager	Sets the number of lines to display in a Telnet session before the "---More---" prompt. This command is saved to the configuration.

Command	Description
show running-config terminal	Displays the current terminal settings.
terminal	Allows syslog messsages to display in the Telnet session.
terminal width	Sets the terminal display width in global configuration mode.

terminal width

To set the width for displaying information during console sessions, use the **terminal width** command in global configuration mode. To disable, use the **no** form of this command.

terminal width *columns*

no terminal width *columns*

Syntax Description

columns	Specifies the terminal width in columns. The default is 80. The range is 40 to 511.

Defaults

The default display width is 80 columns.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

This example shows how to terminal display width to 100 columns:

```
hostname# terminal width 100
```

Related Commands

Command	Description
clear configure terminal	Clears the terminal display width setting.
show running-config terminal	Displays the current terminal settings.
terminal	Sets the terminal line parameters in privileged EXEC mode.

test aaa-server

To check whether the ASA can authenticate or authorize users with a particular AAA server, use the **test aaa-server** command in privileged EXEC mode. Failure to reach the AAA server may be due to incorrect configuration on the ASA, or the AAA server may be unreachable for other reasons, such as restrictive network configurations or server downtime.

test aaa-server {**authentication** *server_tag* [**host** *ip_address*] [**username** *username*] [**password** *password*] | **authorization** *server_tag* [**host** *ip_address*] [**username** *username*][**ad-agent**]}

Syntax Description

ad-agent	Tests connectivity to the AAA AD agent server.
authentication	Tests a AAA server for authentication capability.
authorization	Tests a AAA server for legacy VPN authorization capability.
host *ip_address*	Specifies the server IP address. If you do not specify the IP address in the command, you are prompted for it.
password *password*	Specifies the user password. If you do not specify the password in the command, you are prompted for it.
server_tag	Specifies the AAA server tag as set by the **aaa-server** command.
username *username*	Specifies the username of the account used to test the AAA server settings. Make sure the username exists on the AAA server; otherwise, the test will fail. If you do not specify the username in the command, you are prompted for it.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(4)	This command was introduced.
8.4(2)	The **ad-agent** keyword was added.

Usage Guidelines

The **test aaa-server** command lets you verify that the ASA can authenticate users with a particular AAA server, and for legacy VPN authorization, if you can authorize a user. This command lets you test the AAA server without having an actual user who attempts to authenticate or authorize. It also helps you isolate whether AAA failures are due to misconfiguration of AAA server parameters, a connection problem to the AAA server, or other configuration errors on the ASA.

Examples

The following example configures a RADIUS AAA server named srvgrp1 on host 192.168.3.4, sets a timeout of 9 seconds, sets a retry-interval of 7 seconds, and configures authentication port 1650. The **test aaa-server** command following the setup of the AAA server parameters indicates that the authentication test failed to reach the server.

```
hostname(config)# aaa-server svrgrp1 protocol radius
hostname(config-aaa-server-group)# aaa-server svrgrp1 host 192.168.3.4
hostname(config-aaa-server-host)# timeout 9
hostname(config-aaa-server-host)# retry-interval 7
hostname(config-aaa-server-host)# authentication-port 1650
hostname(config-aaa-server-host)# exit
hostname(config)# test aaa-server authentication svrgrp1
Server IP Address or name: 192.168.3.4
Username: bogus
Password: mypassword
INFO: Attempting Authentication test to IP address <192.168.3.4> (timeout: 10 seconds)
ERROR: Authentication Rejected: Unspecified
```

The following is sample output from the **test aaa-server** command with a successful outcome:

```
hostname# test aaa-server authentication svrgrp1 host 192.168.3.4 username bogus password
mypassword
INFO: Attempting Authentication test to IP address <10.77.152.85> (timeout: 12 seconds)
INFO: Authentication Successful
```

Related Commands

Command	Description
aaa authentication console	Configures authentication for management traffic.
aaa authentication match	Configures authentication for through traffic.
aaa-server	Creates a AAA server group.
aaa-server host	Adds a AAA server to a server group.

test aaa-server ad-agent

To test the Active Directory Agent configuration after you configure, use the **test aaa-server ad-agent** command in AAA Server Group configuration mode.

test aaa-server ad-agent

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
AAA Server Group configuration mode	•	—	•	—	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

To configure the Active Directory Agent for the Identity Firewall, you must enter the **ad-agent-mode** command, which is a submode of the **aaa-server** command. Entering the **ad-agent-mode** command enters the AAA Server Group configuration mode.

After configuring the Active Directory Agent, enter the **test aaa-server ad-agent** command to verify that the ASA has a functional connection to the Active Directory Agent.

Periodically or on-demand, the AD Agent monitors the Active Directory server security event log file via WMI for user login and logoff events. The AD Agent maintains a cache of user ID and IP address mappings. and notifies the ASA of changes.

Configure the primary and secondary AD Agents for the AD Agent Server Group. When the ASA detects that the primary AD Agent is not responding and a secondary agent is specified, the ASA switches to secondary AD Agent. The Active Directory server for the AD agent uses RADIUS as the communication protocol; therefore, you should specify a key attribute for the shared secret between ASA and AD Agent.

Examples

The following example shows how to enable **ad-agent-mode** while configuring the Active Directory Agent for the Identity Firewall and then test the connection:

```
hostname(config)# aaa-server adagent protocol radius
hostname(config)# ad-agent-mode
hostname(config-aaa-server-group)# aaa-server adagent (inside) host 192.168.1.101
hostname(config-aaa-server-host)# key mysecret
```

```
hostname(config-aaa-server-hostkey)# user-identity ad-agent aaa-server adagent
hostname(config-aaa-server-host)# test aaa-server ad-agent
```

Related Commands

Command	Description
aaa-server	Create a AAA server group and configures AAA server parameters that are group-specific and common to all group hosts.
clear configure user-identity	Clears the configuration for the Identity Firewall feature.

test dynamic-access-policy attributes

To enter the dap attributes mode, from Privileged EXEC mode, enter the **test dynamic-access-policy attributes** command. Doing so lets you specify user and endpoint attribute value pairs.

dynamic-access-policy attributes

Defaults

No default value or behaviors.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Normally the ASA retrieves user authorization attributes from the AAA server and retrieves endpoint attributes from Cisco Secure Desktop, Host Scan, CNA or NAC. For the test command, you specify the user authorization and endpoint attributes in this attributes mode. The ASA writes them to an attribute database that the DAP subsystem references when evaluating the AAA selection attributes and endpoint select attributes for a DAP record.

This feature lets you experiment with creating a DAP record.

Examples

The following example shows how to use the **attributes** command.

```
hostname # test dynamic-access-policy attributes
hostname(config-dap-test-attr)#
```

Related Commands

Command	Description
dynamic-access-policy-record	Creates a DAP record.
attributes	Enters attributes mode, in which you can specify user attribute value pairs.
display	Displays current attribute list.

test dynamic-access-policy execute

To test already configured DAP records, use the test dynamic-access-policy execute command in privileged EXEC mode:

test dynamic-access-policy execute

Syntax Description

AAA attribute value	The DAP subsystem on the device references these values when evaluating the AAA and endpoint selection attributes for each record. – AAA Attribute—Identifies the AAA attribute. – Operation Value—Identifies the attribute as =/!= to the given value.
endpoint attribute value	Identifies the endpoint attribute. – Endpoint ID—Provides the endpoint attribute ID. – Name/Operation/Value—

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
8.4(4)	This command was introduced.

Usage Guidelines

This command lets you test the retrieval of the set of DAP records configured on the device by specifying authorization attribute value pairs.

test regex

To test a regular expression, use the **test regex** command in privileged EXEC mode.

test regex *input_text regular_expression*

Syntax Description

input_text	Specifies the text that you want to match with the regular expression.
regular_expression	Specifies the regular expression up to 100 characters in length. See the **regex** command for a list of metacharacters you can use in the regular expression.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The **test regex** command tests a regular expression to make sure it matches what you think it will match.

If the regular expression matches the input text, you see the following message:

```
INFO: Regular expression match succeeded.
```

If the regular expression does not match the input text, you see the following message:

```
INFO: Regular expression match failed.
```

Examples

The following example tests input text against a regular expression:

```
hostname# test regex farscape scape
INFO: Regular expression match succeeded.

hostname# test regex farscape scaper

INFO: Regular expression match failed.
```

Related Commands

Command	Description
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a policy map by associating the traffic class with one or more actions.
policy-map type inspect	Defines special actions for application inspection.
class-map type regex	Creates a regular expression class map.
regex	Creates a regular expression.

test sso-server

To test an SSO server with a trial authentication request, use the **test sso-server** command in privileged EXEC mode.

test sso-server *server-name* **username** *user-name*

Syntax Description

server-name	Specifies the name of the SSO server being tested.
user-name	Specifies the name of a user on the SSO server being tested.

Defaults

No default values or behavior.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Config-webvpn	•	—	•	—	—
Config-webvpn-sso-saml	•	—	•	—	—
Config-webvpn-sso-siteminder	•	—	•	—	—
Global configuration mode	•	—	•	—	—
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Single sign-on support, available only for WebVPN, lets users access different secure services on different servers without entering a username and password more than once. The **test sso-server** command tests whether an SSO server is recognized and responding to authentication requests.

If the SSO server specified by the *server-name* argument is not found, the following error appears:

`ERROR: sso-server` *server-name* `does not exist`

If the SSO server is found but the user specified by the *user-name* argument is not found, the authentication is rejected.

In the authentication, the ASA acts as a proxy for the WebVPN user to the SSO server. The ASA currently supports the SiteMinder SSO server (formerly Netegrity SiteMinder) and the SAML POST-type SSO server. This command applies to both types of SSO Servers.

Examples

The following example, entered in privileged EXEC mode, successfully tests an SSO server named my-sso-server using a username of Anyuser:

```
hostname# test sso-server my-sso-server username Anyuser
INFO: Attempting authentication request to sso-server my-sso-server for user Anyuser
INFO: STATUS: Success
hostname#
```

The following example shows a test of the same server, but the user, Anotheruser, is not recognized and the authentication fails:

```
hostname# test sso-server my-sso-server username Anotheruser
INFO: Attempting authentication request to sso-server my-sso-server for user Anotheruser
INFO: STATUS: Failed
hostname#
```

Related Commands

Command	Description
max-retry-attempts	Configures the number of times the ASA retries a failed SSO authentication attempt.
policy-server-secret	Creates a secret key used to encrypt authentication requests to a SiteMinder SSO server.
request-timeout	Specifies the number of seconds before a failed SSO authentication attempt times out.
show webvpn sso-server	Displays the operating statistics for all SSO servers configured on the security device.
sso-server	Creates a single sign-on server.
web-agent-url	Specifies the SSO server URL to which the ASA makes SiteMinder SSO authentication requests.

text-color

To set a color for text in the WebVPN title bar on the login, home page, and file access page, use the **text-color** command in webvpn mode. To remove a text color from the configuration and reset the default, use the no form of this command.

text-color [*black* | *white* | *auto***]**

no text-color

Syntax Description

auto	Chooses black or white based on the settings for the secondary-color command. That is, if the secondary color is black, this value is white.
black	The default text color for title bars is white.
white	You can change the color to black.

Defaults

The default text color for the title bars is white.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
config-webvpn	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to set the text color for title bars to black:

```
hostname(config)# webvpn
hostname(config-webvpn)# text-color black
```

Related Commands

Command	Description
secondary-text-color	Sets the secondary text color for the WebVPN login, home page, and file access page.

tftp-server

To specify the default TFTP server and path and filename for use with **configure net** or **write net** commands, use the **tftp-server** command in global configuration mode. To remove the server configuration, use the **no** form of this command. This command supports IPv4 and IPv6 addresses.

tftp-server *interface_name server filename*

no tftp-server [*interface_name server filename*]

Syntax Description

filename	Specifies the path and filename.
interface_name	Specifies the gateway interface name. If you specify an interface other than the highest security interface, a warning message informs you that the interface is unsecure.
server	Sets the TFTP server IP address or name. You can enter an IPv4 or IPv6 address.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	The gateway interface is now required.

Usage Guidelines

The **tftp-server** command simplifies entering the **configure net** and **write net** commands. When you enter the **configure net** or **write net** commands, you can either inherit the TFTP server specified by the **tftp-server** command, or provide your own value. You can also inherit the path in the **tftp-server** command as-is, add a path and filename to the end of the **tftp-server** command value, or override the **tftp-server** command value.

The ASA supports only one **tftp-server** command.

Examples

The following example shows how to specify a TFTP server and then read the configuration from the /temp/config/test_config directory:

```
hostname(config)# tftp-server inside 10.1.1.42 /temp/config/test_config
hostname(config)# configure net
```

Related Commands

Command	Description
configure net	Loads the configuration from the TFTP server and path that you specify.
show running-config tftp-server	Displays the default TFTP server address and the directory of the configuration file.

tftp-server address

To specify the TFTP servers in the cluster, use the **tftp-server address** command in phone-proxy configuration mode. To remove the TFTP server from the Phone Proxy configuration, use the **no** form of this command.

tftp-server address *ip_address* [*port*] **interface** *interface*

no tftp-server address *ip_address* [*port*] **interface** *interface*

Syntax Description

ip_address	Specifies the address of the TFTP server.
interface *interface*	Specifies the interface on which the TFTP server resides. This must be the real address of the TFTP server.
port	(Optional) This is the port the TFTP server is listening in on for the TFTP requests. This should be configured if it is not the default TFTP port 69.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Phone-proxy configuration	•	—	•	—	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Usage Guidelines

The Phone Proxy must have at least one CUCM TFTP server configured. Up to five TFTP servers can be configured for the Phone Proxy.

The TFTP server is assumed to be behind the firewall on the trusted network; therefore, the Phone Proxy intercepts the requests between the IP phones and TFTP server. The TFTP server must reside on the same interface as the CUCM.

Create the TFTP server using the internal IP address and specify the interface on which the TFTP server resides.

On the IP phones, the IP address of the TFTP server must be configured as follows:

- If NAT is configured for the TFTP server, use the TFTP server's global IP address.
- If NAT is not configured for the TFTP server, use the TFTP server's internal IP address.

If the service-policy is applied globally, a classification rule will be created to direct any TFTP traffic reaching the TFTP server on all ingress interfaces, except for the interface on which the TFTP server resides. When the service-policy is applied on a specific interface, a classification rule will be created to direct any TFTP traffic reaching the TFTP server on that specified interface to the phone-proxy module.

If a NAT rule is configured for the TFTP server, it must be configured prior to applying the service-policy so that the global address of the TFTP server is used when installing the classification rule.

Examples

The following example shows the use of the **tftp-server address** command to configure two TFTP servers for the Phone Proxy:

```
hostname(config)# phone-proxy asa_phone_proxy
hostname(config-phone-proxy)# tftp-server address 192.168.1.2 in interface outside
hostname(config-phone-proxy)# tftp-server address 192.168.1.3 in interface outside
hostname(config-phone-proxy)# media-termination address 192.168.1.4 interface inside
hostname(config-phone-proxy)# media-termination address 192.168.1.25 interface outside
hostname(config-phone-proxy)# tls-proxy asa_tlsp
hostname(config-phone-proxy)# ctl-file asactl
hostname(config-phone-proxy)# cluster-mode nonsecure
```

Related Commands

Command	Description
phone-proxy	Configures the Phone Proxy instance.

threat-detection basic-threat

To enable basic threat detection, use the **threat-detection basic-threat** command in global configuration mode. To disable basic threat detection, use the **no** form of this command.

threat-detection basic-threat

no threat-detection basic-threat

Syntax Description

This command has no arguments or keywords.

Defaults

Basic threat detection is enabled by default. The following default rate limits are used:

Table 64-1 Basic Threat Detection Default Settings

	Trigger Settings	
Packet Drop Reason	**Average Rate**	**Burst Rate**
• DoS attack detected • Bad packet format • Connection limits exceeded • Suspicious ICMP packets detected	100 drops/sec over the last 600 seconds.	400 drops/sec over the last 20 second period.
	80 drops/sec over the last 3600 seconds.	320 drops/sec over the last 120 second period.
Scanning attack detected	5 drops/sec over the last 600 seconds.	10 drops/sec over the last 20 second period.
	4 drops/sec over the last 3600 seconds.	8 drops/sec over the last 120 second period.
Incomplete session detected such as TCP SYN attack detected or no data UDP session attack detected (combined)	100 drops/sec over the last 600 seconds.	200 drops/sec over the last 20 second period.
	80 drops/sec over the last 3600 seconds.	160 drops/sec over the last 120 second period.
Denial by access lists	400 drops/sec over the last 600 seconds.	800 drops/sec over the last 20 second period.
	320 drops/sec over the last 3600 seconds.	640 drops/sec over the last 120 second period.
• Basic firewall checks failed • Packets failed application inspection	400 drops/sec over the last 600 seconds.	1600 drops/sec over the last 20 second period.
	320 drops/sec over the last 3600 seconds.	1280 drops/sec over the last 120 second period.
Interface overload	2000 drops/sec over the last 600 seconds.	8000 drops/sec over the last 20 second period.
	1600 drops/sec over the last 3600 seconds.	6400 drops/sec over the last 120 second period.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.
8.2(1)	The burst rate interval changed from 1/60th to 1/30th of the average rate.

Usage Guidelines

When you enable basic threat detection, the ASA monitors the rate of dropped packets and security events due to the following reasons:

- Denial by access lists
- Bad packet format (such as invalid-ip-header or invalid-tcp-hdr-length)
- Connection limits exceeded (both system-wide resource limits, and limits set in the configuration)
- DoS attack detected (such as an invalid SPI, Stateful Firewall check failure)
- Basic firewall checks failed (This option is a combined rate that includes all firewall-related packet drops in this bulleted list. It does not include non-firewall-related drops such as interface overload, packets failed at application inspection, and scanning attack detected.)
- Suspicious ICMP packets detected
- Packets failed application inspection
- Interface overload
- Scanning attack detected (This option monitors scanning attacks; for example, the first TCP packet is not a SYN packet, or the TCP connection failed the 3-way handshake. Full scanning threat detection (see the **threat-detection scanning-threat** command) takes this scanning attack rate information and acts on it by classifying hosts as attackers and automatically shunning them, for example.)
- Incomplete session detection such as TCP SYN attack detected or no data UDP session attack detected

When the ASA detects a threat, it immediately sends a system log message (733100) and alerts ASDM.

Basic threat detection affects performance only when there are drops or potential threats; even in this scenario, the performance impact is insignificant.

Table 64-1 in the "Defaults" section lists the default settings. You can view all these default settings using the **show running-config all threat-detection** command. You can override the default settings for each type of event by using the **threat-detection rate** command.

If an event rate is exceeded, then the ASA sends a system message. The ASA tracks two types of rates: the average event rate over an interval, and the burst event rate over a shorter burst interval. The burst event rate is 1/30th of the average rate interval or 10 seconds, whichever is higher. For each event received, the ASA checks the average and burst rate limits; if both rates are exceeded, then the ASA sends two separate system messages, with a maximum of one message for each rate type per burst period.

Examples

The following example enables basic threat detection, and changes the triggers for DoS attacks:

```
hostname(config)# threat-detection basic-threat
hostname(config)# threat-detection rate dos-drop rate-interval 600 average-rate 60
burst-rate 100
```

Related Commands

Command	Description
clear threat-detection rate	Clears basic threat detection statistics.
show running-config all threat-detection	Shows the threat detection configuration, including the default rate settings if you did not configure them individually.
show threat-detection rate	Shows basic threat detection statistics.
threat-detection rate	Sets the threat detection rate limits per event type.
threat-detection scanning-threat	Enables scanning threat detection.

threat-detection rate

When you enable basic threat detection using the **threat-detection basic-threat** command, you can change the default rate limits for each event type using the **threat-detection rate** command in global configuration mode. If you enable scanning threat detection using the **threat-detection scanning-threat** command, then this command with the **scanning-threat** keyword also sets the when a host is considered to be an attacker or a target; otherwise the default **scanning-threat** value is used for both basic and scanning threat detection. To return to the default setting, use the **no** form of this command.

threat-detection rate {**acl-drop** | **bad-packet-drop** | **conn-limit-drop** | **dos-drop** | **fw-drop** | **icmp-drop** | **inspect-drop** | **interface-drop** | **scanning-threat** | **syn-attack**} **rate-interval** *rate_interval* **average-rate** *av_rate* **burst-rate** *burst_rate*

no threat-detection rate {**acl-drop** | **bad-packet-drop** | **conn-limit-drop** | **dos-drop** | **fw-drop** | **icmp-drop** | **inspect-drop** | **interface-drop** | **scanning-threat** | **syn-attack**} **rate-interval** *rate_interval* **average-rate** *av_rate* **burst-rate** *burst_rate*

Syntax Description

acl-drop	Sets the rate limit for dropped packets caused by denial by access lists.
average-rate *av_rate*	Sets the average rate limit between 0 and 2147483647 in drops/sec.
bad-packet-drop	Sets the rate limit for dropped packets caused by denial by a bad packet format (such as invalid-ip-header or invalid-tcp-hdr-length).
burst-rate *burst_rate*	Sets the burst rate limit between 0 and 2147483647 in drops/sec. The burst rate is calculated as the average rate every *N* seconds, where *N* is the burst rate interval. The burst rate interval is 1/30th of the **rate-interval** *rate_interval* value or 10 seconds, whichever is larger.
conn-limit-drop	Sets the rate limit for dropped packets caused by the connection limits being exceeded (both system-wide resource limits, and limits set in the configuration).
dos-drop	Sets the rate limit for dropped packets caused by a detected DoS attack (such as an invalid SPI, Stateful Firewall check failure).
fw-drop	Sets the rate limit for dropped packets caused by basic firewall check failure. This option is a combined rate that includes all firewall-related packet drops in this command. It does not include non-firewall-related drops such as **interface-drop**, **inspect-drop**, and **scanning-threat**.
icmp-drop	Sets the rate limit for dropped packets caused by denial by suspicious ICMP packets detected.
inspect-drop	Sets the rate limit for dropped packets caused by packets failing application inspection.
interface-drop	Sets the rate limit for dropped packets caused by an interface overload.
rate-interval *rate_interval*	Sets the average rate interval between 600 seconds and 2592000 seconds (30 days). The rate interval is used to determine the length of time over which to average the drops. It also determines the burst threshold rate interval.

scanning-threat	Sets the rate limit for dropped packets caused by a scanning attack detected. This option monitors scanning attacks; for example, the first TCP packet is not a SYN packet, or the TCP connection failed the 3-way handshake. Full scanning threat detection (see the **threat-detection scanning-threat** command) takes this scanning attack rate information and acts on it by classifying hosts as attackers and automatically shunning them, for example.
syn-attack	Sets the rate limit for dropped packets caused by an incomplete session, such as TCP SYN attack or no data UDP session attack.

Defaults

When you enable basic threat detection using the **threat-detection basic-threat** command, the following default rate limits are used:

Table 64-2 Basic Threat Detection Default Settings

	Trigger Settings	
Packet Drop Reason	**Average Rate**	**Burst Rate**
• **dos-drop** • **bad-packet-drop** • **conn-limit-drop** • **icmp-drop**	100 drops/sec over the last 600 seconds.	400 drops/sec over the last 20 second period.
	100 drops/sec over the last 3600 seconds.	400 drops/sec over the last 120 second period.
scanning-threat	5 drops/sec over the last 600 seconds.	10 drops/sec over the last 20 second period.
	5 drops/sec over the last 3600 seconds.	10 drops/sec over the last 120 second period.
syn-attack	100 drops/sec over the last 600 seconds.	200 drops/sec over the last 20 second period.
	100 drops/sec over the last 3600 seconds.	200 drops/sec over the last 120 second period.
acl-drop	400 drops/sec over the last 600 seconds.	800 drops/sec over the last 20 second period.
	400 drops/sec over the last 3600 seconds.	800 drops/sec over the last 120 second period.
• **fw-drop** • **inspect-drop**	400 drops/sec over the last 600 seconds.	1600 drops/sec over the last 20 second period.
	400 drops/sec over the last 3600 seconds.	1600 drops/sec over the last 120 second period.
interface-drop	2000 drops/sec over the last 600 seconds.	8000 drops/sec over the last 20 second period.
	2000 drops/sec over the last 3600 seconds.	8000 drops/sec over the last 120 second period.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
	Routed	Transparent	Single	Multiple	
				Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.
8.2(1)	The burst rate interval changed from 1/60th to 1/30th of the average rate.

Usage Guidelines

You can configure up to three different rate intervals for each event type.

When you enable basic threat detection, the ASA monitors the rate of dropped packets and security events due to the event types described in the "Syntax Description" table.

When the ASA detects a threat, it immediately sends a system log message (733100) and alerts ASDM.

Basic threat detection affects performance only when there are drops or potential threats; even in this scenario, the performance impact is insignificant.

Table 64-1 in the "Defaults" section lists the default settings. You can view all these default settings using the **show running-config all threat-detection** command.

If an event rate is exceeded, then the ASA sends a system message. The ASA tracks two types of rates: the average event rate over an interval, and the burst event rate over a shorter burst interval. For each event received, the ASA checks the average and burst rate limits; if both rates are exceeded, then the ASA sends two separate system messages, with a maximum of one message for each rate type per burst period.

Examples

The following example enables basic threat detection, and changes the triggers for DoS attacks:

```
hostname(config)# threat-detection basic-threat
hostname(config)# threat-detection rate dos-drop rate-interval 600 average-rate 60
burst-rate 100
```

Related Commands

Command	Description
clear threat-detection rate	Clears basic threat detection statistics.
show running-config all threat-detection	Shows the threat detection configuration, including the default rate settings if you did not configure them individually.
show threat-detection rate	Shows basic threat detection statistics.
threat-detection basic-threat	Enables basic threat detection.
threat-detection scanning-threat	Enables scanning threat detection.

threat-detection scanning-threat

To enable scanning threat detection, use the **threat-detection scanning-threat** command in global configuration mode. To disable scanning threat detection, use the **no** form of this command.

threat-detection scanning-threat [**shun**
[**except** {**ip-address** *ip_address mask* | **object-group** *network_object_group_id*} | **duration** *seconds*]]

no threat-detection scanning-threat [**shun**
[**except** {**ip-address** *ip_address mask* | **object-group** *network_object_group_id*} | **duration** *seconds*]]

Syntax Description

duration *seconds*	Sets the duration of a shun for an attacking host, between 10 and 2592000 seconds. The default length is 3600 seconds (1 hour).
except	Exempts IP addresses from being shunned. Enter this command multiple times to identify multiple IP addresses or network object groups to exempt from shunning.
ip-address *ip_address mask*	Specifies the IP address you want to exempt from shunning.
object-group *network_object_group_id*	Specifies the network object group that you want to exempt from shunning. See the **object-group network** command to create the object group.
shun	Automatically terminates a host connection when the ASA identifies the host as an attacker, in addition to sending syslog message 733101.

Defaults

The default shun duration is 3600 seconds (1 hour).

The following default rate limits are used for scanning attack events:

Table 64-3 Default Rate Limits for Scanning Threat Detection

Average Rate	Burst Rate
5 drops/sec over the last 600 seconds.	10 drops/sec over the last 20 second period.
5 drops/sec over the last 3600 seconds.	10 drops/sec over the last 120 second period.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.
8.0(4)	The **duration** keyword was added.

Usage Guidelines

A typical scanning attack consists of a host that tests the accessibility of every IP address in a subnet (by scanning through many hosts in the subnet or sweeping through many ports in a host or subnet). The scanning threat detection feature determines when a host is performing a scan. Unlike IPS scan detection that is based on traffic signatures, the ASA scanning threat detection feature maintains an extensive database that contains host statistics that can be analyzed for scanning activity.

The host database tracks suspicious activity such as connections with no return activity, access of closed service ports, vulnerable TCP behaviors such as non-random IPID, and many more behaviors.

Caution The scanning threat detection feature can affect the ASA performance and memory significantly while it creates and gathers host- and subnet-based data structure and information.

You can configure the ASA to send system log messages about an attacker or you can automatically shun the host. By default, the system log message 730101 is generated when a host is identified as an attacker.

The ASA identifies attackers and targets when the scanning threat event rate is exceeded. The ASA tracks two types of rates: the average event rate over an interval, and the burst event rate over a shorter burst interval. For each event detected that is considered to be part of a scanning attack, the ASA checks the average and burst rate limits. If either rate is exceeded for traffic sent from a host, then that host is considered to be an attacker. If either rate is exceeded for traffic received by a host, then that host is considered to be a target. You can change the rate limits for scanning threat events using the **threat-detection rate scanning-threat** command.

To view hosts categorized as attackers or as targets, use the **show threat-detection scanning-threat** command.

To view shunned hosts, use the **show threat-detection shun** command. To release a host from being shunned, use the **clear threat-detection shun** command.

Examples

The following example enables scanning threat detection and automatically shuns hosts categorized as attackers, except for hosts on the 10.1.1.0 network. The default rate limits for scanning threat detection are also changed.

```
hostname(config)# threat-detection scanning-threat shun except ip-address 10.1.1.0
255.255.255.0
hostname(config)# threat-detection rate scanning-threat rate-interval 1200 average-rate 10
burst-rate 20
hostname(config)# threat-detection rate scanning-threat rate-interval 2400 average-rate 10
burst-rate 20
```

Related Commands

Command	Description
clear threat-detection shun	Releases a host from being shunned.
show threat-detection scanning-threat	Shows the hosts that are categorized as attackers and targets.

Command	Description
show threat-detection shun	Shows hosts that are currently shunned.
threat-detection basic-threat	Enables basic threat detection.
threat-detection rate	Sets the threat detection rate limits per event type.

threat-detection statistics

To enable advanced threat detection statistics, use the **threat-detection statistics** command in global configuration mode. To disable advanced threat detection statistics, use the **no** form of this command.

Caution Enabling statistics can affect the ASA performance, depending on the type of statistics enabled. The **threat-detection statistics host** command affects performance in a significant way; if you have a high traffic load, you might consider enabling this type of statistics temporarily. The **threat-detection statistics port** command, however, has modest impact.

threat-detection statistics [**access-list** | [**host** | **port** | **protocol** [**number-of-rate** {**1** | **2** | **3**}] | **tcp-intercept** [**rate-interval** *minutes*] [**burst-rate** *attacks_per_sec*] [**average-rate** *attacks_per_sec*]]

no threat-detection statistics [**access-list** | **host** | **port** | **protocol** | **tcp-intercept** [**rate-interval** *minutes*] [**burst-rate** *attacks_per_sec*] [**average-rate** *attacks_per_sec*]]

Syntax Description

access-list	(Optional) Enables statistics for access list denies. Access list statistics are only displayed using the **show threat-detection top access-list** command.
average-rate *attacks_per_sec*	(Optional) For TCP Intercept, sets the average rate threshold for syslog message generation, between 25 and 2147483647. The default is 200 per second. When the average rate is exceeded, syslog message 733105 is generated.
burst-rate *attacks_per_sec*	(Optional) For TCP Intercept, sets the threshold for syslog message generation, between 25 and 2147483647. The default is 400 per second. When the burst rate is exceeded, syslog message 733104 is generated.
host	(Optional) Enables host statistics. The host statistsics accumulate for as long as the host is active and in the scanning threat host database. The host is deleted from the database (and the statistics cleared) after 10 minutes of inactivity.
number-of-rate {**1** | **2** | **3**}	(Optional) Sets the number of rate intervals maintained for host, port, or protocol statistics. The default number of rate intervals is **1**, which keeps the memory usage low. To view more rate intervals, set the value to **2** or **3**. For example, if you set the value to **3**, then you view data for the last 1 hour, 8 hours, and 24 hours. If you set this keyword to **1** (the default), then only the shortest rate interval statistics are maintained. If you set the value to **2**, then the two shortest intervals are maintained.
port	(Optional) Enables port statistics.
protocol	(Optional) Enables protocol statistics.
rate-interval *minutes*	(Optional) For TCP Intercept, sets the size of the history monitoring window, between 1 and 1440 minutes. The default is 30 minutes. During this interval, the ASA samples the number of attacks 30 times.
tcp-intercept	(Optional) Enables statistics for attacks intercepted by TCP Intercept. See the **set connection embryonic-conn-max command**, or the **nat** or **static** commands to enable TCP Intercept.

Defaults

Access list statistics are enabled by default. If you do not specify any options in this command, then you enable all options.

The default **tcp-intercept rate-interval** is 30 minutes. The default **burst-rate** is 400 per second. The default **average-rate** is 200 per second.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	• [1]	—

1. Only TCP Intercept statistics are supported in multiple context mode.

Command History

Release	Modification
8.0(2)	This command was introduced.
8.0(4)/8.1(2)	The **tcp-intercept** keyword was added.
8.1(2)	The **number-of-rates** keyword was added for host statistics, and the default number of rates was changed from 3 to 1.
8.2(1)	The burst rate interval changed from 1/60th to 1/30th of the average rate.
8.3(1)	The **number-of-rates** keyword was added for port and protocol statistics, and the default number of rates was changed from 3 to 1.

Usage Guidelines

If you do not specify any options in this command, then you enable all statistics. To enable only certain statistics, enter this command for each statistic type, and do not also enter the command without any options. You can enter **threat-detection statistics** (without any options) and then customize certain statistics by entering the command with statistics-specific options (for example, **threat-detection statistics host number-of-rate 2**). If you enter **threat-detection statistics** (without any options) and then enter a command for specific statistics, but without any statistic-specific options, then that command has no effect because it is already enabled.

If you enter the **no** form of this command, it removes all **threat-detection statistics** commands, including the **threat-detection statistics access-list** command, which is enabled by default.

View statistics using the **show threat-detection statistics** commands.

You do not need to enable scanning threat detection using the **threat-detection scanning-threat** command; you can configure detection and statistics separately.

Examples

The following example enables scanning threat detection and scanning threat statistics for all types except host:

```
hostname(config)# threat-detection scanning-threat shun except ip-address 10.1.1.0
255.255.255.0
hostname(config)# threat-detection statistics access-list
hostname(config)# threat-detection statistics port
hostname(config)# threat-detection statistics protocol
```

```
hostname(config)# threat-detection statistics tcp-intercept
```

Related Commands

Command	Description
threat-detection scanning-threat	Enables scanning threat detection.
show threat-detection statistics host	Shows the host statistics.
show threat-detection memory	Shows the memory use for advanced threat detection statistics.
show threat-detection statistics port	Shows the port statistics.
show threat-detection statistics protocol	Shows the protocol statistics.
show threat-detection statistics top	Shows the top 10 statistics.

threshold

To set the threshold value for over threshold events in SLA monitoring operations, use the **threshold** command in SLA monitor configuration mode. To restore the default value, use the **no** form of this command.

threshold *milliseconds*

no threshold

Syntax Description

milliseconds	Specifies the number of milliseconds for a rising threshold to be declared. Valid values are from 0 to 2147483647. This value should not be larger than the value set for the timeout.

Defaults

The default threshold is 5000 milliseconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
SLA monitor configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The threshold value is only used to indicate over threshold events, which do not affect reachability but may be used to evaluate the proper settings for the **timeout** command.

Examples

The following example configures an SLA operation with an ID of 123 and creates a tracking entry with the ID of 1 to track the reachability of the SLA. The frequency of the SLA operation is set to 10 seconds, the threshold to 2500 milliseconds, and the timeout value us set to 4000 milliseconds.

```
hostname(config)# sla monitor 123
hostname(config-sla-monitor)# type echo protocol ipIcmpEcho 10.1.1.1 interface outside
hostname(config-sla-monitor-echo)# threshold 2500
hostname(config-sla-monitor-echo)# timeout 4000
hostname(config-sla-monitor-echo)# frequency 10
hostname(config)# sla monitor schedule 123 life forever start-time now
hostname(config)# track 1 rtr 123 reachability
```

Related Commands

Command	Description
sla monitor	Defines an SLA monitoring operation.
timeout	Defines the amount of time the SLA operation waits for a response.

ticket

To configure the ticket epoch and password for the Cisco Intercompany Media Engine proxy, use the **ticket** command in UC-IME configuration mode. To remove the configuration from the proxy, use the **no** form of this command.

ticket epoch *n* **password** *password*

no ticket epoch *n* **password** *password*

Syntax Description

n	Specifies the length of time between password integrity checks. Enter an integer from 1-255.
password	Sets the password for the Cisco Intercompany Media Engine ticket. Enter a minimum of 10 and a maximum of 64 printable character from the US-ASCII character set. The allowed characters include 0x21 to 0x73 inclusive, and exclude the space character. Only one password can be configured at a time.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
UC-IME configuration	•	—	•	—	—

Command History

Release	Modification
8.3(1)	The command was introduced.

Usage Guidelines

Configures the ticket epoch and password for Cisco Intercompany Media Engine.

The epoch contains an integer that updates each time that the password is changed. When the proxy is configured the first time and a password entered for the first time, enter 1 for the epoch integer. Each time you change the password, increment the epoch to indicate the new password. You must increment the epoch value each time your change the password.

Typically, you increment the epoch sequentially; however, the ASA allows you to choose any value when you update the epoch.

If you change the epoch value, the current password is invalidated and you must enter a new password.

We recommend a password of at least 20 characters. Only one password can be configured at a time.

The ticket password is stored onto flash. The output of the **show running-config uc-ime** command displays ***** instead of the password string.

Note The epoch and password that you configure on the ASA must match the epoch and password configured on the Cisco Intercompany Media Engine server. See the Cisco Intercompany Media Engine server documentation for information.

Examples

The following example shows specify the ticket and epoch in the Cisco Intercompany Media Engine Proxy:

```
hostname(config)# uc-ime local_uc-ime_proxy
hostname(config-uc-ime)# media-termination ime-media-term
hostname(config-uc-ime)# ucm address 192.168.10.30 trunk-security-mode non-secure
hostname(config-uc-ime)# ticket epoch 1 password password1234
hostname(config-uc-ime)# fallback monitoring timer 120
hostname(config-uc-ime)# fallback hold-down timer 30
```

Related Commands

Command	Description
show running-config uc-ime	Shows the running configuration of the Cisco Intercompany Media Engine proxy.
uc-ime	Creates the Cisco Intercompany Media Engine proxy instance on the ASA.

timeout

To set the global maximum idle time duration for various features, use the **timeout** command in global configuration mode. To set all timeouts to the default, use the **no** form of this command. To reset a single feature to its default, reenter the **timeout** command with the default value.

timeout {**conn** | **floating-conn** | **h225** | **h323** | **half-closed** | **icmp** | **mgcp** | **mgcp-pat** | **pat-xlate** | **sip** | **sip-disconnect** | **sip-invite** | **sip_media** | **sip-provisional-media** | **sunrpc** | **tcp-proxy-reassembly** | **udp** | **xlate**} *hh*:*mm*:*ss*

timeout uauth *hh*:*mm*:*ss* [**absolute** | **inactivity**]

no timeout

Syntax Description

absolute	(Optional for **uauth**) Requires a reauthentication after the uauth timeout expires. The **absolute** keyword is enabled by default. To set the uauth timer to timeout after a period of inactivity, enter the **inactivity** keyword instead.
conn	Specifies the idle time after which a connection closes, between 0:5:0 and 1193:0:0. The default is 1 hour (1:0:0). Use **0** to never time out a connection.
floating-conn	When multiple static routes exist to a network with different metrics, the ASA uses the one with the best metric at the time of connection creation. If a better route becomes available, then this timeout lets connections be closed so a connection can be reestablished to use the better route. The default is 0 (the connection never times out). To take advantage of this feature, change the timeout to a new value.
hh:*mm*:*ss*	Specifies the timeout in hours, minutes, and seconds. Use **0** to never time out a connection, if available.
h225	Specifies the idle time after which an H.225 signaling connection closes, between 0:0:0 and 1193:0:0. The default is 1 hour (1:0:0). A timeout value of 0:0:1 disables the timer and closes the TCP connection immediately after all calls are cleared.
h323	Specifies the idle time after which H.245 (TCP) and H.323 (UDP) media connections close, between 0:0:0 and 1193:0:0. The default is 5 minutes (0:5:0). Because the same connection flag is set on both H.245 and H.323 media connections, the H.245 (TCP) connection shares the idle timeout with the H.323 (RTP and RTCP) media connection.
half-closed	Specifies the idle time after which a TCP half-closed connection will be freed, between 0:5:0 (for 9.1(1) and earlier) or 0:0:30 (for 9.1(2) and later) and 1193:0:0. The default is 10 minutes (0:10:0). Use **0** to never time out a connection.
icmp	Specifies the idle time for ICMP, between 0:0:2 and 1193:0:0 The default is 2 seconds (0:0:2).
inactivity	(Optional for **uauth**) Requires uauth reauthentication after the inactivity timeout expires.
mgcp	Sets the idle time after which an MGCP media connection is removed, between 0:0:0 and 1193:0:0. The default is 5 minutes (0:5:0)
mgcp-pat	Sets the absolute interval after which an MGCP PAT translation is removed, between 0:0:0 and 1193:0:0. The default is 5 minutes (0:5:0).

pat-xlate	Specifies the idle time until a PAT translation slot is freed, between 0:0:30 and 0:5:0. The default is 30 seconds. You may want to increase the timeout if upstream routers reject new connections using a freed PAT port because the previous connection might still be open on the upstream device.
sip	Specifies the idle time after which a SIP control connection will be closed, between 0:5:0 and 1193:0:0. The default is 30 minutes (0:30:0). Use **0** to never time out a connection.
sip-disconnect	Specifies the idle time after which a SIP session is deleted if the 200 OK is not received for a CANCEL or a BYE message, between 0:0:1 and 1193:0:0. The default is 2 minutes (0:2:0).
sip-invite	(Optional) Specifies the idle time after which pinholes for PROVISIONAL responses and media xlates will be closed, between 0:1:0 and 1193:0:0. The default is 3 minutes (0:3:0).
sip_media	Specifies the idle time after which a SIP media connection will be closed, between 0:1:0 and 1193:0:0. The default is 2 minutes (0:2:0). Use **0** to never time out a connection. The SIP media timer is used used for SIP RTP/RTCP with SIP UDP media packets, instead of the UDP inactivity timeout.
sip-provisional-media	Specifies timeout value for SIP provisional media connections, between 0:1:0 and 1193:0:0. The default is 2 minutes (0:2:0).
sunrpc	Specifies the idle time after which a SUNRPC slot will be closed, between 0:1:0 and 1193:0:0. The default is 10 minutes (0:10:0). Use **0** to never time out a connection.
tcp-proxy-reassembly	Configures the idle timeout after which buffered packets waiting for reassembly are dropped, between 0:0:10 and 1193:0:0. The default is 1 minute (0:1:0).
uauth	Specifies the duration before the authentication and authorization cache times out and the user has to reauthenticate the next connection, between 0:0:0 and 1193:0:0. The default is 5 minutes (0:5:0). The default timer is **absolute**; you can set the timeout to occur after a period of inactivity by entering the **inactivity** keyword. The **uauth** duration must be shorter than the **xlate** duration. Set to **0** to disable caching. Do not use **0** if passive FTP is used for the connection or if the **virtual http** command is used for web authentication.
udp	Specifies the idle time until a UDP slot is freed, between 0:1:0 and 1193:0:0. The default is 2 minutes (0:2:0). Use **0** to never time out a connection.
xlate	Specifies the idle time until a translation slot is freed, between 0:1:0 and 1193:0:0. The default is 3 hours (3:0:0).

