

# Call Processing

---

**Revised: August 23, 2013; OL-29367-04**

The handling and processing of voice and video calls is a critical function provided by IP telephony systems. This functionality is handled by some type of call processing entity or agent. Given the critical nature of call processing operations, it is important to design unified communications deployments to ensure that call processing systems are scalable enough to handle the required number of users and devices and are resilient enough to handle various network and application outages or failures.

This chapter provides guidance for designing scalable and resilient call processing systems with Cisco call processing products. These products include Cisco Unified Communications Manager (Unified CM), Cisco Business Edition, Cisco Unified Communications Manager Express (Unified CME), and Cisco TelePresence Video Communication Server (VCS). The discussions focus predominately on the following factors:

- Scale — The number of users, locations, gateways, applications, and so forth
- Performance — The call rate
- Resilience — The amount of redundancy

Specifically, this chapter focuses on the following topics:

- [Call Processing Architecture, page 9-2](#)

This section discusses general call processing architecture and the various call processing hardware options. This section also provides information on Unified CM clustering and Cisco TelePresence VCS clustering.

- [High Availability for Call Processing, page 9-16](#)

This section examines high availability considerations for call processing, including network redundancy, server or platform redundancy, and load-balancing.

- [Capacity Planning for Call Processing, page 9-28](#)

This section provides an overview of sizing for call processing deployments.

- [Design Considerations for Call Processing, page 9-32](#)

This section provides a summarized list of high-level design guidelines and best practices for deploying call processing.

- [Computer Telephony Integration \(CTI\), page 9-34](#)

This section explains the Cisco Computer Telephony Integration (CTI) architecture and discusses CTI components and interfaces, CTI functionality, and CTI provisioning and capacity planning.

- [Interoperability of Unified CM and Unified CM Express, page 9-42](#)

This section explains the H.323 and SIP integration between Cisco Unified CM and Cisco Unified Communications Manager Express (Unified CME) in a distributed call processing deployment.

- [Interoperability of Cisco TelePresence VCS with Unified CM, page 9-51](#)

This section explains the integration between Cisco Unified CM and Cisco TelePresence VCS.

## What's New in This Chapter

[Table 9-1](#) lists the topics that are new in this chapter or that have changed significantly from previous releases of this document.

**Table 9-1**      ***New or Changed Information Since the Previous Release of This Document***

New or Revised Topic	Described in	Revision Date
Cisco Business Edition 6000 capacity limits	Various sections in this chapter	August 23, 2013
Enterprise License Manager	<a href="#">Enterprise License Manager, page 9-9</a>	August 23, 2013
Cisco Business Edition 3000 is approaching end-of-life (EoL) and has been removed from this document	End-of-sale and end-of-life notice available at <a href="http://www.cisco.com/en/US/products/ps11370/prod_eol_notices_list.html">http://www.cisco.com/en/US/products/ps11370/prod_eol_notices_list.html</a>	August 23, 2013
Cisco TelePresence Video Communication Server (VCS)	Various sections in this chapter	April 2, 2013
Removal of information on Cisco IOS Gatekeeper	For this information, refer to the <i>Call Processing</i> chapter of the <i>Cisco Unified Communications System 9.0 SRND</i> , available at <a href="http://www.cisco.com/en/US/docs/voice_ip_comm/cucm/srnd/9x/callpros.html">http://www.cisco.com/en/US/docs/voice_ip_comm/cucm/srnd/9x/callpros.html</a>	April 2, 2013
Minor updates for Cisco Business Edition	Various sections in this chapter	October 31, 2012
CTI Remote Device	<a href="#">Computer Telephony Integration (CTI), page 9-34</a>	June 28, 2012
Enterprise License Manager	<a href="#">Enterprise License Manager, page 9-9</a>	June 28, 2012

## Call Processing Architecture

In order to design and deploy a successful Unified Communications system, it is critical to understand the underlying call processing architecture that provides call routing functionality. This functionality is provided by the following Cisco call processing agents:

- Cisco Unified Communications Manager Express (Unified CME)

Cisco Unified CME provides call processing services for small single-site deployments, larger distributed multi-site deployments, and deployments in which a local call processing entity at a remote site is needed to provide backup capabilities for a centralized call processing deployment of Cisco Unified CM.

- Cisco Business Edition 6000

Cisco Business Edition 6000 provides call processing services for small single-site deployments or small distributed multisite deployments.

Cisco Business Edition 6000 supports multiple co-resident Collaboration applications running as separate virtual machines leveraging VMware vSphere Hypervisor. Call processing services are offered through Cisco Unified Communications Manager (Unified CM) and/or Cisco TelePresence Video Communication Server (VCS) virtual machines. Cisco Business Edition 6000 comes with two hardware options of the Cisco Unified Computing System (Cisco UCS) server: the medium-density server supports Cisco Prime Collaboration Provisioning and up to four co-resident applications, while the high-density server supports Cisco Prime Collaboration Provisioning and up to eight co-resident applications. For more information on the medium-density and high-density servers, refer to

[http://docwiki.cisco.com/wiki/UC\\_Virtualization\\_Supported\\_Hardware#UC\\_on\\_UCS\\_Testing\\_Reference\\_Configurations](http://docwiki.cisco.com/wiki/UC_Virtualization_Supported_Hardware#UC_on_UCS_Testing_Reference_Configurations)

The collaboration applications that are considered part of Cisco Business Edition 6000 are Cisco Unified Communications Manager (Unified CM), Cisco Unity Connection, Cisco IM and Presence, Cisco Unified Contact Center Express (Unified CCX), Cisco Unified Attendant Console Services, Cisco TelePresence Video Communication Server (VCS) Control, Cisco Emergency Responder, and Cisco Paging Server. Other Cisco Collaboration applications or third-party collaboration applications can be added on the same server, but with the following limitations: no more than three third-party applications per server and no more than six per deployment. For more details on the third-party application co-residency policy, refer to the Cisco Business Edition 6000 documentation available at

[http://www.cisco.com/en/US/products/ps11369/prod\\_installation\\_guides\\_list.html](http://www.cisco.com/en/US/products/ps11369/prod_installation_guides_list.html)

- Cisco Unified Communications Manager (Unified CM)

Cisco Unified CM provides call processing services for small to very large single-site deployments, multi-site centralized call processing deployments, and/or multi-site distributed call processing deployments. It serves as a foundation to deliver voice, video, TelePresence, messaging, mobility, web conferencing, and security.

- Cisco TelePresence Video Communication Server (VCS)

Cisco TelePresence VCS provides endpoint registration, call processing, and bandwidth management for SIP and H.323 endpoints. VCS acts as a SIP registrar, a SIP proxy server, an H.323 gatekeeper, and a SIP-to-H.323 gateway server to provide interworking between SIP and H.323 devices.

Cisco VCS can be deployed as a Cisco TelePresence Video Communication Server Control (VCS Control) for use within an enterprise and as the Cisco TelePresence Video Communication Server Expressway (VCS Expressway) for external communication. The VCS Expressway enables business-to-business communications, empowers remote and home-based workers, and gives service providers the ability to provide video communications to customers. The Cisco VCS Expressway includes the features of the Cisco VCS Control, augmented with highly secure firewall traversal capability.

In a deployment with Unified CM as the main call processing agent, Cisco VCS can also be deployed to provide full-featured interoperability with H.323 telepresence endpoints and interworking with SIP, integration with third-party video endpoints, and alternate solutions for telepresence conferencing or external communication using NAT/firewall traversal when combined with the VCS Expressway.

The Cisco TelePresence Video Communication Server (VCS) Starter Pack Express is a feature-rich on-premises solution targeted to small and medium-sized businesses (SMBs) that are deploying a telepresence system for the first time. It is built on the Cisco VCS architecture and features a scaled-down Cisco TelePresence Video Communication Server Expressway solution for firewall traversal and business-to-business communications. For more information on Cisco TelePresence Video Communication Server (VCS) Starter Pack Express, refer to the documentation at

[http://www.cisco.com/en/US/prod/collateral/ps7060/ps11305/ps11315/ps11337/data\\_sheet\\_c78-697075.html](http://www.cisco.com/en/US/prod/collateral/ps7060/ps11305/ps11315/ps11337/data_sheet_c78-697075.html)

This section examines various call processing hardware options and then provides an overview of Cisco Unified CM and VCS clustering.

## Call Processing Hardware

Four enterprise call processing types are supported on various types of platforms:

- Cisco Unified CME runs on Cisco Integrated Services Routers (ISR).
- Cisco Business Edition 6000 runs as a combination of virtualized applications with the VMware Hypervisor on specific Cisco Unified Computing System (UCS) C-Series Servers.
- Cisco Unified CM runs either as an appliance directly on MCS (or equivalent) servers or as a virtualized application on the VMware Hypervisor. When Unified CM is deployed as a virtual machine, two hardware options are available: Tested Reference Configurations and specification-based hardware support. Tested Reference Configurations (TRC) are selected hardware configurations based on the Cisco UCS hardware. They are tested and documented for specific guaranteed performance, capacity, and application co-residency scenarios running "full-load" Unified Communications virtual machines. TRCs are intended for customers who want a packaged solution from Cisco that is pre-engineered for a specific deployment scenario and/or customers who are not experienced with hardware virtualization. For more information on the TRC, refer to the documentation at

[http://docwiki.cisco.com/wiki/Tested\\_Reference\\_Configurations\\_\(TRC\)](http://docwiki.cisco.com/wiki/Tested_Reference_Configurations_(TRC))

Alternatively, more flexible hardware configurations are possible with the specification-based hardware support which, for example, adds support for Cisco UCS, Hewlett-Packard, and IBM platforms listed in the VMware Hardware Compatibility List (<http://www.vmware.com/resources/compatibility/search.php>), and for iSCSI, FCoE, and NAS (NFS) storage systems. Specification-based hardware support is intended for customers with extensive expertise in virtualization as well as server and storage sizing, who wish to use their own hardware standards. For more information on the specification-based hardware support, refer to the documentation at

[http://docwiki.cisco.com/wiki/Specification-Based\\_Hardware\\_Support](http://docwiki.cisco.com/wiki/Specification-Based_Hardware_Support)

- Cisco TelePresence Video Communication Server (VCS) also runs either as an appliance or as a virtualized application on VMware. Similarly to Unified CM, when virtualized, Cisco VCS can run on Cisco Unified Computing System (UCS) servers or other servers using the Specifications-based Hardware Support. For more information on running Cisco VCS as a virtualized application, refer to the following documentation:
  - Considerations for designing and deploying virtualization of Cisco Unified Communications, available at

[http://docwiki.cisco.com/wiki/Before\\_You\\_Buy\\_or\\_Deploy\\_-\\_Considerations\\_for\\_Design\\_and\\_Procurement](http://docwiki.cisco.com/wiki/Before_You_Buy_or_Deploy_-_Considerations_for_Design_and_Procurement)

- *Cisco TelePresence Video Communication Server Virtual Machine Deployment Guide*, available at [http://www.cisco.com/en/US/products/ps11337/products\\_installation\\_and\\_configuration\\_guides\\_list.html](http://www.cisco.com/en/US/products/ps11337/products_installation_and_configuration_guides_list.html)

Table 9-2 provides a summary of the four enterprise call processing types, the types of servers or platforms on which these call processing applications reside, and the overall characteristics of those platforms. The table includes the Tested Reference Configurations for the Cisco UCS platforms but not the platforms that are supported with the specification-based hardware support.

**Table 9-2**      **Types of Call Processing Platforms**

Call Processing Type	Platform Type
Cisco Unified CME	Cisco Integrated Services Routers (1800, 2900, and 3900 Series) <sup>1</sup>
Cisco Business Edition 6000	Specific UCS C-Series Tested Reference Configurations (TRC). Two types of platforms are available: <ul style="list-style-type: none"> <li>• Medium density server</li> <li>• High density server</li> </ul>
Cisco Unified CM	MCS servers when Unified CM is not virtualized Hardware options when Unified CM is virtualized <sup>2</sup> : <ul style="list-style-type: none"> <li>• UCS Tested Reference Configurations (TRC);</li> <li>• Other servers supported with the Specifications-based Hardware Support</li> </ul>
Cisco VCS	Cisco VCS appliance when VCS is not virtualized Hardware options when VCS is virtualized: <ul style="list-style-type: none"> <li>• UCS Tested Reference Configurations (TRC);</li> <li>• Other servers supported with the Specifications-based Hardware Support</li> </ul>

1. This is not an exhaustive list of supported Cisco IOS platforms.

2. UCS B-Series and C-Series servers offer no bare metal support for Cisco Unified Communications applications. UCS B-Series and C-Series servers must run VMware ESXi Hypervisor.

For a complete list of supported MCS servers or equivalents, refer to the documentation available at

<http://www.cisco.com/go/swonly>

For a complete list of Tested Reference Configurations or for details on the specification-based hardware support, refer to the documentation available at

<http://www.cisco.com/go/uc-virtualized>

Determining the appropriate call processing type and platform for a particular deployment will depend on the scale, performance, and redundancy required. In general, Unified CM and the higher-end MCS and UCS servers provide more capacity and higher availability, while Cisco Unified CME and Cisco Business Edition provide lower levels of capacity and redundancy. For specifics regarding redundancy and scalability, see the sections on [High Availability for Call Processing](#), page 9-16, and [Capacity Planning for Call Processing](#), page 9-28.

## Unified CM Cluster Services

Cisco Unified CME is a standalone call processing application. However, Unified CM supports the concept of clustering. The Unified CM architecture enables a group of physical servers to work together as a single call processing entity or IP PBX system. This grouping of servers is known as a *cluster*. A cluster of Unified CM servers may be distributed across an IP network, within design limitations, allowing for spatial redundancy and, hence, resilience to be designed into the Unified Communications System.

Within a Unified CM cluster, there are servers that provide unique services. Each of these services can coexist with others on the same physical server. For example, in a small system it is possible to have a single server providing database services, call processing services, and media resource services. As the scale and performance requirements of the cluster increase, many of these services should be moved to dedicated physical servers.

### Note

While Cisco recommends using the same server model for all servers in a cluster, mixing server models within a cluster is supported provided that all of the individual hardware versions are supported and that all servers are running the same version of Unified CM. However, differences in capacity between various server models within a cluster must be considered because the overall cluster capacity might ultimately be dictated by the capacity of the smallest server within the cluster. Mixing servers from different vendors within a cluster is also supported and does not have any adverse capacity implications, provided that all servers in the cluster are the same model type. Similarly, for a virtualized deployment, Cisco recommends using the same OVA for all Unified CM nodes in a cluster. For information on call processing capacity, see the section on [Capacity Planning for Call Processing, page 9-28](#).

The following section describes the various functions performed by the servers that form a Unified CM cluster, and it provides guidelines for deploying the servers in ways that achieve the desired scale, performance, and resilience.

## Cluster Server Nodes

[Figure 9-1](#) illustrates a typical Unified CM cluster consisting of multiple server nodes. There are two types of Unified CM servers, publisher and subscriber. These terms are used to define the database relationship during installation.

**Figure 9-1** Typical Unified CM Cluster

## Publisher

The publisher is a required server in all clusters, and as shown in [Figure 9-1](#), there can be only one publisher per cluster. This server is the first to be installed and provides the database services to all other subscribers in the cluster. The publisher server is the only server that has full read and write access to the configuration database.

On larger systems with more than 1250 users, Cisco recommends a dedicated publisher to prevent administrative operations from affecting the telephony services. A dedicated publisher does not provide call processing or TFTP services running on the server. Instead, other subscriber servers within the cluster provide these services.

The choice of hardware platform for the publisher should be based on the desired scale and performance of the cluster. Cisco recommends that the publisher have the same server performance capability as the call processing subscribers. Ideally the publisher should also be a high-availability server to minimize the impact of a hardware failure.

## Subscriber

When the software is installed initially, only the database and network services are enabled. All subscriber nodes subscribe to the publisher to obtain a copy of the database information. However, in order to reduce initialization time for the Unified CM cluster, all subscriber servers in the cluster attempt to use their local copy of the database when initializing. This reduces the overall initialization time for a Unified CM cluster. All subscriber nodes rely on change notification from the publisher or other subscriber nodes in order to keep their local copy of the database updated.

As shown in [Figure 9-1](#), multiple subscriber nodes can be members of the same cluster. Subscriber nodes include Unified CM call processing subscriber nodes, TFTP subscriber nodes, and media resource subscriber nodes that provide functions such as conferencing and music on hold (MoH).

## Call Processing Subscriber

A call processing subscriber is a server that has the Cisco CallManager Service enabled. Once this service is enabled, the server is able to perform call processing functions. Devices such as phones, gateways, and media resources can register and make calls only to servers with this service enabled. As shown in [Figure 9-1](#), multiple call processing subscribers can be members of the same cluster. In fact, Unified CM supports up to eight call processing subscriber nodes per cluster.

## TFTP Subscriber

A TFTP subscriber or server node performs two main functions as part of the Unified CM cluster:

- The serving of files for services, including configuration files for devices such as phones and gateways, binary files for the upgrade of phones as well as some gateways, and various security files
- Generation of configuration and security files, which are usually signed and in some cases encrypted before being available for download

The Cisco TFTP service that provides this functionality can be enabled on any server in the cluster. However, in a cluster with more than 1250 users, other services might be impacted by configuration changes that can cause the TFTP service to regenerate configuration files. Therefore, Cisco recommends that you dedicate a specific subscriber node to the TFTP service, as shown in [Figure 9-1](#), for a cluster with more than 1250 users or any features that cause frequent configuration changes.

Cisco recommends that you use the same hardware platform for the TFTP subscribers as used for the call processing subscribers.

## Media Resource Subscriber

A media resource subscriber or server node provides media services such as conferencing and music on hold to endpoints and gateways. These types of media resource services are provided by the Cisco IP Voice Media Streaming Application service, which can be enabled on any server node in the cluster.

Media resources include:

- Music on Hold (MoH) — Provides multicast or unicast music to devices that are placed on hold or temporary hold, transferred, or added to a conference. (See [Music on Hold, page 7-18.](#))
- Annunciator service — Provides announcements in place of tones to indicate incorrectly dialed numbers or call routing unavailability. (See [Annunciator, page 7-16.](#))
- Conference bridges — Provide software-based conferencing for ad-hoc and meet-me conferences. (See [Transcoding, page 7-6.](#))
- Media termination point (MTP) services — Provide features for H.323 clients, H.323 trunks, and Session Initiation Protocol (SIP) endpoints and trunks. (See [Media Termination Point \(MTP\), page 7-8.](#))

Because of the additional processing and network requirements for media resource services, it is essential to follow all guidelines for running media resources within a cluster. Generally, Cisco recommends non-dedicated media resource subscribers for multicast MoH and annunciator services, but dedicated media resource subscribers as shown in [Figure 9-1](#) are recommended for unicast MoH as well as large-scale software-based conferencing and MTPs unless those services are within the design guidelines detailed in the chapter on [Media Resources, page 7-1.](#)

## Additional Cluster Services

In addition to the specific types of subscriber nodes within a Unified CM cluster, there are also other services that can be run on the Unified CM call processing subscriber nodes to provide additional functionality and enable additional features.

### Computer Telephony Integration (CTI) Manager

The CTI Manager service acts as a broker between the Cisco CallManager service and TAPI or JTAPI integrated applications. This service is required in a cluster for any applications that utilize CTI. The CTI Manager service provides authentication of the CTI application and enables the application to monitor and/or control endpoint lines. CTI Manager can be enabled only on call processing subscribers, thus allowing for a maximum of eight nodes running the CTI Manager service in a cluster.

For more details on CTI Manager, see [Computer Telephony Integration \(CTI\), page 9-34.](#)

### Unified CM Applications

Various types of application services can be enabled on Unified CM, such as Cisco Unified CM Assistant, Extension Mobility, and Web Dialer. For detailed design guidance on these applications, see the chapter on [Cisco Unified CM Applications, page 18-1.](#)

## Enterprise License Manager

Cisco Unified Communications System 9.x incorporates an Enterprise License Manager (ELM) that administers software licenses. Customers purchase licenses and add them to the ELM application. The ELM application then collects requirements from all the applications, aggregates them, and compares them with the total available licenses.

The following Unified Communications applications use the ELM:

- Cisco Unified Communications Manager (Unified CM) – including Cisco IM and Presence, which is licensed through Unified CM, and Cisco Unified Communications Manager Session Management Edition (Unified CM SME)
- Cisco Unity Connection

Following purchase and product registration, licenses are delivered by email and then installed in the ELM. The ELM is connected to the application instances under license management, and it polls the applications. When polled, a subscribing application sends its license requirements to ELM, and the ELM compares the application's requirements to the available licenses. If the application's requirements, totaled for all application instances, are within the available license count, then ELM returns a status of *in compliance*. Similarly, if license requirements exceed available licenses or if the application is no longer available for polling, then ELM returns a status of “not in compliance.”

An application is allowed 60 days of non-compliance during which administrators can make changes if there are insufficient licenses or if the ELM server has lost communication with the application server. After 60 days of non-compliance, the Unified Communications Manager application(s) will no longer allow administrative changes; however, the application(s) will continue to function (call control) with no loss of service. After 60 days of non-compliance, the Unity Connection application(s) will allow administrative changes, but the application(s) will not continue to function (users will not have access to voice messaging).

For more information on Cisco Unified Communications licensing, refer to the information at

<http://www.cisco.com/go/uclicensing>

## Deployment Scenarios

ELM is installed automatically on the same dedicated server or virtual machine as the Unified CM, SME, and Unity Connection installations. You may choose to use the ELM on one of these servers in a co-resident configuration, as the active managing ELM, or you may opt to run ELM in a standalone configuration where ELM is installed on a dedicated server or virtual machine.

In the co-resident configuration, ELM consumes only a very small amount of resources and hence is considered to have no impact to server or virtual machine sizing. For example, no additional vCPUs would need to be added to the virtual machine configuration because of the ELM service. In the co-resident configuration the ELM resides on the same dedicated server or virtual machine that is sized appropriately for that application.

In a standalone configuration the ELM resides on a separate server or virtual machine created and managed specifically for, or dedicated to, the ELM application. In the standalone configuration, the ELM is sized to the equivalent minimum-sized resource for that application.

The main considerations for choosing between co-resident and standalone deployments center around administration and management. The main benefits of deploying ELM in a standalone configuration are as follows:

- Upgrading a standalone ELM can be done independently from upgrading the applications (Unified CM or Unity Connection). Whereas, in a co-resident configuration, upgrading ELM requires an upgrade to ELM and the co-resident application at the same time.
- Platform changes to Unified Communications applications (Unified CM or Unity Connection) might require changes to a co-resident ELM application. For example, a change in the MAC address would require transferring the registration of the license file(s) for a co-resident ELM; however, such changes for a standalone ELM would not require transferring the registration of the license file(s).
- Administrative changes required on a standalone ELM will not impact the application servers. For example, on a co-resident configuration, having to upgrade or reboot the ELM would require an upgrade or reboot of the application.

The trade-off, however, with a standalone configuration is that it requires a separate server or virtual machine to be created and managed.

### Deployment Recommendations:

- If you are installing only a single application on a single server or cluster, run ELM co-resident.
- If you are installing a very small number of application instances, you may:
  - Run ELM on a separate virtual machine or server. This approach provides more administration and management flexibility but requires a separate virtual machine or server for ELM.
  - Run a different ELM on each application server if you do not need license pooling and do not desire centralized license management.
  - Run a single ELM co-resident with one application server if you want license pooling and/or centralized management, but you are unwilling to dedicate a virtual machine or server for running the ELM.
- With Cisco Business Edition 6000, ELM would typically be co-resident with one of the application servers. However, if desired, it is possible to run ELM as a standalone virtual machine, but it would need to be counted against the maximum number of applications allowed on a Cisco Business Edition 6000 server.
- If you have a medium to large deployment, run ELM on a separate server or virtual machine. The incremental impact on the number of required virtual machines or servers is minimal in this case, and the trade-off between operating expenses and capital expenditures is favorable.