Defaults

The defaults are as follows:

- **conn** *hh*:*mm*:*ss* is 1 hour (**1:0:0**).
- **floating-conn** *hh*:*mm*:*ss* never times out (**0**)
- **h225** *hh*:*mm*:*ss* is 1 hour (**1:0:0**).
- **h323** *hh*:*mm*:*ss* is 5 minutes (**0:5:0**).
- **half-closed** *hh*:*mm*:*ss* is 10 minutes (**0:10:0**).

- **icmp** *hh:mm:ss* is 2 seconds (**0:0:2**)
- **mgcp** *hh:mm:ss* is 5 minutes (**0:5:0**).
- **mgcp-pat** *hh:mm:ss* is 5 minutes (**0:5:0**).
- **rpc** *hh***:***mm***:***ss* is 5 minutes (**0:5:0**).
- **sip** *hh:mm:* is 30 minutes (**0:30:0**).
- **sip-disconnect** *hh:mm:ss* is 2 minutes (**0:2:0**).
- **sip-invite** *hh:mm:ss* is 3 minutes (**0:3:0**).
- **sip_media** *hh:mm:ss* is 2 minutes (**0:2:0**).
- **sip-provisional-media** *hh:mm:ss* is 2 minutes (**0:2:0**).
- **sunrpc** *hh:mm:ss* is 10 minutes (**0:10:0**)
- **tcp-proxy-reassembly** *hh:mm:ss* is 1 minute (**0:1:0**)
- **uauth** *hh:mm:ss* is 5 minutes (**0:5:0**) **absolute**.
- **udp** *hh*:*mm*:*ss* is 2 minutes (**0:02:0**).
- **xlate** *hh***:***mm***:***ss* is 3 hours (**3:0:0**).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration mode	•	•	•	•	—

Command History

Release	Modification
7.2(1)	The **mgcp-pat**, **sip-disconnect**, and **sip-invite** keywords were added.
7.2(4)/8.0(4)	The **sip-provisional-media** keyword was added.
7.2(5)/8.0(5)/8.1(2)/8.2(1)	The **tcp-proxy-reassembly** keyword was added.
8.2(5)/8.4(2)	The **floating-conn** keyword was added.
8.4(3)	The **pat-xlate** keyword was added.
9.1(2)	The minimum **half-closed** value was lowered to 30 seconds (0:0:30).

Usage Guidelines

The **timeout** command lets you set global timeouts. For some features, the **set connection timeout** command takes precedence for traffic identified in the command.

You can enter multiple keywords and values after the **timeout** command.

The connection timer (**conn**) takes precedence over the translation timer (**xlate**); the translation timer works only after all connections have timed out.

Examples

The following example shows how to configure the maximum idle time durations:

```
hostname(config)# timeout uauth 0:5:0 absolute uauth 0:4:0 inactivity
hostname(config)# show running-config timeout
timeout xlate 3:00:00
timeout conn 1:00:00 half-closed 0:10:00 udp 0:02:00 rpc 0:10:00 h323 0:05:00
sip 0:30:00 sip_media 0:02:00
timeout uauth 0:05:00 absolute uauth 0:04:00 inactivity
```

Related Commands

Command	Description
clear configure timeout	Clears the timeout configuration and resets it to the defaults.
set connection timeout	Sets connection timeouts using Modular Policy Framework.
show running-config timeout	Displays the timeout value of the designated protocol.

timeout (aaa-server host)

To configure the host-specific maximum response time, in seconds, allowed before giving up on establishing a connection with the AAA server, use the **timeout** command in aaa-server host mode. To remove the timeout value and reset the timeout to the default value of 10 seconds, use the **no** form of this command.

timeout *seconds*

no timeout

Syntax Description

seconds	Specifies the timeout interval (1-60 seconds) for the request. This is the time after which the ASA gives up on the request to the primary AAA server. If there is a standby AAA server, the ASA sends the request to the backup server.

Defaults

The default timeout value is 10 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
aaa-server host configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command is valid for all AAA server protocol types.

Use the **timeout** command to specify the length of time during which the ASA attempts to make a connection to a AAA server. Use the **retry-interval** command to specify the amount of time the ASA waits between connection attempts.

The timeout is the total amount of time that the ASA spends trying to complete a transaction with a server. The retry interval determines how often the communication is retried during the timeout period. Thus, if the retry interval is greater than or equal to the timeout value, you will see no retries. If you want to see retries, the retry interval musts be less than thte timeout value.

Examples

The following example configures a RADIUS AAA server named “svrgrp1” on host 1.2.3.4 to use a timeout value of 30 seconds, with a retry interval of 10 seconds. Thus, the ASA tries the communication attempt three times before giving up after 30 seconds.

```
hostname(config)# aaa-server svrgrp1 protocol radius
hostname(config-aaa-server-group)# aaa-server svrgrp1 host 1.2.3.4
```

```
hostname(config-aaa-server-host)# timeout 30
hostname(config-aaa-server-host)# retry-interval 10
hostname(config-aaa-server-host)#
```

Related Commands

Command	Description
aaa-server host	Enters aaa server host configuration mode so you can configure AAA server parameters that are host specific.
clear configure aaa-server	Removes all AAA command statements from the configuration.
show running-config aaa	Displays the current AAA configuration values.

timeout (dns-server-group configuration mode)

To specify the amount of time to wait before trying the next DNS server, use the **timeout** command in dns-server-group configuration mode. To restore the default timeout, use the **no** form of this command.

timeout *seconds*

no timeout [*seconds*]

Syntax Description

seconds	Specifies the timeout in seconds between 1 and 30. The default is 2 seconds. Each time the ASA retries the list of servers, this timeout doubles. Use the **retries** command in dns-server-group configuration mode to configure the number of retries.

Defaults

The default timeout is 2 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Examples

The following example sets the timeout to 1 second for the DNS server group “dnsgroup1”:

```
hostname(config)# dns server-group dnsgroup1
hostname(config-dns-server-group)# dns timeout 1
```

Related Commands

Command	Description
clear configure dns	Removes all user-created DNS server-groups and resets the default server group’s attributes to the default values.
domain-name	Sets the default domain name.
retries	Specifies the number of times to retry the list of DNS servers when the ASA does not receive a response.
show running-config dns server-group	Shows the current running DNS server-group configuration.

timeout (gtp-map)

To change the inactivity timers for a GTP session, use the **timeout** command in GTP map configuration mode, which is accessed by using the **gtp-map** command. Use the **no** form of this command to set these intervals to their default values.

timeout {**gsn** | **pdp-context** | **request** | **signaling** | **t3-response** | **tunnel** } *hh*:*mm*:*ss*

no timeout {**gsn** | **pdp-context** | **request** | **signaling** | **t3-response** | **tunnel** } *hh*:*mm*:*ss*

Syntax Description

hh:*mm*:*ss*	This is the timeout where *hh* specifies the hour, *mm* specifies the minutes, *ss* specifies the seconds, and a colon (:) separates these three components. The value 0 means never tear down immediately.
gsn	Specifies the period of inactivity after which a GSN will be removed.
pdp-context	Specifies the maximum period of time allowed before beginning to receive the PDP context.
request	Specifies the the maximum period of time allowed before beginning to receive the GTP message.
signaling	Specifies the period of inactivity after which the GTP signaling will be removed.
t3-response	Specifies the maximum wait time for a response before a GTP connection is removed.
tunnel	Specifies the period of inactivity after which the GTP tunnel will be torn down.

Defaults

The default is 30 minutes for **gsn**, **pdp-context**, and **signaling**.

The default for **request** is 1 minute.

The default for **tunnel** is 1 hour (in the case where a Delete PDP Context Request is not received).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
GTP map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The Packet Data Protocol (PDP) context is identified by the Tunnel Identifier (TID), which is a combination of IMSI and NSAPI. Each MS can have up to 15 NSAPIs, allowing it to create multiple PDP contexts each with a different NSAPI, based on application requirements for varied QoS levels.

A GTP tunnel is defined by two associated PDP Contexts in different GSN nodes and is identified with a Tunnel ID. A GTP tunnel is necessary to forward packets between an external packet data network and a mobile station user.

Examples

The following example sets a timeout value for the request queue of 2 minutes:

```
hostname(config)# gtp-map gtp-policy
hostname(config-gtpmap)# timeout request 00:02:00
```

Related Commands

Commands	Description
clear service-policy inspect gtp	Clears global GTP statistics.
debug gtp	Displays detailed information about GTP inspection.
gtp-map	Defines a GTP map and enables GTP map configuration mode.
inspect gtp	Applies a specific GTP map to use for application inspection.
show service-policy inspect gtp	Displays the GTP configuration.

timeout (radius-accounting)

To change the inactivity timers for RADIUS accounting users, use the **timeout** command in radius-accounting parameter configuration mode, which is accessed by using the **inspect radius-accounting** command. Use the **no** form of this command to set these intervals to their default values.

timeout users *hh*:*mm*:*ss*

no timeout users *hh*:*mm*:*ss*

Syntax Description

hh:*mm*:*ss*	This is the timeout where *hh* specifies the hour, *mm* specifies the minutes, *ss* specifies the seconds, and a colon (:) separates these three components. The value 0 means never tear down immediately. The default is one hour.
users	Specifies the timeout for users.

Defaults

The default timeout for users is one hour.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
radius-accounting parameter configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example sets a timeout value for the user of ten minutes:

```
hostname(config)# policy-map type inspect radius-accounting ra
hostname(config-pmap)# parameters
hostname(config-pmap-p)# timeout user 00:10:00
```

Related Commands

Commands	Description
inspect radius-accounting	Sets inspection for RADIUS accounting.
parameters	Sets parameters for an inspection policy map.

timeout (sla monitor)

To set the amount of time the SLA operation waits for a response to the request packets, use the **timeout** command in SLA monitor protocol configuration mode. To restore the default value, use the **no** form of this command.

timeout *milliseconds*

no timeout

Syntax Description

milliseconds	0 to 604800000.

Defaults

The default timeout value is 5000 milliseconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
SLA monitor protocol configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Use the **frequency** command to set how often the SLA operation sends out the request packets and the **timeout** command to set how long the SLA operation waits to receive a response to those requests. The values specified for the **timeout** command cannot be greater than the value specified for the **frequency** command.

Examples

The following example configures an SLA operation with an ID of 123 and creates a tracking entry with the ID of 1 to track the reachability of the SLA. The frequency of the SLA operation is set to 10 seconds, the threshold to 2500 milliseconds, and the timeout value us set to 4000 milliseconds.

```
hostname(config)# sla monitor 123
hostname(config-sla-monitor)# type echo protocol ipIcmpEcho 10.1.1.1 interface outside
hostname(config-sla-monitor-echo)# threshold 2500
hostname(config-sla-monitor-echo)# timeout 4000
hostname(config-sla-monitor-echo)# frequency 10
hostname(config)# sla monitor schedule 123 life forever start-time now
hostname(config)# track 1 rtr 123 reachability
```

Related Commands

Command	Description
frequency	Specifies the rate at which the SLA operation repeats.
sla monitor	Defines an SLA monitoring operation.

timeout pinhole

To configure the timeout for DCERPC pinholes and override the global system pinhole timeout of two minutes, use the **timeout pinhole** command in parameters configuration mode. Parameters configuration mode is accessible from policy map configuration mode. To disable this feature, use the **no** form of this command.

timeout pinhole *hh:mm:ss*

no timeout pinhole

Syntax Description

hh:mm:ss	The timeout for pinhole connections. Value is between 0:0:1 and 1193:0:0.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to configure the pinhole timeout for pin hole connections in a DCERPC inspection policy map:

```
hostname(config)# policy-map type inspect dcerpc dcerpc_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# timeout pinhole 0:10:00
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

time-range

To enter time-range configuration mode and define a time range that you can attach to traffic rules, or an action, use the **time-range** command in global configuration mode. To disable, use the **no** form of this command.

time-range *name*

no time-range *name*

Syntax Description

name	Name of the time range. The name must be 64 characters or less.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Creating a time range does not restrict access to the device. The **time-range** command defines the time range only. After a time range is defined, you can attach it to traffic rules or an action.

To implement a time-based ACL, use the **time-range** command to define specific times of the day and week. Then use the with the **access-list extended time-range** command to bind the time range to an ACL.

The time range relies on the system clock of the ASA; however, the feature works best with NTP synchronization.

Examples

The following example creates a time range named “New_York_Minute” and enters time range configuration mode:

```
hostname(config)# time-range New_York_Minute
hostname(config-time-range)#
```

After you have created a time range and entered time-range configuration mode, you can define time range parameters with the **absolute** and **periodic** commands. To restore default settings for the **time-range** command **absolute** and **periodic** keywords, use the **default** command in time-range configuration mode.

To implement a time-based ACL, use the **time-range** command to define specific times of the day and week. Then use the with the **access-list extended** command to bind the time range to an ACL. The following example binds an ACL named "Sales" to a time range named "New_York_Minute":

```
hostname(config)# access-list Sales line 1 extended deny tcp host 209.165.200.225 host
209.165.201.1 time-range New_York_Minute
hostname(config)#
```

See the **access-list extended** command for more information about ACLs.

Related Commands

Command	Description
absolute	Defines an absolute time when a time range is in effect.
access-list extended	Configures a policy for permitting or denying IP traffic through the ASA.
default	Restores default settings for the **time-range** command **absolute** and **periodic** keywords.
periodic	Specifies a recurring (weekly) time range for functions that support the time-range feature.

timeout secure-phones

To configure the idle timeout after which the secure-phone entry is removed from the Phone Proxy database, use the **timeout secure-phones** command in phone-proxy configuration mode. To set the timeout value back to the default of 5 minutes, use the **no** form of this command.

timeout secure-phones *hh:mm:ss*

no timeout secure-phones *hh:mm:ss*

Syntax Description

hh:mm:ss	Specifies the idle timeout after which the object is removed. The default is 5 minutes.

Defaults

The default value for secure phone timeout is 5 minutes.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Usage Guidelines

Since secure phones always request a CTL file upon bootup, the Phone Proxy creates a database that marks the phone as secure. The entries in the secure phone database are removed after a specified configured timeout (via the **timeout secure-phones** command). The entry's timestamp is updated for each registration refresh the Phone Proxy receives for SIP phones and KeepAlives for SCCP phones.

The default value for the **timeout secure-phones** command is 5 minutes. Specify a value that is greater than the maximum timeout value for SCCP KeepAlives and SIP Register refresh. For example, if the SCCP Keepalives are configured for 1 minute intervals and the SIP Register Refresh is configured for 3 minutes, configure this timeout value greater than 3 minutes.

Examples

The following example shows the use of the **timeout secure-phones** command to configure the Phone Proxy to timeout entries in the secure phone database after 3 minutes:

```
hostname(config)# phone-proxy asa_phone_proxy
hostname(config-phone-proxy)# tftp-server address 192.168.1.2 in interface outside
hostname(config-phone-proxy)# tftp-server address 192.168.1.3 in interface outside
hostname(config-phone-proxy)# media-termination address 192.168.1.4
hostname(config-phone-proxy)# tls-proxy asa_tlsp
hostname(config-phone-proxy)# ctl-file asactl
```

```
hostname(config-phone-proxy)# timeout secure-phones 00:03:00
```

Related Commands

Command	Description
phone-proxy	Configures the Phone Proxy instance.

timers lsa arrival

To set the minimum interval at which the ASA accepts the same LSA from OSPFv3 neighbors, use the **timers lsa arrival** command in IPv6 router configuration mode. To restore the default value, use the **no** form of this command.

timers lsa arrival *milliseconds*

no timers lsa arrival *milliseconds*

Syntax Description

milliseconds	Specifies the minimum delay in milliseconds that must pass between acceptance of the same LSA that is arriving between neighbors. Valid values are from 0 to 600,000 milliseconds.

Defaults

The default is 1000 millliseconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
IPv6 router configuration	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to indicate the minimum interval that must pass between acceptance of the same LSA that is arriving from neighbors.

Examples

The following example sets the minimum interval for accepting the same LSA at 2000 milliseconds:

```
hostname(config-if)# ipv6 router ospf 1
hostname(config-rtr)# log-adjacency-changes
hostname(config-rtr)# timers lsa arrival 2000
```

Related Commands

Command	Description
ipv6 router ospf	Enters router configuration mode for OSPFv3.
show ipv6 ospf	Displays general information about the OSPFv3 routing processes.
timers pacing flood	Configures LSA flood packet pacing for OSPFv3 routing processes.

timers lsa-group-pacing (OSPFv2)

To specify the interval at which OSPF link-state advertisements (LSAs) are collected into a group and refreshed, checksummed, or aged, use the **timers lsa-group-pacing** command in router configuration mode. To restore the default value, use the **no** form of this command.

timers lsa-group-pacing *seconds*

no timers lsa-group-pacing [*seconds*]

Syntax Description

seconds	The interval at which OSPF link-state advertisements (LSAs) are collected into a group and refreshed, checksummed, or aged. Valid values are from 10 to 1800 seconds.

Defaults

The default interval is 240 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To change the interval at which the OSPF link-state advertisements (LSAs) are collected into a group and refreshed, checksummed, or aged, use the **timers lsa-group-pacing** *seconds* command. To return to the default timer values, use the **no timers lsa-group-pacing** command.

Examples

The following example sets the group processing interval of LSAs to 500 seconds:

```
hostname(config-rtr)# timers lsa-group-pacing 500
hostname(config-rtr)#
```

Related Commands

Command	Description
router ospf	Enters router configuration mode.
show ospf	Displays general information about the OSPF routing processes.
timers spf	Specifies the shortest path first (SPF) calculation delay and hold time

timers pacing flood (OSPFv3)

To configure LSA flood packet pacing, use the **timers pacing flood** command in IPv6 router configuration mode. To restore the default flood packet pacing value, use the **no** form of this command.

timers pacing flood *milliseconds*

no timers pacing flood *milliseconds*

Syntax Description

milliseconds	Specifies the time in milliseconds at which LSAs in the flooding queue are paced in-between updates. The configurable range is from 5 to 100 milliseconds.

Defaults

The default is 33 millliseconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
IPv6 router configuration	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to configure LSA flood packet pacing.

Examples

The following example configures LSA flood packet pacing updates to occur in 20-millisecond intervals for OSPFv3:

```
hostname(config-if)# ipv6 router ospf 1
hostname(config-rtr)# timers pacing flood 20
```

Related Commands

Command	Description
ipv6 router ospf	Enters IPv6 router configuration mode.
timers pacing lsa-group	Specifies the interval at which OSPFv3 LSAs are collected into a group and refreshed, check summed, or aged.

timers pacing lsa-group (OSPFv3)

To specify the interval at which OSPFv3 LSAs are collected into a group and refreshed, check summed, or aged, use the **timers pacing lsa-group** command in IPv6 router configuration mode. To restore the default value, use the **no** form of this command.

timers pacing lsa-group *seconds*

no timers pacing lsa-group [*seconds*]

Syntax Description

seconds	Specifies the number of seconds in the interval at which LSAs are collected into a group and refreshed, check summed, or aged. Valid values are from 10 to 1800 seconds.

Defaults

The default interval is 240 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
IPv6 router configuration	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to indicate the interval at which the OSPFv3 LSAs are collected into a group and refreshed, check summed, or aged.

Examples

The following example configures OSPFv3 group packet pacing updates between LSA groups to occur in 300-seconds intervals for OSPFv3 routing process 1:

```
hostname(config-if)# ipv6 router ospf 1
hostname(config-rtr)# timers pacing lsa-group 300
```

Related Commands

Command	Description
ipv6 router ospf	Enters IPv6 router configuration mode.
show ipv6 ospf	Displays general information about the OSPFv3 routing processes.
timers pacing flood	Configures LSA flood packet pacing for OSPFv3 routing processes.

timers spf

To specify the shortest path first (SPF) calculation delay and hold time, use the **timers spf** command in router configuration mode. To restore the default values, use the **no** form of this command.

timers spf *delay holdtime*

no timers spf [*delay holdtime*]

Syntax Description

delay	Specifies the delay time between when OSPF receives a topology change and when it starts a shortest path first (SPF) calculation in seconds, from 1 to 65535.
holdtime	The hold time between two consecutive SPF calculations in seconds; valid values are from 1 to 65535.

Defaults

The defaults are as follows:

- *delay* is 5 seconds.
- *holdtime* is 10 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

To configure the delay time between when the OSPF protocol receives a topology change and when it starts a calculation, and the hold time between two consecutive SPF calculations, use the **timers spf** command. To return to the default timer values, use the **no timers spf** command.

Examples

The following example sets the SPF calculation delay to 10 seconds and the SPF calculation hold time to 20 seconds:

```
hostname(config-router)# timers spf 10 20
hostname(config-router)#
```

Related Commands

Command	Description
router ospf	Enters router configuration mode.
show ospf	Displays general information about the OSPF routing processes.
timers lsa-group-pacing	Specifies the interval at which OSPF link-state advertisements (LSAs) are collected and refreshed, checksummed, or aged.

timers throttle

To configure LSA or SPF OSPFv3 throttling, use the **timers throttle** command in IPv6 router configuration mode. To remove the throttling configuration, use the **no** form of this command.

timers throttle [**lsa** | **spf**] *milliseconds1 milliseconds2 milliseconds3*

no timers throttle [**lsa** | **spf**]

Syntax Description

lsa	Configures OSPFv3 LSA throttling.
milliseconds1	Specifies the delay in milliseconds to generate the first occurrence of the LSA. Specifies the delay in milliseconds to receive a change to the SPF calculation.
milliseconds2	Specifies the maximum delay in milliseconds to originate the same LSA. Specifies the delay in milliseconds between the first and second SPF calculations.
milliseconds3	Specifies the minimum delay in milliseconds to originate the same LSA. Specifies the maximum wait time in milliseconds for SPF calculations.
spf	Configures OSPFv3 SPF throttling.

Defaults

LSA throttling:

- For *milliseconds1*, the default value is 0 milliseconds.
- For *millseconds2*, the default value is 5000 milliseconds.
- For *milleseconds3*, the default value is 5000 milliseconds.

SPF throttling:

- For *milliseconds1*, the default value is 5000 milliseconds.
- For *millseconds2*, the default value is 10000 milliseconds.
- For *milleseconds3*, the default value is 10000 milliseconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
IPv6 router configuration	•	—	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

LSA and SPF throttling provide a dynamic mechanism to slow down LSA updates in OSPFv3 during times of network instability and allow faster OSPFv3 convergence by providing LSA rate limiting in milliseconds.

For LSA throttling, if the minimum or maximum time is less than the first occurrence value, then OSPFv3 automatically corrects to the first occurrence value. Similarly, if the maximum delay specified is less than the minimum delay, then OSPFv3 automatically corrects to the minimum delay value.

For SPF throttling, if *milliseconds2* or *milliseconds3* is less than *milliseconds1*, then OSPFv3 automatically corrects to the *milliseconds1* value. Similarly, if *milliseconds3* is less than *milliseconds2*, then OSPFv3 automatically corrects to the *milliseconds2* value.

Examples

The following example configures OSPFv3 LSA throttling in milleseconds:

```
hostname(config)# ipv6 router ospf 10
hostname(config-rtr)# timers throttle lsa 100 4000 5000
```

For LSA throttling, the following example shows the automatic correction that occurs if the maximum delay value specified is less than the minimum delay value:

```
hostname(config)# ipv6 router ospf 10
hostname(config-rtr)# timers throttle lsa 100 50 50
% OSPFv3: Throttle timers corrected to: 100 100 100
hostname(config-rtr)# show running-config ipv6
ipv6 router ospf 10
 timers throttle lsa 100 100 100
```

The following example configures OSPFv3 SPF throttling in milleseconds:

```
hostname(config)# ipv6 router ospf 10
hostname(config-rtr)# timers throttle spf 6000 12000 14000
```

For SPF throttling, the following example shows the automatic correction that occurs if the maximum delay value specified is less than the minimum delay value:

```
hostname(config)# ipv6 router ospf 10
hostname(config-rtr)# timers throttle spf 100 50 50
% OSPFv3: Throttle timers corrected to: 100 100 100
hostname(config-rtr)# show running-config ipv6
ipv6 router ospf 10
 timers throttle spf 100 100 100
```

Related Commands

Command	Description
ipv6 router ospf	Enters IPv6 router configuration mode.
show ipv6 ospf	Displays general information about the OSPFv3 routing processes.
timers lsa-group-pacing	Specifies the interval at which OSPFv3 LSAs are collected and refreshed, checksummed, or aged.

title

To customize the title of the WebVPN page displayed to WebVPN users when they connect to the security appliance, use the **title** command from webvpn customization mode:

title {**text** | **style**} *value*

[**no**] **title** {**text** | **style**} *value*

To remove the command from the configuration and cause the value to be inherited, use the **no** form of the command.

Syntax Description

text	Specifies you are changing the text.
style	Specifies you are changing the style.
value	The actual text to display (maximum 256 characters), or Cascading Style Sheet (CSS) parameters (maximum 256 characters).

Defaults

The default title text is “WebVPN Service”.

The default title style is:

background-color:white;color:maroon;border-bottom:5px groove #669999;font-size:larger; vertical-align:middle;text-align:left;font-weight:bold

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Webvpn customization	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

To have no title, use the **title text** command without a *value* argument.

The **style** option is expressed as any valid Cascading Style Sheet (CSS) parameters. Describing these parameters is beyond the scope of this document. For more information about CSS parameters, consult CSS specifications at the World Wide Web Consortium (W3C) website at www.w3.org. Appendix F of the CSS 2.1 Specification contains a convenient list of CSS parameters, and is available at www.w3.org/TR/CSS21/propidx.html.

Here are some tips for making the most common changes to the WebVPN pages—the page colors:

- You can use a comma-separated RGB value, an HTML color value, or the name of the color if recognized in HTML.
- RGB format is 0,0,0, a range of decimal numbers from 0 to 255 for each color (red, green, blue); the comma separated entry indicates the level of intensity of each color to combine with the others.
- HTML format is #000000, six digits in hexadecimal format; the first and second represent red, the third and fourth green, and the fifth and sixth represent blue.

Note To easily customize the WebVPN pages, we recommend that you use ASDM, which has convenient features for configuring style elements, including color swatches and preview capabilities.

Examples

In the following example, the title is customized with the text "Cisco WebVPN Service":

```
hostname(config)# webvpn
hostname(config-webvpn)# customization cisco
hostname(config-webvpn-custom)# title text Cisco WebVPN Service
```

Related Commands

Command	Description
logo	Customizes the logo on the WebVPN page.
page style	Customizes the WebVPN page using Cascading Style Sheet (CSS) parameters.

CHAPTER 65

tls-proxy through type echo Commands

tls-proxy

To configure a TLS proxy instance in TLS configuration mode or to set the maximum sessions, use the **tls-proxy** command in global configuration mode. To remove the configuration, use the **no** form of this command.

tls-proxy [**maximum-sessions** *max_sessions* | *proxy_name*] [**noconfirm**]

no tls-proxy [**maximum-sessions** *max_sessions* | *proxy_name*] [**noconfirm**]

Syntax Description

max_sessions *max_sessions*	Specifies the maximum number of TLS proxy sessions to support on the platform.
noconfirm	Runs the **tls-proxy** command without requiring confirmation.
proxy_name	Specifies the name of the TLS proxy instance.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use the **tls-proxy** command to enter TLS proxy configuration mode to create a TLS proxy instance, or to set the maximum sessions supported on the platform.

Examples

The following example shows how to create a TLS proxy instance:

```
hostname(config)# tls-proxy my_proxy
hostname(config-tlsp)# server trust-point ccm_proxy
hostname(config-tlsp)# client ldc issuer ldc_server
hostname(config-tlsp)# client ldc keypair phone_common
```

Related Commands

Commands	Description
client	Defines a cipher suite and sets the local dynamic certificate issuer or keypair.
ctl-provider	Defines a CTL provider instance and enters provider configuration mode.
server trust-point	Specifies the proxy trustpoint certificate to be presented during the TLS handshake.
show tls-proxy	Shows the TLS proxies.

tos

To define a type of service byte in the IP header of an SLA operation request packet, use the **tos** command in SLA monitor protocol configuration mode. To restore the default value, use the **no** form of this command.

tos *number*

no tos

Syntax Description

number	The service type value to be used in the IP header. Valid values are from 0 to 255.

Defaults

The default type of service value is 0.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
SLA monitor protocol configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This field contains information such as delay, precedence, reliability, and so on. This is can be used by other routers on the network for policy routing and features such as Committed Access Rate.

Examples

The following example configures an SLA operation with an ID of 123 that uses an ICMP echo request/response time probe operation. It sets the payload size of the echo request packets to 48 bytes, the number of echo requests sent during an SLA operation to 5, and the type of service byte to 80.

```
hostname(config)# sla monitor 123
hostname(config-sla-monitor)# type echo protocol ipIcmpEcho 10.1.1.1 interface outside
hostname(config-sla-monitor-echo)# num-packets 5
hostname(config-sla-monitor-echo)# request-data-size 48
hostname(config-sla-monitor-echo)# tos 80
hostname(config-sla-monitor-echo)# timeout 4000
hostname(config-sla-monitor-echo)# threshold 2500
hostname(config-sla-monitor-echo)# frequency 10
hostname(config)# sla monitor schedule 123 life forever start-time now
hostname(config)# track 1 rtr 123 reachability
```

Related Commands

Command	Description
num-packets	Specifies the number of request packets to send during an SLA operation.
request-data-size	Specifies the size of the request packet payload.
sla monitor	Defines an SLA monitoring operation.
type echo	Configures the SLA operation as an echo response time probe operation.

traceroute

To determine the route packets will take to their destination, use the **traceroute** command.

traceroute *destination_ip* | *hostname* [**source** *source_ip* | *source-interface*] [**numeric**] [**timeout** *timeout_value*] [**probe** *probe_num*] [**ttl** *min_ttl max_ttl*] [**port** *port_value*] [**use-icmp**]

Syntax Description

destination_ip	Specifies the destination IP address for the traceroute.
hostname	The hostname of the host to which the route has to be traced. If the hostname is specified, define it with the **name** command, or configure a DNS server to enable traceroute to resolve the hostname to an IP address. Supports DNS domain names such as www.example.com.
source	Specifies an IP address or interface is used as the source for the trace packets.
source_ip	Specifies the source IP address for the packet trace. This IP address must be the IP address of one of the interfaces. In transparent mode, it must be the management IP address of the security appliance.
source_interface	Specifies the source interface for the packet trace. When specified, the IP address of the source interface is used.
numeric	Specifies the output print only the IP addresses of the intermediate gateways. If this keyword is not specified the traceroute attempts to look up the hostnames of the gateways reached during the trace.
timeout	Specifies a timeout value is used
timeout_value	Specifies the amount of time in seconds to wait for a response before the connection times out. The default is three seconds.
probe *probe_num*	The number of probes to be sent at each TTL level. The default count is 3.
ttl	Keyword to specify the range of Time To Live values to use in the probes.
min_ttl	The TTL value for the first probes. The default is 1, but it can be set to a higher value to suppress the display of known hops.
max-ttl	The largest TTL value that can be used. The default is 30. The command terminates when the traceroute packet reaches the destination or when the value is reached.
port *port_value*	The destination port used by the User Datagram Protocol (UDP) probe messages. The default is 33434.
use-icmp	Specifies the use of ICMP probe packets instead of UDP probe packets.

Defaults

This command has no default settings.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
	Routed	Transparent	Single	Multiple Context	System
Priveleged EXEC	•	•	•	•	•

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The traceroute command prints the result of each probe sent. Every line of output corresponds to a TTL value in increasing order. The following are the output symbols printed by the **traceroute** command:

Output Symbol	Description
*	No response was received for the probe within the timeout period.
nn msec	For each node, the round-trip time (in milliseconds) for the specified number of probes.
!N.	ICMP network unreachablee.
!H	ICMP host unreachable.
!P	ICMP protocol unreachable.
!A	ICMP administratively prohibited.
?	Unknown ICMP error.

Examples

The following example shows traceroute output that results when a destination IP address has been specified:

```
hostname# traceroute 209.165.200.225

Tracing the route to 209.165.200.225

 1  10.83.194.1 0 msec 10 msec 0 msec
 2  10.83.193.65 0 msec 0 msec 0 msec
 3  10.88.193.101 0 msec 10 msec 0 msec
 4  10.88.193.97 0 msec 0 msec 10 msec
 5  10.88.239.9 0 msec 10 msec 0 msec
 6  10.88.238.65 10 msec 10 msec 0 msec
 7 172.16.7.221 70 msec 70 msec 80 msec
 8 209.165.200.225 70 msec 70 msec 70 msec
```

Related Commands

Command	Description
capture	Captures packet information, including trace packets.
show capture	Displays the capture configuration when no options are specified.
packet-tracer	Enables packet tracing capabilities.

track rtr

To track the reachability of an SLA operation, use the **track rtr** command in global configuration mode. To remove the SLA tracking, use the **no** form of this command.

track *track-id* **rtr** *sla-id* **reachabilitity**

no track *track-id* **rtr** *sla-id* **reachabilitity**

Syntax Description

reachability	Specifies that the reachability of the object is being tracked.
sla-id	The ID of the SLA used by the tracking entry.
track-id	Creates a tracking entry object ID. Valid values are from 1 to 500.

Defaults

SLA tracking is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The **track rtr** command creates a tracking entry object ID and specifies the SLA used by that tracking entry.

Every SLA operation maintains an operation return-code value, which is interpreted by the tracking process. The return code may be OK, Over Threshold, or several other return codes. Table 65-1 displays the reachability state of an object with respect to these return codes.

Table 65-1 SLA Tracking Return Codes

Tracking	Return Code	Track State
Reachability	OK or Over Threshold	Up
	Any other code	Down

Examples

The following example configures an SLA operation with an ID of 123 and creates a tracking entry with the ID of 1 to track the reachability of the SLA:

```
hostname(config)# sla monitor 123
```

```
hostname(config-sla-monitor)# type echo protocol ipIcmpEcho 10.1.1.1 interface outside
hostname(config-sla-monitor-echo)# timeout 1000
hostname(config-sla-monitor-echo)# frequency 3
hostname(config)# sla monitor schedule 123 life forever start-time now
hostname(config)# track 1 rtr 123 reachability
```

Related Commands

Command	Description
route	Configures a static route.
sla monitor	Defines an SLA monitoring operation.

traffic-forward cxsc

To enable a traffic-forwarding interface for the ASA CX module for demonstration purposes, use the **traffic-forward cxsc** command in interface configuration mode. To disable traffic-forwarding, use the **no** form of this command.

traffic-forward cxsc monitor-only

no traffic-forward cxsc monitor-only

Syntax Description

monitor-only	Sets the ASA CX module to monitor-only mode. In monitor-only mode, the ASA CX module can process traffic for demonstration purposes, but then drops the traffic. You cannot use the traffic-forwarding interface for production purposes.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Interface configuration	—	•	•	—	—

Command History

Release	Modification
9.1(2)	We introduced this command.

Usage Guidelines

For testing and demonstration purposes, you can configure an ASA interface to be a traffic-forwarding interface, where all traffic received is forwarded directly to the ASA CX module without any ASA processing. This feature is only supported in monitor-only mode. In this mode, the ASA CX module inspects the traffic as usual, makes policy decisions, and generates events. However, because the packets are read-only copies, the module actions do not affect the actual traffic. Instead, the module drops the copies after inspection.

See the following guidelines:

- You cannot configure both monitor-only mode and normal inline mode at the same time on the ASA. Only one type of security policy is allowed.
- The following features are not supported in monitor-only mode:
  - Deny policies
  - Active authentication
  - Decryption policies

- The ASA CX does not perform packet buffering in monitor-only mode, and events will be generated on a best effort basis. For example, some events, such as ones with long URLs spanning packet boundaries, may be impacted by the lack of buffering.
- Be sure to configure both the ASA policy and the ASA CX to have matching modes: both in monitor-only mode.
- The ASA must be transparent mode.
- You can configure only one interface as a traffic-forwarding interface. Other ASA interfaces can be used as normal.
- Traffic-forwarding interfaces must be physical interfaces, not VLANs or BVIs. The physical interface also cannot have any VLANs associated with it.
- Traffic-forwarding interfaces cannot be used for ASA traffic; you cannot name them or configure them for ASA features, including failover or management-only.

Examples

The following example makes GigabitEthernet 0/5 a traffic-forwarding interface:

```
interface gigabitethernet 0/5
  no nameif
  traffic-forward cxsc monitor-only
  no shutdown
```

Related Commands

Command	Description
interface	Enters interface configuration mode.

traffic-non-sip

To allow non-SIP traffic using the well-known SIP signaling port, use the **traffic-non-sip** command in parameters configuration mode. Parameters configuration mode is accessible from policy map configuration mode. To disable this feature, use the **no** form of this command.

traffic-non-sip

no traffic-non-sip

Syntax Description

This command has no arguments or keywords.

Defaults

This command is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to allow non-SIP traffic using the well-known SIP signaling port in a SIP inspection policy map:

```
hostname(config)# policy-map type inspect sip sip_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# traffic-non-sip
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

transfer-encoding

To restrict HTTP traffic by specifying a transfer encoding type, use the **transfer-encoding** command in HTTP map configuration mode, which is accessible using the **http-map** command. To disable this feature, use the **no** form of this command.

transfer-encoding type {**chunked** | **compress** | **deflate** | **gzip** | **identity** | **default**} **action** {**allow** | **reset** | **drop**} [**log**]

no transfer-encoding type {**chunked** | **compress** | **deflate** | **gzip** | **identity** | **default**} **action** {**allow** | **reset** | **drop**} [**log**]

Syntax Description

action	Specifies the action taken when a connection using the specified transfer encoding type is detected.
allow	Allows the message.
chunked	Identifies the transfer encoding type in which the message body is transferred as a series of chunks.
compress	Identifies the transfer encoding type in which the message body is transferred using UNIX file compression.
default	Specifies the default action taken by the ASA when the traffic contains a supported request method that is not on a configured list.
deflate	Identifies the transfer encoding type in which the message body is transferred using zlib format (RFC 1950) and deflate compression (RFC 1951).
drop	Closes the connection.
gzip	Identifies the transfer encoding type in which the message body is transferred using GNU zip (RFC 1952).
identity	Identifies connections in which the message body is no transfer encoding is performed.
log	(Optional) Generates a syslog.
reset	Sends a TCP reset message to client and server.
type	Specifies the type of transfer encoding to be controlled through HTTP application inspection.

Defaults

This command is disabled by default. When the command is enabled and a supported transfer encoding type is not specified, the default action is to allow the connection without logging. To change the default action, use the **default** keyword and specify a different default action.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
HTTP map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

When you enable the **transfer-encoding** command, the ASA applies the specified action to HTTP connections for each supported and configured transfer encoding type.

The ASA applies the **default** action to all traffic that does *not* match the transfer encoding types on the configured list. The preconfigured **default** action is to **allow** connections without logging.

For example, given the preconfigured default action, if you specify one or more encoding types with the action of **drop** and **log**, the ASA drops connections containing the configured encoding types, logs each connection, and allows all connections for the other supported encoding types.

If you want to configure a more restrictive policy, change the default action to **drop** (or **reset**) and **log** (if you want to log the event). Then configure each permitted encoding type with the **allow** action.

Enter the **transfer-encoding** command once for each setting you wish to apply. You use one instance of the **transfer-encoding** command to change the default action and one instance to add each encoding type to the list of configured transfer encoding types.

When you use the **no** form of this command to remove an application category from the list of configured application types, any characters in the command line after the application category keyword are ignored.

Examples

The following example provides a permissive policy, using the preconfigured default, which allows all supported application types that are not specifically prohibited.

```
hostname(config)# http-map inbound_http
hostname(config-http-map)# transfer-encoding gzip drop log
hostname(config-http-map)#
```

In this case, only connections using GNU zip are dropped and the event is logged.

The following example provides a restrictive policy, with the default action changed to reset the connection and to log the event for any encoding type that is not specifically allowed.

```
hostname(config)# http-map inbound_http
hostname(config-http-map)# port-misuse default action reset log
hostname(config-http-map)# port-misuse identity allow
hostname(config-http-map)#
```

In this case, only connections using no transfer encoding are allowed. When HTTP traffic for the other supported encoding types is received, the ASA resets the connection and creates a syslog entry.

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
debug appfw	Displays detailed information about traffic associated with enhanced HTTP inspection.
http-map	Defines an HTTP map for configuring enhanced HTTP inspection.
inspect http	Applies a specific HTTP map to use for application inspection.
policy-map	Associates a class map with specific security actions.

trustpoint (SSO Server)

To specify the name of a trustpoint that identifies the certificate to be sent to the SAML POST-type SSO server, use the **trustpoint** command in config-webvpn-sso-saml mode. To eliminate a trustpoint specification, use the **no** form of this command.

trustpoint *trustpoint-name*

no trustpoint *trustpoint-name*

Syntax Description

trustpoint-name	Specifies the name of the trustpoint to use.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Config webvpn sso saml	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command is introduced.

Usage Guidelines

Single sign-on support, available only for WebVPN, lets users access different secure services on different servers without entering a username and password more than once. The ASA currently supports the SAML POST-type SSO server and the SiteMinder-type of SSO server.

This command applies only to SAML-type SSO Servers.

A trustpoint represents a Certificate Authority identity, based on a CA-issued certificate that can be relied upon as being valid without the need for validation testing, especially a public-key certificate used to provide the first public key in a certification path.

Examples

The following example enters config-webvpn-sso-saml mode and names a trustpoint for identifying the certificate to be sent to the SAML POST type SSO Server:

```
hostname(config-webvpn)# sso server
hostname(config-webvpn-sso-saml)# trustpoint mytrustpoint
```

Related Commands

Command	Description
crypto ca trustpoint	Manages trustpoint information.
show webvpn sso server	Displays the operating statistics for all SSO servers configured on the security device.
sso server	Creates, names, and specifies type for an SSO server.

tsig enforced

To require a TSIG resource record to be present, use the **tsig enforced** command in parameters configuration mode. To disable this feature, use the **no** form of this command.

tsig enforced action {**drop** [**log**] | **log**}

no tsig enforced [**action** {**drop** [**log**] | **log**}]

Syntax Description

drop	Drops the packet if TSIG is not present.
log	Generates a system message log.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command enables monitoring and enforcement of TSIG presence in DNS transactions.