The ELM may be deployed in any of the following ways:

- Enterprise or global

As the description implies, one ELM instance can support an entire enterprise or global deployment. This model provides the most simplicity by utilizing one common centralized license pool for all the Unified Communications applications subscribing to the ELM.

- Regional or lines of business

For an enterprise that has multiple Unified Communications deployments across the globe, multiple ELM instances can be configured per region or lines of business (for example, one for North America, a second for EMEA, and a third for APAC). This model enables an enterprise to account more easily for the costs of licenses across differing fiscal boundaries.

- Individual Unified Communications application

For those customers requiring even more granularity, an ELM instance can be configured for each Unified Communications application. For example, if a customer has three Cisco Unified CM clusters, three ELM instances can be configured. This scenario is useful for customers who operate along more granular accounting lines and prefer multiple smaller license pools in order to better manage operating costs and other expenses.

## Redundancy

ELM is deployed as a non-redundant application. In the event that the ELM application becomes unavailable (for example, if the server that it resides on suffers a catastrophic hardware failure), the customer has 60 days to restore the ELM application before license enforcement occurs. The applications will run for a period of 60 days without communication with the ELM.

For restoration of the ELM application, should the original server not be available, another installed ELM application (such as a co-resident instance) can be made the active managing ELM. An alternate ELM application can be restored to the active managing ELM by re-adding the product inventory to the new ELM application and transferring the registration of the license file to this new ELM. If the original server becomes available, a restore from a backup will restore the ELM application, its product inventory, and the license file from backup. If license additions or changes have been made since the backup, or if the MAC address of the server or virtual machine changes, a new license file will have to be requested. If ELM was installed on a MCS server and if the original server is not available, the ELM can be restored from a backup; however, the license registration will have to be transferred to the new server. When performing a DRS restore for ELM in a virtualized deployment, configure the same MAC address on the new and original ELM virtual machine, otherwise the license registration will have to be transferred to the new virtual machine. An ELM co-resident backup can be restored only to a co-resident ELM application, and a standalone backup can be restored only to a standalone ELM.

## Intracuster Communications

There are two primary kinds of intracuster communications, or communications within a Unified CM cluster (see [Figure 9-2](#) and [Figure 9-3](#).) The first is a mechanism for distributing the database that contains all the device configuration information (see “Database replication” in [Figure 9-2](#)). The configuration database is stored on a publisher server, and a copy is replicated to the subscriber nodes of the cluster. Most of the database changes are made on the publisher and are then communicated to the subscriber databases, thus ensuring that the configuration is consistent across the members of the cluster and facilitating spatial redundancy of the database.

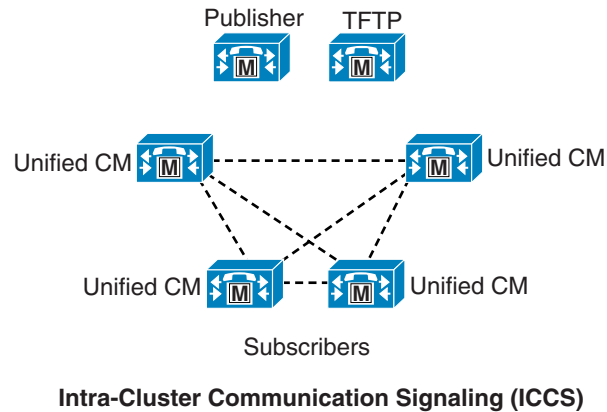

Database modifications for user-facing call processing features are made on the subscriber servers to which an end-user device is registered. The subscriber servers then replicate these database modifications to all the other servers in the cluster, thus providing redundancy for the user-facing features. (See “Call processing user-facing feature replication” in [Figure 9-2](#).) These features include:

- Call Forward All (CFA)
- Message waiting indicator (MWI)
- Privacy Enable/Disable
- Extension Mobility login/logout
- Hunt Group login/logout
- Device Mobility
- Certificate Authority Proxy Function (CAPF) status for end users and applications users
- Credential hacking and authentication

**Figure 9-2** Replication of the Database and User-Facing Features

191955

The second type of intracluster communication, called Intra-Cluster Communication Signaling (ICCS), involves the propagation and replication of run-time data such as registration of devices, locations bandwidth, and shared media resources (see [Figure 9-3](#)). This information is shared across all members of a cluster running the Cisco CallManager Service (call processing subscribers), and it ensures the optimum routing of calls between members of the cluster and associated gateways.

**Figure 9-3** Intra-Cluster Communication Signaling (ICCS)

191954

## Intracuster Security

Each server in a Unified CM cluster runs an internal dynamic firewall. The application ports on Unified CM are protected by source IP filtering. The dynamic firewall opens these application ports only to authenticated or trusted servers. (See [Figure 9-4](#).)

**Figure 9-4 Intracuster Security**

This security mechanism is applicable only between server nodes in a single Unified CM cluster. Unified CM subscribers are authenticated in a cluster before they can access the publisher's database. The intra-cluster communication and database replication take place only between authenticated servers. During the installation process, a subscriber node is authenticated to the publisher using a pre-shared key authentication mechanism. The authentication process involves the following steps:

1. Install the publisher server using a security password.
2. Configure the subscriber server on the publisher by using Unified CM Administration.
3. Install the subscriber server using the same security password used during publisher server installation.
4. After the subscriber is installed, the server attempts to establish connection to the publisher on a management channel using UDP 8500. The subscriber sends all the credentials to the publisher, such as hostname, IP address, and so forth. The credentials are authenticated using the security password used during the installation process.
5. The publisher verifies the subscriber's credentials using its own security password.
6. The publisher adds the subscriber as a trusted source to its dynamic firewall table if the information is valid. The subscriber is allowed access to the database.
7. The subscriber gets a list of other subscriber servers from the publisher. All the subscribers establish a management channel with each other, thus creating a mesh topology.

## General Clustering Guidelines

The following guidelines apply to all Unified CM clusters:

### Note

A cluster may contain a mix of server platforms or virtual machines based on different OVA templates, but all servers in the cluster must run the same Unified CM software release. For details, see the *Note* in the section on [Unified CM Cluster Services, page 9-6](#).

- Under normal circumstances, place all members of the cluster within the same LAN or MAN.
- If the cluster spans an IP WAN, follow the guidelines for clustering over an IP WAN as specified in the section on [Clustering Over the IP WAN, page 10-30](#).
- A Unified CM cluster may contain as many as 20 servers, of which a maximum of eight call processing subscribers (nodes running the Cisco CallManager Service) are allowed. The other server nodes within the cluster may be configured as a dedicated database publisher, dedicated TFTP subscriber, or media resource subscriber.
- When deploying Unified CM on Cisco MCS 7816 or equivalent servers, there is a maximum limit of two servers in a deployment: one acting as the publisher, TFTP, and backup call processing subscriber node, and the other acting as the primary call processing subscriber. A maximum of 500 phones is supported in this configuration with a Cisco MCS 7816 or equivalent server.
- When deploying a two-server cluster, Cisco recommends that you do not exceed 1250 users in the cluster. Above 1250 users, a dedicated publisher and separate servers for primary and backup call processing subscribers is recommended.
- Business Edition 6000 runs on specific UCS C200 or C220 Rack-Mount Servers and provides a single instance of Unified CM (a combined publisher and single subscriber instance). Additional UCS C200 or C220 server(s) may be deployed to provide subscriber redundancy either in an active/standby or load balancing fashion for Unified CM as well as some other co-resident applications. However, the total number of users across this Unified CM cluster may not exceed 1,000, and the total number of configured devices across this Unified CM cluster may not exceed 1,200 with the medium-density server or 2,500 with the high-density server. Cisco recommends deploying redundant servers with load balancing so that the load is distributed among the Unified CM instances. Alternatively an MCS server can be used to provide Unified CM subscriber redundancy either in active/standby or load balancing fashion.
- When deploying Unified CM as a virtualized application, just as with a cluster of MCS servers, each Unified CM node instance can be a publisher node, call processing subscriber node, TFTP subscriber node, or media resource subscriber node. As with any Unified CM cluster, only a single publisher node per cluster is supported.
- While the Cisco UCS B-Series Blade Servers and C-Series Rack-Mount Servers do support a local keyboard, video, and mouse (KVM) cable connection that provides a DB9 serial port, a Video Graphics Array (VGA) monitor port, and two Universal Serial Bus (USB) ports, the Unified CM VMware virtual application has no access to these USB and serial ports. Therefore, there is no ability to attach USB devices such as audio cards (MOH-USB-AUDIO=), serial-to-USB connectors (USB-SERIAL-CA=), or flash drives to these servers. The following alternate options are available:
  - For MoH live audio source feed, consider using Cisco IOS-based gateway multicast MoH for live audio source connectivity or deploying one Unified CM subscriber node on an MCS server as part of the Unified CM cluster to allow connectivity of the USB MoH audio card (MOH-USB-AUDIO=).
  - For SMDI serial connections, deploy one Unified CM subscriber node on an MCS server as part of the Unified CM cluster for USB serial connectivity.

- For saving system install logs, use virtual floppy softmedia.

## Cisco TelePresence VCS Clustering

The Cisco VCS Control and VCS Expressway can be deployed either as a standalone instance or as a cluster of up to six VCS servers.

VCS clusters are designed to extend the resilience and capacity of a Cisco VCS installation. VCS peers in a cluster share bandwidth usage as well as routing, zone, FindMe and other configuration. Endpoints can register to any of the peers in the cluster; if they lose connection to their initial peer, they can re-register to another peer in the cluster.

Call licensing is carried out on a per-cluster basis. Any traversal or non-traversal call licenses that have been installed on a cluster peer are available for use by any peer within the cluster. If a cluster peer becomes unavailable, the call licenses installed on that peer will remain available to the rest of the cluster peers for a grace period of two weeks from the time the cluster lost contact with the peer. This maintains the overall license capacity of the cluster.

Every VCS peer in the cluster must have the same routing capabilities. If any VCS can route a call to a destination, it is assumed that all VCS peers in that cluster can route a call to that destination. If the routing is different on different VCS peers, then separate VCSs or VCS clusters must be used.

One VCS needs to be nominated as the VCS Configuration Master peer in the cluster. This VCS Configuration Master peer holds the cluster configuration and manages the cluster database. Cluster-wide configuration can be performed only on the Configuration Master, and all other VCS peers in the cluster then periodically replicate the configuration from the master. The VCS Configuration Master is configured as Peer 1, and the VCS cluster configuration page lists the VCS call agents in the cluster.

The procedure for forming a VCS cluster is the same for Cisco VCS Control, VCS Expressway, and VCS Directory.

The VCS node that is running the Configuration Master also performs call processing, whereas a Unified CM publisher would not typically perform call processing except for Cisco Business Edition or for small deployments.

Observe the following guidelines when deploying Cisco VCS:

- A VCS cluster can consist of up to six VCS peers.
- Each VCS in the cluster is a peer of every other VCS in the cluster.
- The round trip time between any two VCS peers in the cluster must be less than 30 ms.
- Every VCS must use a static IP address.
- Each VCS peer must have a unique system name.
- Each VCS peer can have a different DNS server.
- All VCS peers in the cluster must have the same software version.
- All VCS peers in the cluster must have the identical option keys installed, with the exception of call processing license numbers which may be different on each peer
- H.323 must be enabled on all VCS peers, even if all endpoints in the cluster are SIP only. H.323 is used for internal clustering between VCS peers.
- A VCS cluster can be formed by a combination of VCS nodes running on an appliance or running as a virtualized application.