Examples

The following example shows how to enable TSIG enforcement in a DNS inspection policy map:

```
hostname(config)# policy-map type inspect dns preset_dns_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# tsig enforced action log
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

ttl-evasion-protection

To enable the Time-To-Live evasion protection, use the **ttl-evasion-protection** command in tcp-map configuration mode. To remove this specification, use the **no** form of this command.

ttl-evasion-protection

no ttl-evasion-protection

Syntax Description

This command has no arguments or keywords.

Defaults

TTL evasion protection offered by the ASA is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tcp-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **tcp-map** command is used along with the Modular Policy Framework infrastructure. Define the class of traffic using the **class-map** command and customize the TCP inspection with **tcp-map** commands. Apply the new TCP map using the **policy-map** command. Activate TCP inspection with **service-policy** commands.

Use the **tcp-map** command to enter tcp-map configuration mode. Use the **ttl-evasion-protection** command in tcp-map configuration mode to prevent attacks that attempt to evade security policy.

For instance, an attacker can send a packet that passes policy with a very short TTL. When the TTL goes to zero, a router between the ASA and the endpoint drops the packet. It is at this point that the attacker can send a malicious packet with a long TTL that appears to the ASA to be a retransmission and is passed. To the endpoint host, however, it is the first packet that has been received by the attacker. In this case, an attacker is able to succeed without security preventing the attack. Enabling this feature prevents such attacks.

Examples

The following example shows how to disable TTL evasion protection on flows from network 10.0.0.0 to 20.0.0.0:

```
hostname(config)# access-list TCP1 extended permit tcp 10.0.0.0 255.0.0.0 20.0.0.0
255.0.0.0
hostname(config)# tcp-map tmap
```

```
hostname(config-tcp-map)# no ttl-evasion-protection
hostname(config)# class-map cmap
hostname(config-cmap)# match access-list TCP1
hostname(config)# policy-map pmap
hostname(config-pmap)# class cmap
hostname(config-pmap)# set connection advanced-options tmap
hostname(config)# service-policy pmap global
```

Related Commands

Command	Description
class	Specifies a class map to use for traffic classification.
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
set connection	Configures connection values.
tcp-map	Creates a TCP map and allows access to tcp-map configuration mode.

tunnel-group

To create and manage the database of connection-specific records for IPsec and WebVPN tunnels, use the **tunnel-group** command in global configuration mode. To remove a tunnel group, use the **no** form of this command.

tunnel-group *name* **type** *type*

no tunnel-group *name*

Syntax Description

name	Specifies the name of the tunnel group. This can be any string you choose. If the name is an IP address, it is usually the IP address of the peer.
type	Specifies the type of tunnel group: • remote-access—Allows a user to connect using either IPsec remote access or WebVPN (portal or tunnel client). • ipsec-l2l—Specifies IPsec LAN-to-LAN, which allows two sites or LANs to connect securely across a public network like the Internet. **Note** The following tunnel-group types are deprecated in Release 8.0(2): ipsec-ra—IPsec remote access webvpn—WebVPN The ASA converts these to the remote-access type.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	See Note.	•	•	—

Note The tunnel-group command is available in transparent firewall mode to allow configuration of a LAN-to-LAN tunnel group, but not a remote-access group or a WebVPN group. All the tunnel-group commands that are available for LAN-to-LAN are also available in transparent firewall mode.

Command History

Release	Modification
7.0(1)	This command was introduced.
7.1(1)	Added webvpn type.
8.0(2)	Added remote-access type and deprecated ipsec-ra and webvpn types.

Release	Modification
8.3(1)	The *name* argument was modified to accept IPv6 addresses.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

SSL VPN users (both AnyConnect and clientless) can choose which tunnel group to access using these different methods:

- group-url
- group-alias
- certificate maps, if using certificates

This command and subcommands configures the ASA to allow users to select a group via a drop-down menu when they log in to the webvpn service. The groups that appear in the menu are either aliases or URLs of real connection profiles (tunnel groups) configured on the ASA.

The ASA has the following default tunnel groups:

- DefaultRAGroup, the default IPsec remote-access tunnel group
- DefaultL2LGroup, the default IPsec LAN-to-LAN tunnel group
- DefaultWEBVPNGroup, the default WebVPN tunnel group.

You can change these groups, but not delete them. The ASA uses these groups to configure default tunnel parameters for remote access and LAN-to-LAN tunnel groups when there is no specific tunnel group identified during tunnel negotiation.

After entering the **tunnel-group** command, you enter the appropriate following commands to configure specific attributes for a particular tunnel group. Each of these commands enters a configuration mode for configuring tunnel-group attributes.

- **tunnel-group general-attributes**
- **tunnel-group ipsec-attributes**
- **tunnel-group webvpn-attributes**
- **tunnel-group ppp-attributes**

For LAN-to-LAN connections, the ASA attempts to select a tunnel group for a connection by matching the peer address specified in the crypto map to a tunnel group of the same name. Therefore, for IPv6 peers, you should configure the tunnel group name as the IPv6 address of the peer. You can specify the tunnel group name in short or long notation. The CLI reduces the name to the shortest notation. For example, if you enter this tunnel group command:

```
hostname(config)# tunnel-group 2001:0db8:0000:0000:0000:0000:1428:57ab type ipsec-l2l
```

The tunnel group appears in the configuration as:

```
tunnel-group 2001:0db8::1428:57ab type ipsec-l2l
```

Examples

The following examples are entered in global configuration mode. The first configures a remote access tunnel group. The group name is group1.

```
hostname(config)# tunnel-group group1 type remote-access
hostname(config)#
```

The following example shows the tunnel-group command configuring the webvpn tunnel group named "group1". You enter this command in global configuration mode:

```
hostname(config)# tunnel-group group1 type webvpn
hostname(config)#
```

Related Commands

Command	Description
clear configure tunnel-group	Clears all configured tunnel groups.
show running-config tunnel-group	Shows the tunnel group configuration for all tunnel groups or for a particular tunnel group.
tunnel-group general-attributes	Enters the config-general mode for configuring general tunnel-group attributes
tunnel-group ipsec-attributes	Enters the config-ipsec mode for configuring IPsec tunnel-group attributes.
tunnel-group ppp-attributes	Enters the config-ppp mode for configuring PPP settings for L2TP connections.
tunnel-group webvpn-attributes	Enters the config-webvpn mode for configuring WebVPN tunnel-group attributes.

tunnel-group-list enable

To enable the tunnel-groups defined in tunnel-group group-alias, use the **tunnel-group-list enable** command:

tunnel-group-list enable

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•		•	•	—

Usage Guidelines

This command is used in conjuction with the tunnel-group group-alias and group-url commands for clientless and AnyConnect VPN client sessions. It enables the feature so that the tunnel-group drop-down is displayed on the login page. The group-alias is a text string such as employees, engineering, or consultants defined by the ASA administrator to display to end users.

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

```
hostname# configure terminal
hostname(config)# tunnel-group ExampleGroup1 webvpn-att
hostname(config-tunnel-webvpn)# group-alias Group1 enable
hostname(config-tunnel-webvpn)# exit
hostname(config)# webvpn
hostname(config-webvpn)# tunnel-group-list enable
```

Related Commands

Command	Description
tunnel-group	Creates a VPN connection profile or accesses the database of VPN connection profiles.
group-alias	Configures an alias for a connection profile (tunnel group).

Command	Description
group-url	Matches the URL or IP address specified by the VPN endpoint to the connection profile.
show running-config tunnel-group	Shows the tunnel group configuration for all tunnel groups or for a particular tunnel group.

tunnel-group-preference

To change the VPN preference to a connection profile with a group URL that matches the one specified by the endpoint, use the **tunnel-group-preference** command in webvpn configuration mode. To remove the command from the configuration, use the **no** form.

tunnel-group-preference group-url

no tunnel-group-preference group-url

Syntax Description

This command has no arguments or keywords.

Command Default

By default, if the ASA matches a certificate field value specified in a connection profile to the field value of the certificate used by the endpoint, the ASA assigns that profile to the VPN connection. This command overrides the default behavior.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Config-webvpn	•	—	•	—	—

Command History

Release	Modification
8.2(5)/8.4(2)	We introduced this command.

Usage Guidelines

This command changes the preference of a connection profile during the connection profile selection process. It lets you rely on the group URL preference used by many older ASA software releases. If the endpoint specifies a group URL that is not present in a connection profile, but it specifies a certificate value that matches that of a connection profile, the ASA assigns that connection profile to the VPN session.

Although you enter this command in webvpn configuration mode, it changes the connection profile selection preference for all clientless and AnyConnect VPN connections negotiated by the ASA.

Examples

The following example changes the preference of a connection profile during the connection profile selection process:

```
hostname(config)# webvpn
hostname(config-webvpn)# tunnel-group-preference group-url
hostname(config-webvpn)#
```

Related Commands

Command	Description
tunnel-group	Creates a VPN connection profile or accesses the database of VPN connection profiles.
group-url	Matches the URL or IP address specified by the VPN endpoint to the connection profile.
show running-config tunnel-group	Shows the tunnel group configuration for all tunnel groups or for a particular tunnel group.

tunnel-group general-attributes

To enter the general-attribute configuration mode, use the **tunnel-group general-attributes** command in global configuration mode. This mode is used to configure settings that are common to all supported tunneling protocols.

To remove all general attributes, use the **no** form of this command.

tunnel-group *name* **general-attributes**

no tunnel-group *name* **general-attributes**

Syntax Description

general-attributes	Specifies attributes for this tunnel-group.
name	Specifies the name of the tunnel-group.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Tunnel-group general-attributes configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.1(1)	Various attributes from other tunnel-group types migrated to the general tunnel-group attributes list, and the prompt for tunnel-group general-attributes mode changed.
9.0(1)	Support for multiple context mode was added.

Examples

The following example entered in global configuration mode, creates a remote-access tunnel group for a remote-access connection using the IP address of the LAN-to-LAN peer, then enters general-attributes configuration mode for configuring tunnel-group general attributes. The name of the tunnel group is 209.165.200.225.

```
hostname(config)# tunnel-group 209.165.200.225 type remote-access
hostname(config)# tunnel-group 209.165.200.225 general-attributes
hostname(config-tunnel-general)#
```

The following example entered in global configuration mode, creates a tunnel group named" remotegrp" for an IPsec remote access connection, and then enters general configuration mode for configuring general attributes for the tunnel group named "remotegrp":

```
hostname(config)# tunnel-group remotegrp type ipsec_ra
hostname(config)# tunnel-group remotegrp general
hostname(config-tunnel-general)
```

Related Commands

Command	Description
clear configure tunnel-group	Clears the entire tunnel-group database or just the specified tunnel-group.
show running-config tunnel-group	Displays the currently running tunnel-group configuration for a specified tunnel group or for all tunnel groups.
tunnel-group	Creates and manages the database of connection-specific records for IPsec and WebVPN tunnels.

tunnel-group ipsec-attributes

To enter the ipsec-attribute configuration mode, use the **tunnel-group ipsec-attributes** command in global configuration mode. This mode is used to configure settings that are specific to the IPsec tunneling protocol.

To remove all IPsec attributes, use the **no** form of this command.

tunnel-group *name* **ipsec-attributes**

no tunnel-group *name* **ipsec-attributes**

Syntax Description

ipsec-attributes	Specifies attributes for this tunnel-group.
name	Specifies the name of the tunnel-group.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.1(1)	Various IPsec tunnel-group attributes migrated to the general tunnel-group attributes list, and the prompt for tunnel-group ipsec-attributes mode changed.
9.0(1)	Support for multiple context mode was added.

Examples

The following example entered in global configuration, creates a tunnel group for the IPsec remote-access tunnel group named remotegrp, and then specifies IPsec group attributes:

```
hostname(config)# tunnel-group remotegrp type ipsec_ra
hostname(config)# tunnel-group remotegrp ipsec-attributes
hostname(config-tunnel-ipsec)
```

Related Commands

Command	Description
clear configure tunnel-group	Clears the entire tunnel-group database or just the specified tunnel-group.

Command	Description
show running-config tunnel-group	Displays the currently running tunnel-group configuration for a specified tunnel group or for all tunnel groups.
tunnel-group	Creates and manages the database of connection-specific records for IPsec and WebVPN tunnels.

tunnel-group ppp-attributes

To enter the ppp-attributes configuration mode and configure PPP settings that are used by L2TP over IPsec connections, use the **tunnel-group ppp-attributes** command in global configuration mode.

To remove all PPP attributes, use the **no** form of this command.

tunnel-group *name* **ppp-attributes**

no tunnel-group *name* **ppp-attributes**

Syntax Description

name	Specifies the name of the tunnel-group.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

PPP settings are used by the Layer 2 Tunneling Protocol (L2TP), a VPN tunneling protocol which allows remote clients to use the dialup telephone service public IP network to securely communicate with private corporate network servers. L2TP is based on the client/server model and uses PPP over UDP (port 1701) to tunnel the data. All of the tunnel-group ppp commands are available for the PPPoE tunnel-group type.

Examples

The following example creates the tunnel group *telecommuters* and enters ppp-attributes configuration mode:

```
hostname(config)# tunnel-group telecommuters type pppoe
hostname(config)# tunnel-group telecommuters ppp-attributes
hostname(tunnel-group-ppp)#
```

Related Commands

Command	Description
clear configure tunnel-group	Clears the entire tunnel-group database or just the specified tunnel-group.
show running-config tunnel-group	Displays the currently running tunnel-group configuration for a specified tunnel group or for all tunnel groups.
tunnel-group	Creates and manages the database of connection-specific records for IPsec and WebVPN tunnels.

tunnel-group webvpn-attributes

To enter the webvpn-attribute configuration mode, use the **tunnel-group webvpn-attributes** command in global configuration mode. This mode configures settings that are common to WebVPN tunneling.

To remove all WebVPN attributes, use the **no** form of this command.

tunnel-group *name* **webvpn-attributes**

no tunnel-group *name* **webvpn-attributes**

Syntax Description

webvpn-attributes	Specifies WebVPN attributes for this tunnel-group.
name	Specifies the name of the tunnel-group.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.1(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

In addition to the general attributes, you can also configure the following attributes specific to WebVPN connections in webvpn-attribute mode:

- authentication
- customization
- dns-group
- group-alias
- group-url
- without-csd

Examples

The following example entered in global configuration mode, creates a tunnel group for a WebVPN connection using the IP address of the LAN-to-LAN peer, then enters webvpn-configuration mode for configuring WebVPN attributes. The name of the tunnel group is 209.165.200.225.

```
hostname(config)# tunnel-group 209.165.200.225 type webvpn
hostname(config)# tunnel-group 209.165.200.225 webvpn-attributes
hostname(config-tunnel-webvpn)#
```

The following example entered in global configuration mode, creates a tunnel group named" remotegrp" for a WebVPN connection, and then enters webvpn configuration mode for configuring WebVPN attributes for the tunnel group named "remotegrp":

```
hostname(config)# tunnel-group remotegrp type webvpn
hostname(config)# tunnel-group remotegrp webvpn-attributes
hostname(config-tunnel-webvpn)#
```

Related Commands

Command	Description
clear configure tunnel-group	Clears the entire tunnel-group database or just the specified tunnel-group.
show running-config tunnel-group	Displays the currently running tunnel-group configuration for a specified tunnel group or for all tunnel groups.
tunnel-group	Creates and manages the database of connection-specific records for IPsec and WebVPN tunnels.

tunnel-group-map

When the adaptive security appliance receives an IPsec connection request with client certificate authentication, it assigns a connection profile to the connection according to a policy you configure.

That policy can be to use rules you configure, use the certificate OU field, use the IKE identity (i.e. hostname, IP address, key ID), the client's IP address, or a default connection profile to assign the connection profile. For SSL connections, the adaptive security appliance only uses the rules you configure to assign the connection profile.

The **tunnel-group-map** command assigns a connection profile to the connection based on rules you configure by associating an existing map name with a connection profile.

Use the **no** form of this command to disassociate a connection profile with a map name. The no form of the command does not delete the map name, just its association with a connection profile.

This is the syntax of the command:

tunnel-group-map [mapname] [rule-index] [connection-profile]

no tunnel-group-map [mapname] [rule-index]

Note

- You create the certificate map name with this command:
  crypto ca certificate map [mapname] [rule-index]
- A "tunnel group" is old terminology for what we now call a "connection profile." Think of the tunnel-group-map command as creating a connection profile map.

Syntax Description

mapname	Required. Identifies the name of the **existing** certificate map.
rule-index	Required. Identifies the rule-index associated with the mapname. The rule-index parameter was defined using the **crypto ca certificate map** command. The values are 1 to 65535.
connection-profile	Designates the connection profile name for this certificate map list.

Defaults

If a tunnel-group-map is not defined, and the ASA receives an IPsec connection request with client certificate authentication, the ASA assigns a connection profile by trying to match the certificate authentication request to one of these policies, in this order:

Certificate ou field—Determines connection profile based on the value of the organizational unit (OU) field in the subject distinguished name (DN).

IKE identity—Determines the connection profile based on the content of the phase1 IKE ID.

peer-ip—Determines the connection profile based on the established client IP address.

Default Connection Profile—If the ASA does not match the previous three policies, it assigns the default connection profile. The default profile is DefaultRAGroup. The default connection profile would otherwise be configured using the tunnel-group-map default-group command.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

The map name you specify must already exist before you can associate it with a connection profile. You create a map name using the **crypto ca certificate map** command. Refer to the documentation on the **crypto ca certificate map** command for more information.

Once you have associated map names with connection profiles, you need to enable the tunnel-group-map to use the rules you have configured rather than the default polices described earlier. To do this you must run the **tunnel-group-map enable rules** command in global configuration mode.

Examples

The following example associates the map name **SalesGroup,** with rule index **10,** to the **SalesConnectionProfile** connection profile.

```
hostname(config)# tunnel-group-map SalesGroup 10 SalesConnectionProfile
hostname(config)#
```

Related Commands

Command	Description
crypto ca certificate map [map name]	Enters ca certificate map configuration mode and you can use it to create a certificate map name.
tunnel-group-map enable	Enables certificate-based IKE sessions based on established rules.
tunnel-group-map default-group	Designates an existing tunnel-group name as the default tunnel group.

tunnel-group-map default-group

The **tunnel-group-map default-group** command specifies the default tunnel-group to use if the name could not be determined using other configured methods.

Use the **no** form of this command to eliminate a tunnel-group-map.

tunnel-group-map [*rule-index*] **default-group** *tunnel-group-name*

no tunnel-group-map

Syntax Description

default-group *tunnel-group-name*	Specifies a default tunnel group to use when the name cannot be derived by other configured methods. The *tunnel-group name* must already exist.
rule index	Optional. Refers to parameters specified by the **crypto ca certificate map** command. The values are 1 to 65535.

Defaults

The default value for the **tunnel-group-map default-group** is DefaultRAGroup.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

The tunnel-group-map commands configure the policy and rules by which certificate-based IKE sessions are mapped to tunnel groups. To associate the certificate map entries, created using the **crypto ca certificate map** command, with tunnel groups, use the **tunnel-group-map** command in global configuration mode. You can invoke this command multiple times as long as each invocation is unique and you do not reference a map index more than once.

The **crypto ca certificate map** command maintains a prioritized list of certificate mapping rules. There can be only one map. But this map can have up to 65535 rules. Refer to the documentation on the **crypto ca certificate map** command for more information.

The processing that derives the tunnel-group name from the certificate ignores entries in the certificate map that are not associated with a tunnel group (any map rule not identified by this command).

Examples

The following example entered in global configuration mode, specifies a default tunnel group to use when the name cannot be derived by other configured methods. The name of the tunnel group to use is group1:

```
hostname(config)# tunnel-group-map default-group group1
hostname(config)#
```

Related Commands

Command	Description
crypto ca certificate map	Enters crypto ca certificate map configuration mode.
subject-name (crypto ca certificate map)	Identifies the DN from the CA certificate that is to be compared to the rule entry string.
tunnel-group-map enable	Configures the policy and rules by which certificate-based IKE sessions are mapped to tunnel groups

tunnel-group-map enable

The **tunnel-group-map enable** command configures the policy and rules by which certificate-based IKE sessions are mapped to tunnel groups. Use the **no** form of this command to restore the default values.

tunnel-group-map [*rule-index*] **enable** *policy*

no tunnel-group-map enable [*rule-index*]

Syntax Description

policy	Specifies the policy for deriving the tunnel group name from the certificate. *Policy* can be one of the following: **ike-id**—Indicates that if a tunnel-group is not determined based on a rule lookup or taken from the ou, then the certificate-based IKE sessions are mapped to a tunnel group based on the content of the phase1 IKE ID. **ou**—Indicates that if a tunnel-group is not determined based on a rule lookup, then use the value of the organizational unit (OU) in the subject distinguished name (DN). **peer-ip**—Indicates that if a tunnel-group is not determined based on a rule lookup or taken from the ou or ike-id methods, then use the established peer IP address. **rules**—Indicates that the certificate-based IKE sessions are mapped to a tunnel group based on the certificate map associations configured by this command.
rule index	Optional. Refers to parameters specified by the **crypto ca certificate map** command. The values are 1 to 65535.

Defaults

The default values for the **tunnel-group-map** command are **enable ou** and **default-group** set to DefaultRAGroup.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

The **crypto ca certificate map** command maintains a prioritized list of certificate mapping rules. There can be only one map. But this map can have up to 65535 rules. Refer to the documentation on the **crypto ca certificate map** command for more information.

Examples

The following example enables mapping of certificate-based IKE sessions to a tunnel group based on the content of the phase1 IKE ID:

```
hostname(config)# tunnel-group-map enable ike-id
hostname(config)#
```

The following example enables mapping of certificate-based IKE sessions to a tunnel group based on the established IP address of the peer:

```
hostname(config)# tunnel-group-map enable peer-ip
hostname(config)#
```

The following example enables mapping of certificate-based IKE sessions based on the organizational unit (OU) in the subject distinguished name (DN):

```
hostname(config)# tunnel-group-map enable ou
hostname(config)#
```

The following example enables mapping of certificate-based IKE sessions based on established rules:

```
hostname(config)# tunnel-group-map enable rules
hostname(config)#
```

Related Commands

Command	Description
crypto ca certificate map	Enters CA certificate map mode.
subject-name (crypto ca certificate map)	Identifies the DN from the CA certificate that is to be compared to the rule entry string.
tunnel-group-map default-group	Designates an existing tunnel-group name as the default tunnel group.

tunnel-limit

To specify the maximum number of GTP tunnels allowed to be active on the ASA, use the **tunnel limit** command in GTP map configuration mode, which is accessed by using the **gtp-map** command. Use the **no** to set the tunnel limit back to its default.

tunnel-limit *max_tunnels*

no tunnel-limit *max_tunnels*

Syntax Description

max_tunnels	This is the maximum number of tunnels allowed. The ranges is from 1 to 4294967295 for the global overall tunnel limit.

Defaults

The default for the tunnel limit is 500.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Gtp map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

New requests will be dropped once the number of tunnels specified by this command is reached.

Examples

The following example specifies a maximum of 10,000 tunnels for GTP traffic:

```
hostname(config)# gtp-map qtp-policy
hostname(config-gtpmap)# tunnel-limit 10000
```

Related Commands

Commands	Description
clear service-policy inspect gtp	Clears global GTP statistics.
debug gtp	Displays detailed information about GTP inspection.
gtp-map	Defines a GTP map and enables GTP map configuration mode.

Commands	Description
inspect gtp	Applies a specific GTP map to use for application inspection.
show service-policy inspect gtp	Displays the GTP configuration.

tx-ring-limit

To specify the depth of the priority queues, use the **tx-ring-limit** command in priority-queue mode. To remove this specification, use the **no** form of this command.

Note This command is not supported on ASA 5580 Ten Gigabit Ethernet interfaces. (Ten Gigabit Ethernet interfaces are supported for priority queues on the ASA 5585-X.) This command is also not supported for the ASA 5512-X through ASA 5555-X Management interface.

This command is not supported on the ASA Services Module.

tx-ring-limit *number-of-packets*

no tx-ring-limit *number-of-packets*

Syntax Description

number-of-packets	Specifies the maximum number of low-latency or normal priority packets allowed into the Ethernet transmit driver before the driver pushes back to the queues on the interface to let them buffer packets until the congestion clears. The range of **tx-ring-limit** values is 3 through 128 packets on the PIX platform and 3 through 256 packets on the ASA platform.

Defaults

The default **tx-ring-limit** is 128 packets.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Priority-queue	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The ASA allows two classes of traffic: low-latency queuing (LLQ) for higher priority, latency sensitive traffic (such as voice and video) and best-effort, the default, for all other traffic. The ASA recognizes priority traffic and enforces appropriate Quality of Service (QoS) policies. You can configure the size and depth of the priority queue to fine-tune the traffic flow.

You must use the **priority-queue** command to create the priority queue for an interface before priority queuing takes effect. You can apply one **priority-queue** command to any interface that can be defined by the **nameif** command.

The **priority-queue** command enters priority-queue mode, as shown by the prompt. In priority-queue mode, you can configure the maximum number of packets allowed in the transmit queue at any given time (**tx-ring-limit** command) and the number of packets of either type (priority or best -effort) allowed to be buffered before dropping packets (**queue-limit** command).

Note You *must* configure the **priority-queue** command in order to enable priority queueing for the interface.

The tx-ring-limit and the queue-limit that you specify affect both the higher priority low-latency queue and the best-effort queue. The tx-ring-limit is the number of either type of packets allowed into the driver before the driver pushes back to the queues sitting in front of the interface to let them buffer packets until the congestion clears. In general, you can adjust these two parameters to optimize the flow of low-latency traffic.

Because queues are not of infinite size, they can fill and overflow. When a queue is full, any additional packets cannot get into the queue and are dropped. This is *tail drop*. To avoid having the queue fill up, you can use the **queue-limit** command to increase the queue buffer size.

Note The upper limit of the range of values for the **queue-limit** and **tx-ring-limit** commands is determined dynamically at run time. To view this limit, enter **help** or **?** on the command line. The key determinant is the memory needed to support the queues and the memory available on the device. The range of **queue-limit** values is 0 through 2048 packets. The range of **tx-ring-limit** values is 3 through 128 packets on the PIX platform and 3 through 256 packets on the ASA platform.

On ASA Model 5505 (only), configuring priority-queue on one interface overwrites the same configuration on all other interfaces. That is, only the last applied configuration is present on all interfaces. Further, if the priority-queue configuration is removed from one interface, it is removed from all interfaces.

To work around this issue, configure the **priority-queue** command on only one interface. If different interfaces need different settings for the **queue-limit** and/or **tx-ring-limit** commands, use the largest of all queue-limits and smallest of all tx-ring-limits on any one interface (CSCsi13132).

Examples

The following example configures a priority queue for the interface named test, specifying a queue limit of 2048 packets and a transmit queue limit of 256 packets.

```
hostname(config)# priority-queue test
hostname(priority-queue)# queue-limit 2048
hostname(priority-queue)# tx-ring-limit 256
```

Related Commands

Command	Description
clear configure priority-queue	Removes the current priority queue configuration on the named interface.
priority-queue	Configures priority queuing on an interface.
queue-limit	Specifies the maximum number of packets that can be enqueued to a priority queue before it drops data.

Command	Description
show priority-queue statistics	Shows the priority-queue statistics for the named interface.
show running-config priority-queue	Shows the current priority queue configuration. If you specify the **all** keyword, this command displays all the current **priority-queue**, **queue-limit**, and **tx-ring-limit** command configuration values.

type echo

To configure the SLA operation as an echo response time probe operation, use the **type echo** command in SLA monitor configuration mode. To remove the type from teh SLA configuration, use the **no** form of this command.

type echo protocol ipIcmpEcho *target* interface *if-name*

no type echoprotocol ipIcmpEcho *target* interface *if-name*

Syntax Description

interface *if-name*	Specifies the interface name, as specified by the **nameif** command, of the interface used to send the echo request packets. The interface source address is used as the source address in the echo request packets.
protocol	The protocol keyword. The only value supported is **ipIcmpEcho**, which specifies using an IP/ICMP echo request for the echo operation.
target	The IP address or host name of the object being monitored.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
SLA monitor configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The default size of the payload of the ICMP packets is 28 bytes, creating a total ICMP packet size of 64 bytes. The payload size can be changed using the **request-data-size** command.

Examples

The following example configures an SLA operation with an ID of 123 that uses an ICMP echo request/response time probe operation. It creates a tracking entry with the ID of 1 to track the reachability of the SLA. The frequency of the SLA operation is set to 10 seconds, the threshold to 2500 milliseconds, and the timeout value us set to 4000 milliseconds.

```
hostname(config)# sla monitor 123
hostname(config-sla-monitor)# type echo protocol ipIcmpEcho 10.1.1.1 interface outside
hostname(config-sla-monitor-echo)# threshold 2500
hostname(config-sla-monitor-echo)# timeout 4000
hostname(config-sla-monitor-echo)# frequency 10
hostname(config)# sla monitor schedule 123 life forever start-time now
```

```
hostname(config)# track 1 rtr 123 reachability
```

Related Commands

Command	Description
num-packets	Specifies the number of request packets to send during an SLA operation.
request-data-size	Specifies the size of the payload for the SLA operation request packet.
sla monitor	Defines an SLA monitoring operation.

CHAPTER 66

uc-ime through username-prompt Commands

uc-ime

To create the Cisco Intercompany Media Engine proxy instance, use the **uc-ime** command in global configuration mode. To remove the proxy instance, use the **no** form of this command.

uc-ime *uc-ime_name*

no uc-ime *uc-ime_name*

Syntax Description

uc-ime_name	Specifies the instance name of the Cisco Intercompany Media Engine proxy configured on the ASA. The *name* is limited to 64 characters. Only one Cisco Intercompany Media Engine proxy can be configured on the ASA.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.3(1)	The command was introduced.

Usage Guidelines

Configures the Cisco Intercompany Media Engine proxy. Cisco Intercompany Media Engine enables companies to interconnect on-demand, over the Internet with advanced features made available by VoIP technologies. Cisco Intercompany Media Engine allows for business-to-business federation between Cisco Unified Communications Manager clusters in different enterprises by utilizing peer-to-peer, security, and SIP protocols to create dynamic SIP trunks between businesses. A collection of enterprises work together to end up looking like one large business with inter-cluster trunks between them.

You must create the media termination instance before you specify it in the Cisco Intercompany Media Engine proxy.

Only one Cisco Intercompany Media Engine proxy can be configured on the ASA.

Examples

The following example shows how to configure a Cisco Intercompany Media Engine proxy by using the **uc-ime** command.

```
hostname(config)# uc-ime local_uc-ime_proxy
hostname(config-uc-ime)# media-termination ime-media-term
hostname(config-uc-ime)# ucm address 192.168.10.30 trunk-security-mode non-secure
```

```
hostname(config-uc-ime)# ticket epoch 1 password password1234
hostname(config-uc-ime)# fallback monitoring timer 120
hostname(config-uc-ime)# fallback hold-down timer 30
```

Related Commands

Command	Description
fallback	Configures the fallback timers that the Cisco Intercompany Media Engine uses to fallback from VoIP to PSTN when connection integrity degrades.
show uc-ime	Displays statistical or detailed information about fallback-notifications, mapping-service-sessions, and signaling-sessions.
ticket	Configures the ticket epoch and password for the Cisco Intercompany Media Engine proxy.
ucm	Configures the Cisco UCMs that the Cisco Intercompany Media Engine Proxy connects to.

ucm

To configure which Cisco Unified Communication Managers (UCM) that the Cisco Intercompany Media Engine Proxy connects to, use the **ucm** command in global configuration mode. To remove the the Cisco UCM that are connected to the Cisco Intercompanuy Media Engine Proxy, use the **no** form of this command.

ucm address *ip_address* **trunk-security-mode** {**nonsecure** | **secure**}

no ucm address *ip_address* **trunk-security-mode** {**nonsecure** | **secure**}

Syntax Description

address	The keyword to configure the IP address of the Cisco Unified Communications Manager (UCM).
ip_address	Specifies the IP address of the Cisco UCM. Enter the IP address in IPv4 format.
nonsecure	Specifies that the Cisco UCM or Cisco UCM cluster is operating in non-secure mode.
secure	Specifies that the Cisco UCM or Cisco UCM cluster is operating in secure mode.
trunk-security-mode	The keyword to configure the security mode of the Cisco UCM or Cisco UCM cluster.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
UC-IME configuration	•	—	•	—	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

Specifies the Cisco UCM server in the enterprise.

You can enter multiple **ucm** commands for the Cisco Intercompany Media Engine proxy.

Note You must include an entry for each Cisco UCM in the cluster with Cisco Intercompany Media Engine that has a SIP trunk enabled.

Specifying **secure** for Cisco UCM or Cisco UCM cluster indicates that Cisco UCM or Cisco UCM cluster is initiating TLS; therefore, you must set up configure TLS for components.

You can specify the **secure** option in this task or you can update it later while configuring TLS for the enterprise.

TLS within the enterprise refers to the security status of the Cisco Intercompany Media Engine trunk as seen by the adaptive security appliance.

If the transport security for the Cisco Intercompany Media Engine trunk changes on Cisco UCM, it must be changed on the adaptive security appliance as well. A mismatch will result in call failure. The adaptive security appliance does not support SRTP with non-secure IME trunks. The adaptive security appliance assumes SRTP is allowed with secure trunks. So 'SRTP Allowed' must be checked for IME trunks if TLS is used. The adaptive security appliance supports SRTP fallback to RTP for secure IME trunk calls.

The proxy sits on the edge of the enterprise and inspects SIP signaling between SIP trunks created between enterprises. It terminates TLS signaling from the Internet and initiates TCP or TLS to Cisco UCM.

Transport Layer Security (TLS) is a cryptographic protocol that provides security for communications over networks such as the Internet. TLS encrypts the segments of network connections at the Transport Layer end-to-end.

This task is not required if TCP is allowable within the inside network.

Key steps for Configuring TLS within the local enterprise:

- local adaptive security appliance, create another RSA key and trustpoint for the self-signed certificate
- exporting and importing the certificates between the local Cisco UCM and local adaptive security appliance
- create a trustpoint for local Cisco UCM on the adaptive security appliance

Authentication via TLS: In order for the ASA to act as a porty on behalf of N enterprises, the Cisco UCMs must be able to accept the one certificate from the ASA. This can be done by associating all the UC-IME SIP trunks with the same SIP security profile containing the same subject name as that of the one presented by the ASA because the Cisco UCM extracts the subject name from the certificate and compares that with the name configured in the security profile.

Examples

The following example shows ...:

```
hostname(config)# uc-ime local_uc-ime_proxy
hostname(config-uc-ime)# media-termination ime-media-term
hostname(config-uc-ime)# ucm address 192.168.10.30 trunk-security-mode non-secure
hostname(config-uc-ime)# ticket epoch 1 password password1234
hostname(config-uc-ime)# fallback monitoring timer 120
hostname(config-uc-ime)# fallback hold-down timer 30
```

undebug

To disable the display of debugging information in the current session, use the **undebug** command in privileged EXEC mode.

undebug {*command* | **all**}

Syntax Description

command	Disables debug for the specified command. See the Usage Guidelines for information about the supported commands.
all	Disables all debug output.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was modified. It includes additional **debug** keywords.

Usage Guidelines

The following commands can be used with the **undebug** command. For more information about debugging a specific command, or for the associated arguments and keywords for a specific **debug** command, see the entry for the **debug** command.

- aaa—AAA information
- acl—ACL information
- all—All debugging
- appfw—Application firewall information
- arp—ARP including NP operations
- asdm—ASDM information
- auto-update—Auto-update information
- boot-mem—Boot memory calculation and set
- cifs—CIFS information
- cmgr—CMGR information
- context—Context information
- cplane—CP information

- crypto—Crypto information
- ctiqbe—CTIQBE information
- ctl-provider—CTL provider debugging information
- dap—DAP information
- dcerpc—DCERPC information
- ddns—Dynamic DNS information
- dhcpc—DHCP client information
- dhcpd—DHCP server information
- dhcprelay—DHCP Relay information
- disk—Disk information
- dns—DNS information
- eap—EAP information
- eigrp—EIGRP protocol information
- email—Email information
- entity—Entity MIB information
- eou—EAPoUDP information
- esmtp—ESMTP information
- fips—FIPS 140-2 information
- fixup—Fixup information
- fover—Failover information
- fsm—FSM information
- ftp—FTP information
- generic—Miscellaneous information
- gtp—GTP information
- h323—H323 information
- http—HTTP information
- icmp—ICMP information
- igmp—Internet Group Management Protocol
- ils—LDAP information
- im—IM inspection information
- imagemgr—Image Manager information
- inspect—inspect debugging information
- integrityfw—Integrity Firewall information
- ip—IP information
- ipsec-over-tcp—IPsec over TCP information
- ipsec-pass-thru—Inspect ipsec-pass-thru information
- ipv6—IPv6 information
- iua-proxy—IUA proxy information

- kerberos—KERBEROS information
- l2tp—L2TP information
- ldap—LDAP information
- mfib—Multicast forwarding information base
- mgcp—MGCP information
- module-boot—Service module boot information
- mrib—Multicast routing information base
- nac-framework—NAC-FRAMEWORK information
- netbios-inspect—NETBIOS inspect information
- npshim—NPSHIM information
- ntdomain—NT domain information
- ntp—NTP information
- ospf—OSPF information
- p2p—P2P inspection information
- parser—Parser information
- pim—Protocol Independent Multicast
- pix—PIX information
- ppp—PPP information
- pppoe—PPPoE information
- pptp—PPTP information
- radius—RADIUS information
- redundant-interface—redundant interface information
- rip—RIP information
- rtp—RTP information
- rtsp—RTSP information
- sdi—SDI information
- sequence—Add sequence number
- session-command—Session command information
- sip—SIP information
- skinny—Skinny information
- sla—IP SLA Monitor Debug
- smtp-client—Email system log messsages
- splitdns—Split DNS information
- sqlnet—SQLNET information
- ssh—SSH information
- sunrpc—SUNRPC information
- tacacs—TACACS information
- tcp—TCP for WebVPN

- tcp-map—TCP map information
- timestamps—Add timestamp
- track—static route tracking
- vlan-mapping—VLAN mapping information
- vpn-sessiondb—VPN session database information
- vpnlb—VPN load balancing information
- wccp—WCCP information
- webvpn—WebVPN information
- xdmcp—XDMCP information
- xml—XML parser information

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Examples

The example disabled all debugging output:

```
hostname(config)# undebug all
```

Related Commands

Command	Description
debug	Displays debug information for the selected command.

unix-auth-gid

To set the UNIX group ID, use the **unix-auth-gid** command in group-policy webvpn configuration mode. To remove this command from the configuration, use the **no** version of this command.

unix-auth-gid *identifier*

no storage-objects

Syntax Description

identifier	Specifies an integer in the range 0 through 4294967294.

Defaults

The default is 65534.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy webvpn configuration mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The string specifies a network file system (NetFS) location. Only SMB and FTP protocols are supported; for example, smb://(NetFS location) or ftp://(NetFS location). You use the name of this location in the **storage-objects** command.

Examples

The following example sets the UNIX group ID to 4567:

```
hostname(config)# group-policy test attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# unix-auth-gid 4567
```

Related Commands

Command	Description
unix-auth-uid	Sets the UNIX user ID.

unix-auth-uid

To set the UNIX user ID, use the **unix-auth-uid** command in group-policy webvpn configuration mode. To remove this command from the configuration, use the **no** version of this command.

unix-auth-gid *identifier*

no storage-objects

Syntax Description

identifier	Specifies an integer in the range 0 through 4294967294.

Defaults

The default is 65534.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy webvpn configuration mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The string specifies a network file system (NetFS) location. Only SMB and FTP protocols are supported; for example, smb://(NetFS location) or ftp://(NetFS location). You use the name of this location in the **storage-objects** command.

Examples

The following example sets the UNIX user ID to 333:

```
hostname(config)# group-policy test attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# unix-auth-gid 333
```

Related Commands

Command	Description
unix-auth-gid	Sets the UNIX group ID.

upload-max-size

To specify the maximum size allowed for an object to upload, use the **upload-max-size** command in group-policy webvpn configuration mode. To remove this object from the configuration, use the **no** version of this command.

upload-max-size *size*

no upload-max-size

Syntax Description

size	Specifies the maximum size allowed for a uploaded object. The range is 0 through 2147483647.

Defaults

The default size is 2147483647.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy webvpn configuration mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Setting the size to 0 effectively disallows object uploading.

Examples

The following example sets the maximum size for a uploaded object to 1500 bytes:

```
hostname(config)# group-policy test attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# upload-max-size 1500
```

Related Commands

Command	Description
post-max-size	Specifies the maximum size of an object to post.
download-max-size	Specifies the maximum size of an object to download.

Command	Description
webvpn	Use in group-policy configuration mode or in username configuration mode. Lets you enter webvpn mode to configure parameters that apply to group policies or usernames.
webvpn	Use in global configuration mode. Lets you configure global settings for WebVPN.

uri-non-sip

To identify the non-SIP URIs present in the Alert-Info and Call-Info header fields, use the **uri-non-sip** command in parameters configuration mode. Parameters configuration mode is accessible from policy map configuration mode. To disable this feature, use the **no** form of this command.

uri-non-sip action {**mask** | **log**} [**log**}

no uri-non-sip action {**mask** | **log**} [**log**}

Syntax Description

log	Specifies standalone or additional log in case of violation.
mask	Masks the non-SIP URIs.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to identify the non-SIP URIs present in the Alert-Info and Call-Info header fields in a SIP inspection policy map:

```
hostname(config)# policy-map type inspect sip sip_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# uri-non-sip action log
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

url

To maintain the list of static URLs for retrieving CRLs, use the **url** command in crl configure configuration mode. The crl configure configuration mode is accessible from the crypto ca trustpoint configuration mode. To delete an existing URL, use the **no** form of this command.

url *index url*

no url *index url*

Syntax Description

index	Specifies a value from 1 to 5 that determines the rank of each URL in the list. The ASA tries the URL at index 1 first.
url	Specifies the URL from which to retrieve the CRL.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crl configure configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You cannot overwrite existing URLs. To replace an existing URL, first delete it using the **no** form of this command.

Examples

The following example enters ca-crl configuration mode, and sets up an index 3 for creating and maintaining a list of URLs for CRL retrieval and configures the URL https://example.com from which to retrieve CRLs:

```
hostname(configure)# crypto ca trustpoint central
hostname(ca-trustpoint)# crl configure
hostname(ca-crl)# url 3 https://example.com
hostname(ca-crl)#
```

Related Commands

Command	Description
crl configure	Enters ca-crl configuration mode.
crypto ca trustpoint	Enters trustpoint configuration mode.
policy	Specifies the source for retrieving CRLs.

url-block

To manage the URL buffers used for web server responses while waiting for a filtering decision from the filtering server, use the **url-block** command. To remove the configuration, use the **no** form of this command.

url-block block *block_buffer*

no url-block block *block_buffer*

url-block mempool-size *memory_pool_size*

no url-block mempool-size *memory_pool_size*

url-block url-size *long_url_size*

no url-block url-size *long_url_size*

Syntax Description

block *block_buffer*	Creates an HTTP response buffer to store web server responses while waiting for a filtering decision from the filtering server. The permitted values are from 1 to 128, which specifies the number of 1550-byte blocks.
mempool-size *memory_pool_size*	Configures the maximum size of the URL buffer memory pool in Kilobytes (KB). The permitted values are from 2 to 10240, which specifies a URL buffer memory pool from 2 KB to 10240 KB.
url-size *long_url_size*	Configures the maximum allowed URL size in KB for each long URL being buffered. The permitted values, which specifies a maximum URL size,: for Websense are 2, 3, or 4, representing 2 KB, 3 KB, or 4KB; or for Secure Computing, 2 or 3, representing 2 KB or 3 KB.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

For Websense filtering servers, the **url-block url-size** command allows filtering of long URLs, up to 4 KB. For Secure Computing, the **url-block url-size** command allows filtering of long URLs, up to 3 KB. For both Websense and N2H2 filtering servers, the **url-block block** command causes the ASA to buffer packets received from a web server in response to a web client request while waiting for a response from the URL filtering server. This improves performance for the web client compared to the default ASA behavior, which is to drop the packets and to require the web server to retransmit the packets if the connection is permitted.

If you use the **url-block block** command and the filtering server permits the connection, the ASA sends the blocks to the web client from the HTTP response buffer and removes the blocks from the buffer. If the filtering server denies the connection, the ASA sends a deny message to the web client and removes the blocks from the HTTP response buffer.

Use the **url-block block** command to specify the number of blocks to use for buffering web server responses while waiting for a filtering decision from the filtering server.

Use the **url-block url-size** command with the **url-block mempool-size** command to specify the maximum length of a URL to be filtered and the maximum memory to assign to the URL buffer. Use these commands to pass URLs longer than 1159 bytes, up to a maximum of 4096 bytes, to the Websense or Secure-Computing server. The **url-block url-size** command stores URLs longer than 1159 bytes in a buffer and then passes the URL to the Websense or Secure-Computing server (through a TCP packet stream) so that the Websense or Secure-Computing server can grant or deny access to that URL.

Examples

The following example assigns 56 1550-byte blocks for buffering responses from the URL filtering server:

```
hostname#(config)# url-block block 56
```

Related Commands

Commands	Description
clear url-block block statistics	Clears the block buffer usage counters.
filter url	Directs traffic to a URL filtering server.
show url-block	Displays information about the URL cache, which is used for buffering URLs while waiting for responses from an N2H2 or Websense filtering server.
url-cache	Enables URL caching while pending responses from an N2H2 or Websense server and sets the size of the cache.
url-server	Identifies an N2H2 or Websense server for use with the **filter** command.

url-cache

To enable URL caching for URL responses received from a Websense server and to set the size of the cache, use the **url-cache** command in global configuration mode. To remove the configuration, use the **no** form of this command.

url-cache { **dst** | **src_dst** } *kbytes* [**kb**]

no url-cache { **dst** | **src_dst** } *kbytes* [**kb**]

Syntax Description

dst	Cache entries based on the URL destination address. Select this mode if all users share the same URL filtering policy on the Websense server.
size *kbytes*	Specifies a value for the cache size within the range 1 to 128 KB.
src_dst	Cache entries based on the both the source address initiating the URL request as well as the URL destination address. Select this mode if users do not share the same URL filtering policy on the Websense server.
statistics	Use the **statistics** option to display additional URL cache statistics, including the number of cache lookups and hit rate.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **url-cache** command provides a configuration option to cache responses from the URL server.

Use the **url-cache** command to enable URL caching, set the size of the cache, and display cache statistics.

Note The N2H2 server application does not support this command for URL filtering.

Caching stores URL access privileges in memory on the ASA. When a host requests a connection, the ASA first looks in the URL cache for matching access privileges instead of forwarding the request to the Websense server. Disable caching with the **no url-cache** command.

Note If you change settings on the Websense server, disable the cache with the **no url-cache** command and then re-enable the cache with the **url-cache** command.

Using the URL cache does not update the Websense accounting logs for Websense protocol Version 1. If you are using Websense protocol Version 1, let Websense run to accumulate logs so you can view the Websense accounting information. After you get a usage profile that meets your security needs, enable **url-cache** to increase throughput. Accounting logs are updated for Websense protocol Version 4 URL filtering while using the **url-cache** command.

Examples

The following example caches all outbound HTTP connections based on the source and destination addresses:

```
hostname(config)# url-cache src_dst 128
```

Related Commands

Commands	Description
clear url-cache statistics	Removes **url-cache** command statements from the configuration.
filter url	Directs traffic to a URL filtering server.
show url-cache statistics	Displays information about the URL cache, which is used for URL responses received from a Websense filtering server.
url-server	Identifies a Websense server for use with the **filter** command.

url-entry

To enable or disable the ability to enter any HTTP/HTTPS URL on the portal page, use the **url-entry** command in dap webvpn configuration mode.

url-entry enable | disable

enable | disable	Enables or disables the ability to browse for file servers or shares..

Defaults

No default value or behaviors.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Dap webvpn configuration	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Examples

The following example shows how to enable URL entryfor the DAP record called Finance:

```
hostname (config) config-dynamic-access-policy-record Finance
hostname(config-dynamic-access-policy-record)# webvpn
hostname(config-dynamic-access-policy-record)# url-entry enable
```

Related Commands

Command	Description
dynamic-access-policy-record	Creates a DAP record.
file-entry	Enables or disables the ability to enter file server names to access.

url-length-limit

To configure the maximum length of the URL allowed in the RTSP message, use the **url-length-limit** command in parameters configuration mode. Parameters configuration mode is accessible from policy map configuration mode. To disable this feature, use the **no** form of this command.

url-length-limit *length*

no url-length-limit *length*

Syntax Description

length	The URL length limit in bytes. Range is 0 to 6000.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Examples

The following example shows how to configure the URL length limit in an RTSP inspection policy map:

```
hostname(config)# policy-map type inspect rtsp rtsp_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# url-length-limit 50
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

url-list (removed)

You can no longer use this command to define URl lists for access over SSL VPN connections. Now use the **import** command to import the XML object that defines a URL list. See the **import-** and **export-url-list** commands for more information.

Defaults

There is no default URL list.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration mode	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0(2)	This command was deprecated. It remains in the software for this release only to provide backward compatibility for pre-existing URL lists, so that the security appliance can convert such lists to XML files. Be aware that you cannot use the command to create a new URL list.

Usage Guidelines

You use the url-list command in global configuration mode to create one or more lists of URLs. To allow access to the URLs in a list for a specific group policy or user, use the *listname* you create here with the **url-list** command in webvpn mode.

Examples

The following example shows how to create a URL list called *Marketing URLs* that provides access to www.cisco.com, www.example.com, and www.example.org. The following table provides values that the example uses for each application.

listname	displayname	url
Marketing URLs	Cisco Systems	http://www.cisco.com
Marketing URLs	Example Company, Inc.	http://www.example.com
Marketing URLs	Example Organization	http://www.example.org

```
hostname(config)# url-list Marketing URLs Cisco Systems http://www.cisco.com
hostname(config)# url-list Marketing URLs Example Company, Inc. http://www.example.com
hostname(config)# url-list Marketing URLs Example Organization http://www.example.org
```

Related Commands

Command	Description
clear configuration url-list	Removes all url-list commands from the configuration. If you include the listname, the ASA removes only the commands for that list.
show running-configuration url-list	Displays the current set of configured urls.
webvpn	Use in group-policy configuration mode or in username configuration mode. Lets you enter webvpn mode to configure parameters that apply to group policies or usernames.
webvpn	Use in global configuration mode. Lets you configure global settings for WebVPN.

url-list (group-policy webvpn)

To apply a list of WebVPN servers and URLs to a particular user or group policy, use the **url-list** command in group-policy webvpn configuration mode or in username webvpn configuration mode. To remove a list, including a null value created by using the **url-list none command,** use the **no** form of this command. The **no** option allows inheritance of a value from another group policy. To prevent inheriting a url list, use the **url-list none** command. Using the command a second time overrides the previous setting.

url-list {**value** *name* | **none**} [*index*]

no url-list

Syntax Description

index	Indicates the display priority on the home page.
none	Sets a null value for url lists. Prevents inheriting a list from a default or specified group policy.
value *name*	Specifies the name of a previously configured list of urls. To configure such a list, use the **url-list** command in global configuration mode.

Defaults

There is no default URL list.

Command Modes

The following table shows the modes in which you enter the commands:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy webvpn confguration	•	—	•	—	—
Username configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Using the command a second time overrides the previous setting.

Before you can use the **url-list** command in webvpn mode to identify a URL list that you want to display on the WebVPN home page for a user or group policy, you must create the list via an XML object. Use the **import** command in global configuration mode to download a URL list to the security appliance. Then use the url-list command to apply a list to a particular group policy or user.

Examples

The following example applies a URL list called FirstGroupURLs for the group policy named FirstGroup and assigns it first place among the URL lists:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# url-list value FirstGroupURLs 1
```

Related Commands

Command	Description
clear configure url-list [*listname*]	Removes all url-list commands from the configuration. If you include the listname, the ASA removes only the commands for that list.
show running-configuration url-list	Displays the current set of configured **url-list** commands.
webvpn	Lets you enter webvpn mode. This can be webvpn configuration mode, group-policy webvpn configuration mode (to configure webvpn settings for a specific group policy), or username webvpn configuration mode (to configure webvpn settings for a specific user).

url-server

To identify an N2H2 or Websense server for use with the **filter** command, use the **url-server** command in global configuration mode. To remove the configuration, use the **no** form of this command.

N2H2

url-server [(*if_name*)] **vendor** {**smartfilter** | **n2h2**} **host** *local_ip* [**port** *number*] [**timeout** *seconds*] [**protocol** {**TCP** [connections *number*]} | **UDP**]

no url-server [(*if_name*)] **vendor** {**smartfilter** | **n2h2**} **host** *local_ip* [**port** *number*] [**timeout** *seconds*] [**protocol** {**TCP** [**connections** *number*]} | **UDP**]

Websense

url-server (*if_name*) **vendor websense host** *local_ip* [**timeout** *seconds*] [**protocol** {**TCP** | **UDP** | **connections** *num_conns*] | *version*]

no url-server (*if_name*) **vendor websense host** *local_ip* [**timeout** *seconds*] [**protocol** {**TCP** | **UDP** [**connections** *num_conns*] | *version*]

Syntax Description

N2H2

connections	Limits the maximum number of TCP connections permitted.
num_conns	Specifies the maximum number of TCP connections created from the security appliance to the URL server. Since this number is per server, different servers can have different connection values.
host *local_ip*	The server that runs the URL filtering application.
if_name	(Optional) The network interface where the authentication server resides. If not specified, the default is inside.
port *number*	The N2H2 server port. The ASA also listens for UDP replies on this port. The default port number is 4005.
protocol	The protocol can be configured using **TCP** or **UDP** keywords. The default is TCP.
timeout *seconds*	The maximum idle time permitted before the ASA switches to the next server you specified. The default is 30 seconds.
vendor	Indicates URL filtering service, using either ‘smartfilter’ or ‘n2h2’ (for backward compatibility); however, ‘smartfilter’ is saved as the vendor string.

Websense

connections	Limits the maximum number of TCP connections permitted.
num_conns	Specifies the maximum number of TCP connections created from the security appliance to the URL server. Since this number is per server, different servers can have different connection values.
host *local_ip*	The server that runs the URL filtering application.
if_name	The network interface where the authentication server resides. If not specified, the default is inside.

timeout *seconds*	The maximum idle time permitted before the ASA switches to the next server you specified. The default is 30 seconds.
protocol	The protocol can be configured using **TCP** or **UDP** keywords. The default is TCP protocol, Version 1.
vendor websense	Indicates URL filtering service vendor is Websense.
version	Specifies protocol Version **1** or **4**. The default is TCP protocol Version 1. TCP can be configured using Version 1 or Version 4. UDP can be configured using Version 4 only.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•		•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **url-server** command designates the server running the N2H2 or Websense URL filtering application. The limit is 16 URL servers in single context mode and 4 URL servers in multi mode; however, and you can use only one application at a time, either N2H2 or Websense. Additionally, changing your configuration on the ASA does not update the configuration on the application server; this must be done separately, according to the vendor instructions.

The **url-server** command must be configured before issuing the **filter** command for HTTPS and FTP. If all URL servers are removed from the server list, then all **filter** commands related to URL filtering are also removed.

Once you designate the server, enable the URL filtering service with the **filter url** command.

Use the **show url-server statistics** command to view server statistic information including unreachable servers.

Follow these steps to filter URLs:

Step 1 Designate the URL filtering application server with the appropriate form of the vendor-specific **url-server** command.

Step 2 Enable URL filtering with the **filter** command.

Step 3 (Optional) Use the **url-cache** command to enable URL caching to improve perceived response time.

Step 4 (Optional) Enable long URL and HTTP buffering support using the **url-block** command.

Step 5 Use the **show url-block block statistics**, **show url-cache statistics**, or the **show url-server statistics** commands to view run information.

For more information about filtering by N2H2, visit N2H2's website at:

http://www.n2h2.com

For more information about Websense filtering services, visit the following website:

http://www.websense.com/

Examples

Using N2H2, the following example filters all outbound HTTP connections except those from the 10.0.2.54 host:

```
hostname(config)# url-server (perimeter) vendor n2h2 host 10.0.1.1
hostname(config)# filter url http 0 0 0 0
hostname(config)# filter url except 10.0.2.54 255.255.255.255 0 0
```

Using Websense, the following example filters all outbound HTTP connections except those from the 10.0.2.54 host:

```
hostname(config)# url-server (perimeter) vendor websense host 10.0.1.1 protocol TCP
version 4
hostname(config)# filter url http 0 0 0 0
hostname(config)# filter url except 10.0.2.54 255.255.255.255 0 0
```

Related Commands

Commands	Description
clear url-server	Clears the URL filtering server statistics.
filter url	Directs traffic to a URL filtering server.
show url-block	Displays information about the URL cache, which is used for URL responses received from an N2H2 or Websense filtering server.
url-cache	Enables URL caching while pending responses from an N2H2 or Websense server and sets the size of the cache.

urgent-flag

To allow or clear the URG pointer through the TCP normalizer, use the **urgent-flag** command in tcp-map configuration mode. To remove this specification, use the **no** form of this command.

urgent-flag {**allow** | **clear**}

no urgent-flag {**allow** | **clear**}

Syntax Description

allow	Allows the URG pointer through the TCP normalizer.
clear	Clears the URG pointer through the TCP normalizer.

Defaults

The urgent flag and urgent offset are clear by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tcp-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **tcp-map** command is used along with the Modular Policy Framework infrastructure. Define the class of traffic using the **class-map** command and customize the TCP inspection with **tcp-map** commands. Apply the newTCP map using the **policy-map** command. Activate TCP inspection with **service-policy** commands.

Use the **tcp-map** command to enter tcp-map configuration mode. Use the **urgent-flag** command in tcp-map configuration mode to allow the urgent flag.

The URG flag is used to indicate that the packet contains information that is of higher priority than other data within the stream. The TCP RFC is vague about the exact interpretation of the URG flag, therefore, end systems handle urgent offsets in different ways, which may make the end system vulnerable to attacks. The default behavior is to clear the URG flag and offset.

Examples

The following example shows how to allow the urgent flag:

```
hostname(config)# tcp-map tmap
hostname(config-tcp-map)# urgent-flag allow
hostname(config)# class-map cmap
hostname(config-cmap)# match port tcp eq 513
hostname(config)# policy-map pmap
```

```
hostname(config-pmap)# class cmap
hostname(config-pmap)# set connection advanced-options tmap
hostname(config)# service-policy pmap global
```

Related Commands

Command	Description
class	Specifies a class map to use for traffic classification.
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
set connection	Configures connection values.
tcp-map	Creates a TCP map and allows access to tcp-map configuration mode.

user

To create a user in a user group object that supports the Identity Firewall feature, use the **user** command in the user-group object configuration mode. Use the **no** form of this command to remove the user. from the object.

user [*domain_nickname*\]*user_name*

[no] user [*domain_nickname*\]*user_name*

Syntax Description

domain_nickname	(Optional) Specifies the domain in which to add the user.
user_name	Specifies the name for the user. The user name can contain any character including [a-z], [A-Z], [0-9], [!@#$%^&()-_{}.]. If the user name contains a space, you must enclose the name in quotation marks. The *user_name* argument that you specify with the **user** keyword contains an ASCII user name and does not specify an IP address.

Defaults

If you do not specify the *domain_nickname* argument, the user is created in the LOCAL domain configured for the Identity Firewall feature.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Object-group user configuration	•	•	•	•	—

Command History

Release	Modification
8.4(2)	This command was introduced.

Usage Guidelines

The ASA sends an LDAP query to the Active Directory server for user groups globally defined in the Active Directory domain controller. The ASA imports these groups for the Identity Firewall feature. However, the ASA might have localized network resources that are not defined globally that require local user groups with localized security policies. Local user groups can contain nested groups and user groups that are imported from Active Directory. The ASA consolidates local and Active Directory groups. A user can belong to local user groups and user groups imported from Active Directory.

The ASA supports up to 256 user groups (including imported user groups and local user groups).

You active user group objects by including them within an access group, capture, or service policy.

Within a user group object, you can define the following object types:

- **User**—adds a single user to the object-group user. The user can be either a LOCAL user or imported user.

The name of an imported user must be the sAMAccountName, which is unique, rather than the common name (cn), which might not be unique. However, some Active Directory server administrators might require that the sAMAccountName and the cn be identical. In this case, the cn that the ASA displays in the output of the **show user-identity ad-group-member** command can be used for imported users defined by the user object.

- **User-group**—adds an imported user group, which is defined by an external directory server, such as Microsoft Active Directory server, to the group-object user.

  The group name of the user-group must be the sAMAccountName, which is unique, rather than the cn, which might not be unique. However, some Active Directory server administrators might require that the sAMAccountName and the cn be identical. In this case, the cn that the ASA displays in the output of the **show user-identity ad-group-member** command can be used in the *user_group_name* argument specified with the **user-group** keyword.

  Note You can add *domain_nickname**user_group_name* or *domain_nickname**user_ name* directly within a user group object without specifying them in the object first. If the *domain_nickname* is associated with a AAA server, the ASA imports the detailed nested user groups and the users defined in the external directory server, such as the Microsoft Active Directory server, to the ASA when the user object group is activated.

- **Group-object**—adds a group defined locally on the ASA to the object-group user.

  Note When including an object-group within a object-group user object, the ASA does not expand the object-group in access groups even when you enable ACL optimization. The output of the **show object-group** command does not display the hit count, which is available only for regular network object-group when ACL optimization is enabled.

- **Description**—adds a description for the object-group user.

Examples

The following example shows how to use the **user** command with the **user-group object** command to add a user in a user group object for use with the Identity Firewall feature:

```
hostname(config)# object-group user sampleuser1-group
hostname(config-object-group user)# description group members of sampleuser1-group
hostname(config-object-group user)# user-group CSCO\\group.sampleusers-all
hostname(config-object-group user)# user CSCO\user2
hostname(config-object-group user)# exit
hostname(config)# object-group user sampleuser2-group
hostname(config-object-group user)# description group members of sampleuser2-group
hostname(config-object-group user)# group-object sampleuser1-group
hostname(config-object-group user)# user-group CSCO\\group.sampleusers-marketing
hostname(config-object-group user)# user CSCO\user3
```

Related Commands

Command	Description
description	Adds a description to the group created with the **object-group user** command.
group-object	Adds a locally defined object group to a user object group created with the **object-group user** command for use with the Identity Firewall feature.

Command	Description
object-group user	Creates an user group object for the Identity Firewall feature.
user-group	Adds a user group imported from Microsoft Active Directory to the group created with the **object-group user** command.
user-identity enable	Creates the Cisco Identify Firewall instance.

user-alert

To enable broadcast of an urgent message to all clientless SSL VPN users with currently active session, use the **user-alert** command in privileged EXEC mode. To disable the message, use the **no** form of this command.

user-alert *string cancel*

no user-alert

Syntax Description

string	An alpha-numeric.
cancel	Cancels pop-up browser window launch.

Defaults

No message.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

When you issue this command, end users see a pop-up browser window with the configured message. This command causes no change in the ASA configuration file.

Examples

The following example shows how to enable DAP trace debugging:

```
hostname # We will reboot the security appliance at 11:00 p.m. EST time. We apologize for
any inconvenience.
hostname #
```

user-authentication

To enable user authentication, use the **user-authentication enable** command in group-policy configuration mode. To disable user authentication, use the **user-authentication disable** command. To remove the user authentication attribute from the running configuration, use the **no** form of this command. This option allows inheritance of a value for user authentication from another group policy.

When enabled, user authentication requires that individual users behind a hardware client authenticate to gain access to the network across the tunnel.

user-authentication {**enable | disable**}

no user-authentication

Syntax Description

disable	Disables user authentication.
enable	Enables user authentication.

Defaults

User authentication is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Individual users authenticate according to the order of authentication servers that you configure.

If you require user authentication on the primary ASA, be sure to configure it on any backup servers as well.

Examples

The following example shows how to enable user authentication for the group policy named "FirstGroup":

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# user-authentication enable
```

Related Commands

Command	Description
ip-phone-bypass	Lets IP phones connect without undergoing user authentication. Secure unit authentication remains in effect.
leap-bypass	Lets LEAP packets from wireless devices behind a VPN client travel across a VPN tunnel prior to user authentication, when enabled. This lets workstations using Cisco wireless access point devices establish LEAP authentication. Then they authenticate again per user authentication.
secure-unit-authentication	Provides additional security by requiring the VPN client to authenticate with a username and password each time the client initiates a tunnel.
user-authentication-idle-timeout	Sets an idle timeout for individual users. If there is no communication activity on a user connection in the idle timeout period, the ASA terminates the connection.

user-authentication-idle-timeout

To set an idle timeout for individual users behind hardware clients, use the **user-authentication-idle-timeout** command in group-policy configuration mode. To delete the idle timeout value, use the **no** form of this command. This option allows inheritance of an idle timeout value from another group policy. To prevent inheriting an idle timeout value, use the **user-authentication-idle-timeout none** command.

If there is no communication activity by a user behind a hardware client in the idle timeout period, the ASA terminates the connection.

user-authentication-idle-timeout {*minutes* | **none**}

no user-authentication-idle-timeout

Syntax Description

minutes	Specifies the number of minutes in the idle timeout period. The range is from 1 through 35791394 minutes
none	Permits an unlimited idle timeout period. Sets idle timeout with a null value, thereby disallowing an idle timeout. Prevents inheriting an user authentication idle timeout value from a default or specified group policy.

Defaults

30 minutes.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The minimum is 1 minute, the default is 30 minutes, and the maximum is 10,080 minutes.

This timer terminates only the client's access through the VPN tunnel, not the VPN tunnel itself.

The idle timeout indicated in response to the **show uauth** command is always the idle timeout value of the user who authenticated the tunnel on the Cisco Easy VPN remote device.

Examples

The following example shows how to set an idle timeout value of 45 minutes for the group policy named "FirstGroup":

```
hostname(config)# group-policy FirstGroup attributes
```

```
hostname(config-group-policy)# user-authentication-idle-timeout 45
```

Related Commands

Command	Description
user-authentication	Requires users behind hardware clients to identify themselves to the ASA before connecting.

user-group

To add a user group imported from Microsoft Active Directory to the group created with the **object-group user** command for use with the Identity Firewall feature, use the **user-group** command in the **user-group object** configuration mode. Use the **no** form of this command to remove the user group from the object.

user-group [*domain_nickname*\]*user_group_name*

[no] user-group [*domain_nickname*\]*user_group_name*

Syntax Description

domain_nickname	(Optional) Specifies the domain in which to create the user group.
user_group_name	Specifies the name for the user group. The group name can contain any character including [a-z], [A-Z], [0-9], [!@#$%^&()-_{}.]. If the group name contains a space, you must enclose the name in quotation marks.

Defaults

If you do not specify the *domain_nickname* argument, the user group is created in the LOCAL domain configured for the Identity Firewall feature.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Object-group user configuration	•	•	•	•	—

Command History

Release	Modification
8.4(2)	This command was introduced.

Usage Guidelines

The ASA sends an LDAP query to the Active Directory server for user groups globally defined in the Active Directory domain controller. The ASA imports these groups for the Identity Firewall feature. However, the ASA might have localized network resources that are not defined globally that require local user groups with localized security policies. Local user groups can contain nested groups and user groups that are imported from Active Directory. The ASA consolidates local and Active Directory groups. A user can belong to local user groups and user groups imported from Active Directory.

The ASA supports up to 256 user groups (including imported user groups and local user groups).

You activate user group objects by including them within an access group, capture, or service policy.

Within a user group object, you can define the following object types:

- **User**—Adds a single user to the object-group user. The user can be either a LOCAL user or imported user.

The name of an imported user must be the sAMAccountName, which is unique, rather than the common name (cn), which might not be unique. However, some Active Directory server administrators might require that the sAMAccountName and the cn be identical. In this case, the cn that the ASA displays in the output of the **show user-identity ad-group-member** command can be used for imported users defined by the user object.

- **User-group**—Adds an imported user group, which is defined by an external directory server, such as Microsoft Active Directory server, to the group-object user.

  The group name of the user group must be the sAMAccountName, which is unique, rather than the cn, which might not be unique. However, some Active Directory server administrators might require that the sAMAccountName and the cn be identical. In this case, the cn that the ASA displays in the output of the **show user-identity ad-group-member** command can be used in the *user_group_name* argument specified with the **user-group** keyword.

  Note You can add *domain_nickname**user_group_name* or *domain_nickname**user_ name* directly within a user group object without specifying them in the object first. If the *domain_nickname* is associated with a AAA server, the ASA imports the detailed nested user groups and the users defined in the external directory server, such as the Microsoft Active Directory server, to the ASA when the user object group is activated.

- **Group-object**—Adds a group defined locally on the ASA to the object group user.

  Note When including an object group within a object group user object, the ASA does not expand the object group in access groups even when you enable ACL optimization. The output of the **show object-group** command does not display the hit count, which is available only for a regular network object group when ACL optimization is enabled.

- **Description**—Adds a description for the object group user.

Examples

The following example shows how to use the **user-group** command with the **user-group object** command to add a user group in a user group object for use with the Identity Firewall feature:

```
hostname(config)# object-group user sampleuser1-group
hostname(config-object-group user)# description group members of sampleuser1-group
hostname(config-object-group user)# user-group CSCO\\group.sampleusers-all
hostname(config-object-group user)# user CSCO\user2
hostname(config-object-group user)# exit
hostname(config)# object-group user sampleuser2-group
hostname(config-object-group user)# description group members of sampleuser2-group
hostname(config-object-group user)# group-object sampleuser1-group
hostname(config-object-group user)# user-group CSCO\\group.sampleusers-marketing
hostname(config-object-group user)# user CSCO\user3
```

Related Commands

Command	Description
description	Adds a description to the group created with the **object-group user** command.
group-object	Adds a locally defined object group to a user object group created with the **object-group user** command for use with the Identity Firewall feature.

Command	Description
object-group user	Creates a user group object for the Identity Firewall feature.
user	Adds a user to the object group created with the **object-group user** command.
user-identity enable	Creates the Cisco Identify Firewall instance.

user-identity action ad-agent-down

To set the action for the Cisco Identify Firewall instance when the Active Directory Agent is unresponsive, use the **user-identity action ad-agent-down** command in global configuration mode. To remove this action for the Identity Firewall instance, use the **no** form of this command.

user-identity action ad-agent-down disable-user-identity-rule

no user-identity action ad-agent-down disable-user-identity-rule

Syntax Description

This command has no arguments or keywords.

Defaults

By default, this command is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

Specifies the action when the AD Agent is not responding.

When the AD Agent is down and the **user-identity action ad-agent-down** command is configured, the ASA disables the user identity rules associated with the users in that domain. Additionally, the status of all user IP addresses in that domain are marked as disabled in the output displayed by the **show user-identity user** command.

Examples

The following example shows how to enable this action for the Identity Firewall:

```
hostname(config)# user-identity action ad-agent-down disable-user-identity-rule
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.

user-identity action domain-controller-down

To set the action for the Cisco Identify Firewall instance when the Active Directory domain controller is down, use the **user-identity action domain-controller-down** command in global configuration mode. To remove the action, use the **no** form of this command.

user-identity action domain-controller-down *domain_nickname* **disable-user-identity-rule**

no user-identity action domain-controller-down *domain_nickname* **disable-user-identity-rule**

Syntax Description

domain_nickname	Specifies the domain name for the Identity Firewall.

Defaults

By default, this command is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

Specifies the action when the domain is down because Active Directory domain controller is not responding.

When the domain is down and the **disable-user-identity-rule** keyword is configured, the ASA disables the user identity-IP address mapping for that domain. Additionally, the status of all user IP addresses in that domain are marked as disabled in the output displayed by the **show user-identity user** command.

Examples

The following example shows how to configure this action for the Identity Firewall:

```
hostname(config)# user-identity action domain-controller-down SAMPLE
disable-user-identity-rule
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.

user-identity action mac-address-mismatch

To set the action for the Cisco Identify Firewall instance when a user's MAC address is found to be inconsistent with the ASA device IP address, use the **user-identity action mac-address mismatch** command in global configuration mode. To remove the action, use the **no** form of this command.

user-identity action mac-address mismatch remove-user-ip

no user-identity action mac-address mismatch remove-user-ip

Syntax Description

This command has no arguments or keywords.

Defaults

By default, the ASA uses **remove-user-ip** when this command is specified.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

Specifies the action when a user's MAC address is found to be inconsistent with the ASA device IP address currently mapped to that MAC address. The action is to disable the effect of user identity rules.

When the **user-identity action mac-address-mismatch** command is configured, the ASA removes the user identity-IP address mapping for that client.

Examples

The following example shows how to configure the Identity Firewall:

```
hostname(config)# user-identity action mac-address-mismatch remove-user-ip
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.

user-identity action netbios-response-fail

To set the action when a client does not respond to a NetBIOS probe for the Cisco Identify Firewall instance, use the **user-identity action netbios-response-fail** command in global configuration mode. To remove the action, use the **no** form of this command.

user-identity action netbios-response-fail remove-user-ip

no user-identity action netbios-response-fail remove-user-ip

Syntax Description

This command has no arguments or keywords.

Defaults

By default, this command is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

Specifies the action when a client does not respond to a NetBIOS probe. For example, the network connection might be blocked to that client or the client is not active.

When the **user-identity action remove-user-ip** command is configured, the ASA removed the user identity-IP address mapping for that client.

Examples

The following example shows how to configure the Identity Firewall:

```
hostname(config)# user-identity action netbios-response-fail remove-user-ip
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.

user-identity ad-agent aaa-server

To define the server group of the AD Agent for the Cisco Identify Firewall instance, use the **user-identity ad-agent aaa-server** command in AAA server host configuration mode. To remove the action, use the **no** form of this command.

user-identity user-identity ad-agent aaa-server *aaa_server_group_tag*

no user-identity user-identity ad-agent aaa-server *aaa_server_group_tag*

Syntax Description

aaa_server_group_tag	Specifies the AAA server group associated with the Identity Firewall.

Defaults

This command has no defaults.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa server host configuration	•	•	•	—	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

The first server defined in *aaa_server_group_tag* variable is the primary AD Agent and the second server defined is the secondary AD Agent.

The Identity Firewall supports defining only two AD Agent hosts.

When the ASA detects that the primary AD Agent is down and a secondary agent is specified, it switches to secondary AD Agent. The AAA server for the AD agent uses RADIUS as the communication protocol, and should specify the key attribute for the shared secret between the ASA and AD Agent.

Examples

The following example shows how to define the AD Agent AAA server host for the Identity Firewall:

```
hostname(config-aaa-server-hostkey)# user-identity ad-agent aaa-server adagent
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.

user-identity ad-agent active-user-database

To define how the ASA retrieves the user identity-IP address mapping information from the AD Agent for the Cisco Identify Firewall instance, use the **user-identity action netbios-response-fail** command in global configuration mode. To remove the configuration, use the **no** form of this command.

user-identity ad-agent active-user-database {**on-demand**|**full-download**}

no user-identity ad-agent active-user-database {**on-demand**|**full-download**}

Syntax Description

This command has no arguments or keywords.

Defaults

By default, the ASA 5505 uses the on-demand option. The other ASA platforms use the full-download option.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

Defines how the ASA retrieves the user identity-IP address mapping information from the AD Agent:

- **full-download**—Specifies that the ASA send a request to the AD Agent to download the entire IP-user mapping table when the ASA starts and then to receive incremental IP-user mapping when users log in and log out.
- **on-demand**—Specifies that the ASA retrieve the user mapping information of an IP address from the AD Agent when the ASA receives a packet that requires a new connection, and the user of its source IP address is not in the user-identity database.

By default, the ASA 5505 uses the on-demand option. The other ASA platforms use the full-download option.

Full downloads are event driven, meaning that subsequent requests to download the database, send just the updates to the user identity-IP address mapping database.

When the ASA registers a change request with the AD Agent, the AD Agent sends a new event to the ASA.

Examples

The following example shows how to configure this option for the Identity Firewall:

```
hostname(config)# user-identity ad-agent active-user-database full-download
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.

user-identity ad-agent hello-timer

To define the timer between the ASA and the AD Agent for the Cisco Identify Firewall instance, use the **user-identity ad-agent hello-timer** command in global configuration mode. To remove the configuration, use the **no** form of this command.

user-identity ad-agent hello-timer seconds *seconds* **retry-times** *number*

no user-identity ad-agent hello-timer seconds *seconds* **retry-times** *number*

Syntax Description

number	Specifies the number of times to retry the timer.
seconds	Specifies the length of time for the timer.

Defaults

By default, the hello timer is set to 30 seconds and 5 retries.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

Defines the hello timer between the ASA and the AD Agent.

The hello timer between the ASA and the AD Agent defines how frequently the ASA exchanges hello packets. The ASA uses the hello packet to obtain ASA replication status (in-sync or out-of-sync) and domain status (up or down). If the ASA does not receive a response from the AD Agent, it resends a hello packet after the specified interval.

By default, the hello timer is set to 30 seconds and 5 retries.

Examples

The following example shows how to configure this option for the Identity Firewall:

```
hostname(config)# user-identity ad-agent hello-timer seconds 20 retry-times 3
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.

user-identity default-domain

To specify the default domain for the Cisco Identify Firewall instance, use the **user-identity default-domain** command in global configuration mode. To remove the default domain, use the **no** form of this command.

user-identity default-domain *domain_NetBIOS_name*

no user-identity default-domain *domain_NetBIOS_name*

Syntax Description

domain_NetBIOS_name	Specifies the default domain for the Identity Firewall.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

For *domain_NetBIOS_name,* enter a name up to 32 characters consisting of [a-z], [A-Z], [0-9], [!@#$%^&()-_=+[]{};,.] except '.' and ' ' at the first character. If the domain name contains a space, enclose the entire name in quotation marks. The domain name is not case sensitive.

The default domain is used for all users and user groups when a domain has not been explicitly configured for those users or groups. When a default domain is not specified, the default domain for users and groups is LOCAL. For multiple context mode, you can set a default domain name for each context, as well as within the system execution space.

Note The default domain name you specify must match the NetBIOS domain name configured on the Active Directory domain controller. If the domain name does not match, the AD Agent will incorrectly associate the user identity-IP address mapping with the domain name that you enter when configuring the ASA. To view the NetBIOS domain name, open the Active Directory user event security log in any text editor.

The Identity Firewall uses the LOCAL domain for all locally defined user groups or locally defined users. Users logging in through a web portal (cut-through proxy) are designated as belonging to the Active Directory domain with which they authenticated. Users logging in through a VPN are designated as belonging to the LOCAL domain unless the VPN is authenticated by LDAP with Active Directory, so that the Identity Firewall can associate the users with their Active Directory domain.

Examples

The following example shows how to configure the default domain for the Identity Firewall:

```
hostname(config)# user-identity default-domain SAMPLE
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.

user-identity domain

To associate the domain for the Cisco Identify Firewall instance, use the **user-identity domain** command in global configuration mode. To remove the domain association, use the **no** form of this command.

user-identity domain *domain_nickname* **aaa-server** *aaa_server_group_tag*

no user-identity *domain_nickname* **aaa-server** *aaa_server_group_tag*

Syntax Description

domain_nickname	Specifies the domain name for the Identity Firewall.
aaa_server_group_tag	Specifies the AAA server group associated with the Identity Firewall.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

Associates the LDAP parameters defined for the AAA server for importing user group queries with the domain name.

For *domain_nickname,* enter a name up to 32 characters consisting of [a-z], [A-Z], [0-9], [!@#$%^&()-_=+[]{};,.] except '.' and ' ' at the first character. If the domain name contains a space, you must enclose that space character in quotation marks. The domain name is not case sensitive.

Examples

The following example shows how to associate the domain for the Identity Firewall:

```
hostname(config)# user-identity domain SAMPLE aaa-server ds
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.

user-identity enable

To create the Cisco Identify Firewall instance, use the **user-identity enable** command in global configuration mode. To disable the Identity Firewall instance, use the **no** form of this command.

user-identity enable

no user-identity enable

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

No usage guidelines.

Examples

The following example shows how to enable the Identity Firewall:

```
hostname(config)# user-identity enable
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.

user-identity inactive-user-timer

To specify the amount of time before a user is considered idle for the Cisco Identify Firewall instance, use the **user-identity inactive-user-timer** command in global configuration mode. To remove the timer, use the **no** form of this command.

user-identity inactive-user-timer minutes *minutes*

no user-identity inactive-user-timer minutes *minutes*

Syntax Description

minutes	Specifies the amount of time in minutes before a user is considered idle, meaning the ASA has not received traffic from the user's IP address for the specified amount of time.

Defaults

By default, the idle timeout is set to 60 minutes.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

When the timer expires, the user's IP address is marked as inactive and removed from the local cached user identity-IP address mapping database and the ASA no longer notifies the AD Agent about that IP address removal. Existing traffic is still allowed to pass. When this command is specified, the ASA runs an inactive timer even when the NetBIOS Logout Probe is configured.

Note The Idle Timeout option does not apply to VPN or cut-through-proxy users.

Examples

The following example shows how to configure the Identity Firewall:

```
hostname(config)# user-identity inactive-user-timer minutes 120
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.

user-identity logout-probe

To enable NetBIOS probing for the Cisco Identify Firewall instance, use the **user-identity logout-probe** command in global configuration mode. To remove the disable probing, use the **no** form of this command.

user-identity logout-probe netbios local-system probe-time minutes *minutes* **retry-interval seconds** *seconds* **retry-count** *times* [**user-not-needed | match-any | exact-match**]

no user-identity logout-probe netbios local-system probe-time minutes *minutes* **retry-interval seconds** *seconds* **retry-count** *times* [**user-not-needed | match-any | exact-match**]

Syntax Description

minutes	Specifies the number of minutes between probes.
seconds	Specifies the length of time for the retry interval.
times	Specifies the number of times to retry the probe.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

To minimize the NetBIOS packets, the ASA only sends a NetBIOS probe to a client when the user has been idle for more than the specified number of minutes.

Set the NetBIOS probe timer from1 to 65535 minutes and the retry interval from 1 to 256 retries. Specify the number of times to retry the probe:

- **match-any**—As long as the NetBIOS response from the client contains the user name of the user assigned to the IP address, the user identity is be considered valid. Specifying this option requires that the client enabled the Messenger service and configured a WINS server.
- **exact-match**—The user name of the user assigned to the IP address must be the only one in the NetBIOS response. Otherwise, the user identity of that IP address is considered invalid. Specifying this option requires that the client enabled the Messenger service and configured a WINS server.
- **user-not-needed**—As long as the ASA received a NetBIOS response from the client the user identity is considered valid.

The Identity Firewall only performs NetBIOS probing for those users identities that are in the active state and exist in at least one security policy. The ASA does not perform NetBIOS probing for clients where the users logged in through cut-through proxy or by using VPN.