For more information on Cisco VCS clusters, refer to the latest version of the *Cisco TelePresence Video Communication Server Cluster Creation and Maintenance Deployment Guide*, available at

[http://www.cisco.com/en/US/products/ps11337/products\\_installation\\_and\\_configuration\\_guides\\_list.html](http://www.cisco.com/en/US/products/ps11337/products_installation_and_configuration_guides_list.html)

## High Availability for Call Processing

You should deploy the call processing services within a Unified Communications System in a highly available manner so that a failure of a single call processing component will not render all call processing services unavailable.

### Hardware Platform High Availability

You should select the call processing platform based not only on the size and scalability of a particular deployment, but also on the redundant nature of the platform hardware.

For example, for highly available deployments you should select platforms with multiple processors and multiple hard disk drives. Not only is this important for higher-scale deployments, but it is also critical for deployments that require high availability so that an individual component failure does not result in loss of features or services.

Furthermore, when possible, choose platforms with dual power supplies to ensure that a single power supply failure will not result in the loss of a platform. Plug platforms with dual power supplies into two different power sources to avoid the failure of one power circuit causing the entire platform to fail. The use of dual power supplies combined with the use of uninterruptible power supply (UPS) sources will ensure maximum power availability. In deployments where dual power supply platforms are not feasible, Cisco still recommends the use of a UPS in situations where building power does not have the required level of power availability.

Providing hardware platform high availability is even more critical when deploying virtualization because a platform failure could result in the failure of all the virtual machines running on that hardware platform. When possible, avoid running multiple instances of the same application that have similar functions on the same physical server; instead, distribute those virtual machines across multiple servers and even across multiple chassis if possible when using Cisco UCS B-Series Blade Servers.

### Network Connectivity High Availability

Connectivity to the IP network is also a critical consideration for maximum performance and high availability. Connect call processing platforms to the network at the highest possible speed to ensure maximum throughput, typically 1000 Mbps or 100 Mbps full-duplex depending on the platform. Whenever possible, ensure that platforms are connected to the network using full-duplex, which can be achieved with 100 Mbps by hard-coding the network switch port and the platform interface port. For 1000 Mbps, Cisco recommends using Auto/Auto for speed and duplex configuration on both the platform interface port and the network switch port.

**Note**

A mismatch will occur if either the platform interface port or the network switch port is left in Auto mode and the other port is configured manually. The best practice is to configure both the platform port and the network switch port manually, with the exception of Gigabit Ethernet ports which should be set to Auto/Auto.

In addition to speed and duplex of IP network connectivity, equally important is the resilience of this network connectivity. Unified communications deployments are highly dependent on the underlying network connectivity for true redundancy. For this reason it is critical to deploy and configure the underlying network infrastructure in a highly resilient manner. For details on designing highly available network infrastructures, see the chapter on [Network Infrastructure, page 3-1](#). In all cases, the network should be designed so that, given a switch or router failure within the infrastructure, a majority of users will have access to a majority of the services provided within the deployment.

To maximize call processing availability, locate and connect call processing platforms in separate buildings and/or separate network switches when possible to ensure that the impact to call processing will be minimized if there is a failure of the building or network infrastructure switch. With Unified CM call processing, this means distributing cluster server nodes among multiple buildings or locations within the LAN or MAN deployment whenever possible. And at the very least, it means physically distributing network connections between different physical network switches in the same location.

Furthermore, even though Cisco Unified CME is a standalone call processing entity, providing physical distribution and therefore redundancy for this call processing entity still makes sense when deploying multiple call processing entities. Whenever possible in those scenarios, install each instance of Unified CME in a different physical location within the network, or at the very least physically attach them to different network switches.

Besides deploying a highly available network infrastructure and physically distributing call processing platforms across network components and locations, it is also good practice to provide highly available physical connections to the network from each call processing entity. Whenever possible, use dual network attachments to connect the platform to two different ports on two physically separate network switches so that a single upstream hardware port or switch failure will not result in loss of network connectivity for the platform. A Unified CME router platform can have more than one physical network interface and can be dual-attached to a network. Likewise, the MCS server platform for Unified CM can also be dual-attached to the network using network interface card (NIC) teaming.

Cisco VCS Control uses only one network interface. A second network interface can be used with Cisco VCS Expressway for high-security deployments, for example, where the VCS Expressway is located in a DMZ between two separate firewalls on separate network segments.

### **NIC Teaming with MCS Servers for Network Fault Tolerance**

The NIC teaming feature allows a Cisco MCS (or HP or IBM equivalent server) to be connected to the IP network through two NICs and, therefore, two physical cables. NIC teaming prevents network downtime by transferring the workload from the failed port to the working port. NIC teaming cannot be used for load balancing or increasing the interface speed. NIC teaming is supported on dual-NIC Cisco MCS platforms (or HP or IBM equivalents).

### **UCS Network Fault Tolerance**

Cisco C-Series Rack Mount Servers have multiple NIC ports. Cisco recommends assigning multiple ports for VMware management and especially for the virtual machine traffic, using VMware NIC teaming, and connecting those ports to separate upstream physical switches. For more information, refer to VMware documentation available at

<http://www.vmware.com>

Cisco UCS B-Series Blade Servers leverage the UCS network attachment infrastructure as well as the underlying network attached storage area network (SAN). This back-end UCS network infrastructure, including redundant parallel switching fabric extenders and interconnects as well as Fibre Channel or gigabit ethernet uplinks, provides highly available network attachment and storage for these servers. For

details on highly available virtual data center deployments of the UCS network and storage infrastructure, refer to the document on *Designing Secure Multi-Tenancy into Virtualized Data Centers*, available at

[http://www.cisco.com/en/US/docs/solutions/Enterprise/Data\\_Center/Virtualization/secureldg.html](http://www.cisco.com/en/US/docs/solutions/Enterprise/Data_Center/Virtualization/secureldg.html)

Whether it is managed through VMware with the Cisco UCS C-Series or through VMware and UCS architecture with the B-Series, both C-Series and B-Series provide high resiliency for the network connectivity. Therefore, NIC teaming configuration at the virtual NIC (vNIC) level for a virtual machine is not necessary, and generally only one vNIC is defined in the OVAs.

## Unified CM High Availability

Because of the underlying Unified CM clustering mechanism, a Unified Communications System has additional high availability considerations above and beyond hardware platform disk and power component redundancy, physical network location, and connectivity redundancy. This section examines call processing subscriber redundancy considerations, call processing load balancing, and redundancy of additional cluster services.

### Call Processing Redundancy

Unified CM provides the following call processing redundancy configuration options or schemes:

- Two to one (2:1) — For every two primary call processing subscribers, there is one shared secondary or backup call processing subscriber.
- One to one (1:1) — For every primary call processing subscriber, there is a secondary or backup call processing subscriber.

These redundancy schemes are facilitated by the built-in registration failover mechanism within the Unified CM cluster architecture, which enables endpoints to re-register to a backup call processing subscriber node when the endpoint's primary call processing subscriber node fails. The registration failover mechanism can achieve failover rates for Skinny Client Control Protocol (SCCP) IP phones of approximately 125 registrations per second. The registration failover rate for Session Initiation Protocol (SIP) phones is approximately 40 registrations per second.

The call processing redundancy scheme you select determines not only the fault tolerance of the deployment, but also the fault tolerance of any upgrade.

**Note**

Some endpoints such as the Cisco TelePresence System EX Series video endpoints might not support Unified CM registration redundancy. For details, see the chapter on [Collaboration Endpoints](#), page 8-1.

With 1:1 redundancy, multiple primary call processing subscriber failures can occur without impacting call processing capabilities. With 2:1 redundancy, on the other hand, only one of the primary call processing subscribers out of the two primary call processing subscribers that share a backup call processing subscriber can fail without impacting call processing. If the total number of endpoints registered across both primary subscribers and the traffic to those two primary subscribers are within the capacity limits of a single subscriber, then the backup subscriber is able to handle the failure of both primary subscribers.

**Note**

Do not deploy 2:1 redundancy if the total capacity utilization across the two primary subscribers would exceed the capacity of the backup subscriber. For example, if the call processing capacity or endpoints capacity utilization exceeds 50% on both primary subscribers, the backup subscriber would not be able

to handle call processing services properly if both primary subscribers fail. In these scenarios, for example, some endpoints might not be able to register, some new calls might not be established, and some services and features might not operate properly because the backup subscriber system capacity has been exceeded.

Likewise, with the 1:1 redundancy scheme, upgrades to the cluster can be performed with only a single set of endpoint registration failover periods impacting the call processing services. Whereas with the 2:1 redundancy scheme, upgrades to the cluster can require multiple registration failover periods.

A Unified CM cluster can be upgraded with minimal impact to the services. Two different versions (releases) of Unified CM may be on the same server, one in the active partition and the other in the inactive partition. All services and devices use the Unified CM version in the active partition for all Unified CM functionality. During the upgrade process, the cluster operations continue using its current release of Unified CM in the active partition, while the upgrade version gets installed in the inactive partition. Once the upgrade process is complete, the servers can be rebooted to switch the inactive partition to the active partition, thus running the new version of Unified CM.

With the 1:1 redundancy scheme, the following steps enable you to upgrade the cluster while minimizing downtime:

- 
- Step 1** Install the new version of Unified CM in the inactive partition, first on the publisher and then on all subscribers (call processing, TFTP, and media resource subscribers). Do not reboot.
  - Step 2** Reboot the publisher and switch to the new version.
  - Step 3** Reboot the TFTP subscriber node(s) one at a time and switch to the new version.
  - Step 4** Reboot any dedicated media resource subscriber nodes one at a time and switch to the new version.
  - Step 5** Reboot the backup call processing subscribers one at a time and switch to the new version.
  - Step 6** Reboot the primary call processing subscribers one at a time and switch to the new version. Device registrations will fail-over to the previously upgraded and rebooted backup call processing subscribers. After each primary call processing subscriber is rebooted, devices will begin to re-register to the primary call processing subscriber.
- 

With this upgrade method, there is no period (except for the registration failover period) when devices are registered to subscriber servers that are running different versions of the Unified CM software.

While the 2:1 redundancy scheme allows for fewer servers in a cluster, registration failover occurs more frequently during upgrades, increasing the overall duration of the upgrade as well as the amount of time call processing services for a particular endpoint will be unavailable. Because there is only a single backup call processing subscriber per pair of primary call processing subscribers, it might be possible to reboot to the new version on only one of the primary call processing subscribers in a pair at a time in order to prevent oversubscribing the single backup call processing subscriber. As a result, there may be a period of time after the first primary call processing subscriber in each pair is switched to the new version, in which endpoint registrations will have to be moved from the backup subscriber to the newly upgraded primary subscriber before the endpoint registrations on the second primary subscriber can be moved to the backup subscriber to allow a reboot to the new version. During this time, not only will endpoints on the second primary call processing subscriber be unavailable while they re-register to the backup subscriber, but until they re-register to a node running the new version, they will also be unable to reach endpoints on other subscriber nodes that have already been upgraded.

**Note**

Before you do an upgrade, Cisco recommends that you back up the Unified CM and Call Detail Record (CDR) database to an external network directory using the Disaster Recovery Framework. This practice will prevent any loss of data if the upgrade fails.

**Note**

Because an upgrade of a Unified CM cluster results in a period of time in which some or most devices lose registration and call processing services temporarily, you should plan upgrades in advance and implement them during a scheduled maintenance window. While downtime and loss of services to devices can be minimized by selecting the 1:1 redundancy scheme, there will still be some period of time in which call processing services are not available to some or all users.

For more information on upgrading Unified CM, refer to the install and upgrade guides available at

[http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod\\_installation\\_guides\\_list.html](http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_installation_guides_list.html)

### **Unified CM Redundancy with Survivable Remote Site Telephony (SRST)**

Cisco IOS SRST provides highly available call processing services for endpoints in locations remote from the Unified CM cluster. Unified CM clustering redundancy schemes certainly provide a high level of redundancy for call processing and other application services within a LAN or MAN environment. However, for remote locations separated from the central Unified CM cluster by a WAN or other low-speed links, SRST can be used as a redundancy method to provide basic call processing services to these remote locations in the event of loss of network connectivity between the remote and central sites. Cisco recommends deploying SRST-capable Cisco IOS routers at each remote site where call processing services are considered critical and need to be maintained in the event that connectivity to the Unified CM cluster is lost. Endpoints at these remote locations must be configured with an appropriate SRST reference within Unified CM so that the endpoint knows what address to use to connect to the SRST router for call processing services when connectivity to Unified CM subscribers is unavailable.