Examples

The following example shows how to configure the Identity Firewall:

```
hostname(config)# user-identity logout-probe netbios local-system probe-time minutes 10
retry-interval seconds 10 retry-count 2 user-not-needed
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.

user-identity monitor

For Cloud Web Security, to download the specified user or group information from the AD agent, use the user-identity monitor command in global configuration mode. To stop monitoring, use the **no** form of this command.

user-identity monitor {**user-group** [*domain-name*\\]*group-name* | **object-group-user** *object-group-name*}

no user-identity monitor {**user-group** [*domain-name*\\]*group-name* | **object-group-user** *object-group-name*}

Syntax Description

user-group [*domain-name*\\] *group-name*	Specifies a group name inline. Although you specify 2 backslashes (\\) between the domain and the group, the ASA modifies the name to include only one backslash when it sends it to Cloud Web Security, to comply with Cloud Web Security notation conventions.
object-group-user *object-group-name*	Specifies an **object-group user** name. This group can include multiple groups.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

When you use the Identity Firewall feature, the ASA only downloads user identity information from the AD server for users and groups included in active ACLs; the ACL must be used in a feature such as an access rule, AAA rule, service policy rule, or other feature to be considered active. Because Cloud Web Security can base its policy on user identity, you may need to download groups that are not part of an active ACL to get full Identity Firewall coverage for all your users. For example, although you can configure your Cloud Web Security service policy rule to use an ACL with users and groups, thus activating any relevant groups, it is not required; you could use an ACL based entirely on IP addresses. The user identity monitor feature lets you download group information directly from the AD Agent.

The ASA can only monitor a maximum of 512 groups, including those configured for the user identity monitor and those monitored through active ACLs.

Examples

The following example monitors the CISCO\\Engineering usergroup:

```
hostname(config)# user-identity monitor user-group CISCO\\Engineering
```

Related Commands

Command	Description
class-map type inspect scansafe	Creates an inspection class map for whitelisted users and groups.
default user group	Specifies the default username and/or group if the ASA cannot determine the identity of the user coming into the ASA.
http[**s**] (parameters)	Specifies the service type for the inspection policy map, either HTTP or HTTPS.
inspect scansafe	Enables Cloud Web Security inspection on the traffic in a class.
license	Configures the authentication key that the ASA sends to the Cloud Web Security proxy servers to indicate from which organization the request comes.
match user group	Matches a user or group for a whitelist.
policy-map type inspect scansafe	Creates an inspection policy map so you can configure essential parameters for the rule and also optionally identify the whitelist.
retry-count	Enters the retry counter value, which is the amount of time that the ASA waits before polling the Cloud Web Security proxy server to check its availability.
scansafe	In multiple context mode, allows Cloud Web Security per context.
scansafe general-options	Configures general Cloud Web Security server options.
server {**primary** | **backup**}	Configures the fully qualified domain name or IP address of the primary or backup Cloud Web Security proxy servers.
show conn scansafe	Shows all Cloud Web Security connections, as noted by the capitol Z flag.
show scansafe server	Shows the status of the server, whether it's the current active server, the backup server, or unreachable.
show scansafe statistics	Shows total and current HTTP connections.
whitelist	Performs the whitelist action on the class of traffic.

user-identity poll-import-user-group-timer

To specify the amount of time before the ASA queries the Active Directory server for user group information for the Cisco Identify Firewall instance, use the **user-identity poll-import-user-group-timer** command in global configuration mode. To remove the timer, use the **no** form of this command.

user-identity poll-import-user-group-timer hours *hours*

no user-identity poll-import-user-group-timer hours *hours*

Syntax Description

hours	Sets the hours for the poll timer.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

Specifies the amount of time before the ASA queries the Active Directory server for user group information.

If a user is added to or deleted from to an Active Directory group, the ASA received the updated user group after import group timer runs.

By default, the poll timer is 8 hours.

To immediately update user group information, enter the **user-identity update import-user** command:

Examples

The following example shows how to configure the Identity Firewall:

```
hostname(config)# user-identity poll-import-user-group-timer hours 1
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.

user-identity static user

To create a new user-IP address mapping or set a user's IP address to inactive for the Cisco Identify Firewall feature, use the **user-identity static user** command in global configuration mode. To remove this configuration for the Identity Firewall, use the **no** form of this command.

user-identity static user [*domain*\] *user_name host_ip*

no user-identity static user [*domain*\] *user_name host_ip*

Syntax Description

domain	Creates a new user-IP address mapping or sets the IP address to inactive for the user in the specified domain.
host_ip	Specifies the IP address of the user for which to create a new user-IP address mapping or to set as inactive.
user_name	Specifies the user name for which to create a new user-IP address mapping or the user or sets the users IP address to inactive.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

There are no usage guidelines for this command.

Examples

The following example shows how to enable this action for the Identity Firewall:

```
hostname(config)# user-identity static user SAMPLE\user1 192.168.1.101
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.

user-identity update active-user-database

To download the entire active-user database from the Active Directory Agent, use the **user-identity update active-user-database** command in global configuration mode.

user-identity update active-user-database [**timeout minutes** *minutes*]

Syntax Description

minutes	Specifies the number of minutes for the timeout.

Defaults

The default timeout is 5 minutes.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

This command downloads the entire active-user database from Active Directory Agent.

This command starts the update operation, generates a starting update log and returns immediately. When the update operation finishes or is aborted at timer expiration, another syslog message is generated. Only one outstanding update operation is allowed. Rerunning the command displays an error message.

When the command finishes running, the ASA displays [Done] at the command prompt then generates a syslog message.

Examples

The following example shows how to enable this action for the Identity Firewall:

```
hostname# user-identity update active-user-database
ERROR: one update active-user-database operation is already in progress
[Done] user-identity update active-user-database
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.

user-identity update import-user

To download the entire active user database from the Active Directory Agent, use the **user-identity update active-user-database** command in global configuration mode.

user-identity update import-user [[*domain_nickname*\\] *user_group_name* [**timeout seconds** *seconds*]]

Syntax Description

domain_nickname	Specifies the domain of the group to update.
seconds	Specifies the number of seconds for the timeout.
user_group_name	When *user_group_name* is specified, only the specified import-user group is updated. Only activated groups (for example, groups in an access group, access list, capture, or service policy) can be updated. If the given group is not activated, this command rejects the operation. If the specified group has multiple levels of hierarchies, recursive LDAP queries are conducted. If *user_group_name* is not specified, the ASA starts the LDAP update service immediately and tries to periodically update all activated groups.

Defaults

The ASA retries the update up to 5 times and generates warning messages as necessary.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

This command updates the specified import user group database by querying the Active Directory server immediately without waiting for the expiration of the poll import user group timer. There is no command to update the local user group, because the group ID database is updated whenever the local user group has a configuration change.

This command does not block the console to wait for the return of the LDAP query.

This command starts the update operation, generates a starting update log and returns immediately. When the update operation finishes or is aborted at timer expiration, another syslog message is generated. Only one outstanding update operation is allowed. Rerunning the command displays an error message.

If the LDAP query is successful, the ASA stores retrieved user data in the local database and changes the user/group association accordingly. If the update operation is successful, you can run the **show user-identity user-of-group** *domain**group* command to list all stored users under this group.

The ASA checks after each update for all imported groups. If an activated Active Directory group does not exist in Active Directory, the ASA generates a syslog message.

If *user_group_name* is not specified, the ASA starts the LDAP update service immediately and tries to periodically update all activated groups. The LDAP update service runs in the background and periodically updates import user groups via an LDAP query on the Active Directory server.

At system boot up time, if there are import user groups defined in access groups, the ASA retrieves user/group data via LDAP queries. If errors occur during the update, the ASA retries the update up to 5 times and generates warning messages as necessary.

When the command finishes running, the ASA displays [Done] at the command prompt then generates a syslog message.

Examples

The following example shows how to enable this action for the Identity Firewall:

```
hostname# user-identity update import-user group.sample-group1
ERROR: Update import-user group is already in progress
[Done] user-identity update import-user group.sample-group1
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.

user-identity user-not-found

To enable user-not-found tracking for the Cisco Identify Firewall instance, use the **user-identity user-not-found** command in global configuration mode. To remove this tracking for the Identity Firewall instance, use the **no** form of this command.

user-identity user-not-found enable

no user-identity user-not-found enable

Syntax Description

This command has no arguments or keywords.

Defaults

By default, this command is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

Only the last 1024 IP addresses are tracked.

Examples

The following example shows how to enable this action for the Identity Firewall:

```
hostname(config)# user-identity user-not-found enable
```

Related Commands

Command	Description
clear configure user-identity	Clears the configuration for the Identity Firewall feature.

user-message

To specify a text message to display when a DAP record is selected, use the user-message command in dynamic-access-policy-record mode. To remove this message, use the **no** version of the command. If you use the command more than once for the same DAP record, the newer message replaces the previous message.

user-message *message*

no user-message

Syntax Description

message	The message for users assigned to this DAP record. Maximum 128 characters. If the message contains spaces, enclose it in double quotation marks.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Dynamic-access-policy- record	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

For a successful SSL VPN connection, the portal page displays a flashing, clickable icon that lets the user see the message(s) associated with the connection. If the connection is terminated from a DAP policy (action = terminate), and if there is a user message configured in that DAP record, then that message displays on the login screen.

If more than one DAP record applies to a connection, the ASA combines the applicable user messages and displays them as a single string.

Examples

The following example shows how to set a user message of “Hello Money Managers” for the DAP record called Finance.

```
hostname (config) config-dynamic-access-policy-record Finance
hostname(config-dynamic-access-policy-record)# user-message “Hello Money Managers”
hostname(config-dynamic-access-policy-record)#
```

Related Commands

Command	Description
dynamic-access-policy-record	Creates a DAP record.
show running-config dynamic-access-policy-record [*name*]	Displays the running configuration for all DAP records, or for the named DAP record.

user-parameter

To specify the name of the HTTP POST request parameter in which a username must be submitted for SSO authentication, use the **user-parameter** command in aaa-server-host configuration mode.

user-parameter *name*

Note To configure SSO with the HTTP protocol correctly, you must have a thorough working knowledge of authentication and HTTP protocol exchanges.

Syntax Description

string	The name of the username parameter included in the HTTP POST request. The maximum name size is 128 characters.

Defaults

There is no default value or behavior.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server-host configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

This is an SSO with HTTP Forms command. The WebVPN server of the ASA uses an HTTP POST request to submit a single sign-on authentication request to an SSO server. The required command **user-parameter** specifies that the HTTP POST request must include a username parameter for SSO authentication.

Note At login, the user enters the actual name value which is entered into the HTTP POST request and passed on to the authenticating web server.

Examples

The following example, entered in aaa-server-host configuration mode, specifies that the username parameter userid be included in the HTTP POST request used for SSO authentication:

```
hostname(config)# aaa-server testgrp1 host example.com
hostname(config-aaa-server-host)# user-parameter userid
hostname(config-aaa-server-host)#
```

Related Commands

Command	Description
action-uri	Specifies a web server URI to receive a username and password for single sign-on authentication.
auth-cookie-name	Specifies a name for the authentication cookie.
hidden-parameter	Creates hidden parameters for exchange with the authenticating web server.
password-parameter	Specifies the name of the HTTP POST request parameter in which a user password must be submitted for SSO authentication.
start-url	Specifies the URL at which to retrieve a pre-login cookie.

user-statistics

To activate the collection of user statistics by MPF and match lookup actions for the Identify Firewall, use the **user-statistics** command in policy-map configuration mode. To remove collection of user statistics, use the **no** form of this command.

user-statistics [**accounting | scanning**]

no user-statistics [**accounting | scanning**]

Syntax Description

accounting	(Optional) Specifies that the ASA collect the sent packet count, sent drop count, and received packet count.
scanning	(Optional) Specifies that the ASA collect only the sent drop count.

Defaults

By default, this command is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Policy-map configuration	•	•	•	•	—

Command History

Release	Modification
8.4(2)	The command was introduced.

Usage Guidelines

When you configure a policy map to collect user statistics, the ASA collects detailed statistics for selected users. When you specify the **user-statistics** command without the **accounting** or **scanning** keywords, the ASA collects both accounting and scanning statistics.

Examples

The following example shows how to activate user statistics for the Identity Firewall:

```
hostname(config)# class-map c-identity-example-1
hostname(config-cmap)# match access-list identity-example-1
hostname(config-cmap)# exit
hostname(config)# policy-map p-identity-example-1
hostname(config-pmap)# class c-identity-example-1
hostname(config-pmap)# user-statistics accounting
hostname(config-pmap)# exit
hostname(config)# service-policy p-identity-example-1 interface outside
```

Related Commands

Command	Description
policy-map	Assigns actions to traffic that you identified with a Layer 3/4 class map when using the Modular Policy Framework.
service-policy(**global**)	Activates a policy map globally on all interfaces or on a targeted interface.
show service-policy [**user-statistics**]	Displays user statistics for configured service policies when you enable user-statistics scanning or accounting for the Identity Firewall.
show user-identity ip-of-user [**detail**]	Displays received packets, sent packets, and drops statistics for the IP address for a specified user when you enable user statistics scanning or accounting for the Identity Firewall.
show user-identity user active [**detail**]	Displays received packets, sent packets and drops statistics in the specified time period for active users when you enable user statistics scanning or accounting for the Identity Firewall.
show user-identity user-of-ip [**detail**]	Displays received packets, sent packets, and drops statistics for the user for a specified IP address when you enable user statistics scanning or accounting for the Identity Firewall.
user-identity enable	Creates the Identity Firewall instance.

user-storage

To store personalized user information between clientless SSL VPN sessions, use the **user storage** command in group-policy webvpn configuration mode. To disable user storage, use the **no** form of the command.

user-storage *NETFS-location*

no user-storage]

Syntax Description

NETFS-location	Specifies a file system desination in the form proto://user:password@host:port/path If the username and password are embedded in the NETFS-location then the password input is treated as clear.

Defaults

User storage is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy webvpn mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.
8.4(6)	Prevented the password being shown in clear text during **show-run**.

Usage Guidelines

User-storage enables you to store cached credentials and cookies at a location other than the ASA flash. This command provides single sign on for personal bookmarks of a clientless SSL VPN user. The user credentials are stored in an encrypted format on the FTP/CIFS/SMB server as a <user_id>.cps file that is not decryptable.

Although the username, password, and preshared key are shown in the configuration, this poses no security risk because the ASA stores this information in encrypted form, using an internal algorithm.

If data is encrypted on an external FTP or SMB server, you can define personal bookmarks within the portal page by selecting add bookmark (for example: user-storage cifs://jdoe:test@10.130.60.49/SharedDocs). You can create personalized URLs for all plugin protocols as well.

Note If you have a cluster of ASAs that all refer to the same FTP/CIFS/SMB server and use the same "storage-key," you can access the bookmarks through any of the ASAs in the cluster.

Examples

The following example shows how to set user storage for a user called newuser with a password of 12345678 at a file share called anyshare, and a path of anyfiler02a/new_share:

```
hostname(config)# wgroup-policy DFLTGrpPolicy attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# user-storage cifs://newuser:12345678@anyfiler02a/new_share
hostname(config-group_webvpn)#
```

Related Commands

Command	Description
storage-key	Specifies a storage key to protect the data stored between sessions.
storage-objects	Configures storage objects for the data stored between sessions.

username (8.4(3) and earlier)

To add a user to the ASA database, enter the **username** command in global configuration mode. To remove a user, use the **no** version of this command with the username that you want to remove. To remove all usernames, use the **no** version of this command without appending a username.

username *name* {**nopassword** | **password** *password* [**mschap** | **encrypted** | **nt-encrypted**]} [**privilege** *priv_level*]

no username *name*

Syntax Description

encrypted	Indicates that the password is encrypted (if you did not specify **mschap**). When you define a password in the **username** command, the ASA encrypts it when it saves it to the configuration for security purposes. When you enter the **show running-config** command, the **username** command does not show the actual password; it shows the encrypted password followed by the **encrypted** keword. For example, if you enter the password "test," the **show running-config** command output would appear to be something like the following: `username pat password rvEdRh0xPC8bel7s encrypted` The only time you would actually enter the **encrypted** keyword at the CLI is if you are cutting and pasting a configuration to another ASA and you are using the same password.
mschap	Specifies that the password will be converted to unicode and hashed using MD4 after you enter it. Use this keyword if users are authenticated using MSCHAPv1 or MSCHAPv2.
name	Specifies the name of the user as a string from 4 to 64 characters in length.
nopassword	Indicates that this user needs no password.
nt-encrypted	Indicates that the password is encrypted for use with MSCHAPv1 or MSCHAPv2. If you specified the **mschap** keyword when you added the user, then this keyword is displayed instead of the **encrypted** keyword when you view the configuration using the **show running-config** command. When you define a password in the **username** command, the ASA encrypts it when it saves it to the configuration for security purposes. When you enter the **show running-config** command, the **username** command does not show the actual password; it shows the encrypted password followed by the **nt-encrypted** keword. For example, if you enter the password "test," the **show running-config** display would appear to be something like the following: `username pat password DLaUiAX3l78qgoB5c7iVNw== nt-encrypted` The only time you would actually enter the **nt-encrypted** keyword at the CLI is if you are cutting and pasting a configuration to another ASA and you are using the same password.
password *password*	Sets the password as a string from 3 to 32 characters in length.
privilege *priv_level*	Sets a privilege level for this use from 0 to 15 (lowest to highest). The default privilege level is 2. This privilege level is used with command authorization.

Defaults

The default privilege level is 2.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0.1	This command was introduced.
7.2(1)	The **mschap** and **nt-encrypted** keywords were added.

Usage Guidelines

The **login** command uses this database for authentication.

If you add users to the local database who can gain access to the CLI and whom you do not want to enter privileged mode, you should enable command authorization. (See the **aaa authorization command** command.) Without command authorization, users can access privileged EXEC mode (and all commands) at the CLI using their own password if their privilege level is 2 or greater (2 is the default). Alternatively, you can use AAA authentication so the user will not be able to use the **login** command, or you can set all local users to level 1 so you can control who can use the **enable** password to access privileged EXEC mode.

By default, VPN users that you add with this command have no attributes or group policy association. You must configure all values explicitly using the **username attributes** command.

When password authentication policy is enabled, you can no longer change your own password or delete your own account with the **username** command. You can, however, change your password with the **change-password** command.

Examples

The following example shows how to configure a user named “anyuser” with a password of 12345678 and a privilege level of 12:

```
hostname(config)# username anyuser password 12345678 privilege 12
```

Related Commands

Command	Description
aaa authorization command	Configues command authorization.
clear config username	Clears the configuration for a specific user or all users.
show running-config username	Displays the running configuration for a specific user or all users.
username attributes	Enters username attributes mode, which lets you configure attributes for specific users.
webvpn	Enters config-group-webvpn mode, which lets you configure the WebVPN attributes for the specified group.

username (8.4(4.1) and later)

To add a user to the ASA database, enter the **username** command in global configuration mode. To remove a user, use the **no** version of this command with the username that you want to remove. To remove all usernames, use the **no** version of this command without appending a username. To enable the system to restore a password creation date at boot time or when copying a file to the running configuration, enter the **username** command in non-interactive configuration mode.

[no] username *name* {**nopassword** | **password** *password* [**mschap** | **encrypted** | **nt-encrypted**]} [**privilege** *priv_level*]

username *name* [**password-date** *date*]

Syntax Description

encrypted	Indicates that the password is encrypted (if you did not specify **mschap**). When you define a password in the **username** command, the ASA encrypts it when it saves it to the configuration for security purposes. When you enter the **show running-config** command, the **username** command does not show the actual password; it shows the encrypted password followed by the **encrypted** keword. For example, if you enter the password "test," the **show running-config** command output would appear to be something like the following: `username pat password rvEdRh0xPC8bel7s encrypted` The only time you would actually enter the **encrypted** keyword at the CLI is if you are cutting and pasting a configuration to another ASA and you are using the same password.
mschap	Specifies that the password will be converted to Unicode and hashed using MD4 after you enter it. Use this keyword if users are authenticated using MSCHAPv1 or MSCHAPv2.
name	Specifies the name of the user as a string from 4 to 64 characters in length.
nopassword	Indicates that this user needs no password.
nt-encrypted	Indicates that the password is encrypted for use with MSCHAPv1 or MSCHAPv2. If you specified the **mschap** keyword when you added the user, then this keyword is displayed instead of the **encrypted** keyword when you view the configuration using the **show running-config** command. When you define a password in the **username** command, the ASA encrypts it when it saves it to the configuration for security purposes. When you enter the **show running-config** command, the **username** command does not show the actual password; it shows the encrypted password followed by the **nt-encrypted** keword. For example, if you enter the password "test," the **show running-config** display would appear to be something like the following: `username pat password DLaUiAX3178qgoB5c7iVNw== nt-encrypted` The only time you would actually enter the **nt-encrypted** keyword at the CLI is if you are cutting and pasting a configuration to another ASA and you are using the same password.
password *password*	Sets the password as a string from 3 to 32 characters in length.

password-date *date*	Enables the system to restore password creation dates as usernames are read in during bootup. If not present, the password date is set to the current date. The date is in the format, mmm-dd-yyyy.
privilege *priv_level*	Sets a privilege level for this use from 0 to 15 (lowest to highest). The default privilege level is 2. This privilege level is used with command authorization.

Defaults

The default privilege level is 2.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—
Non-interactive configuration	•	•	•	•	—

Command History

Release	Modification
7.0.1	This command was introduced.
7.2(1)	The **mschap** and **nt-encrypted** keywords were added.
9.1(2)	The **password-date** *date* option was added.

Usage Guidelines

The **login** command uses this database for authentication.

If you add users to the local database who can gain access to the CLI and whom you do not want to enter privileged mode, you should enable command authorization. (See the **aaa authorization command** command.) Without command authorization, users can access privileged EXEC mode (and all commands) at the CLI using their own password if their privilege level is 2 or greater (2 is the default). Alternatively, you can use AAA authentication so the user will not be able to use the **login** command, or you can set all local users to level 1 so you can control who can use the **enable** password to access privileged EXEC mode.

By default, VPN users that you add with this command have no attributes or group policy association. You must configure all values explicitly using the **username attributes** command.

When password authentication policy is enabled, you can no longer change your own password or delete your own account with the **username** command. You can, however, change your password with the **change-password** command.

To display the username password date, use the **show running-config all username** command.

Note You cannot enter **password-date** values from a CLI prompt; therefore, no interactive help exists for this keyword. The password date is saved to the startup configuration only if the password policy lifetime is not zero. This means that password dates are saved only if password expiration is configured. You cannot use the **password-date** option to prevent users from changing password creation dates.

Examples

The following example shows how to configure a user named “anyuser” with a password of 12345678 and a privilege level of 12:

```
hostname(config)# username anyuser password 12345678 privilege 12
```

Related Commands

Command	Description
aaa authorization command	Configues command authorization.
clear config username	Clears the configuration for a particular user or for all users.
show running-config username	Displays the running configuration for a particular user or for all users.
username attributes	Enters username attributes mode, which lets you configure attributes for specific users.
webvpn	Enters config-group-webvpn mode, in which you can configure the WebVPN attributes for the specified group.

username attributes

To enter the username attributes mode, use the **username attributes** command in username configuration mode. To remove all attributes for a particular user, use the **no** form of this command and append the username. To remove all attributes for all users, use the **no** form of this command without appending a username. The attributes mode lets you configure attribute-value pairs for a specified user.

username {*name*} **attributes**

no username [*name*] **attributes**

Syntax Description

name	Provides the name of the user.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Username configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0(2)	The **service-type** attribute was added.
9.1(2)	The **ssh authentication** {**pkf** [**nointeractive**] | **publickey** *key* [**hashed**]} attribute was added.

Usage Guidelines

The internal user authentication database consists of the users entered with the **username** command. The **login** command uses this database for authentication. You can configure the username attributes using either the **username** command or the **username attributes** command.

The command syntax in username configuration mode has the following characteristics in common:

- The **no** form removes the attribute from the running configuration.
- The **none** keyword also removes the attribute from the running configuration. But it does so by setting the attribute to a null value, thereby preventing inheritance.
- Boolean attributes have explicit syntax for enabled and disabled settings.

The **username attributes** command enters username attributes mode, in which you can configure any of the following attributes:

Attribute	Function
group-lock	Names an existing tunnel group with which the user is required to connect.
password-storage	Enables or disables storage of the login password on the client system.
service-type [**remote-access** | **admin** | **nas-prompt**]	Restricts console login and enables login for users who are assigned the appropriate level. The **remote-access** option specifies basic AAA sevices for remote access. The **admin** option specifies AAA serives, login console privileges, EXEC mode privileges, the enable privilege, and CLI privileges. The **nas-prompt** option specifies AAA services, login console privileges, EXEC mode privileges, but no enable privileges.
ssh authentication {**pkf** [**nointeractive**] | **publickey** *key* [**hashed**]}	Enables public key authentication on a per-user basis. The value of the *key* argument can refer to the following: • When the *key* argument is supplied and the hashed tag is not specified, the value of the key must be a base64 encoded public key that is generated by SSH key generation software that can generate SSH-RSA raw keys (that is, with no certificates). After you submit the base64 encoded public key, that key is then hashed via SHA-256 and the corresponding 32-byte hash is used for all further comparisons. • When the *key* argument is supplied and the hashed tag is specified, the value of the key must have been previously hashed with SHA-256 and be 32 bytes long, with each byte separated by a colon (for parsing purposes). The **pkf** option enables you to authenticate using 4096-bit RSA keys as an SSH public key file (PKF). This option is not restricted to 4096-bit RSA keys, but can be used for any size less than or equal to 4096-bit RSA keys. The **nointeractive** option suppresses all prompts when importing an SSH public key formatted key. This noninteractive data entry mode is only intended for ASDM use. The *key* field and the **hashed** keyword are only available with the **publickey** option, and the **nointeractive** keyword is only available with the **pkf** option. When you save the configuration, the hashed key value is saved to the configuration and used when the ASA is rebooted. **Note** You can use the PKF option when failover is enabled, but the PKF data is not automatically replicated to the standby system. You must enter the **write standby** command to synchronize the PKF setting to the standby system in the failover pair.
vpn-access-hours	Specifies the name of a configured time-range policy.
vpn-filter	Specifies the name of a user-specific ACL.

Attribute	Function
vpn-framed-ip-address	Specifies the IP address and the netmask to be assigned to the client.
vpn-group-policy	Specifies the name of a group policy from which to inherit attributes.
vpn-idle-timeout [**alert-interval**]	Specifies the idle timeout period in minutes, or **none** to disable it. Optionally specifies a pre-timeout alert interval.
vpn-session-timeout [**alert-interval**]	Specifies the maximum user connection time in minutes, or **none** for unlimited time. Optionally specifies a pre-timeout alert interval.
vpn-simultaneous-logins	Specifies the maximum number of simultaneous logins allowed.
vpn-tunnel-protocol	Specifies permitted tunneling protocols.
webvpn	Enters username webvpn configuration mode, in which you configure WebVPN attributes.

You configure webvpn-mode attributes for the username by entering the **username attributes** command and then entering the **webvpn** command in username webvpn configuration mode. See the **webvpn** command (group-policy attributes and username attributes modes) for details.

Examples

The following example shows how to enter username attributes configuration mode for a user named "anyuser":

```
hostname(config)# username anyuser attributes
hostname(config-username)#
```

Related Commands

Command	Description
clear config username	Clears the username database.
show running-config username	Displays the running configuration for a particular user or for all users.
username	Adds a user to the ASA database.
webvpn	Enters webvpn configuration mode, in which you can configure the WebVPN attributes for the specified group.

username-from-certificate

To specify the field in a certificate to use as the username for authorization, use the **username-from-certificate** command in tunnel-group general-attributes mode. The DN of the peer certificate used as username for authorization

To remove the attribute from the configuration and restore default values, use the **no** form of this command.

username-from-certificate {*primary-attr* [*secondary-attr*] | **use-entire-name**}

no username-from-certificate

Syntax Description

primary-attr	Specifies the attribute to use to derive a username for an authorization query from a certificate. If pre-fill-username is enabled, the derived name can also be used in an authentication query.
secondary-attr	(Optional) Specifies an additional attribute to use with the primary attribute to derive a username for an authentication or authorization query from a digital certificate. If pre-fill-username is enable, the derived name can also be used in an authentication query.
use-entire-name	Specifies that the ASA must use the entire subject DN (RFC1779) to derive a name for an authorization query from a digital certificate.
use-script	Specifies the use of a script file generated by ASDM to extract the DN fields from a certificate for use as a username.

Defaults

The default value for the primary attribute is CN (Common Name).

The default value for the secondary attribute is OU (Organization Unit).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group general-attributes configuration	•	—	•	—	—

Command History

Release	Modification
8.0(4)	This command was introduced.

Usage Guidelines

This command selects the field in the certificate to use as the username. It replaces the deprecated **authorization-dn-attributes** command in Release 8.0.4 and following. The **username-from-certificate** command forces the security appliance to use the specified certificate field as the username for username/password authorization.

To use this derived username in the pre-fill username from certificate feature for username/passwordauthentication or authorization, you must also configure the **pre-fill-username** command in tunnel-group webvpn-attributes mode. That is, to use the pre-fill username feature, you must configure both commands.

Possible values for primary and secondary attributes include the following:

Attribute	Definition
C	Country: the two-letter country abbreviation. These codes conform to ISO 3166 country abbreviations.
CN	Common Name: the name of a person, system, or other entity. Not available a s a secondary attribute.
DNQ	Domain Name Qualifier.
EA	E-mail address.
GENQ	Generational Qualifier.
GN	Given Name.
I	Initials.
L	Locality: the city or town where the organization is located.
N	Name.
O	Organization: the name of the company, institution, agency, association or other entity.
OU	Organizational Unit: the subgroup within the organization (O).
SER	Serial Number.
SN	Surname.
SP	State/Province: the state or province where the organization is located
T	Title.
UID	User Identifier.
UPN	User Principal Name.
use-entire-name	Use entire DN name. Not available a s a secondary attribute.
use-script	Use a script file generated by ASDM.

Examples

The following example, entered in global configuration mode, creates an IPsec remote access tunnel group named remotegrp and specifies the use of CN (Common Name) as the primary attribute and OU as the secondary attribute to use to derive a name for an authorization query from a digital certificate:

```
hostname(config)# tunnel-group remotegrp type ipsec_ra
hostname(config)# tunnel-group remotegrp general-attributes
hostname(config-tunnel-general)# username-from-certificate CN OU
hostname(config-tunnel-general)#
```

The following example shows how to modify the tunnel-group attributes to configure the pre-fill username.

```
username-from-certificate {use-entire-name | use-script | <primary-attr>} [secondary-attr]
secondary-username-from-certificate {use-entire-name | use-script | <primary-attr>}
[secondary-attr] ; used only for double-authentication
```

Related Commands

Command	Description
pre-fill-username	Enables the pre-fill username feature.
show running-config tunnel-group	Shows the indicated tunnel-group configuration.
tunnel-group general-attributes	Specifies the general attributes for the named tunnel-group.

username-prompt

To customize the username prompt of the WebVPN page login box that is displayed to WebVPN users when they connect to the security appliance, use the **username-prompt** command from webvpn customization mode:

username-prompt {**text** | **style**} *value*

[**no**] **username-prompt** {**text** | **style**} *value*

To remove the command from the configuration and cause the value to be inherited, use the **no** form of the command.

Syntax Description

text	Specifies you are changing the text.
style	Specifies you are changing the style.
value	The actual text to display (maximum 256 characters), or Cascading Style Sheet (CSS) parameters (maximum 256 characters).

Defaults

The default is text of the username prompt is “USERNAME:”.

The default style of the username prompt is color:black;font-weight:bold;text-align:right.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Webvpn customization	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The **style** option is expressed as any valid Cascading Style Sheet (CSS) parameters. Describing these parameters is beyond the scope of this document. For more information about CSS parameters, consult CSS specifications at the World Wide Web Consortium (W3C) website at www.w3.org. Appendix F of the CSS 2.1 Specification contains a convenient list of CSS parameters, and is available at www.w3.org/TR/CSS21/propidx.html.

Here are some tips for making the most common changes to the WebVPN pages—the page colors:

- You can use a comma-separated RGB value, an HTML color value, or the name of the color if recognized in HTML.
- RGB format is 0,0,0, a range of decimal numbers from 0 to 255 for each color (red, green, blue); the comma separated entry indicates the level of intensity of each color to combine with the others.

- HTML format is #000000, six digits in hexadecimal format; the first and second represent red, the third and fourth green, and the fifth and sixth represent blue.

Note To easily customize the WebVPN pages, we recommend that you use ASDM, which has convenient features for configuring style elements, including color swatches and preview capabilities.

Examples

In the following example, the text is changed to "Corporate Username:", and the default style is changed with the font weight increased to bolder:

```
hostname(config)# webvpn
hostname(config-webvpn)# customization cisco
hostname(config-webvpn-custom)# username-prompt text Corporate Username:
hostname(config-webvpn-custom)# username-prompt style font-weight:bolder
```

Related Commands

Command	Description
group-prompt	Customizes the group prompt of the WebVPN page.
password-prompt	Customizes the password prompt of the WebVPN page.

CHAPTER 67

validate-attribute through vpnsetup Commands

validate-attribute

To validate RADIUS attributes when using RADIUS accounting, use the **validate attribute** command in radius-accounting parameter configuration mode, which is accessed by using the **inspect radius-accounting** command.

This option is disabled by default.

validate-attribute [*attribute_number*]

no validate-attribute [*attribute_number*]

Syntax Description

attribute_number	The RADIUS attribute to be validated with RADIUS accounting. Values range from 1-191. Vendor Specific Attributes are not supported.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Radius-accounting parameter configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

When this command is configured, the security appliance will also do a match on these attributes in addition to the Framed IP attribute. Multiple instances of this command are allowed.

You can find a list of RADIUS attribute types here:

http://www.iana.org/assignments/radius-types

Examples

The following example shows how to enable RADIUS accounting for the user name RADIUS attribute:

```
hostname(config)# policy-map type inspect radius-accounting ra
hostname(config-pmap)# parameters
hostname(config-pmap-p)# validate attribute 1
```

Related Commands

Commands	Description
inspect radius-accounting	Sets inspection for RADIUS accounting.
parameters	Sets parameters for an inspection policy map.

validation-policy (crypto ca trustpoint)

To specify the conditions under which a trustpoint can be used to validate the certificates associated with an incoming user connection, use the **validation-policy command** in crypto ca trustpoint configuration mode. To specify that the trustpoint cannot be used for the named condition, use the **no** form of the command.

[no] validation-policy {ssl-client | ipsec-client} [no-chain] [subordinate-only]

Syntax Description

ipsec-client	Specifies that the Certificate Authority (CA) certificate and policy associated with the trustpoint can be used to validate IPsec connections.
no-chain	Disables the chaining of subordinate certificates that are not resident on the security device.
ssl-client	Specifies that the Certificate Authority (CA) certificate and policy associated with the trustpoint can be used to validate SSL connections.
subordinate-only	Disables validation of client certificates issued directly from the CA represented by this trustpoint.

Defaults

No default value or behavior.

Command Modes

The following table shows the modes in which you can enter the command:

Command History

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Crypto ca trustpoint configuration	•	•	•	•	—

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Remote-access VPNs can use Secure Sockets Layer (SSL) VPN, IP Security (IPsec), or both, depending on deployment requirements, to permit access to virtually any network application or resource. The **validation-policy** command allows you to specify the protocol type permitted to access on-board CA certificates.

The **no-chain** option with this command prevents a security applicance from supporting subordinate CA certificates that are not configured as trustpoints on the security appliance.

The security appliance can have two trustpoints with the same CA resulting in two different identity certificates from the same CA. This option is disabled automatically if the trustpoint is authenticated to a CA that is already associated with another trustpoint that has enabled this feature. This prevents ambiguity in the choice of path-validation parameters. If the user attempts to activate this feature on a trustpoint that has been authenticated to a CA already associated with another trustpoint that has enabled this feature, the action is not permitted. No two trustpoints can have this setting enabled and be authenticated to the same CA.

Examples

The following example enters crypto ca trustpoint configuration mode for trustpoint, central, and designates it an SSL trustpoint:

```
hostname(config)# crypto ca trustpoint central
hostname(config-ca-trustpoint)# validation-policy ssl
hostname(config-ca-trustpoint)#
```

The following example enters crypto ca trustpoint configuration mode for trustpoint, checkin1,and sets it to accept certificates that are subordinate to the specified trustpoint.

```
hostname(config)# crypto ca trustpoint checkin1
hostname(config-ca-trustpoint)# validation-policy subordinates-only
hostname(config-ca-trustpoint)#
```

Related Commands

Command	Description
crypto ca trustpoint	Enters trustpoint configuration mode.
id-usage	Specifies how the enrolled identity of a trustpoint can be used
ssl trust-point	Specifies the certificate trustpoint that represents the SSL certificate for an interface.

validation-usage

To specify the usage types for which validation with this trustpoint is allowed, use the **validation-usage** command in crypto ca trustpoint configuration mode. To not specify the usage types, use the **no** form of the command.

validation-usage ipsec-client | ssl-client | ssl-server

no validation-usage ipsec-client | ssl-client | ssl-server

Syntax Description

ipsec-client	Indicates that IPsec client connections can be validated using this trustpoint.
ssl-client	Indicates that SSL client connections can be validated using this trustpoint.
ssl-server	Indicates that SSL server certificates can be validated using this trustpoint.

Defaults

ipsec-client, ssl-client

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Crypto ca trustpoint configuration	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced to replace the client-types command.

Usage Guidelines

When there are multiple trustpoints associated with the same CA certificate, only one of the trustpoints can be configured for a specific client type. However, one of the trustpoints can be configured for one client type and the other trustpoint with another client type.

If there is a trustpoint associated with the same CA certificate that is already configured with a client type, the new trustpoint is not allowed to be configured with the same client-type setting. The **no** form of the command clears the setting so that a trustpoint cannot be used for any client validation.

Remote access VPNs can use Secure Sockets Layer (SSL) VPN, IP Security (IPsec), or both, depending on deployment requirements, to permit access to any network application or resource.

Related Commands

Command	Description
crypto ca trustpoint	Enters the crypto ca trustpoint configuration mode for the specified trustpoint.

vdi

To provide secure remote access for Citrix Receiver applications running on mobile devices to XenApp and XenDesktop VDI servers through the ASA, use the **vdi** command.

vdi type citrix url *url* **domain** *domain* **username** *username* **password** *password*

Syntax Description

domain *domain*	Domain for logging into the virtualization infrastructure server. This value can be a clientless macro.
password *password*	Password for logging into the virtualization infrastructure server. This value can be a clientless macro.
type	Type of VDI. For a Citrix Receiver type, this value must be *citrix*.
url *url*	Full URL of the XenApp or XenDesktop server including http or https, hostname, and port number, as well as the path to the XML service.
username *username*	Username for logging into the virtualization infrastructure server. This value can be a clientless macro.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

In a VDI model, administrators publish desktops pre-loaded with enterprise applications, and end users remotely access these desktops. These virtualized resources appear just as any other resources, such as email, so that users do not need to go through a Citrix Access Gateway to access them. Users log onto the ASA using Citrix Receiver mobile client, and the ASA connects to a pre-defined Citrix XenApp or XenDesktop Server. The administrator must configure the Citrix server's address and logon credentials under Group Policy so that when users connect to their Citrix Virtualized resource, they enter the ASA's SSL VPN IP address and credentials instead of pointing to the Citrix Server's address and credentials. When the ASA has verified the credentials, the receiver client starts to retrieve entitled applications through the ASA.

Supported Mobile Devices

- iPad—Citrix Receiver version 4.x or later
- iPhone/iTouch—Citrix Receiver version 4.x or later
- Android 2.x phone—Citrix Receiver version 2.x or later

- Android 3.x tablet—Citrix Receiver version 2.x or later
- Android 4.0 phone—Citrix Receiver version 2.x or later

Examples

If both username and group policy are configured, username settings take precedence over group policy.