Unified CME on a Cisco IOS router can also be used at a remote site to provide enhanced SRST functionality in the event that connectivity to the central Unified CM cluster is lost. Unified CME provides more backup call processing features for the IP phones than are available with the regular SRST feature on a router. However, the endpoint capacities for Unified CME acting as SRST are typically less than for basic SRST.

## **Call Processing Subscriber Redundancy**

Depending on the redundancy scheme chosen (see [Call Processing Redundancy, page 9-18](#)), the call processing subscriber will be either a primary (active) subscriber or a backup (standby) subscriber. In the load-balancing option, the subscriber can be both a primary and backup subscriber. When planning the design of a cluster, you should generally dedicate the call processing subscribers to this function. In larger-scale or higher-performance clusters, the call processing service should not be enabled on the publisher and TFTP subscriber nodes. 1:1 redundancy uses dedicated pairs of primary and backup subscribers, while 2:1 redundancy uses a pair of primary subscribers that share one backup subscriber.

The following figures illustrate typical cluster configurations to provide call processing redundancy with Unified CM.

**Figure 9-5 Basic Redundancy Schemes**

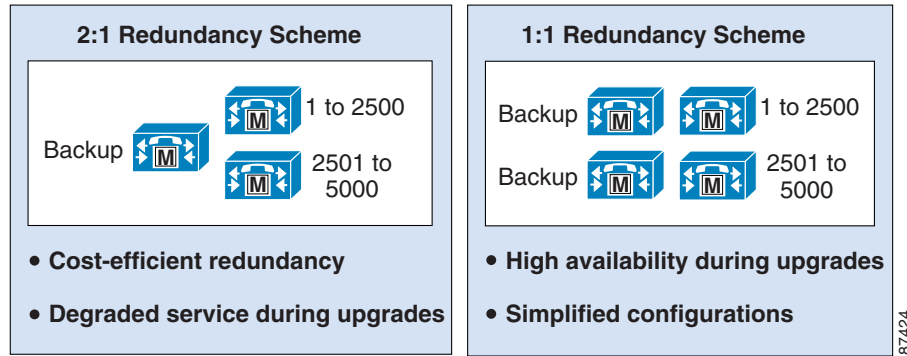

Figure 9-5 illustrates the two basic redundancy schemes available. In each case the backup server must be capable of handling the capacity of at least a single primary call processing server failure. In the 2:1 redundancy scheme, the backup might have to be capable of handling the failure of a single call processing server or potentially both primary call processing servers, depending on the requirements of a particular deployment. For information on sizing the capacity of the servers and choosing the hardware platforms, see the section on [Capacity Planning for Call Processing, page 9-28](#).

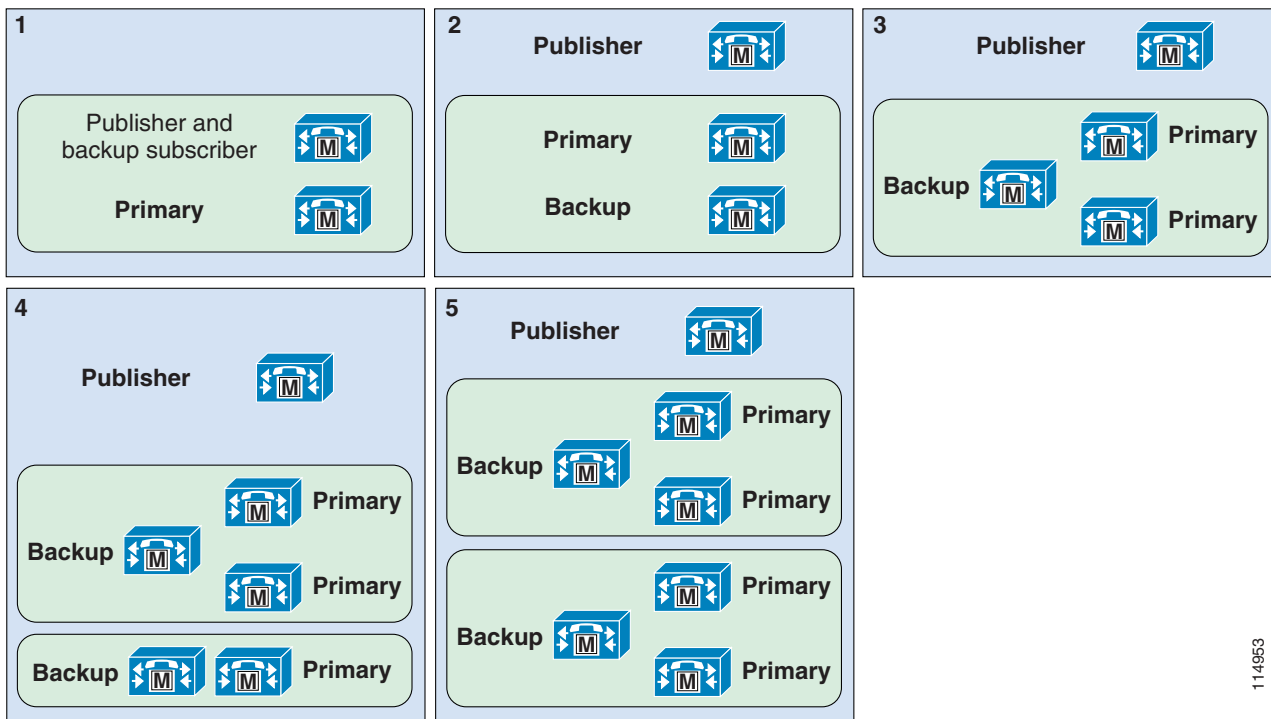

**Note**

2:1 redundancy is not supported when using the Cisco MCS 7845-I3 server or a virtual machine deployed with the 10K-User OVA due to potential overload on the backup subscriber.

**Figure 9-6** 1:1 Redundancy Configuration Options

114952

**Figure 9-7** 2:1 Redundancy Configuration Options

114953

In [Figure 9-6](#), the five options shown all indicate 1:1 redundancy. In [Figure 9-7](#), the five options shown all indicate 2:1 redundancy. In both cases, Option 1 is used for clusters supporting less than 1250 users. Options 2 through 5 illustrate increasingly scalable clusters for each redundancy scheme. The exact scale depends on the hardware platforms chosen or required.

These illustrations show only publisher and call processing subscribers. They do not account for other subscriber nodes such as TFTP and media resources.

**Note**

It is possible to define up to three call processing subscribers per Unified CM group. Adding a tertiary subscriber for additional backup extends the above redundancy schemes to 2:1:1 or 1:1:1 redundancy. However, with the exception of using tertiary subscriber servers in deployments with clustering over the WAN (see [Remote Failover Deployment Model, page 10-41](#)), tertiary subscriber redundancy is not recommended for endpoint devices located in remote sites because failover to SRST will be further delayed if the endpoint must check for connectivity to a tertiary subscriber. The tertiary subscribers also count against the maximum number of call processing subscribers in a cluster (8 call processing subscriber nodes).

Although not shown in the [Figure 9-6](#) or [Figure 9-7](#), it is also possible to deploy a single-server cluster with an MCS 7825 or larger server. With an MCS 7825 or equivalent server, the endpoint configuration and registration limit is 500 for a single-server cluster. With a higher-availability server, the single-server cluster should not exceed 1000 endpoint configuration and registrations. Note that in a single-server configuration, there is no backup call processing subscriber and therefore no cluster redundancy mechanism. Survivable Remote Site Telephony (SRST) can be used as a redundancy mechanism in these types of deployments to provide minimal call processing services during periods when Unified CM is not available. However, Cisco does not recommend a single-server deployment for production environments.

**Load Balancing**

In Unified CM clusters with the 1:1 redundancy scheme, device registration and call processing services can be load-balanced across the primary and backup call processing subscriber.

Normally a backup server has no devices registered to it unless its primary is unavailable. This makes it easier to troubleshoot a deployment because there is a maximum of four primary call processing subscriber nodes that will be handling the call processing load at a given time. Further, this potentially simplifies configuration by reducing the number of Unified CM redundancy groups and device pools.

In a load-balanced deployment, up to half of the device registration and call processing load can be moved from the primary to the secondary subscriber by using the Unified CM redundancy groups and device pool settings. In this way each primary and backup call processing subscriber pair provides device registration and call processing services to as many as half of the total devices serviced by this pair of call processing subscribers. This is referred to as 50/50 load balancing. The 50/50 load balancing model provides the following benefits:

- Load sharing — The registration and call processing load is distributed on multiple servers, which can provide faster response time.
- Faster failover and failback — Because all devices (such as IP phones, CTI ports, gateways, trunks, voicemail ports, and so forth) are distributed across all active subscribers, only some of the devices fail-over to the secondary subscriber if the primary subscriber fails. In this way, you can reduce by 50% the impact of any server becoming unavailable.

To plan for 50/50 load balancing, calculate the capacity of a cluster without load balancing, and then distribute the load across the primary and backup subscribers based on devices and call volume. To allow for failure of the primary or the backup server, do not let the total load on the primary and secondary subscribers exceed that of a single subscriber server.

**Note**

During upgrades of a Unified CM cluster with 50/50 load balancing, upgrades to the backup call processing subscriber will result in devices registered to that subscriber (up to half of the total devices serviced by the primary and backup subscriber pair) failing over to the primary call processing subscriber.

## TFTP Redundancy

Cisco recommends deploying more than one dedicated TFTP subscriber node for a large Unified CM cluster, thus providing redundancy for TFTP services. While two TFTP subscribers are typically sufficient, more than two TFTP servers can be deployed in a cluster.

In addition to providing one or more redundant TFTP subscribers, you must configure endpoints to take advantage of these redundant TFTP nodes. When configuring the TFTP options using DHCP or statically, define a TFTP subscriber node IP address array containing the IP addresses of both TFTP subscriber nodes within the cluster. In this way, by creating two DHCP scopes with two different IP address arrays (or by manually configuring endpoints with two different TFTP subscriber node IP addresses), you can assign half of the endpoint devices to use TFTP subscriber A as the primary and TFTP subscriber B as the backup, and the other half to use TFTP subscriber B as the primary and TFTP subscriber A as the backup. In addition to providing redundancy during a failure of one TFTP subscriber, this method of distributing endpoints across multiple TFTP subscribers provides load balancing so that one TFTP subscriber is not handling all the TFTP service load.

**Note**

When adding a specific binary or firmware load for a phone or gateway, you must add the file(s) to each TFTP subscriber node in the cluster.

## CTI Manager Redundancy

All CTI integrated applications communicate with a call processing subscriber node running the CTI Manager service. Further, most CTI applications have the ability to specify redundant CTI Manager service nodes. For this reason, Cisco recommends activating the CTI Manager service on at least two call processing subscribers within the cluster. With both a primary and backup CTI Manager configured, in the event of a failure the application will switch to a backup CTI Manager to receive CTI services.

As stated previously, the CTI Manager service can be enabled only on call processing subscribers, therefore there is a maximum of eight CTI Managers per cluster. Cisco recommends that you load-balance CTI applications across the enabled CTI Managers in the cluster to provide maximum resilience, performance, and redundancy.

Generally, it is good practice to associate devices that will be controlled or monitored by a CTI application with the same server pair used for the CTI Manager service. For example, an interactive voice response (IVR) application requires four CTI ports. They would be provisioned as follows, assuming the use of 1:1 redundancy and 50/50 load balancing:

- Two CTI ports would have a Unified CM redundancy group of server A as the primary call processing subscriber and server B as the backup subscriber. The other two ports would have a Unified CM redundancy group of server B as the primary subscriber and server A as the backup subscriber.
- The IVR application would be configured to use the CTI Manager on subscriber A as the primary and subscriber B as the backup.

The above example allows for redundancy in case of failure of the CTI Manager on subscriber A and also allows for the IVR call load to be spread across two servers. This approach also minimizes the impact of a Unified CM subscriber node failure.

For more details on CTI and CTI Manager, see [Computer Telephony Integration \(CTI\)](#), page 9-34.

## Virtualized Call Processing Redundancy

For deployments of Unified CM as a virtual application, all previous call processing, TFTP, and CTI Manager redundancy schemes still apply. With virtualization there are additional redundancy considerations because of the virtual nature of server nodes: namely, the installation and residency of Unified CM server node instances across servers.

As illustrated in [Figure 9-8](#), observe the following guidelines when deploying Unified CM on a UCS server to ensure the highest level of call processing redundancy:

- Each primary call processing subscriber node instance should reside on a different physical UCS B-Series or C-Series server than its backup call processing subscriber node instance. This ensures that the failure of a server containing the primary call processing node instance does not impact the system's ability to provide endpoints with access to their backup call processing subscriber node.
- When deploying multiple TFTP or media resource subscriber nodes instances for redundancy of those services, always distribute redundant subscriber nodes across more than one UCS B-Series or C-Series server to ensure that a failure of a single server does not eliminate those services. This ensures that, given the failure of a blade containing a TFTP or media resource subscriber, endpoints will still be able to access TFTP and media resource services on a subscriber node residing on another server. Endpoints can also be distributed among redundant TFTP and media resource subscriber node instances to balance system load in non-failure scenarios.
- When deploying CTI applications, always make sure that call processing subscriber node instances running the CTI Manager service are distributed across more than one UCS B-Series or C-Series server to ensure that a failure of a single server does not eliminate CTI services. Further, CTI applications should be configured to use the CTI Manager service running on the subscriber node instance on one server as the primary CTI Manager and the CTI Manager service running on the subscriber node on another server as the backup CTI Manager.

**Figure 9-8** Unified CM Server Node Distribution on UCS

In addition to distributing subscriber node instances across multiple blades, you may distribute subscriber node instances across multiple Cisco UCS 5100 Blade Chassis for additional redundancy and scalability.

For more information about redundancy and provisioning of host resources for virtual machines, refer to the documentation at <http://www.cisco.com/go/uc-virtualized>.

## Cisco Business Edition High Availability

Cisco Business Edition 6000 provides redundancy for call processing and registration services by clustering additional Cisco Unified CM node(s). Additional Business Edition 6000 server(s) (UCS C200 or C220 Rack-Mount Server or MCS server) can be deployed to provide high availability for call processing as well as other applications and services.

**Note**

More than two UCS C200 or C220 Rack-Mount Servers may be clustered for a Business Edition 6000 deployment to provide additional redundancy and/or geographic distribution as with a clustering over the WAN deployment. However, the total number of users across the cluster may not exceed 1,000, and the total number of configured devices across the cluster may not exceed 1,200 with a medium-density server or 2,500 with a high-density server. A deployment of UCS C200 or C220 Rack-Mount Servers in a cluster exceeding these limits is considered to be a regular Unified CM cluster, and as such the deployment must follow high availability design guidance for regular Unified CM. (See [Unified CM High Availability](#), page 9-18.)

## Cisco TelePresence VCS High Availability

Cisco VCS offers high availability by allowing deployment of up to six VCS peers in a VCS cluster. This applies to Cisco VCS Control and Cisco VCS Expressway. All VCS peers in a VCS cluster must be of the same type; a VCS Expressway node and a VCS Control node cannot be deployed in the same VCS cluster. If a VCS peer becomes unavailable, endpoints use another peer in the VCS cluster for registration and call processing.

High availability can be achieved through different methods depending on the endpoint capabilities.

SIP-capable endpoints that support SIP Outbound (RFC 5626) can be configured to register to multiple peers simultaneously. The benefit of maintaining simultaneous registrations is to avoid any downtime if a VCS server fails. If endpoints are SIP-based and RFC 5626 compliant, then this is the preferred method for providing VCS registration redundancy.

**Note**

In this configuration, because a SIP endpoint is actively registered to multiple VCS peers, that SIP endpoint has to be accounted for on each of those VCS peers with regard to capacity and registration license.

If SIP endpoints do not support SIP Outbound, high availability can be achieved by using the Domain Name Server (DNS) record for the VCS cluster.

For H.323 endpoints, the high availability mechanism depends on whether the endpoint registers to VCS for the first time or whether it re-registers subsequently. Redundancy for the initial registration is provided by the use of DNS Record for the VCS cluster. Redundancy for subsequent registration is done through the H.323 Alternate Gatekeepers list that is returned by VCS to the H.323 endpoint through the

initial registration. This list contains the addresses of VCS cluster peer members. If the endpoint loses connection with the first VCS peer it registered with, it will select another peer from the Alternate Gatekeepers list and try to re-register with that VCS.

For SIP and H.323 endpoints, it is also possible to configure the IP address of one of the VCS peers, but this method should be used only as a last resort because it does not provide registration redundancy.

As mentioned above, Domain Name Server (DNS) Records can be used to provide redundancy. SIP or H.323 endpoints may leverage a DNS server to find the IP address of another VCS node with which to attempt registration if initial registration failed with the previous node. Relying on DNS for registration redundancy does introduce some delay because endpoints must wait some period of time after sending an initial registration request before sending a new registration request to another VCS node. There are two methods for enabling DNS record types, depending on the endpoint:

- **DNS SRV (Service Records)** — For endpoints that support DNS SRV records, set up a DNS SRV record for the DNS name of the VCS cluster, giving each cluster peer an equal weighting and priority. The endpoint should then be configured with the DNS name of the cluster. On startup the endpoint issues a DNS SRV request and receives back the addresses of each VCS cluster peer. The endpoint will then try to register with each peer in turn. If you are using DNS to achieve registration redundancy, DNS SRV records are recommended if supported by the endpoint, because this method provides faster failover times than relying on round-robin between DNS A-records.
- **DNS Round-Robin** — For endpoints that do not support DNS SRV records, set up a DNS A-record for the DNS name of the VCS cluster, and configure it to supply a round-robin list of IP addresses for each VCS cluster peer. The endpoint should then be configured with the DNS name of the cluster. On startup the endpoint performs a DNS A-record lookup and receives back an address of a peer taken from the round-robin list. The endpoint will try to register with that peer. If that peer is not available, the endpoint performs another DNS lookup, and the server will respond with the next peer in the list. This process is repeated until the endpoint registers with a VCS.

For more information, refer to the latest version of the *Cisco TelePresence Video Communication Server Cluster Creation and Maintenance Deployment Guide*, available at

[http://www.cisco.com/en/US/products/ps11337/products\\_installation\\_and\\_configuration\\_guides\\_list.html](http://www.cisco.com/en/US/products/ps11337/products_installation_and_configuration_guides_list.html)

When deploying Cisco VCS as a virtual application and clustering VCS nodes, Cisco strongly recommends using at least two physical hardware hosts and having VCS peers running on those separate hosts. The same guidelines as with Unified CM can be applied (see [Virtualized Call Processing Redundancy](#), page 9-25).

When Cisco VCS Control is deployed as part of Cisco Business Edition 6000, high availability is also possible by adding other Cisco VCS Control peer(s) in the same VCS Control cluster. When Cisco VCS Expressway is added to a Cisco Business Edition 6000 system, high availability is also possible by adding other Cisco VCS Expressway peer(s) in the same VCS Expressway cluster. When you add Cisco VCS peer(s) for high availability, Cisco recommends deploying them on separate host(s). A two-node VCS Control cluster and a two-node VCS Expressway cluster can be deployed on two servers, for example, with each server hosting one VCS Control node and one VCS Expressway node. For more details on deploying a VCS Control node and a VCS Expressway node on the same ESXi host, refer to the document *Installing Cisco Video Communications Server Expressway on a Business Edition 6000 Server*, available at

[http://www.cisco.com/en/US/products/ps11369/prod\\_technical\\_reference\\_list.html](http://www.cisco.com/en/US/products/ps11369/prod_technical_reference_list.html)

# Capacity Planning for Call Processing

Call processing capacity planning is critical for successful unified communications deployments. Given the many features and functions provided by call processing services as well as the many types of devices for which call processing entities can provide registration and transaction services, it is important to size the call processing infrastructure and its individual components to ensure they meet the capacity needs of a particular deployment.

IP phones, software clients, voicemail ports, CTI (TAPI or JTAPI) devices, gateways, and DSP resources for media services such as transcoding and conferencing, all register to a call processing entity. Each of these devices requires resources from the call processing platform with which it is registered. The required resources can include memory, processor usage, and disk I/O.

Besides adding registration load to call processing platforms, after registration each device then consumes additional platform resources during transactions, which are normally in the form of calls. For example, a device that makes only 6 calls per hour consumes fewer resources than a device making 12 calls per hour.

For more information about call processing sizing and for a complete discussion of system sizing, capacity planning, and deployment considerations, see the chapter on [Collaboration Solutions Design and Deployment Sizing Considerations](#), page 27-1.

## Unified CME Capacity Planning

When deploying Unified CME, it is critical to select a Cisco IOS router platform that provides the desired capacity in terms of number of supported endpoints required. In addition, platform memory capacity should also be considered if the Unified CME router is providing additional services above and beyond call processing, such as IP routing, DNS lookup, dynamic host configuration protocol (DHCP) address services, or VXML scripting.

Unified CME can support a maximum of 450 endpoints on a single Cisco IOS platform; however, each router platform has a different endpoint capacity based on the size of the system. Because Unified CME is not supported within the Cisco Unified Communications Sizing Tool, it is imperative to follow capacity information provided in the product data sheets available at

[http://www.cisco.com/en/US/products/sw/voicesw/ps4625/products\\_data\\_sheets\\_list.html](http://www.cisco.com/en/US/products/sw/voicesw/ps4625/products_data_sheets_list.html)

## Unified CM Capacity Planning

This section examines capacity planning for Unified CM. The recommendations provided in this section are based on calculations made using the Unified Communications Sizing Tool, with default trace levels and call detail records (CDRs) enabled. In some cases higher levels of performance and capacity can be achieved by disabling, reducing, or reconfiguring other functions that are not directly related to processing calls. Enabling and increasing utilization of these functions can also have an impact on the call processing capabilities of the system and in some cases can reduce the overall capacity. These functions include tracing, call detail recording, highly complex dial plans, and other services that are co-resident on the Unified CM platform. Highly complex dial plans can include multiple line appearances as well as large numbers of partitions, calling search spaces, route patterns, translations, route groups, hunt groups, pickup groups, route lists, call forwarding, co-resident services, and other co-resident applications. All of these functions can consume additional resources within the Unified CM system.

You can use the following techniques to improve system performance:

- Install additional certified memory in the server, up to the maximum supported for the particular platform. Cisco recommends doubling the RAM in MCS 7825 and MCS 7835 or equivalent servers with large configurations for that server class. Verification using the Cisco Real Time Monitoring Tool (RTMT) will indicate if this memory upgrade is required. As the server approaches maximum utilization of physical memory, the operating system will start to swap to disk. This swapping is a sign that additional physical memory should be installed.
- A Unified CM cluster with a very large dial plan containing many gateways, route patterns, translation patterns, and partitions, can take an extended amount of time to initialize when the Cisco CallManager Service is first started. If the system does not initialize within the default time, you can modify the system initialization timer (a Unified CM service parameter) to allow additional time for the configuration to initialize. For details on the system initialization time, refer to the online help for Service Parameters in Unified CM Administration.

## Unified CM Capacity Planning with Virtualized Platforms

In a virtualized deployment, most Unified Communications applications such as Unified CM must be installed using a predefined template that specifies the configuration of the virtual machine's virtual hardware. These templates are distributed through Open Virtualization Archives (OVA), an open standards-based method for packaging and distributing virtual machine templates.