```
configure terminal
    group-policy DfltGrpPolicy attributes
        webvpn
            vdi type <citrix> url <url> domain <domain> username <username> password
            <password>
configure terminal
    username <username> attributes
        webvpn
            vdi type <citrix> url <url> domain <domain> username <username> password
            <password>]
```

Related Commands

Command	Description
debug webvpn citrix	Provides insight into the process of launching Citrix-based applications and desktops.

verify

To verify the checksum of a file, use the **verify** command in privileged EXEC mode.

verify *path*

verify [**/md5** *path*] [*md5-value*]

Syntax Description

/md5	(Optional) Calculates and displays the MD5 value for the specified software image. Compare this value with the value available on Cisco.com for this image.
md5-value	(Optional) The known MD5 value for the specified image. When an MD5 value is specified in the command, the system will calculate the MD5 value for the specified image and display a message verifying that the MD5 values match or that there is a mismatch.
path	• **disk0:/**[*path*/]*filename* This option is only available for the ASA 5500 series, and indicates the internal Flash memory. You can also use **flash** instead of **disk0**; they are aliased. • **disk1:/**[*path*/]*filename* This option is only available for the ASA 5500 series, and indicates the external Flash memory card. • **flash:/**[*path*/]*filename* This option indicates the internal Flash card. For the ASA 5500 series, **flash** is an alias for **disk0:**. • **ftp://**[*user*[**:***password*]@]*server*[:*port*]**/**[*path*/]*filename*[**;type=***xx*] The **type** can be one of the following keywords: – **ap**—ASCII passive mode – **an**—ASCII normal mode – **ip**—(Default) Binary passive mode – **in**—Binary normal mode • **http**[**s**]**://**[*user*[**:***password*]@]*server*[:*port*]**/**[*path*/]*filename* • **tftp://**[*user*[**:***password*]@]*server*[:*port*]**/**[*path*/]*filename*[**;int=***interface_name*] Specify the interface name if you want to override the route to the server address. The pathname cannot contain spaces. If a pathname has spaces, set the path in the **tftp-server** command instead of in the **verify** command.

Defaults

The current flash device is the default file system.

Note When you specify the **/md5** option, you can use a network file, such as ftp, http and tftp as the source. The **verify** command without the **/md5** option only lets you verify local images in Flash.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Use the **verify** command to verify the checksum of a file before using it.

Each software image that is distributed on disk uses a single checksum for the entire image. This checksum is displayed only when the image is copied into Flash memory; it is not displayed when the image file is copied from one disk to another.

Before loading or duplicating a new image, record the checksum and MD5 information for the image so that you can verify the checksum when you copy the image into Flash memory or onto a server. A variety of image information is available on Cisco.com.

To display the contents of Flash memory, use the **show flash** command. The Flash contents listing does not include the checksum of individual files. To recompute and verify the image checksum after the image has been copied into Flash memory, use the **verify** command. Note, however, that the **verify** command only performs a check on the integrity of the file after it has been saved in the file system. It is possible for a corrupt image to be transferred to the ASA and saved in the file system without detection. If a corrupt image is transferred successfully to the ASA, the software will be unable to tell that the image is corrupted and the file will verify successfully.

To use the message-digest5 (MD5) hash algorithm to ensure file validation, use the **verify** command with the **/md5** option. MD5 is an algorithm (defined in RFC 1321) that is used to verify data integrity through the creation of a unique 128-bit message digest. The **/md5** option of the **verify** command allows you to check the integrity of the security appliance software image by comparing its MD5 checksum value against a known MD5 checksum value for the image. MD5 values are now made available on Cisco.com for all security appliance software images for comparison against local system image values.

To perform the MD5 integrity check, issue the **verify** command using the **/md5** keyword. For example, issuing the **verify /md5 flash:cdisk.bin** command will calculate and display the MD5 value for the software image. Compare this value with the value available on Cisco.com for this image.

Alternatively, you can get the MD5 value from Cisco.com first, then specify this value in the command syntax. For example, issuing the **verify /md5 flash:cdisk.bin 8b5f3062c4cacdbae72571440e962233** command will display a message verifying that the MD5 values match or that there is a mismatch. A mismatch in MD5 values means that either the image is corrupt or the wrong MD5 value was entered.

Examples

The following example shows the **verify** command used on an image file called cdisk.bin. Some of the text was removed for clarity:

```
hostname# verify cdisk.bin
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!Done!
Embedded Hash MD5: af5a155f3d5c128a271282c33277069b
Computed Hash MD5: af5a155f3d5c128a271282c33277069b
CCO Hash      MD5: b569fff8bbf8087f355aaf22ef46b782
Signature Verified
Verified disk0:/cdisk.bin
hostname#
```

Related Commands

Command	Description
copy	Copies files.
dir	Lists the files in the system.

verify-header

To allow only known IPv6 extension headers and enforces the order of IPv6 extension headers, use the **verify-header** command in parameters configuration mode. You can access the parameters configuration mode by first entering the **policy-map type inspect ipv6** command. To disable these parameters, use the **no** form of this command.

verify-header {**order** | **type**}

no verify-header {**order** | **type**}

Syntax Description

order	Enforces the order of IPv6 extension headers as defined in the RFC 2460 specification.
type	Allows only known IPv6 extension headers.

Command Default

Both order and type are enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
8.2(1)	We introduced this command.

Usage Guidelines

These parameters are enabled by default. To disable them, enter the no keyword.

Examples

The following example disables the order and type parameters for an IPv6 inspection policy map:

```
hostname(config)# policy-map type inspect ipv6 ipv6-map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# no verify-header order
hostname(config-pmap-p)# no verify-header type
```

Related Commands

Command	Description
inspect ipv6	Enables IPv6 inspection.
parameters	Enters parameters configuration mode for an inspection policy map.

Command	Description
policy-map type inspect ipv6	Creates an IPv6 inspection policy map.

version

To specify the version of RIP used globally by the ASA, use the **version** command in router configuration mode. To restore the defaults, use the **no** form of this command.

version {**1** | **2**}

no version

Syntax Description

1	Specifies RIP Version 1.
2	Specifies RIP Version 2.

Defaults

The ASA accepts Version 1 and Version 2 packets but sends only Version 1 packets.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Router configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

You can override the global setting on a per-interface basis by entering the **rip send version** and **rip receive version** commands on an interface.

If you specify RIP version 2, you can enable neighbor authentication and use MD5-based encryption to authenticate the RIP updates.

Examples

The following example configures the ASA to send and receive RIP Version 2 packets on all interfaces:

```
hostname(config)# router rip
hostname(config-router)# network 10.0.0.0
hostname(config-router)# version 2
```

Related Commands

Command	Description
rip send version	Specifies the RIP version to use when sending update out of a specific interface.
rip receive version	Specifies the RIP version to accept when receiving updates on a specific interface.
router rip	Enables the RIP routing process and enter router configuration mode for that process.

virtual http

To configure a virtual HTTP server, use the **virtual http** command in global configuration mode. To disable the virtual server, use the **no** form of this command.

virtual http *ip_address* [**warning**]

no virtual http *ip_address* [**warning**]

Syntax Description

ip_address	Sets the IP address for the virtual HTTP server on the ASA. Make sure this address is an unused address that is routed to the ASA.
warning	(Optional) Notifies users that the HTTP connection needs to be redirected to the ASA. This keyword applies only for text-based browsers, where the redirect cannot happen automatically.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was deprecated because the inline basic HTTP authentication method used in prior releases was replaced by the redirection method; this command was no longer needed.
7.2(2)	This command was revived because you can now choose between using basic HTTP authentication (the default) or using HTTP redirection using the **aaa authentication listener** command. The redirection method does not require an extra command for cascading HTTP authentications.

Usage Guidelines

When you use HTTP authentication on the ASA (see the **aaa authentication match** or the **aaa authentication include** command), the ASA uses basic HTTP authentication by default. You can change the authentication method so that the ASA redirects HTTP connections to web pages generated by the ASA itself using the **aaa authentication listener** command with the **redirect** keyword.

However, if you continue to use basic HTTP authentication, then you might need the **virtual http** command when you have cascading HTTP authentications.

If the destination HTTP server requires authentication in addition to the ASA, then the **virtual http** command lets you authenticate separately with the ASA (via a AAA server) and with the HTTP server. Without virtual HTTP, the same username and password you used to authenticate with the ASA is sent

to the HTTP server; you are not prompted separately for the HTTP server username and password. Assuming the username and password is not the same for the AAA and HTTP servers, then the HTTP authentication fails.

This command redirects all HTTP connections that require AAA authentication to the virtual HTTP server on the ASA. The ASA prompts for the AAA server username and password. After the AAA server authenticates the user, the ASA redirects the HTTP connection back to the original server, but it does not include the AAA server username and password. Because the username and password are not included in the HTTP packet, the HTTP server prompts the user separately for the HTTP server username and password.

For inbound users (from lower security to higher security), you must also include the virtual HTTP address as a destination interface in the access list applied to the source interface. Moreover, you must add a **static** command for the virtual HTTP IP address, even if NAT is not required (using the **no nat-control** command). An identity NAT command is typically used (where you translate the address to itself).

For outbound users, there is an explicit permit for traffic, but if you apply an access list to an inside interface, be sure to allow access to the virtual HTTP address. A **static** statement is not required.

Note Do not set the **timeout uauth** command duration to 0 seconds when using the **virtual http** command, because this setting prevents HTTP connections to the real web server.

Examples

The following example shows how to enable virtual HTTP along with AAA authentication:

```
hostname(config)# virtual http 209.165.202.129
hostname(config)# access-list ACL-IN extended permit tcp any host 209.165.200.225 eq http
hostname(config)# access-list ACL-IN remark This is the HTTP server on the inside
hostname(config)# access-list ACL-IN extended permit tcp any host 209.165.202.129 eq http
hostname(config)# access-list ACL-IN remark This is the virtual HTTP address
hostname(config)# access-group ACL-IN in interface outside
hostname(config)# static (inside, outside) 209.165.202.129 209.165.202.129 netmask
255.255.255.255
hostname(config)# access-list AUTH extended permit tcp any host 209.165.200.225 eq http
hostname(config)# access-list AUTH remark This is the HTTP server on the inside
hostname(config)# access-list AUTH extended permit tcp any host 209.165.202.129 eq http
hostname(config)# access-list AUTH remark This is the virtual HTTP address
hostname(config)# aaa authentication match AUTH outside tacacs+
```

Related Commands

Command	Description
aaa authentication listener http	Sets the method by which the ASA authentica
clear configure virtual	Removes **virtual** command statements from the configuration.
show running-config virtual	Displays the IP address of the ASA virtual server.
sysopt uauth allow-http-cache	When you enable the **virtual http** command, this command lets you use the username and password in the browser cache to reconnect to the virtual server.
virtual telnet	Provides a virtual Telnet server on the ASA to let users authenticate with the ASA before initiating other types of connections that require authentication.

virtual telnet

To configure a virtual Telnet server on the ASA, use the **virtual telnet** command in global configuration mode. You might need to authenticate users with the virtual Telnet server if you require authentication for other types of traffic for which the ASA does not supply an authentication prompt. To disable the server, use the **no** form of this command.

virtual telnet *ip_address*

no virtual telnet *ip_address*

Syntax Description

ip_address	Sets the IP address for the virtual Telnet server on the ASA. Make sure this address is an unused address that is routed to the ASA.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Although you can configure network access authentication for any protocol or service (see the **aaa authentication match** or **aaa authentication include** command), you can authenticate directly with HTTP, Telnet, or FTP only. A user must first authenticate with one of these services before other traffic that requires authentication is allowed through. If you do not want to allow HTTP, Telnet, or FTP through the ASA, but want to authenticate other types of traffic, you can configure virtual Telnet; the user Telnets to a given IP address configured on the ASA, and the ASA provides a Telnet prompt.

You must configure authentication for Telnet access to the virtual Telnet address as well as the other services you want to authenticate using the **authentication match** or **aaa authentication include** command.

When an unauthenticated user connects to the virtual Telnet IP address, the user is challenged for a username and password, and then authenticated by the AAA server. Once authenticated, the user sees the message “Authentication Successful.” Then, the user can successfully access other services that require authentication.

For inbound users (from lower security to higher security), you must also include the virtual Telnet address as a destination interface in the access list applied to the source interface. Moreover, you must add a **static** command for the virtual Telnet IP address, even if NAT is not required (using the **no nat-control** command). An identity NAT command is typically used (where you translate the address to itself).

For outbound users, there is an explicit permit for traffic, but if you apply an access list to an inside interface, be sure to allow access to the virtual Telnet address. A **static** statement is not required.

To logout from the ASA, reconnect to the virtual Telnet IP address; you are prompted to log out.

Examples

This example shows how to enable virtual Telnet along with AAA authentication for other services:

```
hostname(config)# virtual telnet 209.165.202.129
hostname(config)# access-list ACL-IN extended permit tcp any host 209.165.200.225 eq smtp
hostname(config)# access-list ACL-IN remark This is the SMTP server on the inside
hostname(config)# access-list ACL-IN extended permit tcp any host 209.165.202.129 eq
telnet
hostname(config)# access-list ACL-IN remark This is the virtual Telnet address
hostname(config)# access-group ACL-IN in interface outside
hostname(config)# static (inside, outside) 209.165.202.129 209.165.202.129 netmask
255.255.255.255
hostname(config)# access-list AUTH extended permit tcp any host 209.165.200.225 eq smtp
hostname(config)# access-list AUTH remark This is the SMTP server on the inside
hostname(config)# access-list AUTH extended permit tcp any host 209.165.202.129 eq telnet
hostname(config)# access-list AUTH remark This is the virtual Telnet address
hostname(config)# aaa authentication match AUTH outside tacacs+
```

Related Commands

Command	Description
clear configure virtual	Removes **virtual** command statements from the configuration.
show running-config virtual	Displays the IP address of the ASA virtual server.
virtual http	When you use HTTP authentication on the ASA, and the HTTP server also requires authentication, this command allows you to authenticate separately with the ASA and with the HTTP server. Without virtual HTTP, the same username and password you used to authenticate with the ASA is sent to the HTTP server; you are not prompted separately for the HTTP server username and password.

vlan

To assign a VLAN ID to a subinterface, use the **vlan** command in interface configuration mode. To remove a VLAN ID, use the **no** form of this command. Subinterfaces require a VLAN ID to pass traffic. VLAN subinterfaces let you configure multiple logical interfaces on a single physical interface. VLANs let you keep traffic separate on a given physical interface, for example, for multiple security contexts.

vlan *id*

no vlan

Syntax Description

id	Specifies an integer between 1 and 4094. Some VLAN IDs might be reserved on connected switches, so check the switch documentation for more information.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was moved from a keyword of the **interface** command to an interface configuration mode command.

Usage Guidelines

You can only assign a single VLAN to a subinterface, and not to the physical interface. Each subinterface must have a VLAN ID before it can pass traffic. To change a VLAN ID, you do not need to remove the old VLAN ID with the **no** option; you can enter the **vlan** command with a different VLAN ID, and the ASA changes the old ID.

You need to enable the physical interface with the **no shutdown** command to let subinterfaces be enabled. If you enable subinterfaces, you typically do not also want the physical interface to pass traffic, because the physical interface passes untagged packets. Therefore, you cannot prevent traffic from passing through the physical interface by bringing down the interface. Instead, ensure that the physical interface does not pass traffic by leaving out the **nameif** command. If you want to let the physical interface pass untagged packets, you can configure the **nameif** command as usual.

The maximum number of subinterfaces varies depending on your platform. See the CLI configuration guide for the maximum subinterfaces per platform.

Examples

The following example assigns VLAN 101 to a subinterface:

```
hostname(config)# interface gigabitethernet0/0.1
hostname(config-subif)# vlan 101
hostname(config-subif)# nameif dmz1
hostname(config-subif)# security-level 50
hostname(config-subif)# ip address 10.1.2.1 255.255.255.0
hostname(config-subif)# no shutdown
```

The following example changes the VLAN to 102:

```
hostname(config)# show running-config interface gigabitethernet0/0.1
interface GigabitEthernet0/0.1
   vlan 101
   nameif dmz1
   security-level 50
   ip address 10.1.2.1 255.255.255.0

hostname(config)# interface gigabitethernet0/0.1
hostname(config-interface)# vlan 102

hostname(config)# show running-config interface gigabitethernet0/0.1
interface GigabitEthernet0/0.1
   vlan 102
   nameif dmz1
   security-level 50
   ip address 10.1.2.1 255.255.255.0
```

Related Commands

Command	Description
allocate-interface	Assigns interfaces and subinterfaces to a security context.
interface	Configures an interface and enters interface configuration mode.
show running-config interface	Shows the current configuration of the interface.

vlan (group-policy)

To assign a VLAN to a group policy, use the **vlan** command in group-policy configuration mode. To remove the VLAN from the configuration of the group policy and replace it with the VLAN setting of the default group policy, use the **no** form of this command.

[**no**] **vlan** {*vlan_id* |**none**}

Syntax Description

vlan_id	Number of the VLAN, in decimal format, to assign to remote access VPN sessions that use this group policy. The VLAN must be configured on this ASA, using the **vlan** command in interface configuration mode.
none	Disables the assignment of a VLAN to the remote access VPN sessions that match this group policy. The group policy does not inherit the vlan value from the default group policy.

Defaults

The default value is none.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

This command specifies the egress VLAN interface for sessions assigned to this group policy. The ASA forwards all traffic on this group to that VLAN. You can assign a VLAN to each group policy to simplify access control. Use this command as an alternative to using ACLs to filter traffic on a session.

Examples

The following command assigns the VLAN 1 to the group policy:

```
hostname(config-group-policy)# vlan 1
hostname(config-group-policy)
```

The following command removes VLAN mapping from the group policy:

```
hostname(config-group-policy)# vlan none
hostname(config-group-policy)
```

Related Commands

Command	Description
show vlan	Shows the VLANs configured on the ASA.
vlan (interface configuration mode)	Assigns a VLAN ID to a subinterface.
show vpn-session_summary.db	Displays the number IPsec, Cisco AnyConnect, and NAC sessions, and the number of VLANs in use.
show vpn-session.db	Displays information about VPN sessions, including VLAN mapping and NAC results.

vpdn group

To create or edit a vpdn group and configure PPPoE client settings, use the **vpdn group** command in global configuration mode. To remove a group policy from the configuration, use the **no** form of this command.

vpdn group *group_name* {**localname** *username* | **request dialout pppoe** | **ppp authentication** {**chap** | **mschap** | **pap**}}

no vpdn group *group_name* {**localname** *name* | **request dialout pppoe** | **ppp authentication** {**chap** | **mschap** | **pap**}}

Note PPPoE is not supported when failover is configured on the ASA, or in multiple context or transparent mode. PPPoE is only supported in single, routed mode, without failover.

Syntax Description

vpdn group *group_name*	Specifies a name for the vpdn group
localname *username*	Links the user name to the vpdn group for authentication, and must match the name configured with the **vpdn username** command.
request dialout pppoe	Specifies to allow dialout PPPoE requests.
**ppp authentication {chap | mschap | pap}}	Specifies the Point-to-Point Protocol (PPP) authentication protocol. The Windows client dial-up networking settings lets you specify what authentication protocol to use (PAP, CHAP, or MS-CHAP). Whatever you specify on the client must match the setting you use on the security appliance. Password Authentication Protocol (PAP) lets PPP peers authenticate each other. PAP passes the host name or username in clear text. Challenge Handshake Authentication Protocol (CHAP) lets PPP peers prevent unauthorized access through interaction with an access server. MS-CHAP is a Microsoft derivation of CHAP. PIX Firewall supports MS-CHAP Version 1 only (not Version 2.0). If an authentication protocol is not specified on the host, do not specify the **ppp authentication** option in your configuration.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•		—

Command History

Release	Modification
7.2.1	This command was introduced.

Usage Guidelines

Virtual Private Dial-up Networking (VPDN) is used to provide long distance, point-to-point connections between remote dial-in users and a private network. VDPN on the security appliance uses the Layer 2 tunnelling technology PPPoE to establish dial-up networking connections from the remote user to the private network across a public network.

PPPoE is the Point-to-Point Protocol (PPP) over Ethernet. PPP is designed to work with network layer protocols such as IP, IPX, and ARA. PPP also has CHAP and PAP as built-in security mechanisms.

The **show vpdn session pppoe** command displays session information for PPPOE connections. The **clear configure vpdn group** command removes all **vpdn group** commands from the configuration and stops all the active L2TP and PPPoE tunnels. The **clear configure vpdn username** command removes all the **vpdn username** commands from the configuration.

Because PPPoE encapsulates PPP, PPPoE relies on PPP to perform authentication and ECP and CCP functions for client sessions operating within the VPN tunnel. Additionally, PPPoE is not supported in conjunction with DHCP because PPP assigns the IP address for PPPoE.

Note Unless the VPDN group for PPPoE is configured, PPPoE cannot establish a connection.

To define a VPDN group to be used for PPPoE, use the **vpdn group** *group_name* **request dialout pppoe** command. Then use the **pppoe client vpdn group** command from interface configuration mode to associate a VPDN group with a PPPoE client on a particular interface.

If your ISP requires authentication, use the **vpdn group** *group_name* **ppp authentication** {**chap** | **mschap** | **pap**} command to select the authentication protocol used by your ISP.

Use the **vpdn group** *group_name* **localname** *username* command to associate the username assigned by your ISP with the VPDN group.

Use the **vpdn username** *username* password *password* command to create a username and password pair for the PPPoE connection. The username must be a username that is already associated with the VPDN group specified for PPPoE.

Note If your ISP is using CHAP or MS-CHAP, the username may be called the remote system name and the password may be called the CHAP secret.

The PPPoE client functionality is turned off by default, so after VPDN configuration, enable PPPoE with the **ip address** *if_name* **pppoe** [**setroute**] command. The **setroute** option causes a default route to be created if no default route exists.

As soon as PPPoE is configured, the security appliance attempts to find a PPPoE access concentrator with which to communicate. When a PPPoE connection is terminated, either normally or abnormally, the security appliance attempts to find a new access concentrator with which to communicate.

The following **ip address** commands should not be used after a PPPoE session is initiated because they will terminate the PPPoE session:

- **ip address outside pppoe**, because it attempts to initiate a new PPPoE session.
- **ip address outside dhcp**, because it disables the interface until the interface gets its DHCP configuration.
- **ip address outside** *address netmask*, because it brings up the interface as a normally initialized interface.

Examples

The following example creates a vdpn group *telecommuters* and configures the PPPoE client:

```
F1(config)# vpdn group telecommuters request dialout pppoe
F1(config)# vpdn group telecommuters localname user1
F1(config)# vpdn group telecommuters ppp authentication pap
F1(config)# vpdn username user1 password test1
F1(config)# interface GigabitEthernet 0/1
F1(config-subif)# ip address pppoe setroute
```

Related Commands

Command	Description
clear configure vpdn group	Removes all vpdn group commands from the configurations.
clear configure vpdn username	Removes all vpdn username commands from the configuration.
show vpdn group *group_name*	Displays the vpdn group configuration.
vpdn username	Creates a username and password pair for the PPPoE connection.

vpdn username

To create a username and password pair for PPPoE connections, use the **vpdn username** command in global configuration mode.

vpdn username *username* **password** *password* [**store-local**]

no vpdn username *username* **password** *password* [**store-local**]

Note PPPoE is not supported when failover is configured on the ASA, or in multiple context or transparent mode. PPPoE is only supported in single, routed mode, without failover.

Syntax Description

username	Specifies the username.
password	Specifies the password.
store-local	Stores the username and password in a special location of NVRAM on the security appliance. If an Auto Update Server sends a clear config command to the security appliance and the connection is then interrupted, the security appliance can read the username and password from NVRAM and re-authenticate to the Access Concentrator.

Defaults

No default behavior or values. See Usage Guidelines.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•		—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The vpdn username must be a username that is already associated with the VPDN group specified with the **vpdn group** *group_name* **localname** *username* command.

The **clear configure vpdn username** command removes all the **vpdn username** commands from the configuration.

Examples

The following example creates the vpdn username *bob_smith* with the password *telecommuter*9/8:

```
F1(config)# vpdn username bob_smith password telecommuter9/8
```

Related Commands

Command	Description
clear configure vpdn group	Removes all vpdn group commands from the configurations.
clear configure vpdn username	Removes all vpdn username commands from the configuration.
show vpdn group	Displays the vpdn group configuration.
vpdn group	Create a vpdn group and configures PPPoE client settings,

vpn-access-hours

To associate a group policy with a configured time-range policy, use the **vpn-access-hours** command in group-policy configuration mode or username configuration mode. To remove the attribute from the running configuration, use the **no** form of this command. This option allows inheritance of a time-range value from another group policy. To prevent inheriting a value, use the **vpn-access-hours none** command.

vpn-access hours value {*time-range*} | **none**

no vpn-access hours

Syntax Description

none	Sets VPN access hours to a null value, thereby allowing no time-range policy. Prevents inheriting a value from a default or specified group policy.
time-range	Specifies the name of a configured time-range policy.

Defaults

Unrestricted.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group-policy configuration	•	—	•	—	—
Username configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to associate the group policy named FirstGroup with a time-range policy called 824:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# vpn-access-hours 824
```

Related Commands

Command	Description
time-range	Sets days of the week and hours of the day for access to the network, including start and end dates.

vpn-addr-assign

To specify a method for assigning IPv4 addresses to remote access clients, use the **vpn-addr-assign** command in global configuration mode. To remove the attribute from the configuration, use the **no** version of this command. To remove all configured VPN address assignment methods from the ASA, user the **no** version of this command. without arguments.

vpn-addr-assign {**aaa | dhcp | local** [**reuse-delay** *delay*]}

no vpn-addr-assign {**aaa | dhcp | local** [**reuse-delay** *delay*]}

Syntax Description

aaa	Assigns IPv4 addresses from an external or internal (LOCAL) AAA authentication server.
dhcp	Obtains IP addresses via DHCP.
local	Assigns IP addresses from an IP adress pool configured on the ASA and associates them with a tunnel group.
reuse-delay *delay*	The delay before a released IP address can be reused. The range is 0 to 480 minutes. The default is 0 (disabled).

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•		—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0.3	The **reuse-delay** option was introduced.

Usage Guidelines

If you choose DHCP, you should also use the **dhcp-network-scope** command to define the range of IP addresses that the DHCP server can use. You must use the **dhcp-server** command to indicate the IP addresses that the DHCP server uses.

If you choose local, you must also use the **ip-local-pool** command to define the range of IP addresses to use. You then use the **vpn-framed-ip-address** and **vpn-framed-netmask** commands to assign IP addresses and netmasks to individual users.

With the local pool, you can use the **reuse-delay** *delay* option to adjust the delay before a released IP address can be reused. Increasing the delay prevents problems firewalls may experience when an IP address is returned to the pool and reassigned quickly.

If you choose AAA, you obtain IP addresses from either a previously configured RADIUS server.

Examples

The following example shows how to configure DHCP as the address assignment method:

```
hostname(config)# vpn-addr-assign dhcp
```

Related Commands

Command	Description
dhcp-network-scope	Specifies the range of IP addresses the ASA DHCP server should use to assign addresses to users of a group policy.
ip-local-pool	Creates a local IP address pool.
ipv6-addr-assign	Specifies a method for assigning IPv6 addresses to remote access clients.
vpn-framed-ip-address	Specifies the IP address to assign to a particular user.
vpn-framed-ip-netmask	Specifies the netmask to assign to a particular user.

vpn-filter

To specify the name of the ACL to use for VPN connections, use the **vpn-filter** command in group policy or username mode. To remove the ACL, including a null value created by issuing the **vpn-filter none** command, use the **no** form of this command. The **no** option allows inheritance of a value from another group policy. To prevent inheriting values, use the **vpn-filter none** command.

You configure ACLs to permit or deny various types of traffic for this user or group policy. You then use the **vpn-filter** command to apply those ACLs.

vpn-filter {**value** *ACL name* | **none**}

no vpn-filter

Syntax Description

none	Indicates that there is no access list. Sets a null value, thereby disallowing an access list. Prevents inheriting an access list from another group policy.
value *ACL name*	Provides the name of the previously configured access list.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy	•	—	•	—	—
Username	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Command can now be used for IPv4 and IPv6 ACLs.
9.1.(4)	Command must now be used for IPv4 and IPv6 ACLs. If the deprecated command ipv6-vpn-filter is mistakenly used to specify IPv6 ACLs the connection will be terminated.

Usage Guidelines

Clientless SSL VPN does not use the ACL defined in the **vpn-filter** command.

By design, the vpn-filter feature allows for traffic to be filtered in inbound direction only. The outbound rule is automatically compiled. When creating an icmp access-list, do not specify icmp type in the access-list formatting if you want directional filters.

Examples

The following example shows how to set a filter that invokes an access list named acl_vpn for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# vpn-filter value acl_vpn
```

Related Commands

Command	Description
access-list	Creates an access list, or uses a downloadable access list.
ipv6-vpn-filter	Deprecated command which was used previously to specify IPv6 ACLs.

vpn-framed-ip-address

To specify the IPv4 address to assign to an individual user, use the **vpn-framed-ip-address** command in username mode. To remove the IP address, use the **no** form of this command.

vpn-framed-ip-address {*ip_address*} {*subnet_mask*}

no vpn-framed-ip-address

Syntax Description

ip_address	Provides the IP address for this user.
subnet_mask	Specifies the subnetwork mask.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Username	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to set an IP address of 10.92.166.7 for a user named anyuser:

```
hostname(config)# username anyuser attributes
hostname(config-username)# vpn-framed-ip-address 10.92.166.7 255.255.255.254
```

vpn-framed-ipv6-address

Use the **vpn-framed-ipv6-address** command in username mode to assign a dedicated IPv6 address to a user. To remove the IP address, use the **no** form of this command.

vpn-framed-ipv6-address *ip_address/subnet_mask*

no vpn-framed-ipv6-address *ip_address/subnet_mask*

Syntax Description

ip_address	Provides the IP address for this user.
subnet_mask	Specifies the subnetwork mask.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Username	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Examples

The following example shows how to set an IP address and netmask of 2001::3000:1000:2000:1/64 for a user named *anyuser*. This address indicates a prefix value of 2001:0000:0000:0000 and an interface ID of 3000:1000:2000:1.

```
hostname(config)# username anyuser attributes
hostname(config-username)# vpn-framed-ipv6-address 2001::3000:1000:2000:1/64
hostname(config-username)
```

Related Commands

Command	Description
vpn-framed-ip-address	Specifies an IPv4 address to assign to an individual user.

vpn-group-policy

To have a user inherit attributes from a configured group policy, use the **vpn-group-policy** command in username configuration mode. To remove a group policy from a user configuration, use the **no** version of this command. Using this command lets users inherit attributes that you have not configured at the username level.

vpn-group-policy {*group-policy name*}

no vpn-group-policy {*group-policy name*}

Syntax Description

group-policy name	Provides the name of the group policy.

Defaults

By default, VPN users have no group policy association.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Username configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can override the value of an attribute in a group policy for a particular user by configuring it in username mode, if that attribute is available in username mode.

Examples

The following example shows how to configure a user named anyuser to use attributes from the group policy named FirstGroup:

```
hostname(config)# username anyuser attributes
hostname(config-username)# vpn-group-policy FirstGroup
```

Related Commands

Command	Description
group-policy	Adds a group policy to the ASA database.
group-policy attributes	Enters group-policy attributes mode, which lets you configure AVPs for a group policy.

Command	Description
username	Adds a user to the ASA database.
username attributes	Enters username attributes mode, which lets you configure AVPs for specific users.

vpn-idle-timeout

To configure a user timeout period use the **vpn-idle-timeout** command in group-policy configuration mode or in username configuration mode. If there is no communication activity on the connection in this period, the ASA terminates the connection. You can optionally extend the timeout alert-interval from the default one minute.

To remove the attribute from the running configuration, use the **no** form of this command. This option allows inheritance of a time-out value from another group policy. To prevent inheriting a value, use the **vpn-idle-timeout none** command.

vpn-idle-timeout {*minutes* | **none**} [**alert-interval** *minutes*]

no vpn-idle-timeout

no vpn-idle-timeout alert-interval

Syntax Description

minutes	Specifies the number of minutes in the timeout period, and the number of minutes before the time-out alert. Use an integer between 1 and 35791394.
none	AnyConnect (SSL IPsec/IKEv2): Use the global WebVPN default-idle-timeout value (seconds) from the command: **hostname(config-webvpn)# default-idle-timeout** The range for this value in the WebVPN **default-idle-timeout** command is 60-86400 seconds; the default Global WebVPN Idle timeout in seconds -- default is 1800 seconds (30 min). **Note** A non-zero idle timeout value is required by ASA for all AnyConnect connections. For a WebVPN user, the **default-idle-timeout** value is enforced only if vpn-idle-timeout none is set in the group policy/username attribute. Site-to-Site (IKEv1, IKEv2) and IKEv1 remote-access: Disable timeout and allow for an unlimited idle period.

Defaults

30 minutes.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy	•	—	•	—	—
Username	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The AnyConnect client supports session resumption for SSL and IKEv2 connection. With this capability, end user devices can go into sleep mode, lose their WiFi, or any of the like and resume the same connection upon return.

Examples

The following example shows how to set a VPN idle timeout of 15 minutes for the group policy named "FirstGroup":

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# vpn-idle-timeout 30
```

The security appliance uses the default-idle-timeout value if no idle timeout is defined for a user, if the vpn-idle-timeout value is 0, or if the value does not fall into the valid range.

Related Commands

default-idle-timeout	Specifies the global WebVPN default idle timeout.
group-policy	Creates or edits a group policy.
vpn-session-timeout	Configures the maximum amount of time allowed for VPN connections. At the end of this period of time, the ASA terminates the connection.

vpn load-balancing

To enter vpn load-balancing mode, in which you can configure VPN load balancing and related functions, use the **vpn load-balancing** command in global configuration mode.

vpn load-balancing

Note To use VPN load balancing, you must have an ASA 5510 with a Plus license or an ASA 5520 or higher. VPN load balancing also requires an active 3DES/AES license. The security appliance checks for the existence of this crypto license before enabling load balancing. If it does not detect an active 3DES or AES license, the security appliance prevents the enabling of load balancing and also prevents internal configuration of 3DES by the load balancing system unless the license permits this usage.

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•		—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0(2)	Added support for ASA 5510 with a Plus license and models above 5520.

Usage Guidelines

A load-balancing cluster can include security appliance models 5510 (with a Plus license), or ASA 5520 and above. You can also include VPN 3000 Series Concentrators in the cluster. While mixed configurations are possible, administration is generally simpler if the cluster is homogeneous.

Use the **vpn load-balancing** command to enter vpn load-balancing mode. The following commands are available in vpn load-balancing mode:

- cluster encryption
- cluster ip address
- cluster key
- cluster port
- interface

- nat
- participate
- priority
- redirect-fqdn

See the individual command descriptions for detailed information.

Examples

The following is an example of the **vpn load-balancing** command; note the change in the prompt:

```
hostname(config)# vpn load-balancing
hostname(config-load-balancing)#
```

The following is an example of a VPN load-balancing command sequence that includes an interface command that specifies the public interface of the cluster as “test” and the private interface of the cluster as “foo”:

```
hostname(config)# interface GigabitEthernet 0/1
hostname(config-if)# ip address 209.165.202.159 255.255.255.0
hostname(config)# nameif test
hostname(config)# interface GigabitEthernet 0/2
hostname(config-if)# ip address 209.165.201.30 255.255.255.0
hostname(config)# nameif foo
hostname(config)# vpn load-balancing
hostname(config-load-balancing)# nat 192.168.10.10
hostname(config-load-balancing)# priority 9
hostname(config-load-balancing)# interface lbpublic test
hostname(config-load-balancing)# interface lbprivate foo
hostname(config-load-balancing)# cluster ip address 209.165.202.224
hostname(config-load-balancing)# cluster key 123456789
hostname(config-load-balancing)# cluster encryption
hostname(config-load-balancing)# cluster port 9023
hostname(config-load-balancing)# participate
```

Related Commands

Command	Description
clear configure vpn load-balancing	Removes the load-balancing runtime configuration and disables load balancing.
show running-config vpn load-balancing	Displays the the current VPN load-balancing virtual cluster configuration.
show vpn load-balancing	Displays VPN load-balancing runtime statistics.

vpn-session-db

To specify the maximum number of VPN sessions or AnyConnect client VPN sessions, use the **vpn-session-db** command from global configuration mode. To remove the limit from the configuration, use the **no** form of the command:

vpn-sessiondb {**max-anyconnect-premium-or-essentials-limit** *number* | **max-other-vpn-limit** *number*}

Syntax Description

max-anyconnect-premium-or-essentials-limit *number*	Specifies the maximum number of AnyConnect sessions, from 1 to the maximum sessions allowed by the license.
max-other-vpn-limit *number*	Specifies the maximum number of VPN sessions other than AnyConnect client sessions, from 1 to the maximum sessions allowed by the license. This includes Cisco VPN client (IPsec IKEv1), Lan-to-Lan VPN, and clientless SSL VPN sessions.

Defaults

By default, the ASA does not limit the number of VPN sessions lower than the licensed maximum.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.4(1)	The following keywords were changed: • **max-anyconnect-premium-or-essentials-limit** replaced **max-session-limit** • **max-other-vpn-limit** replaced **max-webvpn-session-limit**
9.0(1)	Support for multiple context mode was added for max-other-vpn-limit and logoff.

Examples

The following example sets the maximum AnyConnect sessions to 200:

```
hostname(config)# vpn-sessiondb max-anyconnect-premium-or-essentials-limit 200
```

Related Commands

Command	Description
vpn-sessiondb logoff	Logs off all or specific types of IPsec VPN and WebVPN sessions.
vpn-sessiondb max-webvpn-session-limit	Sets a maximum number of WebVPN sessions.

vpn-sessiondb logoff

To log off all or selected VPN sessions, use the **vpn-sessiondb logoff** command in global configuration mode.

vpn-sessiondb logoff {**all** | **anyconnect** | **email-proxy** | **index** ***index_number*** | **ipaddress** *IPaddr* | **l2l** | **name** *username* | **protocol** *protocol-name* | **ra-ikev1-ipsec** | **tunnel-group** *groupname* | **vpn-lb** | **webvpn**} [**noconfirm**]

Syntax Description

all	Logs off all VPN sessions.
anyconnect	Logs of all AnyConnect VPN client sessions.
email-proxy	Logs off all e-mail proxy sessions.
index *index_number*	Logs off a single session by index number. Specify the index number for the session. You can view index numbers for each session with the **show vpn-sessiondb detail** command.
ipaddress *IPaddr*	Logs off sessions for the IP address hat you specify.
l2l	Logs off all LAN-to-LAN sessions.
name *username*	Logs off sessions for the username that you specify.

protocol *protocol-name*	Logs off sessions for protocols that you specify. The protocols include: **ikev1**—Sessions using the Internet Key Exchange version 1 (IKEv1) protocol. **ikev2**—Sessions using the Internet Key Exchange version 2 (IKEv2) protocol. **ipsec**—IPsec sessions using either IKEv1 or IKEv2. **ipseclan2lan**—IPsec Lan-to-Lan sessions. **ipseclan2lanovernatt**—IPsec Lan-to-Lan over NAT-T sessions. **ipsecovernatt**—IPsec over NAT-T sessions. **ipsecovertcp**—IPsec over TCP sessions. **ipsecoverudp**—IPsec over UDP sessions. **l2tpOverIpSec**—L2TP over IPsec sessions. **l2tpOverIpsecOverNatT**—L2TP over IPsec over NAT-T sessions. **webvpn**—Clientless SSL VPN sessions. **imap4s**—IMAP4 sessions. **pop3s**—POP3 sessions. **smtps**—SMTP sessions. **anyconnectParent**—AnyConnect client sessions, regardless of the protocol used for the session (terminates AnyConnect IPsec IKEv2 and SSL sessions). **ssltunnel**—SSL VPN sessions, including AnyConnect sessions using SSL and clientless SSL VPN sessions. **dtlstunnel**—AnyConnect client sessions with DTLS enabled.
ra-ikev1-ipsec	Logs off all IPsec IKEv1 remote-access sessions.
tunnel-group *groupname*	Logs off sessions for the tunnel group (connection profile) that you specify.
webvpn	Logs off all clientless SSL VPN sessions.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.4(1)	The following **protocol** keywords were changed or added: • **remote** was changed to **ra-ikev1-ipsec**. • **ike** was changed to **ikev1**. • **ikev2** was added. • **anyconnectParent** was added.
9.0(1)	Support for multiple context mode was added.

Examples

The following example shows how to log off all AnyConnect client sessions:

```
hostname# vpn-sessiondb logoff anyconnect
```

The next example shows how to log off all IPsec sessions:

```
hostname# vpn-sessiondb logoff protocol IPsec
```

vpn-session-timeout

To configure a maximum amount of time allowed for VPN connections, use the **vpn-session-timeout** command in group-policy configuration mode or in username configuration mode. At the end of this period of time, the ASA terminates the connection. You can optionally extend the timeout alert-interval from the default one minute.

To remove the attribute from the running configuration, use the **no** form of this command. This option allows inheritance of a time-out value from another group policy. To prevent inheriting a value, use the **vpn-session-timeout none** command.

vpn-session-timeout {*minutes* | **none**} [**alert-interval** *minutes*]

no vpn-session-timeout

no vpn-session-timeout alert-interval

Syntax Description

minutes	Specifies the number of minutes in the timeout period, and the number of minutes before the time-out alert. Use an integer between 1 and 35791394.
none	Permits an unlimited session timeout period. Sets session timeout with a null value, thereby disallowing a session timeout. Prevents inheriting a value from a default or specified group policy.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—
Username configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to set a VPN session timeout of 180 minutes for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# vpn-session-timeout 180
```

Related Commands

group-policy	Creates or edits a group policy.
vpn-idle-timeout	Configures the user timeout period. If there is no communication activity on the connection in this period, the ASA terminates the connection.

vpn-simultaneous-logins

To configure the number of simultaneous logins permitted for a user, use the **vpn-simultaneous-logins** command in group-policy configuration mode or username configuration mode. To remove the attribute from the running configuration, use the **no** form of this command. This option allows inheritance of a value from another group policy. Enter 0 to disable login and prevent user access.

vpn-simultaneous-logins {*integer***}**

no vpn-simultaneous-logins

Syntax Description

integer	A number between 0 and 2147483647.

Defaults

The default is 3 simultaneous logins.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—
Username configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Enter 0 to disable login and prevent user access.

Note While the maximum limit for the number of simultaneous logins is very large, allowing several simultaneous logins could compromise security and affect performance.

Stale AnyConnect, IPsec Client, or Clientless sessions (sessions that are terminated abnormally) might remain in the session database, even though a “new” session has been established with the same username.

If the value of vpn-simultaneous-logins is 1, and the same user logs in again after an abnormal termination, then the stale session is removed from the database and the new session is established. If, however, the existing session is still an active connection and the same user logs in again, perhaps from another PC, the first session is logged off and removed from the database, and the new session is established.

If the number of simultaneous logins is a value greater than 1, then, when you have reached that maximum number and try to log in again, the session with the longest idle time is logged off. If all current sessions have been idle an equally long time, then the oldest session is logged off. This action frees up a session and allows the new login.

Examples

The following example shows how to allow a maximum of 4 simultaneous logins for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# vpn-simultaneous-logins 4
```

vpn-tunnel-protocol

To configure a VPN tunnel type (IPsec with IKEv1 or IKEv2, L2TP over IPsec, SSL, or clientless SSL), use the **vpn-tunnel-protocol** command in group-policy configuration mode or username configuration mode. To remove the attribute from the running configuration, use the **no** form of this command.

vpn-tunnel-protocol {**ikev1 ikev2 l2tp-ipsec ssl-client ssl-clientless**}

no vpn-tunnel-protocol {**ikev1 ikev2 l2tp-ipsec ssl-client ssl-clientless**}

Syntax Description

ikev1	Negotiates an IPsec tunnel with IKEv1 between two peers (a remote access client or another secure gateway). Creates security associations that govern authentication, encryption, encapsulation, and key management.
ikev2	Negotiates an IPsec tunnel with IKEv2 between two peers (a remote access client or another secure gateway). Creates security associations that govern authentication, encryption, encapsulation, and key management.
l2tp-ipsec	Negotiates an IPsec tunnel for an L2TP connection.
ssl-client	Negotiates an SSL VPN tunnel with an SSL VPN client.
ssl-clientless	Provides VPN services to remote users via an HTTPS-enabled web browser, and does not require a client.

Defaults

The default is IPsec.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group-policy configuration	•	—	•	—	—
Username configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	The **l2tp-ipsec** keyword was added.
7.3(1)	The **svc** keyword was added.
8.4(1)	The **ipsec** keyword was replaced by the **ikev1** and **ikev2** keywords.

Usage Guidelines

Use this command to configure one or more tunneling modes. You must configure at least one tunneling mode for users to connect over a VPN tunnel.

Note To support fallback from IPsec to SSL, the **vpn-tunnel-protocol** command must have both the **svc** and **ipsec** arguments configured.