These OVA templates define the number of virtual CPU, the amount of virtual memory, the number and size of hard drives, and so forth, and they determine the capacity of the application. For Unified CM, there are multiple OVA templates available, one for almost each server class (although there is no template corresponding to the MCS 7816). A Unified CM node running as a virtual machine typically has the same capacity as a Unified CM node running directly on a Cisco MCS server when using the corresponding OVA template. For example, the OVA template for Unified CM supporting 7,500 users and/or devices has the same capacity as the MCS 7845-H2/I2 server.

## Unified CM Capacity Planning Guidelines and Endpoint Limits

The following capacity guidelines apply to Cisco Unified CM:

- Within a cluster, a maximum of 8 call processing subscriber nodes can be enabled with the Cisco CallManager Service. Other servers may be used for more dedicated functions such as publisher, TFTP subscribers, and media resources subscribers.
- Each cluster can support configuration and registration for a maximum of 40,000 secured or unsecured SCCP or SIP endpoints.
- A cluster consisting of server node instances running on VMware can support different capacities depending on the OVA template that is chosen. For most Cisco MCS server classes, there is a corresponding OVA template that provides a Unified CM instance with the same capacities (number of phones, gateways, locations, regions, CTI connections, and so forth) as the MCS server class. Because multiple virtual machine instances can run on the same blade or server, the total capacity on a blade or server can therefore be higher than on an MCS server.
- The maximum recommended trace setting for Unified CM is 2,000 files of 2 MB for both System Diagnostic Interface (SDI) and Signaling Distribution Layer (SDL) traces, for a total of 4,000 files. Each process has a setting for maximum number of files, and each process is allowed 2,000 files for SDL and 2,000 files for SDI. Trace settings for all other components must be configured within the

limit of 126 MB (for example, 63 files of 2 MB each). These are suggested upper limits. Unless specific troubleshooting under high call rates requires increasing the maximum file setting, the default settings are sufficient for collecting sufficient traces in most circumstances.

For more information about Unified CM capacity planning considerations, including sizing limits as well as a complete discussion of system sizing, capacity planning, and deployment considerations, see the chapter on [Collaboration Solutions Design and Deployment Sizing Considerations, page 27-1](#).

## Megacluster

The term *megacluster* defines and identifies certain Unified CM deployments that allow for further increases in scalability. A megacluster provides more device capacity through the support of additional Unified CM subscriber nodes, with a maximum of eight Unified CM subscriber pairs (1:1 redundancy) per megacluster, thus allowing for a maximum of 80,000 devices.

A megacluster can also be deployed where customers simply require non-locally redundant call processing functionality, rather than using Survivable Remote Site Telephony (SRST), to scale beyond the maximum eight sites allowed in a standard cluster deployment and up to 16 Unified CM subscriber nodes per megacluster. For example, consider a large hospital that has twelve locations and each location has only 1,000 devices. This total of 12,000 devices could be accommodated within a standard cluster, which has a maximum device capacity of 40,000 devices. However, in this case it is the need for additional Unified CM subscribers, rather than additional device capacity, that requires a megacluster deployment. In this example, a Unified CM subscriber node could be deployed in each location, and each Unified CM subscriber could serve as the primary subscriber for the local endpoints and as a backup subscriber for endpoints from another location.

When considering a megacluster deployment, the primary areas impacting capacity are as follows:

- The megacluster may contain a total of 21 servers consisting of 16 subscribers, 2 TFTP servers, 2 music on hold (MoH) servers, and 1 publisher
- Server type must be either Cisco MCS 7845-I3/H3 class or Cisco Unified Computing System (UCS) C-Series or B-Series using the 10K Open Virtualization Archive (OVA) template.
- Redundancy model must be 1:1.

All other capacities relating to a standard cluster also apply to a megacluster. Note that support for a megacluster deployment is granted only following the successful review of a detailed design, including the submission of the results from the Cisco Unified Communications Sizing Tool. For more information about the Cisco Unified Communications Sizing Tool and the sizing of Unified CM standard clusters and megaclusters, see the chapter on [Collaboration Solutions Design and Deployment Sizing Considerations, page 27-1](#).

Due to the many potential complexities surrounding megacluster deployments, customers who wish to pursue such a deployment must engage either their Cisco Account Team, Cisco Advanced Services, or their certified Cisco Unified Communications Partner.

### Note

Unless otherwise specified, all information contained within this SRND that relates to call processing deployments (including capacity, high availability, and general design considerations) applies only to a standard cluster.

## Cisco Business Edition Capacity Planning

Just as with Unified CM, many types of devices can register with Cisco Business Edition, and each of these devices requires registration and transaction resources from the platform with which it is registered. Likewise the users and their busy hour call attempts (BHCA) consume additional system resources. Each Cisco Business Edition system has specific user, endpoint, and BHCA capacity thresholds based on the available system resources of the platform. With Cisco Business Edition 6000 the maximum number of users is 1,000, and the maximum number of endpoints is 1,200 with the medium-density server or 2,500 with the high-density server. Cisco Business Edition 6000 supports a maximum of 5,000 BHCA.

When Cisco VCS is deployed as part of Cisco Business Edition 6000, the maximum number of non-traversal calls is 100 and the maximum number of traversal calls is 100.

For more information about Cisco Business Edition capacity planning considerations, including sizing examples and per-platform sizing limits as well as a complete discussion of system sizing, capacity planning, and deployment considerations, see the chapter on [Collaboration Solutions Design and Deployment Sizing Considerations](#), page 27-1.

For additional details on Cisco Business Edition 6000 capacities as well as all other information, refer to the following product documentation:

- Cisco Business Edition 6000 data sheets  
[http://www.cisco.com/en/US/products/ps11369/products\\_data\\_sheets\\_list.html](http://www.cisco.com/en/US/products/ps11369/products_data_sheets_list.html)
- *Cisco Business Edition 6000 Co-residency Policy Requirements*  
[http://www.cisco.com/en/US/products/ps11369/prod\\_installation\\_guides\\_list.html](http://www.cisco.com/en/US/products/ps11369/prod_installation_guides_list.html)

## Cisco TelePresence VCS Capacity Planning

In terms of capacity, one Cisco VCS Control node can support:

- Up to 2,500 registrations
- Up to 500 non-traversal calls
- Up to 100 traversal calls
- Up to 1,000 subzones

To increase the capacity, you can deploy a VCS cluster with up to six VCS peer members. A VCS cluster not only provides higher scalability but also provides redundancy in an N+2 configuration. A cluster has a total maximum capacity equal to four times that of a single VCS, and the cluster supports up to two VCS nodes failing without impacting the cluster capacity.

Therefore the capacity of a cluster with six VCSs can support:

- Up to 10,000 registrations
- Up to 2,000 non-traversal calls
- Up to 400 traversal calls

Multiple separate VCS clusters can also be deployed. They could be interconnected through a directory VCS, for example.

For more information about Cisco TelePresence VCS capacity planning considerations, including sizing limits as well as a complete discussion of system sizing, capacity planning, and deployment considerations, see the chapter on [Collaboration Solutions Design and Deployment Sizing Considerations, page 27-1](#), and refer to the Cisco VCS product documentation available at [http://www.cisco.com/en/US/products/ps11337/tsd\\_products\\_support\\_series\\_home.html](http://www.cisco.com/en/US/products/ps11337/tsd_products_support_series_home.html)

## Design Considerations for Call Processing

Observe the following design recommendations and guidelines when deploying Cisco call processing:

### Cisco Unified CME

- Unified CME supports a maximum of 450 endpoints. However, depending on the Cisco IOS router model, endpoint capacity could be significantly lower. For additional information about Unified CME platforms and capacities, refer to the Cisco Unified Communications Manager Express compatibility information available at [http://www.cisco.com/en/US/products/sw/voicesw/ps4625/products\\_device\\_support\\_tables\\_list.html](http://www.cisco.com/en/US/products/sw/voicesw/ps4625/products_device_support_tables_list.html).
- When possible, dual-attach the Unified CME router to the network using multiple IP interfaces to provide maximum network availability. Likewise, if multiple instances of Unified CME are required in the same deployment, distribute them across multiple physical switches or locations.
- When possible, deploy the Unified CME router with dual power supplies and/or an uninterruptible power supply (UPS) in order to provide maximum availability of the platform.

### Cisco Business Edition

- Business Edition 6000 runs on a UCS C200 or C220 Rack-Mount Server acting as a combined publisher and single subscriber instance. Additional UCS C200 or C220 server(s) can be deployed to provide call processing redundancy by adding subscriber server(s). Alternatively an MCS server can be used to provide redundancy.

**Note**

More than two UCS C200 or C220 Rack-Mount Servers may be clustered for a Business Edition 6000 deployment to provide additional redundancy and/or geographic distribution. However, the total number of users across the cluster may not exceed 1,000, and the total number of configured devices across the cluster may not exceed 1,200 with the medium-density server or 2,500 with the high-density server.

- Business Edition 6000 supports a maximum of 1,200 endpoints with the medium-density server or 2,500 with the high-density server. However, actual endpoint capacity depends on total system BHCA, which cannot exceed a maximum of 5,000. For additional information about Cisco Business Edition capacity, including sizing examples and per-platform sizing limits, see the chapter on [Collaboration Solutions Design and Deployment Sizing Considerations, page 27-1](#).
- If multiple Business Edition 6000 servers are required in the same deployment, distribute them across multiple physical switches.
- Use an uninterruptible power supply (UPS) to provide maximum availability, especially if the server has only one power supply.

- When deploying Business Edition 6000 with two servers for high availability (two UCS C200/C220 Rack-Mount Servers, or one UCS C200/C220 Rack-Mount Server and one MCS server), device registration should be load-balanced between the two servers in order to distribute system load. This is preferable to using the second server for standby redundancy.

### Cisco Unified CM

- You can enable a maximum of 8 call processing subscriber nodes (nodes running the Cisco CallManager Service) within a Cisco Unified CM cluster. Additional servers may be dedicated and used for publisher, TFTP, and media resources services. An approved megacluster deployment supports a maximum of 16 call processing subscriber nodes.
- Each Unified CM cluster can support configuration and registration for a maximum of 40,000 secured or unsecured endpoints. For additional information about Unified CM capacity planning, including per-platform sizing limits, see the chapter on [Collaboration Solutions Design and Deployment Sizing Considerations](#), page 27-1.
- When deploying a two-server cluster with high-capacity servers, Cisco recommends that you do not exceed 1250 users in the cluster. Above 1250 users, Cisco recommends a dedicated publisher and separate servers for primary and backup call processing subscribers.
- Cisco recommends using the same server model for all servers in a cluster. However, mixing server models and even different server vendor models within a cluster is supported, provided that all of the individual hardware versions are supported and that all servers are running the same version of Unified CM.
- 2:1 redundancy is not supported when using the Cisco MCS 7845-I3 server or the 10K-User OVA due to potential overload on the backup subscriber
- Dual-attach MCS servers to the network using NIC teaming to provide maximum high availability.
- Whenever possible, distribute the Unified CM servers across multiple physical switches within the network and across multiple physical locations within the same network to minimize the impact of a switch failure or the loss of a particular network location.
- Deploy SRST or Unified CME acting as SRST on Cisco IOS routers at remote locations to provide fallback call processing services in the event that these locations lose connectivity to the Unified CM cluster.
- Cisco recommends that you leave voice activity detection (VAD) disabled within the Unified CM cluster. VAD is disabled by default in the Unified CM service parameters, and you should disable it on H.323 and SIP dial peers configured on Cisco IOS gateways by using the **no vad** command.
- When deploying Unified CM as a virtualized application, ensure that server node instances are distributed across rack-mount servers or blades servers within the UCS chassis so that backup or redundant subscriber nodes are on different physical blades than primary subscriber nodes.
- Both UCS B-Series Blade Servers and high-end C-Series Rack-Mount Servers (for example, C210, C240, and C260) can be configured with multiple Open Virtualization Archive (OVA) templates. The largest OVA template supports 10,000 devices and provides the same capacities (number of endpoints, gateways, locations, regions, and so forth) as an MCS 7845-I3 server. For information on proper OVA sizing as well as the use of the Cisco Unified Communications Sizing Tool, see the chapter on [Collaboration Solutions Design and Deployment Sizing Considerations](#), page 27-1.