Examples

The following example shows how to configure WebVPN and IPsec tunneling modes for the group policy named "FirstGroup":

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# vpn-tunnel-protocol webvpn
hostname(config-group-policy)# vpn-tunnel-protocol IPsec
```

Related Commands

Command	Description
address pools	Specifies a list of address pools for allocating addresses to remote clients.
show running-config group-policy	Displays the configuration for all group-policies or for a specific group-policy.

vpnclient connect

To attempt to establish an Easy VPN Remote connection to the configured server or servers, use the **vpnclient connect** command in global configuration mode.

vpnclient connect

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command applies only to the ASA 5505.

Examples

The following example shows how to attempt to establish an Easy VPN Remote connection to a configured EasyVPN server:

```
hostname(config)# vpnclient connect
hostname(config)#
```

vpnclient enable

To enable the Easy VPN Remote feature, use the **vpnclient enable** command in global configuration mode. To disable the Easy VPN Remote feature, use the **no** form of this command:

vpnclient enable

no vpnclient enable

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command applies only to the ASA 5505.

If you enter the **vpnclient enable** command, the ASA 5505 functions as a Easy VPN hardware client (also called “Easy VPN Remote”).

Examples

The following example shows how to enable the Easy VPN Remote feature:

```
hostname(config)# vpnclient enable
hostname(config)#
```

The following example shows how to disable the Easy VPN Remote feature:

```
hostname(config)# no vpnclient enable
hostname(config)#
```

vpnclient ipsec-over-tcp

To configure the ASA 5505 running as an Easy VPN hardware client to use TCP-encapsulated IPsec, use the **vpnclient ipsec-over-tcp** command in global configuration mode. To remove the attribute from the running configuration, use the **no** form of this command.

vpnclient ipsec-over-tcp [**port** *tcp_port*]

no vpnclient ipsec-over-tcp

Syntax Description

port	(Optional) Specifies the use of a particular port.
tcp_port	(Required if you specify the keyword **port**.) Specifies the TCP port number to be used for a TCP-encapsulated IPsec tunnel.

Defaults

The Easy VPN Remote connection uses port 10000 if the command does not specify a port number.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command applies only to the ASA 5505 running as an Easy VPN hardware client (also called "Easy VPN Remote").

By default, the Easy VPN client and server encapsulate IPsec in User Datagram Protocol (UDP) packets. Some environments, such as those with certain firewall rules, or NAT and PAT devices, prohibit UDP. To use standard Encapsulating Security Protocol (ESP, Protocol 50) or Internet Key Exchange (IKE, UDP 500) in such environments, you must configure the client and the server to encapsulate IPsec within TCP packets to enable secure tunneling. If your environment allows UDP, however, configuring IPsec over TCP adds unnecessary overhead.

If you configure an ASA 5505 to use TCP-encapsulated IPsec, enter the following command to let it send large packets over the outside interface:

```
hostname(config)# crypto ipsec df-bit clear-df outside
hostname(config)#
```

This command clears the Don't Fragment (DF) bit from the encapsulated header. A DF bit is a bit within the IP header that determines whether the packet can be fragmented. This command lets the Easy VPN hardware client send packets that are larger than the MTU size.

Examples

The following example shows how to configure the Easy VPN hardware client to use TCP-encapsulated IPsec, using the default port 10000, and to let it send large packets over the outside interface:

```
hostname(config)# vpnclient ipsec-over-tcp
hostname(config)# crypto ipsec df-bit clear-df outside
hostname(config)#
```

The next example shows how to configure the Easy VPN hardware client to use TCP-encapsulated IPsec, using the port 10501, and to let it send large packets over the outside interface:

```
hostname(config)# vpnclient ipsec-over-tcp port 10501
hostname(config)# crypto ipsec df-bit clear-df outside
hostname(config)#
```

vpnclient mac-exempt

To exempt devices behind an Easy VPN Remote connection from individual user authentication requirements, use the **vpnclient mac-exempt** command in global configuration mode. To remove the attribute from the running configuration, use the **no** form of this command.

vpnclient mac-exempt *mac_addr_1 mac_mask_1* [*mac_addr_2 mac_mask_2...mac_addr_n mac_mask_n*]

no vpnclient mac-exempt

Syntax Description

mac_addr_1	MAC address, in dotted hexadecimal notation, specifying a manufacturer and serial number of a device for which to exempt individual user authentication. For more than one device, specify each MAC address, separating each with a space and the respective network mask. The first 6 characters of the MAC address identify the device manufacturer, and the last 6 characters are the serial number. The last 24 bits are the unit's serial number in hexadecimal format.
mac_mask_1	Network mask for the corresponding MAC address. Use a space to separate the network mask and any subsequent MAC address and network mask pairs.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command applies only to the ASA 5505.

Devices such as Cisco IP phones, wireless access points, and printers are incapable of performing authentication, and therefore do not authenticate when individual unit authentication is enabled. If individual user authentication is enabled, you can use this command to exempt such devices from authentication. The exemption of devices from individual user authentication is also called "device pass-through."

The format for specifying the MAC address and mask in this command uses three hex digits, separated by periods; for example, the MAC mask ffff.ffff.ffff matches just the specified MAC address. A MAC mask of all zeroes matches no MAC address, and a MAC mask of ffff.ff00.0000 matches all devices made by the same manufacturer.

Note You must have Individual User Authentication and User Bypass configured on the headend device. For example, if you have the ASA as the headend, configure the following under group policy:

```
hostname(config-group-policy)# user-authentication enable
hostname(config-group-policy)# ip-phone-bypass enable
```

Examples

Cisco IP phones have the Manufacturer ID 00036b, so the following command exempts any Cisco IP phone, including Cisco IP phones, you might add in the future:

```
hostname(config)# vpnclient mac-exempt 0003.6b00.0000 ffff.ff00.0000
hostname(config)#
```

The next example provides greater security but less flexibility because it exempts one specific Cisco IP phone:

```
hostname(config)# vpnclient mac-exempt 0003.6b54.b213 ffff.ffff.ffff
hostname(config)#
```

vpnclient management

To generate IPsec tunnels for management access to the Easy VPN hardware client, use the **vpnclient management** command in global configuration mode.

vpnclient management tunnel *ip_addr_1 ip_mask_1* [*ip_addr_2 ip_mask_2...ip_addr_n ip_mask_n*]

vpnclient management clear

To remove the attribute from the running configuration, use the **no** form of this command, which sets up IPsec tunnels exclusively for management in accordance with the **split-tunnel-policy** and **split-tunnel-network-list** commands.

no vpnclient management

Syntax Description

clear	Uses normal routing to provide management access from the corporate network to the outside interface of the ASA 5505 running as an Easy VPN Client. This option does not create management tunnels. **Note** Use this option if a NAT device is operating between the client and the Internet.
ip_addr	IP address of the host or network for which to build a management tunnel from the Easy VPN hardware client. Use this argument with the **tunnel** keyword. Specify one or more IP addresses, separating each with a space and the respective network mask.
ip_mask	Network mask for the corresponding IP address. Use a space to separate the network mask and any subsequent IP address and network mask pairs.
tunnel	Automates the setup of IPsec tunnels specifically for management access from the corporate network to the outside interface of the ASA 5505 running as an Easy VPN Client.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command applies only to the ASA 5505 running as an Easy VPN Client (also called "Easy VPN Remote"). It assumes the ASA 5505 configuration contains the following commands:

vpnclient server to specify the peer.

vpnclient mode to specify the client mode (PAT) or network extension mode.

One of the following:

- **vpnclient vpngroup** to name the tunnel group and the IKE pre-shared key used for authentication on the Easy VPN server.
- **vpnclient trustpoint** to name the trustpoint identifying the RSA certificate to use for authentication

vpnclient enable to enable the ASA 5505 as an Easy VPN Client.

Note The public address of an ASA 5505 behind a NAT device is inaccessible unless you add static NAT mappings on the NAT device.

Note Regardless of your configuration, DHCP requests (including renew messages) should not flow over IPsec tunnels. Even with a vpnclient management tunnel, DHCP traffic is prohibited.

Examples

The following example shows how to generate an IPsec tunnel from the outside interface of the ASA 5505 to the host with the IP address/mask combination 192.168.10.10 255.255.255.0:

```
hostname(config)# vpnclient management tunnel 192.168.10.0 255.255.255.0
hostname(config)#
```

The following example shows how to provide management access to the outside interface of the ASA 5505 without using IPsec:

```
hostname(config)# vpnclient management clear
hostname(config)#
```

vpnclient mode

To configure the Easy VPN Remote connection for either client mode or network extension mode, use the **vpnclient mode** command in global configuration mode. To remove the attribute from the running configuration, use the **no** form of this command.

vpnclient mode {**client-mode** | **network-extension-mode**}

no vpnclient mode

Syntax Description

client-mode	Configures the Easy VPN Remote connection to use client mode (PAT).
network-extension-mode	Configures the Easy VPN Remote connection to use network extension mode (NEM).

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command applies only to the ASA 5505 running as an Easy VPN Client (also called "Easy VPN Remote). The Easy VPN Client supports one of two modes of operation: client mode or NEM. The mode of operation determines whether the inside hosts, relative to the Easy VPN Client, are accessible from the Enterprise network over the tunnel. Specifying a mode of operation is mandatory before making a connection because Easy VPN Client does not have a default mode.

- In client mode, the Easy VPN client performs port address translation (PAT) for all VPN traffic from its inside hosts. This mode requires no IP address management for either the inside address of the hardware client (which has a default RFC 1918 address assigned to it) or the inside hosts. Because of PAT, the inside hosts are not accessible from the enterprise network.
- In NEM, all nodes on the inside network and the inside interface are assigned addresses routable across the enterprise network. The inside hosts are accessible from the enterprise network over a tunnel. Hosts on the inside network are assigned IP addresses from an accessible subnet (statically or through DHCP). PAT is not applied to the VPN traffic when in network extension mode.

Note If the Easy VPN hardware client is using NEM and has connections to secondary servers, use the **crypto map set reverse-route** command on each headend device to configure dynamic announcements of the remote network using Reverse Route Injection (RRI).

Examples

The following example shows how to configure an Easy VPN Remote connection for client mode:

```
hostname(config)# vpnclient mode client-mode
hostname(config)#
```

The following example shows how to configure an Easy VPN Remote connection for NEM:

```
hostname(config)# vpnclient mode network-extension-mode
hostname(config)#
```

vpnclient nem-st-autoconnect

To configure the Easy VPN Remote connection to automatically initiate IPsec data tunnels when NEM and split tunneling are configured, use the **vpnclient nem-st-autoconnect** command in global configuration mode. To remove the attribute from the running configuration, use the **no** form of this command.

vpnclient nem-st-autoconnect

no vpnclient nem-st-autoconnect

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command applies only to the ASA 5505 running as an Easy VPN Client (also called "Easy VPN Remote").

Before entering the **vpnclient nem-st-autoconnect** command, ensure that network extension mode is enabled for the hardware client. Network extension mode lets hardware clients present a single, routable network to the remote private network over the VPN tunnel. IPsec encapsulates all traffic from the private network behind the hardware client to networks behind the ASA. PAT does not apply. Therefore, devices behind the ASA have direct access to devices on the private network behind the hardware client over the tunnel, and only over the tunnel, and vice versa. The hardware client must initiate the tunnel. After the tunnel is up, either side can initiate data exchange.

Note You must also configure the Easy VPN server to enable network extension mode. To do so, use the **nem enable** command in group-policy configuration mode.

IPsec data tunnels are automatically initiated and sustained when in network extension mode, except when split-tunneling is configured.

Examples

The following example shows how to configure an Easy VPN Remote connection to automatically connect in network extension mode with split-tunneling configured. Network extension mode is enabled for the group policy FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# nem enable
hostname(config)# vpnclient nem-st-autoconnect
hostname(config)#
```

Related Commands

Command	Description
nem	Enables network extension mode for hardware clients.

vpnclient server-certificate

To configure the Easy VPN Remote connection to accept only connections to Easy VPN servers with the specific certificates specified by the certificate map, use the **vpnclient server-certificate** command in global configuration mode. To remove the attribute from the running configuration, use the **no** form of this command.

vpnclient server-certificate *certmap_name*

no vpnclient server-certificate

Syntax Description

certmap_name	Specifies the name of a certificate map that specifies the acceptable Easy VPN server certificate. The maximum length is 64 characters.

Defaults

Easy VPN server certificate filtering is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command applies only to the ASA model 5505.

Use this command to enable Easy VPN server certificate filtering. You define the certificate map itself using the crypto ca certificate map and crypto ca certificate chain commands.

Examples

The following example shows how to configure an Easy VPN Remote connection to support only connections to Easy VPN servers with the certificate map name homeservers:

```
hostname(config)# vpnclient server-certificate homeservers
hostname(config)#
```

Related Commands

Command	Description
certificate	Adds the indicated certificate.
vpnclient trustpoint	Configures the RSA identity certificate to be used by the Easy VPN Remote connection.

vpnclient server

To configure the primary and secondary IPsec servers, for the Easy VPN Remote connection, use the **vpnclient server** command in global configuration mode. To remove the attribute from the running configuration, use the **no** form of this command.

vpnclient server *ip_primary_address* [*ip_secondary_address_1 ... ipsecondary_address_10*]

no vpnclient server

Syntax Description

ip_primary_address	IP address or DNS name of the primary Easy VPN (IPsec) server. Any ASA or VPN 3000 Concentrator Series can act as an Easy VPN server.
ip_secondary_address_n	(Optional) List of the IP addresses or DNS names of up to ten backup Easy VPN servers. Use a space to separate the items in the list.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command applies only to the ASA model 5505.

A server must be configured before a connection can be established. The **vpnclient server** command supports IPv4 addresses, the names database, or DNS names and resolves addresses in that order.

You can use either the IP address or the hostname of a server.

Examples

The following example associates the name headend-1 with the address 10.10.10.10 and uses the **vpnclient server** command to specify three servers: headend-dns.example.com (primary), headend-1 (secondary), and 192.168.10.10 (secondary):

```
hostname(config)# names
hostname(config)# 10.10.10.10 headend-1
hostname(config)# vpnclient server headend-dns.example.com headend-1 192.168.10.10
hostname(config)#
```

The following example shows how to configure a VPN client primary IPsec server with the IP address 10.10.10.15 and secondary servers with the IP addresses 10.10.10.30 and 192.168.10.45.

```
hostname(config)# vpnclient server 10.10.10.15 10.10.10.30 192.168.10.10
hostname(config)#
```

vpnclient trustpoint

To configure the RSA identity certificate to be used by the Easy VPN Remote connection, use the **vpnclient trustpoint** command in global configuration mode. To remove the attribute from the running configuration, use the **no** form of this command.

vpnclient trustpoint *trustpoint_name* [**chain**]

no vpnclient trustpoint

Syntax Description

chain	Sends the entire certificate chain.
trustpoint_name	Specifies the name of a trustpoint identifying the RSA certificate to use for authentication.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command applies only to the ASA model 5505 and only when using digital certificates.

Define the trustpoint using the **crypto ca trustpoint** command. A trustpoint represents a CA identity and possibly a device identity, based on a certificate issued by the CA. The commands within the trustpoint sub mode control CA-specific configuration parameters which specify how the ASA obtains the CA certificate, how the ASA obtains its certificate from the CA, and the authentication policies for user certificates issued by the CA.

Examples

The following example shows how to configure an Easy VPN Remote connection to use the specific identity certificate named central and to send the entire certificate chain:

```
hostname(config)# crypto ca trustpoint central
hostname(config)# vpnclient trustpoint central chain
hostname(config)#
```

Related Commands

Command	Description
crypto ca trustpoint	Enters the trustpoint submode for the specified trustpoint and manages trustpoint information.

vpnclient username

To configure the VPN username and password for the Easy VPN Remote connection, use the **vpnclient username** command in global configuration mode. To remove the attribute from the running configuration, use the **no** form of this command.

vpnclient username *xauth_username* **password** *xauth password*

no vpnclient username

Syntax Description

xauth_password	Specifies the password to use for XAUTH. The maximum length is 64 characters.
xauth_username	Specifies the username to use for XAUTH. The maximum length is 64 characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command applies only to the ASA 5505.

The XAUTH username and password parameters are used when secure unit authentication is disabled and the server requests XAUTH credentials. If secure unit authentication is enabled, these parameters are ignored, and the ASA prompts the user for a username and password.

Examples

The following example shows how to configure the Easy VPN Remote connection to use the XAUTH username testuser and the password ppurkm1:

```
hostname(config)# vpnclient username testuser password ppurkm1
hostname(config)#
```

vpnclient vpngroup

To configure the VPN tunnel group name and password for the Easy VPN Remote connection, use the **vpnclient vpngroup** command in global configuration mode. To remove the attribute from the running configuration, use the **no** form of this command.

vpnclient vpngroup *group_name* **password** *preshared_key*

no vpnclient vpngroup

Syntax Description

group_name	Specifies the name of the VPN tunnel group configured on the Easy VPN server. The maximum length is 64 characters, and no spaces are allowed.
preshared_key	The IKE pre-shared key used for authentication by the Easy VPN server. The maximum length is 128 characters.

Defaults

If the configuration of the ASA 5505 running as an Easy VPN client does not specify a tunnel group, the client attempts to use an RSA certificate.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command applies only to the ASA 5505 running as an Easy VPN client (also called "Easy VPN Remote").

Use the pre-shared key as the password. You must configure a server before establishing a connection.

Examples

The following example shows how to configure an Easy VPN Remote connectionwith a VPN tunnel group with the group name TestGroup1 and the password my_key123.

```
hostname(config)# vpnclient vpngroup TestGroup1 password my_key123
hostname(config)#
```

Related Commands

Command	Description
vpnclient trustpoint	Configures the RSA identity certificate to be used by the Easy VPN connection.

vpnsetup

To display a list of steps for configuring VPN connections on the ASA, use the **vpnsetup** command from global configuration mode.

vpnsetup {**ipsec-remote-access** | **l2tp-remote-access** | **site-to-site** | **ssl-remote-access**} **steps**

Syntax Description

ipsec-remote-access	Displays steps to configure the ASA to accept IPsec connections.
l2tp-remote-access	Displays steps to configure the ASA to accept L2TP connections.
site-to-site	Displays steps to configure the ASA to accept LAN-to-LAN connections.
ssl-remote-access	Displays steps to configure the ASA to accept SSL connections.
steps	Specifies to display the steps for the connection type.

Defaults

This command has no default settings

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
8.0(3)	This command was introduced.
9.0(1)	Support for multiple context mode was added for site-to-site connections.

Examples

The following example shows the output of the **vpnsetup ssl-remote-access steps** command:

```
hostname(config-t)# vpnsetup ssl-remote-access steps

Steps to configure a remote access SSL VPN remote access connection and AnyConnect with
examples:

1. Configure and enable interface

    interface GigabitEthernet0/0
     ip address 10.10.4.200 255.255.255.0
     nameif outside
     no shutdown

    interface GigabitEthernet0/1
     ip address 192.168.0.20 255.255.255.0
     nameif inside
     no shutdown

2. Enable WebVPN on the interface
```

```
    webvpn
     enable outside

3. Configure default route

    route outside 0.0.0.0 0.0.0.0 10.10.4.200

4. Configure AAA authentication and tunnel group

    tunnel-group DefaultWEBVPNGroup type remote-access
    tunnel-group DefaultWEBVPNGroup general-attributes
     authentication-server-group LOCAL

5. If using LOCAL database, add users to the Database

    username test password t3stP@ssw0rd
    username test attributes
     service-type remote-access

Proceed to configure AnyConnect VPN client:

6. Point the ASA to an AnyConnect image

    webvpn
     svc image anyconnect-win-2.1.0148-k9.pkg

7. enable AnyConnect

    svc enable

8. Add an address pool to assign an ip address to the AnyConnect client

    ip local pool client-pool 192.168.1.1-192.168.1.254 mask 255.255.255.0

9. Configure group policy

    group-policy DfltGrpPolicy internal
    group-policy DfltGrpPolicy attributes
     vpn-tunnel-protocol svc webvpn

hostname(config-t)#
```

Related Commands

Command	Description
show running-config	Displays the running configuration of the ASA.

CHAPTER 68

wccp through zonelabs integrity ssl-client-authentication Commands

wccp

To allocate space and to enable support of the specified Web Cache Communication Protocol (WCCP) service for participation in a service group, use the **wccp** command in global configuration mode. To disable the service group and deallocate space, use the no form of this command.

wccp {**web-cache** | *service-number*} [**redirect-list** *access-list*] [**group-list** *access-list*] [**password** password]

no wccp {**web-cache** | *service-number*} [**redirect-list** *access-list*] [**group-list** *access-list*] [**password** password [**0** | **7**]]

Syntax Description

web-cache	Specifies the web-cache service. **Note** Web cache counts as one service. The maximum number of services, including those assigned with the service-number argument are 256
service-number	A dynamic service identifier, which means the service definition is dictated by the cache. The dynamic service number can be from 0 to 254 and up to 255. There is a maximum allowable number of 256 that includes the web-cache service specified with the **web-cache** keyword.
redirect-list	(Optional) Used with an access list that controls traffic redirected to this service group. The access-list argument should consist of a string of no more than 64 characters (name or number) that specifies the access list. The access list should only contain network addresses. Port-specific entries are not supported
access-list	Specifies the name of the access list.
group-list	(Optional) Access list that determines which web caches are allowed to participate in the service group. The access-list argument should consist of a string of no more than 64 characters (name or number) that specifies the access list.
password	(Optional) Specifies Message Digest 5 (MD5) authentication for messages received from the service group. Messages that are not accepted by the authentication are discarded.
password	Specifies the password to be used for authentication. The password argument can be up to seven characters in length.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to enable WCCP for participation in a service group:

```
hostname(config)# wccp web-cache redirect-list jeeves group-list wooster password whatho
```

Related Commands

Commands	Description
show wccp	Displays the WCCP configuration.
wccp redirect	Enables support of WCCP redirection.

wccp redirect

To enable packet redirection on the ingress of an interface using Web Cache Communication Protocol (WCCP), use the **wccp redirect** command. To disable WCCP redirection, use the no form of this command.

wccp interface *interface_name service* **redirect in**

no wccp interface *interface_name service* **redirect in**

Syntax Description

interface_name	Name of the interface where packets should be redirected..
service	Specifies the service group. You can specify the **web-cache** keyword, or you can specify the identification number (from 0 to 99) of the service.
in	Specifies redirection when packet comes into this interface

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to enable WCCP redirection on the inside interface for the web-cache service:

```
hostname(config)# wccp interface inside web-cache redirect in
```

Related Commands

Commands	Description
show wccp	Displays the WCCP configuration.
wccp	Enables support of WCCP with service groups.

web-agent-url

To specify the SSO server URL to which the ASA makes SiteMinder-type SSO authentication requests, use the **web-agent-url** command in config-webvpn-sso-siteminder mode.

To remove an SSO server authentication URL, use the **no** form of this command.

web-agent-url *url*

no web-agent-url *url*

Note This command is required for SiteMinder-type SSO authentication.

Syntax Description

url	Specifies the authentication URL of the SiteMinder-type SSO server. Must contain http:// or https://.

Defaults

By default, an authentication URL is not configured.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Config-webvpn-sso-siteminder	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Single-sign-on support, available only for WebVPN, lets users access different secure services on different servers without entering a username and password more than once. The SSO server has a URL that handles authentication requests.

This command applies only to the SiteMinder type of SSO server.

Use the **web-agent-url** command to configure the ASA to send authentications to this URL. Before configuring the authentication URL, you must create the SSO server using the **sso-server** command.

For https communication between the security appliance and SSO-server, make sure that the SSL encryption settings match on both sides. On the security appliance, verify this with the **ssl encryption** command.

Examples

The following example, entered in config-webvpn-sso-siteminder mode, specifies an authentication URL of http://www.example.com/webvpn:

```
hostname(config-webvpn)# sso-server example type siteminder
hostname(config-webvpn-sso-siteminder)# web-agent-url http://www.example.com/webvpn
hostname(config-webvpn-sso-siteminder)#
```

Related Commands

Command	Description
max-retry-attempts	Configures the number of times the ASA retries a failed SSO authentication attempt.
policy-server-secret	Creates a secret key used to encrypt authentication requests to a SiteMinder-type SSO server.
request-timeout	Specifies the number of seconds before a failed SSO authentication attempt times out.
show webvpn sso-server	Displays the operating statistics for all SSO servers configured on the security device.
ssl encryption	Specifies the encryption algorithms the SSL/TLS protocol uses.
sso-server	Creates a single sign-on server.

web-applications

To customize the Web Application box of the WebVPN Home page that is displayed to authenticated WebVPN users, use the **web-applications** command from webvpn customization mode:

web-applications {**title** | **message** | **dropdown**} {**text** | **style**} *value*

[**no**] **web-applications** {**title** | **message** | **dropdown**} {**text** | **style**} *value*

To remove the command from the configuration and cause the value to be inherited, use the **no** form of the command.

Syntax Description

title	Specifies you are changing the title.
message	Specifies you are changing the message displayed under the title.
dropdown	Specifies you are changing the dropdown box.
text	Specifies you are changing the text.
style	Specifies you are changing the HTML style.
value	The actual text to display (maximum 256 characters), or Cascading Style Sheet (CSS) parameters (maximum 256 characters).

Defaults

The default title text is “Web Application”.

The default title style is background-color:#99CCCC;color:black;font-weight:bold;text-transform: uppercase

The default message text is “Enter Web Address (URL)”.

The default message style is background-color:#99CCCC;color:maroon;font-size:smaller.

The default dropdown text is “Web Bookmarks”.

The default dropdown style is border:1px solid black;font-weight:bold;color:black;font-size:80%.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Webvpn customization	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The **style** option is expressed as any valid Cascading Style Sheet (CSS) parameters. Describing these parameters is beyond the scope of this document. For more information about CSS parameters, consult CSS specifications at the World Wide Web Consortium (W3C) website at www.w3.org. Appendix F of the CSS 2.1 Specification contains a convenient list of CSS parameters, and is available at www.w3.org/TR/CSS21/propidx.html.

Here are some tips for making the most common changes to the WebVPN pages—the page colors:

- You can use a comma-separated RGB value, an HTML color value, or the name of the color if recognized in HTML.
- RGB format is 0,0,0, a range of decimal numbers from 0 to 255 for each color (red, green, blue); the comma separated entry indicates the level of intensity of each color to combine with the others.
- HTML format is #000000, six digits in hexadecimal format; the first and second represent red, the third and fourth green, and the fifth and sixth represent blue.

Note To easily customize the WebVPN pages, we recommend that you use ASDM, which has convenient features for configuring style elements, including color swatches and preview capabilities.

Examples

The following example changes the title to “Applications”, and the color of the text to blue:

```
hostname(config)# webvpn
hostname(config-webvpn)# customization cisco
hostname(config-webvpn-custom)# web-applications title text Applications
hostname(config-webvpn-custom)# web-applications title style color:blue
```

Related Commands

Command	Description
application-access	Customizes the Application Access box of the WebVPN Home page.
browse-networks	Customizes the Browse Networks box of the WebVPN Home page.
web-bookmarks	Customizes the Web Bookmarks title or links on the WebVPN Home page.
file-bookmarks	Customizes the File Bookmarks title or links on the WebVPN Home page.

web-bookmarks

To customize the Web Bookmarks title or links on the WebVPN Home page that is displayed to authenticated WebVPN users, use the **web-bookmarks** command from webvpn customization mode:

web-bookmarks {**link** {**style** *value*} | **title** {**style** *value* | **text** *value*}}

[**no**] **web-bookmarks** {**link** {**style** *value*} | **title** {**style** *value* | **text** *value*}}

To remove the command from the configuration and cause the value to be inherited, use the **no** form of the command.

Syntax Description

link	Specifies you are changing the links.
title	Specifies you are changing the title.
style	Specifies you are changing the HTML style.
text	Specifies you are changing the text.
value	The actual text to display (maximum 256 characters), or Cascading Style Sheet (CSS) parameters (maximum 256 characters).

Defaults

The default link style is color:#669999;border-bottom: 1px solid #669999;text-decoration:none.

The default title style is color:#669999;background-color:#99CCCC;font-weight:bold.

The default title text is “Web Bookmarks”.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Webvpn customization	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The **style** option is expressed as any valid Cascading Style Sheet (CSS) parameters. Describing these parameters is beyond the scope of this document. For more information about CSS parameters, consult CSS specifications at the World Wide Web Consortium (W3C) website at www.w3.org. Appendix F of the CSS 2.1 Specification contains a convenient list of CSS parameters, and is available at www.w3.org/TR/CSS21/propidx.html.

Here are some tips for making the most common changes to the WebVPN pages—the page colors:

- You can use a comma-separated RGB value, an HTML color value, or the name of the color if recognized in HTML.

- RGB format is 0,0,0, a range of decimal numbers from 0 to 255 for each color (red, green, blue); the comma separated entry indicates the level of intensity of each color to combine with the others.
- HTML format is #000000, six digits in hexadecimal format; the first and second represent red, the third and fourth green, and the fifth and sixth represent blue.

Note To easily customize the WebVPN pages, we recommend that you use ASDM, which has convenient features for configuring style elements, including color swatches and preview capabilities.

Examples

The following example customizes the Web Bookmarks title to "Corporate Web Bookmarks":

```
hostname(config)# webvpn
hostname(config-webvpn)# customization cisco
hostname(config-webvpn-custom)# web-bookmarks title text Corporate Web Bookmarks
```

Related Commands

Command	Description
application-access	Customizes the Application Access box of the WebVPN Home page.
browse-networks	Customizes the Browse Networks box of the WebVPN Home page.
file-bookmarks	Customizes the File Bookmarks title or links on the WebVPN Home page.
web-applications	Customizes the Web Application box of the WebVPN Home page.

webvpn

To enter webvpn mode, in global configuration mode, enter the **webvpn** command. To remove any commands entered with this command, use the **no webvpn** command. These webvpn commands apply to all WebVPN users.

These webvpn commands let you configure AAA servers, default group policies, default idle timeout, http and https proxies, and NBNS servers for WebVPN, as well as the appearance of WebVPN screens that end users see.

webvpn

no webvpn

Syntax Description

This command has no arguments or keywords.

Defaults

WebVPN is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•		—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This WebVPN mode lets you configure global settings for WebVPN. WebVPN mode, which you enter from either group-policy mode or username mode, lets you customize a WebVPN configuration for specific users or group policies. The ASA clientless SSL VPN configuration supports only one http-proxy and one https-proxy command each.

Note You must enable browser caching for WebVPN to work.

Examples

The following example shows how to enter WebVPN command mode:

```
hostname(config)# webvpn
hostname(config-webvpn)#
```

webvpn (group-policy and username modes)

To enter this webvpn mode, use the **webvpn** command in group-policy configuration mode or in username configuration mode. To remove all commands entered in webvpn mode, use the **no** form of this command. These webvpn commands apply to the username or group policy from which you configure them.

Webvpn commands for group policies and usernames define access to files, MAPI proxy, URLs and TCP applications over WebVPN. They also identify ACLs and types of traffic to filter.

webvpn

no webvpn

Syntax Description

This command has no arguments or keywords.

Defaults

WebVPN is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•		—
Username configuration	•	—	•		—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Webvpn mode, which you enter from global configuration mode, lets you configure global settings for WebVPN. The **webvpn** command in group-policy attributes configuration mode or username attributes configuration mode applies the settings specified in the webvpn command to the group or user specified in the parent command. In other words, webvpn mode, described in this section, and which you enter from group-policy or username mode, lets you customize a WebVPN configuration for specific users or group policies.

The webvpn attributes that you apply for a specific group policy in group-policy attributes mode override those specified in the default group policy. The WebVPN attributes that you apply for a specific user in username attributes mode override both those in the default group policy and those in the group policy to which that user belongs. Essentially, these commands let you tweak the settings that would otherwise be inherited from the default group or the specified group policy. For information about the WebVPN settings, see the description of the **webvpn** command in global configuration mode.

The following table lists the attributes you can configure in webvpn group-policy attributes and username attributes mode. See the individual command descriptions for details.

Attribute	Description
auto-signon	Configures the ASA to automatically pass WebVPN user login credentials on to internal servers, providing a single sign-on method for WebVPN users.
customization	Specifies a preconfigured WebVPN customization to apply.
deny-message	Specifies a message to display to the user when access is denied.
filter	Identifies the access list to be used for WebVPN connections.
functions	Configures file access and file browsing, MAPI Proxy, and URL entry over WebVPN.
homepage	Sets the URL of the webpage that displays when WebVPN users log in.
html-content-filter	Identifies Java, ActiveX, images, scripts, and cookies to filter for WebVPN sessions.
http-comp	Specifies the HTTP compression algorithm to use.
keep-alive-ignore	Specifies the maximum object size to ignore for updating the session.
port-forward	Enables WebVPN application access.
port-forward-name	Configures the display name that identifies TCP port forwarding to end users.
sso-server	Configures the SSO server name.
svc	Configures SSL VPN Client attributes.
url-list	Identifies a list of servers and URLs that users can access via WebVPN.

Examples

The following example shows how to enter webvpn mode for the group policy named "FirstGroup":

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# webvpn
hostname(config-webvpn)#
```

The following example shows how to enter webvpn mode for the username named "test":

```
hostname(config)# group-policy test attributes
hostname(config-username)# webvpn
hostname(config-webvpn)#
```

Related Commands

clear configure group-policy	Removes the configuration for a particular group policy or for all group policies.
group-policy attributes	Enters config-group-policy mode, which lets you configure attributes and values for a specified group policy or lets you enter webvpn mode to configure webvpn attributes for the group.

show running-config group-policy	Displays the running configuration for a particular group policy or for all group policies.
webvpn	Enters config-group-webvpn mode, in which you can configure the WebVPN attributes for the specified group.

whitelist

For Cloud Web Security, to perform the whitelist action on the class of traffic, use the **whitelist** command in class configuration mode. You can access the class configuration mode by first entering the **policy-map type inspect scansafe** command, then the **parameters** command. To disable whitelisting, use the **no** form of this command.

whitelist

no whitelist

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

Identify the traffic you want to whitelist using the **class-map type inspect scansafe** command. Use the inspection class map in the **policy-map type inspect scansafe** command, and specify the **whitelist** action for the class. Call the inspection policy map in the **inspect scansafe** command.

Examples

The following example whitelists the same users and groups for the HTTP and HTTPS inspection policy maps:

```
hostname(config)# class-map type inspect scansafe match-any whitelist1
hostname(config-cmap)# match user user1 group cisco
hostname(config-cmap)# match user user2
hostname(config-cmap)# match group group1
hostname(config-cmap)# match user user3 group group3

hostname(config)# policy-map type inspect scansafe cws_inspect_pmap1
hostname(config-pmap)# parameters
hostname(config-pmap-p)# http
hostname(config-pmap-p)# default group default_group
hostname(config-pmap-p)# class whitelist1
hostname(config-pmap-c)# whitelist
```

```
hostname(config)# policy-map type inspect scansafe cws_inspect_pmap2
hostname(config-pmap)# parameters
hostname(config-pmap-p)# https
hostname(config-pmap-p)# default group2 default_group2
hostname(config-pmap-p)# class whitelist1
hostname(config-pmap-c)# whitelist
```

Related Commands

Command	Description
class-map type inspect scansafe	Creates an inspection class map for whitelisted users and groups.
default user group	Specifies the default username and/or group if the ASA cannot determine the identity of the user coming into the ASA.
http[**s**] (parameters)	Specifies the service type for the inspection policy map, either HTTP or HTTPS.
inspect scansafe	Enables Cloud Web Security inspection on the traffic in a class.
license	Configures the authentication key that the ASA sends to the Cloud Web Security proxy servers to indicate from which organization the request comes.
match user group	Matches a user or group for a whitelist.
policy-map type inspect scansafe	Creates an inspection policy map so you can configure essential parameters for the rule and also optionally identify the whitelist.
retry-count	Enters the retry counter value, which is the amount of time that the ASA waits before polling the Cloud Web Security proxy server to check its availability.
scansafe	In multiple context mode, allows Cloud Web Security per context.
scansafe general-options	Configures general Cloud Web Security server options.
server {**primary** | **backup**}	Configures the fully qualified domain name or IP address of the primary or backup Cloud Web Security proxy servers.
show conn scansafe	Shows all Cloud Web Security connections, as noted by the capitol Z flag.
show scansafe server	Shows the status of the server, whether it's the current active server, the backup server, or unreachable.
show scansafe statistics	Shows total and current http connections.
user-identity monitor	Downloads the specified user or group information from the AD agent.

who

To display active Telnet administration sessions on the ASA, use the **who** command in privileged EXEC mode.

who [*local_ip*]

Syntax Description

local_ip	(Optional) Specifies to limit the listing to one internal IP address or network address, either IPv4 or IPv6.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **who** command allows you to display the TTY_ID and IP address of each Telnet client that is currently logged into the ASA.

Examples

This example shows the output of the **who** command when a client is logged into the ASA through a Telnet session:

```
hostname# who
0: 100.0.0.2
hostname# who 100.0.0.2
0: 100.0.0.2
hostname#
```

Related Commands

Command	Description
kill	Terminate a Telnet session.
telnet	Adds Telnet access to the ASA console and sets the idle timeout.

window-variation

To drop a connection with a window size variation, use the **window-variation** command in tcp-map configuration mode. To remove this specification, use the **no** form of this command.

window variation {**allow-connection** | **drop-connection**}

no window variation {**allow-connection** | **drop-connection**}

Syntax Description

allow-connection	Allows the connection.
drop-connection	Drops the connection.

Defaults

The default action is to allow the connection.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tcp-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **tcp-map** command is used along with the Modular Policy Framework infrastructure. Define the class of traffic using the **class-map** command and customize the TCP inspection with **tcp-map** commands. Apply the new TCP map using the **policy-map** command. Activate TCP inspection with **service-policy** commands.

Use the **tcp-map** command to enter tcp-map configuration mode. Use the **window-variation** command in tcp-map configuration mode to drop all connections with a window size that has been shrunk.

The window size mechanism allows TCP to advertise a large window and to subsequently advertise a much smaller window without having accepted too much data. From the TCP specification, “shrinking the window” is strongly discouraged. When this condition is detected, the connection can be dropped.

Examples

The following example shows how to drop all connections with a varied window size:

```
hostname(config)# access-list TCP extended permit tcp any any
hostname(config)# tcp-map tmap
hostname(config-tcp-map)# window-variation drop-connection
hostname(config)# class-map cmap
hostname(config-cmap)# match access-list TCP
hostname(config)# policy-map pmap
```

```
hostname(config-pmap)# class cmap
hostname(config-pmap)# set connection advanced-options tmap
hostname(config)# service-policy pmap global
```

Related Commands

Command	Description
class	Specifies a class map to use for traffic classification.
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
set connection	Configures connection values.
tcp-map	Creates a TCP map and allows access to tcp-map configuration mode.

wins-server

To set the IP address of the primary and secondary WINS servers, use the **wins-server** command in group-policy configuration mode. To remove the attribute from the running configuration, use the **no** form of this command. This option allows inheritance of a WINS server from another group policy. To prevent inheriting a server, use the **wins-server none** command.

wins-server value {*ip_address*} [*ip_address*] | none

no wins-server

Syntax Description

none	Sets wins-servers to a null value, thereby allowing no WINS servers. Prevents inheriting a value from a default or specified group policy.
value *ip_address*	Specifies the IP address of the primary and secondary WINS servers.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group-policy	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Every time you issue the **wins-server** command you overwrite the existing setting. For example, if you configure WINS server x.x.x.x and then configure WINS server y.y.y.y, the second command overwrites the first, and y.y.y.y becomes the sole WINS server. The same holds true for multiple servers. To add a WINS server rather than overwrite previously configured servers, include the IP addresses of all WINS servers when you enter this command.

Examples

The following example shows how to configure WINS servers with the IP addresses 10.10.10.15, 10.10.10.30, and 10.10.10.45 for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# wins-server value 10.10.10.15 10.10.10.30 10.10.10.45
```

without-csd

To exempt certain users from running Cisco Secure Desktop on a per connection profile basis if they enter one of the entries in the group-urls table to establish the VPN session, use the **without-csd** command in tunnel webvpn configuration mode. To remove this command from the configuration, use the **no** form of the command.

```
hostname(config-tunnel-webvpn)# without-csd
hostname(config-tunnel-webvpn)#
```

Syntax Description

This command has no arguments or keywords.

Defaults

No default values. If the configuration of this ASA contains a **csd enable** command, the default behavior is to run Cisco Secure Desktop on each endpoint.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel webvpn configuration mode	•	—	•	—	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

This command prevents Cisco Secure Desktop from running on the endpoint if the user enters a URL in the url-group list configured on this connection profile (called a tunnel group in the CLI). Entering this command prevents the detection of endpoint conditions for these sessions, so you may need to adjust the dynamic access policy (DAP) configuration.

Examples

The first command in the following example creates a group-url in which “example.com” is the domain of the security appliance and “no-csd” is the unique portion of the URL. When the user enters this URL, the ASA assigns this connection profile to the session. The **group-url** command is required for the **without-csd** command to have an effect. The **without-csd** command exempts the user from running Cisco Secure Desktop.

```
hostname(config-tunnel-webvpn)# group-url https://example.com/no-csd enable
hostname(config-tunnel-webvpn)# without-csd
hostname(config-tunnel-webvpn)#
```

Related Commands

Command	Description
csd enable	Enables Cisco Secure Desktop for all connection profiles that do not have a without-csd command.
csd image	Copies the Cisco Secure Desktop image named in the command, from the flash drive specified in the path to the running configuration.
group-url	Creates a group-url unique to this connection profile.

write erase

To erase the startup configuration, use the **write erase** command in privileged EXEC mode. The running configuration remains intact.

write erase

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command is not supported within a security context. Context startup configurations are identified by the **config-url** command in the system configuration. If you want to delete a context configuration, you can remove the file manually from the remote server (if specified) or clear the file from Flash memory using the **delete** command in the system execution space.

Examples

The following example erases the startup configuration:

```
hostname# write erase
Erase configuration in flash memory? [confirm] y
```

Related Commands

Command	Description
configure net	Merges a configuration file from the specified TFTP URL with the running configuration.
delete	Removes a file from Flash memory.
show running-config	Shows the running configuration.
write memory	Saves the running configuration to the startup configuration.

write memory

To save the running configuration to the startup configuration, use the **write memory** command in privileged EXEC mode.

write memory [**all** [**/noconfirm**]]

Syntax Description

/noconfirm	Eliminates the confirmation prompt when you use the **all** keyword.
all	From the system execution space in multiple context mode, this keyword saves all context configurations as well as the system configuration.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.2(1)	You can now save all context configurations with the **all** keyword.

Usage Guidelines

The running configuration is the configuration currently running in memory, including any changes you made at the command line. Changes are only preserved between reboots if you save them to the startup configuration, which is the configuration loaded into running memory at startup. The location of the startup configuration for single context mode and for the system in multiple context mode can be changed from the default location (a hidden file) to a location of your choosing using the **boot config** command. For multiple context mode, a context startup configuration is at the location specified by the **config-url** command in the system configuration.

In multiple context mode, you can enter the **write memory** command in each context to save the current context configuration. To save all context configurations, enter the **write memory all** command in the system execution space. Context startup configurations can reside on external servers. In this case, the ASA saves the configuration back to the server specified by the **config-url** command, except for HTTP and HTTPS URLs, which do not allow you to save the configuration back to the server. After the ASA saves each context with the **write memory all** command, the following message appears:

```
'Saving context 'b' ... ( 1/3 contexts saved ) '
```

Sometimes, a context is not saved because of an error. See the following information for errors:

- For contexts that are not saved because of low memory, the following message appears:

  ```
  The context 'context a' could not be saved due to Unavailability of resources
  ```

- For contexts that are not saved because the remote destination is unreachable, the following message appears:

```
The context 'context a' could not be saved due to non-reachability of destination
```

- For contexts that are not saved because the context is locked, the following message appears:

```
Unable to save the configuration for the following contexts as these contexts are
locked.
context ‘a’ , context ‘x’ , context ‘z’ .
```

  A context is only locked if another user is already saving the configuration or in the process of deleting the context.

- For contexts that are not saved because the startup configuration is read-only (for example, on an HTTP server), the following message report is printed at the end of all other messages:

```
Unable to save the configuration for the following contexts as these contexts have
read-only config-urls:
context ‘a’ , context ‘b’ , context ‘c’ .
```

- For contexts that are not saved because of bad sectors in the Flash memory, the following message appears:

```
The context 'context a' could not be saved due to Unknown errors
```

Because the system uses the admin context interfaces to access context startup configurations, the **write memory** command also uses the admin context interfaces. The **write net** command, however, uses the context interfaces to write a configuration to a TFTP server.

The **write memory** command is equivalent to the **copy running-config startup-config** command.

Examples

The following example saves the running configuration to the startup configuration:

```
hostname# write memory
Building configuration...
Cryptochecksum: e43e0621 9772bebe b685e74f 748e4454

19319 bytes copied in 3.570 secs (6439 bytes/sec)
[OK]
hostname#
```

Related Commands

Command	Description
admin-context	Sets the admin context.
configure memory	Merges the startup configuration with the running configuration.
config-url	Specifies the location of the context configuration.
copy running-config startup-config	Copies the running configuration to the startup configuration.
write net	Copies the running configuration to a TFTP server.

write net

To save the running configuration to a TFTP server, use the **write net** command in privileged EXEC mode.

write net [*server*:[*filename*] | :*filename*]

Syntax Description

:*filename*	Specifies the path and filename. If you already set the filename using the **tftp-server** command, then this argument is optional. If you specify the filename in this command as well as a name in the **tftp-server** command, the ASA treats the **tftp-server** command filename as a directory, and adds the **write net** command filename as a file under the directory. To override the **tftp-server** command value, enter a slash in front of the path and filename. The slash indicates that the path is not relative to the tftpboot directory, but is an absolute path. The URL generated for this file includes a double slash (//) in front of the filename path. If the file you want is in the tftpboot directory, you can include the path for the tftpboot directory in the filename path. If your TFTP server does not support this type of URL, use the **copy running-config tftp** command instead. If you specified the TFTP server address using the **tftp-server** command, you can enter the filename alone preceded by a colon (:).
server:	Sets the TFTP server IP address or name. This address overrides the address you set in the **tftp-server** command, if present. The default gateway interface is the highest security interface; however, you can set a different interface name using the **tftp-server** command.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The running configuration is the configuration currently running in memory, including any changes you made at the command line.

In multiple context mode, this command saves only the current configuration; you cannot save all contexts with a single command. You must enter this command separately for the system and for each context. The **write net** command uses the context interfaces to write a configuration to a TFTP server. The **write memory** command, however, uses the admin context interfaces to save to the startup configuration because the system uses the admin context interfaces to access context startup configurations.

The **write net** command is equivalent to the **copy running-config tftp** command.

Examples

The following example sets the TFTP server and filename in the **tftp-server** command:

```
hostname# tftp-server inside 10.1.1.1 /configs/contextbackup.cfg
hostname# write net
```

The following example sets the server and filename in the **write net** command. The **tftp-server** command is not populated.

```
hostname# write net 10.1.1.1:/configs/contextbackup.cfg
```

The following example sets the server and filename in the **write net** command. The **tftp-server** command supplies the directory name, and the server address is overridden.

```
hostname# tftp-server 10.1.1.1 configs
hostname# write net 10.1.2.1:context.cfg
```

Related Commands

Command	Description
configure net	Merges a configuration file from the specified TFTP URL with the running configuration.
copy running-config tftp	Copies the running configuration to a TFTP server.
show running-config	Shows the running configuration.
tftp-server	Sets a default TFTP server and path for use in other commands.
write memory	Saves the running configuration to the startup configuration.

write standby

To copy the ASA or context running configuration to the failover standby unit, use the **write standby** command in privileged EXEC mode.

write standby

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You should only use this command if the configuration standby unit or failover group becomes out-of-sync with the configuration of the active unit or failover group. This typically happens when commands are entered on the standby unit or failover group.

For Active/Standby failover, the **write standby** command writes the configuration stored in the RAM of the active failover unit to the RAM on the standby unit. Use the **write standby** command if the primary and secondary unit configurations have different information. Enter this command on the active unit.

For Active/Active failover, the **write standby** command behaves as follows:

- If you enter the **write standby** command in the system execution space, the system configuration and the configurations for all of the security contexts on the ASA is written to the peer unit. This includes configuration information for security contexts that are in the standby state. You must enter the command in the system execution space on the unit that has failover group 1 in the active state.
- If you enter the **write standby** command in a security context, only the configuration for the security context is written to the peer unit. You must enter the command in the security context on the unit where the security context appears in the active state.

Note After you enter the **write standby** command, the failover interfaces may go down momentarily while the configuration becomes re-synchronized.

Note The **write standby** command replicates the configuation to the running configuration of the peer unit; it does not save the configuration to the startup configuration. To save the configuration changes to the startup configuration, use the **copy running-config startup-config** command on the same unit that you entered the **write standby** command. The command will be replicated to the peer unit and the configuration saved to the startup configuration.

When Stateful Failover is enabled, the **write standby** command also replicates state information to the standby unit after the configuration replication is complete.

Examples

The following example writes the current running configuration to the standby unit:

```
hostname# write standby
Building configuration...
[OK]
hostname#
```

Related Commands

Command	Description
failover reload-standby	Forces the standby unit to reboot.

write terminal

To show the running configuration on the terminal, use the **write terminal** command in privileged EXEC mode.

write terminal

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command is equivalent to the **show running-config** command.

Examples

The following example writes the running configuration to the terminal:

```
hostname# write terminal
: Saved
:
ASA Version 7.0(0)61
multicast-routing
names
name 10.10.4.200 outside
!
interface GigabitEthernet0/0
 nameif inside
 security-level 100
 ip address 10.86.194.60 255.255.254.0
 webvpn enable
...
```

Related Commands

Command	Description
configure net	Merges a configuration file from the specified TFTP URL with the running configuration.
show running-config	Shows the running configuration.
write memory	Saves the running configuration to the startup configuration.

xlate per-session

To use multi-session PAT, use the **xlate per-session** command in global configuration mode. To remove a multi-session PAT rule, use the **no** form of this command.

xlate per-session {**permit** | **deny**} {**tcp** | **udp**} *source_ip* [*operator src_port*] *destination_ip operator dest_port*

no xlate per-session {**permit** | **deny**} {**tcp** | **udp**} *source_ip* [*operator src_port*] *destination_ip operator dest_port*

Syntax Description

permit	Creates a permit rule.
deny	Creates a deny rule.
tcp	Specifies TCP traffic.
udp	Specifies UDP traffic.
source_ip	For the source IP address, you can configure the following: • **host** *ip_address*—Specifies an IPv4 host address. • *ip_address mask*—Specifies an IPv4 network address and subnet mask. • *ipv6-address*/*prefix-length*—Specifies an IPv6 host or network address and prefix. • **any4** and **any6**—**any4** specifies only IPv4 traffic; and **any6** specifies any6 traffic.
operator src_port	(Optional) The *operator* matches the port numbers used by the source. The permitted operators are as follows: • lt—less than • gt—greater than • eq—equal to • neq—not equal to • range—an inclusive range of values. When you use this operator, specify two port numbers, for example: `range 100 200`

destination_ip	For the destination IP address, you can configure the following: • **host** *ip_address*—Specifies an IPv4 host address. • *ip_address mask*—Specifies an IPv4 network address and subnet mask. • *ipv6-address/prefix-length*—Specifies an IPv6 host or network address and prefix. • **any4** and **any6**—**any4** specifies only IPv4 traffic; and **any6** specifies any6 traffic.
operator dest_port	The *operator* matches the port numbers used by the destination. The permitted operators are as follows: • lt—less than • gt—greater than • eq—equal to • neq—not equal to • range—an inclusive range of values. When you use this operator, specify two port numbers, for example: `range 100 200`

Command Default

By default, all TCP traffic and UDP DNS traffic use a per-session PAT xlate. The following default rules are installed:

```
xlate per-session permit tcp any4 any4
xlate per-session permit tcp any4 any6
xlate per-session permit tcp any6 any4
xlate per-session permit tcp any6 any6
xlate per-session permit udp any4 any4 eq domain
xlate per-session permit udp any4 any6 eq domain
xlate per-session permit udp any6 any4 eq domain
xlate per-session permit udp any6 any6 eq domain
```

Note You cannot remove these rules, and they always exist after any manually-created rules. Because rules are evaluated in order, you can override the default rules. For example, to completely negate these rules, you could add the following deny rules:

```
xlate per-session deny tcp any4 any4
xlate per-session deny tcp any4 any6
xlate per-session deny tcp any6 any4
xlate per-session deny tcp any6 any6
xlate per-session deny udp any4 any4 eq domain
xlate per-session deny udp any4 any6 eq domain
xlate per-session deny udp any6 any4 eq domain
xlate per-session deny udp any6 any6 eq domain
```

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

The per-session PAT feature improves the scalability of PAT and, for clustering, allows each member unit to own PAT connections; multi-session PAT connections have to be forwarded to and owned by the master unit. At the end of a per-session PAT session, the ASA sends a reset and immediately removes the xlate. This reset causes the end node to immediately release the connection, avoiding the TIME_WAIT state. Multi-session PAT, on the other hand, uses the PAT timeout, by default 30 seconds. For "hit-and-run" traffic, such as HTTP or HTTPS, the per-session feature can dramatically increase the connection rate supported by one address. Without the per-session feature, the maximum connection rate for one address for an IP protocol is approximately 2000 per second. With the per-session feature, the connection rate for one address for an IP protocol is 65535/*average-lifetime*.

By default, all TCP traffic and UDP DNS traffic use a per-session PAT xlate. For traffic that can benefit from multi-session PAT, such as H.323, SIP, or Skinny, you can disable per-session PAT be creating a per-session deny rule.

When you add a per-session PAT rule, the rule is placed above the default rules, but below any other manually-created rules. Be sure to create your rules in the order you want them applied.

Examples

The following example creates a deny rule for H.323 traffic, so that it uses multi-session PAT:

```
hostname(config)# xlate per-session deny tcp any4 209.165.201.7 eq 1720
hostname(config)# xlate per-session deny udp any4 209.165.201.7 range 1718 1719
```

Related Commands

Command	Description
clear configure xlate	Clears the **xlate per-session** rules.
nat (global)	Adds a twice NAT rule.
nat (object)	Adds an object NAT rule.
show running-config xlate	Shows the **xlate per-session** rules.

zonelabs-integrity fail-close

To configure the ASA so that connections to VPN clients close when the connection between the ASA and the Zone Labs Integrity Firewall Server fails, use the **zonelabs-integrity fail-close** command in global configuration mode.To reinstate the default whereby the VPN connections remain open on failure of the Zone Labs connection, use the **no** form of this command.

zonelabs-integrity fail-close

no zonelabs-integrity fail-close

Syntax Description

This command has no arguments or keywords.

Defaults

By default, the conncection remains open on failure.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

If the primary Zone Labs Integrity Firewall Server does not respond to the ASA, the ASA still establishes VPN client connections to the private network by default. It also maintains open, existing connections. This ensures that the enterprise VPN is not distrupted by the failure of a firewall server. If, however, you do not want the VPN connections to remain operational if the Zone Labs Integrity Firewall Server fails, use the **zonelabs-integrity fail-close** command.

To return to the default condition whereby the ASA maintains client VPN connections if the connection to the Zone Labs Integrity Firewall Server fails, use the **zonelabs-integrity fail-open** command.

Examples

The following example configures the ASA to close the VPN client connections if the Zone Labs Integrity Firewall Server fails to respond or if the connection is interrupted:

```
hostname(config)# zonelabs-integrity fail-close
hostname(config)#
```

Related Commands

Command	Description
zonelabs-integrity fail-open	Specifies that VPN client connections to the ASA remain open after the connection between the ASA and the Zone Labs Integrity Firewall Server fails.
zonelabs-integrity fail-timeout	Specifies the time in seconds before the ASA declares a nonresponsive Zone Labs Integrity Firewall Server unreachable.
zonelabs-integrity server-address	Adds Zone Labs Integrity Firewall Servers to the ASA configuration.

zonelabs-integrity fail-open

To keep remote VPN client connections to the ASA open after the connection between the ASA and the Zone Labs Integrity Firewall Server fails, use the **zonelabs-integrity fail-open** command in global configuration mode. To close connections to VPN clients upon failure of the Zone Labs server connection, use the **no** form of this command.

zonelabs-integrity fail-open

no zonelabs-integrity fail-open

Syntax Description

This command has no arguments or keywords.

Defaults

By default, remote VPN connections remain open if the ASA does not establish or maintain a connection to the Zone Labs Integrity Firewall Server.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

If the primary Zone Labs Integrity Firewall Server does not respond to the ASA, the ASA still establishes VPN client connections to the private network by default. It also maintains existing open connections. This ensures that the enterprise VPN is not disrupted by the failure of a firewall server. If, however, you do not want the VPN connections to remain operational if the Zone Labs Integrity Firewall Server fails, use the **zonelabs-integrity fail-close** command. To then return to the default condition whereby the ASA maintains client VPN connections if the connection to the Zone Labs Integrity Firewall Server fails, use the **zonelabs-integrity fail-open** command or the **no zonelabs-integrity fail-open** command.

Examples

The following example reinstates the default condition whereby the VPN client connections remain open if the connection to the Zone Labs Integrity Firewall Server fails:

```
hostname(config)# zonelabs-integrity fail-open
hostname(config)#
```

Related Commands

Command	Description
zonelabs-integrity fail-close	Specifies that the ASA close VPN client connections when the connection between the ASA and the Zone Labs Integrity Firewall Server fails.
zonelabs-integrity fail-timeout	Specifies the time in seconds before the ASA declares a nonresponsive Zone Labs Integrity Firewall Server unreachable.

zonelabs-integrity fail-timeout

To specify the time in seconds before the ASA declares a nonresponsive Zone Labs Integrity Firewall Server unreachable, use the **zonelabs-integrity fail-timeout** command in global configuration mode. To restore the default timeout of 10 seconds, use the **no** form of this command without an argument.

zonelabs-integrity fail-timeout *timeout*

no zonelabs-integrity fail-timeout

Syntax Description

timeout	The number of seconds before the ASA declares a nonresponsive Zone Labs Integrity Firewall Servers unreachable. The acceptable range is from 5 to 20 seconds.

Defaults

The default timeout value is 10 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

If the ASA waits for the specified number of seconds without a response from the Zone Labs server, the server is declared nonresponsive. Connections to VPN clients either remain open by default or if configured to do so with the **zonelabs-integrity fail-open** command. If, however, the **zonelabs-integrity fail-close** command has been issued, the connections will close when the ASA declares the Integrity server unresponsive.

Examples

The following example configures the ASA to declare the active Zone Labs Intergity Server to be unreachable after 12 seconds:

```
hostname(config)# zonelabs-integrity fail-timeout 12
hostname(config)#
```

Related Commands

Command	Description
zonelabs-integrity fail-open	Specifies that VPN client connections to the ASA remain open after the connection between the ASA and the Zone Labs Integrity Firewall Server fails.
zonelabs-integrity fail-close	Specifies that the ASA close VPN client connections when the connection between the ASA and the Zone Labs Integrity Firewall Server fails.
zonelabs-integrity server-address	Adds Zone Labs Integrity Firewall Servers to the ASA configuration.

zonelabs-integrity interface

To specify an ASA interface for communication with the Zone Labs Integrity Server, use the **zonelabs-integrity interface** command in global configuration mode. To reset the Zone Labs Integrity Firewall Server interface back to the default of none, use the **no** form of this command.

zonelabs-integrity interface *interface*

no zonelabs-integrity interface

Syntax Description

interface	Specifies the ASA interface on which the Zone Labs Integrity Firewall Server communicates. It is often an interface name created with the **nameif** command.

Defaults

By default, the Zone Labs Integrity Firewall Server interface is set to none.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example configures three Zone Labs Intergity Servers using IP addresses ranging from 10.0.0.5 to 10.0.0.7. The commands also configure the ASA to listen to the server on port 300 and on an interface called inside:

```
hostname(config)# zonelabs-integrity server-address 10.0.0.5 10.0.0.6 10.0.0.7
hostname(config)# zonelabs-integrity port 300
hostname(config)# zonelabs-integrity interface inside
hostname(config)#
```

Related Commands

Command	Description
zonelabs-integrity port	Specifies a port on the ASA for communicating with a Zone Labs Integrity Firewall Server.
zonelabs-integrity server-address	Adds Zone Labs Integrity Firewall Servers to the ASA configuration.

Command	Description
zonelabs-integrity ssl-certificate-port	Specifies an ASA port to which the Zone Labs Integrity Firewall Server will connect when retrieving an SSL certificate.
zonelabs-integrity ssl-client-authentication	Enables authentication of the Zone Labs Integrity Firewall Server SSL certificate by the ASA.

zonelabs-integrity port

To specify a port on the ASA for communicating with a Zone Labs Integrity Firewall Server, use the **zonelabs-integrity port** command in global configuration mode. To revert to the default port of 5054 for the Zone Labs Integrity Firewall Server, use the **no** form of this command.

zonelabs-integrity port *port_number*

no zonelabs-integrity port *port_number*

Syntax Description

port	Specifies a Zone Labs Integrity Firewall Server port on the ASA.
port_number	The number of the Zone Labs Integrity Firewall Server port. It can range from 10 to 10000.

Defaults

The default Zone Labs Integrity Firewall Server port is 5054.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The ASA listens to the Zone Labs Integrity Firewall Server on the port and interface configured with the **zonelabs-integrity port** and **zonelabs-integrity interface** commands respectively.

Note The current release of the ASA supports one Integrity Server at a time even though the user interfaces support the configuration of up to five Integrity Servers. If the active Server fails, configure another Integrity Server on the ASA and then reestablish the client VPN session.

Examples

The following example configures a Zone Labs Integrity Servers using the IP address 10.0.0.5. The commands also configure the ASA to listen to the active Zone Labs server on port 300 instead of the default 5054 port:

```
hostname(config)# zonelabs-integrity server-address 10.0.0.5
hostname(config)# zonelabs-integrity port 300
hostname(config)#
```

Related Commands

Command	Description
zonelabs-integrity interface	Specifies the ASA interface on which it communicates with the active Zone Labs Integrity Server.
zonelabs-integrity server-address	Adds Zone Labs Integrity Firewall Servers to the ASA configuration.
zonelabs-integrity ssl-certificate-port	Specifies an ASA port to which the Zone Labs Integrity Firewall Server will connect when retrieving an SSL certificate.
zonelabs-integrity ssl-client-authentication	Enables authentication of the Zone Labs Integrity Firewall Server SSL certificate by the ASA.

zonelabs-integrity server-address

To add Zone Labs Integrity Firewall Servers to the ASA configuration, use the **zonelabs-integrity server-address** command in global configuration mode. Specify the Zone Labs server by either IP address or hostname.

To remove Zone Labs Integrity Firewall Servers from the running configuration, use the **no** form of this command without arguments.

zonelabs-integrity server-address {*hostname1* | *ip-address1*}

no zonelabs-integrity server-address

Note While the user interfaces appear to support the configuration of multiple Integrity Servers, the ASA only supports one server at a time in the current release.

Syntax Description

hostname	Specifies the hostname of the Zone Labs Integrity Firewall Server. See the **name** command for hostname guidelines.
ip-address	Specifies the IP address of the Zone Labs Integrity Firewall Server.

Command Default

By default, no Zone Labs Integrity Firewall Servers are configured.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

With this release, you can configure one Zone Labs Integrity Firewall Server. If that server fails, configure another Integrity Server first and then reestablish the client VPN session.

To specify a server by hostname, you must first configure the Zone Labs server name using the **name** command. Before using the **name** command, use the **names** command to enable it.

Note The current release of the security appliance supports one Integrity Server at a time even though the user interfaces support the configuration of up to five Integrity Servers. If the active Server fails, configure another Integrity Server on the ASA and then reestablish the client VPN session.

Examples

The following example assigns the server name ZL-Integrity-Svr to the IP address 10.0.0.5 and configures a Zone Labs Intergity Server using that name:

```
hostname(config)# names
hostname(config)# name 10.0.0.5 ZL-Integrity-Svr
hostname(config)# zonelabs-integrity server-address ZL-Integrity-Svr
hostname(config)#
```

Related Commands

Command	Description
zonelabs-integrity fail-close	Specifies that the ASA close VPN client connections when the connection between the ASA and the Zone Labs Integrity Firewall Server fails.
zonelabs-integrity interface	Specifies the ASA interface on which it communicates with the active Zone Labs Integrity Server.
zonelabs-integrity port	Specifies a port on the ASA for communicating with a Zone Labs Integrity Firewall Server.
zonelabs-integrity ssl-certificate-port	Specifies an ASA port to which the Zone Labs Integrity Firewall Server will connect when retrieving an SSL certificate.
zonelabs-integrity ssl-client-authentication	Enables authentication of the Zone Labs Integrity Firewall Server SSL certificate by the ASA.

zonelabs-integrity ssl-certificate-port

To specify an ASA port to which the Zone Labs Integrity Firewall Server will connect when retrieving an SSL certificate, use the **zonelabs-integrity ssl-certificate-port** command in global configuration mode. To revert to the default port number (80), use the **no** form of this command without an argument.

zonelabs-integrity ssl-certificate-port *cert-port-number*

no zonelabs-integrity ssl-certificate-port

Syntax Description

cert-port-number	Specifies a port number on which the ASA expects the Zone Labs Integrity Firewall Server to connect when requesting an SSL certificate.

Defaults

By default, the ASA expects the Zone Labs Integrity Firewall Server to request an SSL certificate on port 80.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

For SSL communications between the ASA and the Zone Labs Integrity Firewall Server, the ASA is the SSL server and the Zone Labs server is the SSL client. When initiating an SSL connection, the certificate of the SSL server (ASA) must be authenticated by the client (Zone Labs server). The **zonelabs-integrity ssl-certificate-port** command specifies the port to which the Zone Labs server connects when requesting the SSL server certificate.

Examples

The following example configures port 30 on the ASA to receive SSL certificate requests from the Zone Labs Integrity Server:

```
hostname(config)# zonelabs-integrity ssl-certificate-port 30
hostname(config)#
```

Related Commands

Command	Description
zonelabs-integrity port	Specifies a port on the ASA for communicating with a Zone Labs Integrity Firewall Server.
zonelabs-integrity interface	Specifies the ASA interface on which it communicates with the active Zone Labs Integrity Server.
zonelabs-integrity server-address	Adds Zone Labs Integrity Firewall Servers to the ASA configuration.
zonelabs-integrity ssl-client-authentication	Enables authentication of the Zone Labs Integrity Firewall Server SSL certificate by the ASA.

zonelabs-integrity ssl-client-authentication

To enable authentication of the Zone Labs Integrity Firewall Server SSL certificate by the ASA, use the **zonelabs-integrity ssl-client-authentication** command in global configuration mode with the *enable* argument. To disable authentication of the Zone Labs SSL certificate, use the *disable* argument or use the **no** form of this command without an argument.

zonelabs-integrity ssl-client-authentication {*enable* | *disable*}

no zonelabs-integrity ssl-client-authentication

Syntax Description

disable	Specifies the IP address of the Zone Labs Integrity Firewall Server.
enable	Specifies that the ASA authenticates the SSL certificate of the Zone Labs Integrity Firewall Server.

Defaults

By default, ASA authentication of the Zone Labs Integrity Firewall Server SSL certificate is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

For SSL communications between the ASA and the Zone Labs Integrity Firewall Server, the ASA is the SSL server and the Zone Labs server is the SSL client. When initiating an SSL connection, the certificate of the SSL server (ASA) must be authenticated by the client (Zone Labs server). Authentication of the client certificate is optional, however. You use the **zonelabs-integrity ssl-client-authentication** command to enable or disable ASA authentication of the Zone Lab server (SSL client) certificate.

Examples

The following example configures the ASA to authenticate the SSL certificate of the Zone Labs Integrity Server:

```
hostname(config)# zonelabs-integrity ssl-client-authentication enable
hostname(config)#
```

Related Commands

Command	Description
zonelabs-integrity interface	Specifies the ASA interface on which it communicates with the active Zone Labs Integrity Server.
zonelabs-integrity port	Specifies a port on the ASA for communicating with a Zone Labs Integrity Firewall Server.
zonelabs-integrity server-address	Adds Zone Labs Integrity Firewall Servers to the ASA configuration.
zonelabs-integrity ssl-certificate-port	Specifies an ASA port to which the Zone Labs Integrity Firewall Server will connect when retrieving an SSL certificate.

Cisco IOS Commands for the ASASM

clear diagnostics loopback

To clear the online diagnostic test configuration, use the **clear diagnostic loopback** command command in privileged EXEC mode.

clear diagnostics loopback

Syntax Description

This command has no arguments or keywords

Defaults

No default behavior or values.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(18)SXF5	This command was introduced.

Usage Guidelines

The **clear diagnostics loopback command** clears the online diagnostic test configuration.

Examples

The following is sample output from the **clear diagnostics loopback** command:

```
hostname# clear diagnostics loopback

Port    Test    Pkts-received  Failures
0       0       0              0
1       0       0              0
```

Related Commands

Command	Description
show diagnostics loopback	Shows the information related to the PC loopback test, the number of tests run, the number of loopback packets received, and the number of failures detected.

firewall autostate

To enable autostate messaging, use the **firewall autostate** command in global configuration mode. To disable autostate, use the **no** form of this command.

firewall autostate

no firewall autostate

Syntax Description

This command has no arguments or keywords.

Defaults

By default, autostate is disabled.

Command Modes

Global configuration

Command History

Release	Modification
12.2(18)SXF5	This command was introduced.

Usage Guidelines

Autostate messaging lets the ASA quickly detect that a switch interface has failed or has come up. The supervisor engine can send autostate messages to the ASA about the status of physical interfaces associated with ASA VLANs. For example, when all physical interfaces associated with a VLAN go down, the autostate message tells the ASA that the VLAN is down. This information lets the ASA declare the VLAN as down, bypassing the interface monitoring tests normally required for determining which side suffered a link failure. Autostate messaging provides a dramatic improvement in the time the ASA takes to detect a link failure (a few milliseconds as compared to up to 45 seconds without autostate support).

The switch supervisor sends an autostate message to the ASA when:

- The last interface belonging to a VLAN goes down.
- The first interface belonging to a VLAN comes up.

Examples

The following example enables autostate messaging:

```
Router(config)# firewall autostate
```

Related Commands

Command	Description
show firewall autostate	Shows the setting of the autostate feature.

firewall module

To assign firewall groups to the ASA, enter the **firewall module** command in global configuration mode. To remove the groups, use the **no** form of this command.

firewall module *module_number* **vlan-group** *firewall_group*

no firewall module *module_number* **vlan-group** *firewall_group*

Syntax Description

module_number	Specifies the module number. Use the **show module** command to view installed modules and their numbers.
vlan-group *firewall_group*	Specifies one or more group numbers as defined by the **firewall vlan-group** command: • A single number (*n*) • A range (*n-x*) Separate numbers or ranges by commas. For example, enter the following numbers: `5,7-10`

Defaults

No default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
12.2(18)SXF5	This command was introduced.

Usage Guidelines

- You can assign up to 16 firewall VLAN groups to each ASASM. (You can create more than 16 VLAN groups in Cisco IOS software, but only 16 can be assigned per ASASM.) See the **firewall vlan-group** command to create a group. For example, you can assign all the VLANs to one group; or you can create an inside group and an outside group; or you can create a group for each customer.
- There is no limit on the number of VLANs per group, but the ASASM can only use VLANs up to the ASASM system limit (see the ASASM licensing documentation for more information).
- You cannot assign the same VLAN to multiple firewall groups.
- You can assign a single firewall group to multiple ASASMs. VLANs that you want to assign to multiple ASASMs, for example, can reside in a separate group from VLANs that are unique to each ASASM.
- If you are using ASASM failover within the same switch chassis, do not assign the VLAN(s) that you are reserving for failover and stateful communications to a switch port. However, if you are using failover between chassis, you must include the VLANs in the trunk port between the chassis.

- If you do not add the VLANs to the switch before you assign them to the ASASM, the VLANs are stored in the supervisor engine database and are sent to the ASASM as soon as they are added to the switch.
- You can configure a VLAN in the ASASM configuration before it has been assigned on the switch. Note that when the switch sends the VLAN to the ASASM, the VLAN defaults to be administratively up on the ASASM, regardless of whether the you shut them down in the ASASM configuration. You need to shut them down again in this case.

Examples

The following example shows how to create three firewall VLAN groups: one for each ASA, and one that includes VLANs assigned to both ASAs.

```
Router(config)# firewall vlan-group 50 55-57
Router(config)# firewall vlan-group 51 70-85
Router(config)# firewall vlan-group 52 100
Router(config)# firewall module 5 vlan-group 50,52
Router(config)# firewall module 8 vlan-group 51,52
```

The following is sample output from the **show firewall vlan-group** command:

```
Router# show firewall vlan-group
Group vlans
----- ------
   50 55-57
   51 70-85
   52 100
```

The following is sample output from the **show firewall module** command, which shows all VLAN groups:

```
Router# show firewall module
Module Vlan-groups
  5    50,52
  8    51,52
```

Related Commands

Command	Description
firewall vlan-group	Assigns VLANs to a VLAN group.
show firewall module vlan-group	Shows the VLAN groups and the VLANs assigned to them.
show module	Shows all installed modules.

firewall multiple-vlan-interfaces

To allow you to add more than one SVI to the ASA, use the **firewall multiple-vlan-interfaces** command in global configuration mode. To disable this feature, use the **no** form of this command.

firewall multiple-vlan-interfaces

no firewall multiple-vlan-interfaces

Syntax Description

This command has no arguments or keywords.

Defaults

By default, multiple SVIs are not allowed.

Command Modes

Global configuration

Command History

Release	Modification
12.2(18)SXF5	This command was introduced.

Usage Guidelines

A VLAN defined on the MSFC is called a switched virtual interface. If you assign the VLAN used for the SVI to the ASA, then the MSFC routes between the ASA and other Layer 3 VLANs. For security reasons, by default, only one SVI can exist between the MSFC and the ASA. For example, if you misconfigure the system with multiple SVIs, you could accidentally allow traffic to pass around the ASA by assigning both the inside and outside VLANs to the MSFC.

However, you might need to bypass the ASA in some network scenarios. For example, if you have an IPX host on the same Ethernet segment as IP hosts, you will need multiple SVIs. Because the ASA in routed firewall mode only handles IP traffic and drops other protocol traffic like IPX (transparent firewall mode can optionally allow non-IP traffic), you might want to bypass the ASA for IPX traffic. Make sure to configure the MSFC with an access list that allows only IPX traffic to pass on the VLAN.

For transparent firewalls in multiple context mode, you need to use multiple SVIs because each context requires a unique VLAN on its outside interface. You might also choose to use multiple SVIs in routed mode so you do not have to share a single VLAN for the outside interface.

Examples

The following example shows a typical configuration with multiple SVIs:

```
Router(config)# firewall vlan-group 50 55-57
Router(config)# firewall vlan-group 51 70-85
Router(config)# firewall module 8 vlan-group 50-51
Router(config)# firewall multiple-vlan-interfaces
Router(config)# interface vlan 55
Router(config-if)# ip address 10.1.1.1 255.255.255.0
Router(config-if)# no shutdown
Router(config-if)# interface vlan 56
Router(config-if)# ip address 10.1.2.1 255.255.255.0
Router(config-if)# no shutdown
Router(config-if)# end
```

```
Router#
```

The following is sample output from the **show interface** command:

```
Router# show interface vlan 55
Vlan55 is up, line protocol is up
  Hardware is EtherSVI, address is 0008.20de.45ca (bia 0008.20de.45ca)
  Internet address is 55.1.1.1/24
  MTU 1500 bytes, BW 1000000 Kbit, DLY 10 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  ARP type:ARPA, ARP Timeout 04:00:00
  Last input never, output 00:00:08, output hang never
  Last clearing of "show interface" counters never
  Input queue:0/75/0/0 (size/max/drops/flushes); Total output drops:0
  Queueing strategy:fifo
  Output queue :0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
  L2 Switched:ucast:196 pkt, 13328 bytes - mcast:4 pkt, 256 bytes
  L3 in Switched:ucast:0 pkt, 0 bytes - mcast:0 pkt, 0 bytes mcast
  L3 out Switched:ucast:0 pkt, 0 bytes
     0 packets input, 0 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     4 packets output, 256 bytes, 0 underruns
     0 output errors, 0 interface resets
     0 output buffer failures, 0 output buffers swapped out
```

Related Commands

Command	Description
firewall module	Assigns a VLAN group to the ASA.
firewall vlan-group	Defines a VLAN group.

firewall vlan-group

To assign VLANs to a firewall group, enter the **firewall vlan-group** command in global configuration mode. To remove the VLANs, use the **no** form of this command.

firewall [**switch** {**1** |**2**}] **vlan-group** *firewall_group vlan_range*

no firewall [**switch** {**1** |**2**}] **vlan-group** *firewall_group vlan_range*

Syntax Description

firewall_group	Specifies the group ID as an integer.
vlan_range	Specifies the VLANs assigned to the group. The *vlan_range* value can be one or more VLANs (2 to 1000 and from 1025 to 4094) identified in one of the following ways: • A single number (*n*) • A range (*n-x*) Separate numbers or ranges by commas. For example, enter the following numbers: `5,7-10,13,45-100` **Note** Routed ports and WAN ports consume internal VLANs, so it is possible that VLANs in the 1020-1100 range might already be in use.
switch {**1** | **2**}	(Optional) For VSS configurations, specifies the switch number.

Defaults

No default behavior or values.

Command Modes

Global configuration.

Command History

Release	Modification
12.2(18)SXF5	This command was introduced.

Usage Guidelines

- You can assign up to 16 firewall VLAN groups to each ASASM using the **firewall module** command. (You can create more than 16 VLAN groups in Cisco IOS software, but only 16 can be assigned per ASASM.) For example, you can assign all the VLANs to one group; or you can create an inside group and an outside group; or you can create a group for each customer.
- There is no limit on the number of VLANs per group, but the ASASM can only use VLANs up to the ASASM system limit (see the ASASM licensing documentation for more information).
- You cannot assign the same VLAN to multiple firewall groups.
- You can assign a single firewall group to multiple ASASMs. VLANs that you want to assign to multiple ASASMs, for example, can reside in a separate group from VLANs that are unique to each ASASM.
- Use VLAN IDs 2 to 1000 and from 1025 to 4094.

- Routed ports and WAN ports consume internal VLANs, so it is possible that VLANs in the 1020-1100 range might already be in use.
- You cannot use reserved VLANs.
- You cannot use VLAN 1.
- If you are using ASASM failover within the same switch chassis, do not assign the VLAN(s) that you are reserving for failover and stateful communications to a switch port. However, if you are using failover between chassis, you must include the VLANs in the trunk port between the chassis.
- If you do not add the VLANs to the switch before you assign them to the ASASM, the VLANs are stored in the supervisor engine database and are sent to the ASASM as soon as they are added to the switch.
- You can configure a VLAN in the ASASM configuration before it has been assigned on the switch. Note that when the switch sends the VLAN to the ASASM, the VLAN defaults to be administratively up on the ASASM, regardless of whether the you shut them down in the ASASM configuration. You need to shut them down again in this case.

Examples

The following example shows how to create three firewall VLAN groups: one for each ASA, and one that includes VLANs assigned to both ASAs.

```
Router(config)# firewall vlan-group 50 55-57
Router(config)# firewall vlan-group 51 70-85
Router(config)# firewall vlan-group 52 100
Router(config)# firewall module 5 vlan-group 50,52
Router(config)# firewall module 8 vlan-group 51,52
```

The following is sample output from the **show firewall vlan-group** command:

```
Router# show firewall vlan-group
Group vlans
----- ------
   50 55-57
   51 70-85
   52 100
```

The following is sample output from the **show firewall module** command, which shows all VLAN groups:

```
Router# show firewall module
Module Vlan-groups
  5    50,52
  8    51,52
```

Related Commands

Command	Description
firewall module	Assigns a VLAN group to an ASA.
show firewall vlan-group	Shows the VLAN groups and the VLANs assigned to them.
show module	Shows all installed modules.

service-module session

To gain console access to the ASASM from the switch CLI, enter the **service-module session** command in privileged EXEC mode.

service-module session [**switch** {**1** | **2**}] **slot** *number*

Syntax Description

slot *number*	Specifies the slot number of the ASASM. To view the module slot numbers, enter the **show module** command at the switch prompt.
switch {**1** | **2**}	(Optional) For VSS configurations, specifies the switch number.

Defaults

No default behavior or values.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(33)SXJ1	This command was introduced.

Usage Guidelines

Using the **service-module session** command, you create a virtual console connection to the ASASM, with all the benefits and limitations of an actual console connection.

Benefits include:

- The connection is persistent across reloads and does not time out.
- You can stay connected through ASASM reloads and view startup messages.
- You can access ROMMON if the ASASM cannot load the image.

Limitations include:

- The connection is slow (9600 baud).
- You can only have one console connection active at a time.

Note Because of the persistence of the connection, if you do not properly log out of the ASASM, the connection may exist longer than intended. If someone else wants to log in, they will need to kill the existing connection. See the CLI configuration guide for more information.

Examples

The following example shows how to gain console access to an ASASM in slot 3:

```
Router# service-module session slot 3
hostname>
```

Related Commands

Commands	Description
session	Telnets to the ASASM over the backplane.

session

To Telnet from the switch CLI to the ASASM over the backplane, use the **session** command in privileged EXEC mode.

session [**switch** {**1** | **2**}] **slot** *number* **processor 1**

Syntax Description

processor 1	Specifies the processor number, which is always 1.
slot *number*	Specifies the slot number. To view the module slot numbers, enter the **show module** command at the switch prompt.
switch {**1** | **2**}	(Optional) For VSS configurations, specifies the switch number.

Defaults

No default behavior or values.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Using the **session** command, you create a Telnet connection to the ASASM.

Benefits include:

- You can have multiple sessions to the ASASM at the same time.
- The Telnet session is a fast connection.

Limitations include:

- The Telnet session is terminated when the ASASM reloads, and can time out.
- You cannot access the ASASM until it completely loads; you cannot access ROMMON.

Note The **session** *slot* **processor 0** command, which is supported on other services modules, is not supported on the ASASM; the ASASM does not have a processor 0.

You are prompted for the login password. Enter the login password to the ASASM. By default, the password is **cisco**.

You access user EXEC mode.

Examples

The following example Telnets to an ASASM in processor 1:

```
Router# session slot number processor 1
hostname passwd: cisco
hostname>
```

Related Commands

Command	Description
service-module session	Obtains console access to the ASASM from the switch CLI.

show diagnostic loopback

To display information related to the PC loopback test, including the number of tests run, the number of loopback packets received, and the number of failures detected, use the **show diagnostics loopback** command in privileged EXEC mode.

show diagnostics loopback

Syntax Description

This command has no arguments or keywords

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
12.2(18)SXF5	This command was introduced.

Usage Guidelines

The **show diagnostics loopback command provides** information related to the PC loopback test, including the number of tests run, the number of loopback packets received, and the number of failures detected.

Examples

The following is sample output from the **show diagnostics loopback** command:

```
hostname# show diagnostics loopback

Port    Test    Pkts-received  Failures
0       447     447            0
1       447     447            0
```

Related Commands

Command	Description
clear diagnostics loopback	Clears the online diagnostic test configuration.
firewall autostate	Enables the autostate feature.

show firewall autostate

To view the setting of the autostate feature, use the **show firewall autostate** command in privileged EXEC mode.

show firewall autostate

Syntax Description

This command has no arguments or keywords.

Defaults

By default, autostate is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
12.2(18)SXF5	This command was introduced.

Usage Guidelines

Autostate messaging in Cisco IOS software allows the ASA to quickly detect that a switch interface has failed or come up. The switch supervisor sends an autostate message to the ASA when:

- The last interface belonging to a VLAN goes down.
- The first interface belonging to a VLAN comes up.

Related Commands

Command	Description
clear diagnostics loopback	Clears the online diagnostic test configuration.
firewall autostate	Enables the autostate feature.

show firewall module

To view the VLAN groups assigned to each ASA, enter the **show firewall module** command in privileged EXEC mode.

show firewall [**switch** {**1** | **2**}] **module** [*module_number*]

Syntax Description

module_number	(Optional) Specifies the module number. Use the **show module** command to view installed modules and their numbers.
switch {**1** | **2**}	(Optional) For VSS configurations, specifies the switch number.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
12.2(18)SXF5	This command was introduced.

Examples

The following is sample output from the **show firewall module** command, which shows all VLAN groups:

```
Router# show firewall module
Module Vlan-groups
  5    50,52
  8    51,52
```

Related Commands

Command	Description

show firewall module vlan-group

To view VLAN groups that can be assigned to the ASA, enter the **show firewall module vlan-group** command in privileged EXEC mode.

show firewall [**switch** {**1** | **2**}] **module** [*module_number*] **vlan-group** [*firewall_group*]

Syntax Description

firewall_group	(Optional) Specifies the group ID.
module_number	(Optional) Specifies the module number.
switch {**1** | **2**}	(Optional) For VSS configurations, specifies the switch number.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
12.2(18)SXF5	This command was introduced.

Examples

The following is sample output from the **show firewall module vlan-group** command:

```
Router# show firewall module vlan-group
Group vlans
----- ------
   50 55-57
   51 70-85
   52 100
```

Related Commands

Command	Description
firewall module	Assigns a VLAN group to an ASA.
firewall vlan-group	Creates a group of VLANs.
show module	Shows all installed modules.

show firewall multiple-vlan-interfaces

To show the state of multiple firewall VLAN interfaces for the ASASM, enter the **show firewall multiple-vlan-interfaces** command in privileged EXEC mode.

show firewall multiple-vlan-interfaces

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
8.5(1)	This command was introduced.

Examples

The following is sample output from the **show firewall multiple-vlan-interfaces** command:

```
Router# show firewall multiple-vlan-interfaces
Multiple firewall vlan interfaces feature is enabled
```

Related Commands

Command	Description
firewall module	Assigns a VLAN group to an ASA.
firewall vlan-group	Creates a group of VLANs.
show module	Shows all installed modules.

show module

To verify that the switch acknowledges the ASASM and has brought it online, use the **show module** command in privileged EXEC mode.

show module [**switch** {**1** | **2**}] [*mod-num* | **all**]

Syntax Description

all	(Optional) Specifies all the modules.
mod_num	(Optional) Specifies the module number.
switch {**1** | **2**}	(Optional) For VSS configurations, specifies the switch number.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