- While the UCS B-Series Blade Servers and C-Series Rack-Mount Servers do support USB and serial ports through a KVM cable, the Unified CM VMware virtual application has no access to those ports. Therefore, if you deploy Unified CM on UCS, it will not be possible to attach fixed live audio sources for MoH, to make a serial SMDI connection to a legacy voicemail system, or to attach a USB flash drive for writing log files. The following alternate options are available:
  - For MoH live audio source feed, consider using Cisco IOS-based gateway multicast MoH for live audio source connectivity or deploying one Unified CM subscriber node on an MCS server as part of the Unified CM cluster to allow connectivity of the USB MoH audio card (MOH-USB-AUDIO=).
  - For SMDI serial connections, deploy one Unified CM subscriber node on an MCS server as part of the Unified CM cluster for USB serial connectivity.
  - For saving system installation logs, use virtual floppy softmedia.
- Cisco supports Unified CM clusters running some subscriber server node instances on UCS B-Series Blade Servers, some on C-Series Rack-Mount Servers, and other subscriber server node instances on MCS server platforms.

#### Cisco TelePresence VCS

- A Cisco VCS cluster can be formed by a combination of VCS nodes running on an appliance or running as a virtualized application.
- VCS nodes running on an appliance or running as a virtualized application perform identically and have the same capacity limits.

## Computer Telephony Integration (CTI)

Cisco Computer Telephony Integration (CTI) extends the rich feature set available on Cisco Unified CM to third-party applications. Cisco CTI is not available on Cisco VCS. The CTI-enabled applications improve user productivity, enhance the communication experience, and deliver superior customer service. At the desktop, Cisco CTI enables third-party applications to make calls from within Microsoft Outlook, open windows or start applications based on incoming caller ID, and remotely track calls and contacts for billing purposes. Cisco CTI-enabled server applications can intelligently route contacts through an enterprise network, provide automated caller services such as auto-attendant and interactive voice response (IVR), as well as capture media for contact recording and analysis.

CTI applications generally fall into one of two major categories:

- First-party applications — Monitor, control, and media termination

First-party CTI applications are designed to register devices such as CTI ports and route points for call setup, tear-down, and media termination. Because these applications are directly in the media path, they can respond to media-layer events such as in-band DTMF. Interactive voice response and Cisco Attendant Console are examples of first-party CTI applications that monitor and control calls while also interacting with call media.

- Third-party application — Monitor and control

Third-party CTI applications can also monitor and control calls, but they do not directly control media termination.

- Monitoring applications

A CTI application that monitors the state of a Cisco IP device is called a monitoring application. A busy-lamp-field application that displays on-hook/off-hook status or uses that information to indicate a user's availability in the form of Presence are both examples of third-party CTI monitoring applications.

- Call control applications

Any application that uses Cisco CTI to remotely control a Cisco IP device using out-of-band signaling is a call control application. Cisco Jabber, when configured to remotely control a Cisco IP device, is a good example of a call control application.

- Monitor + call control applications

These are any CTI applications that monitor and control a Cisco IP device. Cisco Unified Contact Center Enterprise is a good example of a combined monitor and control application because it monitors the status of agents and controls agent phones through the agent desktop.

**Note**

While the distinction between a monitor, call control, and monitor + control application is called out here, this granularity is not exposed to the application developer. All CTI applications using Cisco CTI are enabled for both monitoring and control.

The following devices can be monitored or controlled through CTI:

- CTI Route Point
- CTI Port
- Cisco Unified IP Phones supporting CTI
- CTI Remote Device

CTI Remote Device provides the ability for a CTI application to have monitoring and limited call control capabilities over phones that do not support CTI, such as traditional PSTN phones, mobile phones, third-party phones, or phones attached to a third-party PBX.

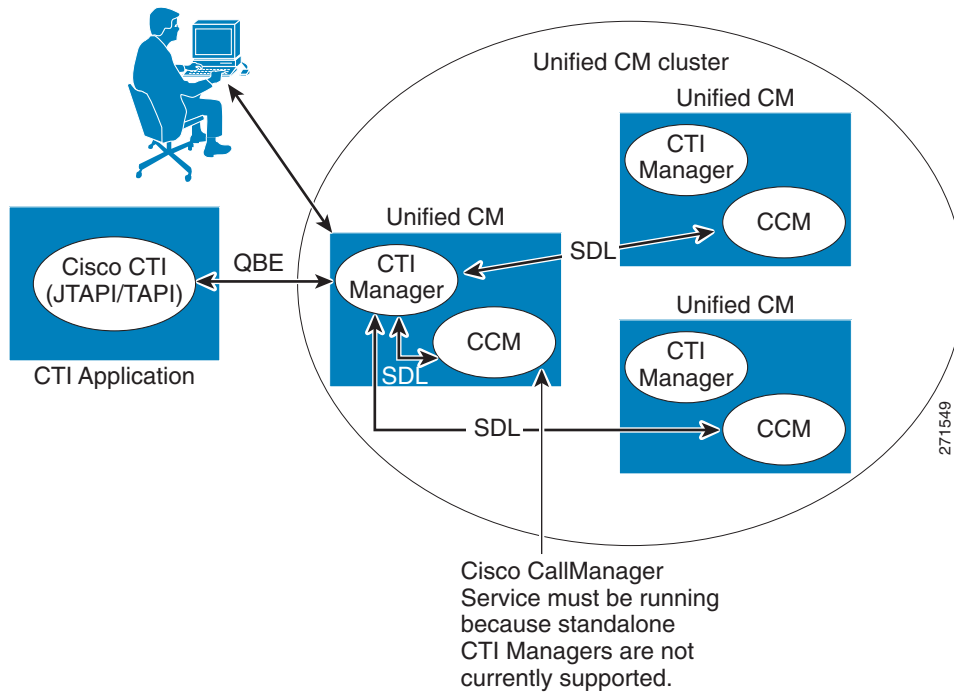

## CTI Architecture

Cisco CTI consists of the following components (see [Figure 9-9](#)), which interact to enable applications to take advantage of the telephony feature set available in Cisco Unified CM:

- CTI-enabled application — Cisco or third-party application written to provide specific telephony features and/or functionality.
- JTAPI and TAPI — Two standard interfaces supported by Cisco CTI. Developers can choose to write applications using their preferred method library.
- Unified JTAPI and Unified TSP Client — Converts external messages to internal Quick Buffer Encoding (QBE) messages used by Cisco Unified CM.
- Quick Buffer Encoding (QBE) — Unified CM internal communication messages.
- Provider — A logical representation of a connection between the application and CTI Manager, used to facilitate communication. The provider sends device and call events to the application while accepting control instructions that allow the application to control the device remotely.
- Signaling Distribution Layer (SDL) — Unified CM internal communication messages.
- Publisher and subscriber — Cisco Unified Communications Manager (Unified CM) servers.
- CCM — The Cisco CallManager Service (ccm.exe), the telephony processing engine.

- **CTI Manager (CTIM)** — A service that runs on one or more Unified CM subscribers operating in primary/secondary mode and that authenticates and authorizes telephony applications to control and/or monitor Cisco IP devices.

**Figure 9-9 Cisco CTI Architecture**

Once an application is authenticated and authorized, the CTIM acts as the broker between the telephony application and the Cisco CallManager Service. (This service is the call control agent and should not be confused with the overall product name Cisco Unified Communications Manager.) The CTIM responds to requests from telephony applications and converts them to Signaling Distribution Layer (SDL) messages used internally in the Unified CM system. Messages from the Cisco CallManager Service are also received by the CTIM and directed to the appropriate telephony application for processing.

The CTIM may be activated on any of the Unified CM subscriber servers in a cluster that have the Cisco CallManager Service active. This allows up to eight CTIMs to be active within a Unified CM cluster. Standalone CTIMs are currently not supported.

## CTI Applications and Clustering Over the WAN

Deployments that employ clustering over the WAN are supported in the following two scenarios:

- CTI Manager over the WAN (see [Figure 9-10](#))

In this scenario, the CTI application and its associated CTI Manager are on one side of the WAN (Site 1), and the monitored or controlled devices are on the other side, registered to a Unified CM subscriber (Site 2). The round-trip time (RTT) must not exceed the currently supported limit of 80 ms for clustering over the WAN. To calculate the necessary bandwidth for CTI traffic, use the formula in the section on [Local Failover Deployment Model, page 10-35](#). Note that this bandwidth is in addition to the Intra-Cluster Communication Signaling (ICCS) bandwidth calculated as described in the section on [Local Failover Deployment Model, page 10-35](#), as well as any bandwidth required for audio (RTP traffic).

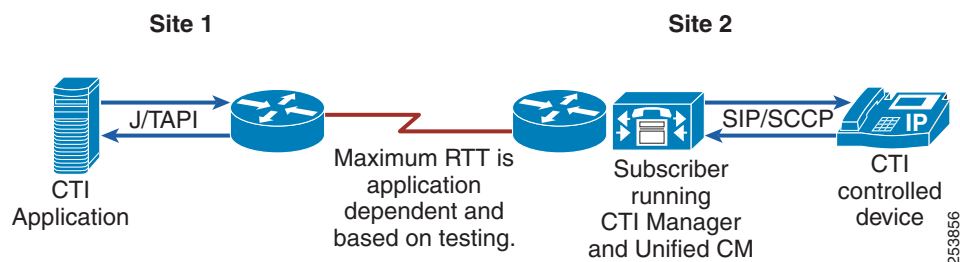

**Figure 9-10 CTI Over the WAN**

- TAPI and JTAPI applications over the WAN (CTI application over the WAN; see [Figure 9-11](#))

In this scenario, the CTI application is on one side of the WAN (Site 1), and its associated CTI Manager is on the other side (Site 2). In this scenario, it is up to the CTI application developer or provider to ascertain whether or not their application can accommodate the RTT as implemented. In some cases failover and failback times might be higher than if the application is co-located with its CTI Manager. In those cases, the application developer or provider should provide guidance as to the behavior of their application under these conditions.

**Figure 9-11 JTAPI Over the WAN**

### Note

Support for TAPI and JTAPI over the WAN is application dependent. Both customers and application developers or providers should ensure that their applications are compatible with any such deployment involving clustering over the WAN.

## Capacity Planning for CTI

The maximum number of supported CTI-controlled devices is 40,000 per cluster. For more information on CTI capacity planning, including per-platform node and cluster CTI capacities as well as CTI resource calculation formulas and examples, see the chapter on [Collaboration Solutions Design and Deployment Sizing Considerations](#), page 27-1.

## High Availability for CTI

This section provides some guidelines for provisioning CTI for high availability.

### CTI Manager

CTI Manager must be enabled on at least one and possibly all call processing subscribers within the Unified CM cluster. The client-side interfaces (TAPI TSP or JTAPI client) allow for two IP addresses each, which then point to Unified CM servers running the CTIM service. For CTI application redundancy, Cisco recommends having the CTIM service activated on at least two Unified CM servers in a cluster, as shown in [Figure 9-12](#).

### Redundancy, Failover, and Load Balancing

For CTI applications that require redundancy, the TAPI TSP or JTAPI client can be configured with two IP addresses, thereby allowing an alternate CTI Manager to be used in the event of a failure. It should be noted that this redundancy is not stateful in that no information is shared and/or made available between the two CTI Managers, and therefore the CTI application will have some degree of re-initialization to go through, depending on the exact nature of the failover.

When a CTI Manager fails-over, just the CTI application login process is repeated on the now-active CTI Manager. Whereas, if the Unified CM server itself fails, then the re-initialization process is longer due to the re-registration of all the devices from the failed Unified CM to the now-active Unified CM, followed by the CTI application login process.

For CTI applications that require load balancing or that could benefit from this configuration, the CTI application can simply connect to two CTI Managers simultaneously, as shown in [Figure 9-12](#).

**Figure 9-12 Redundancy and Load Balancing**

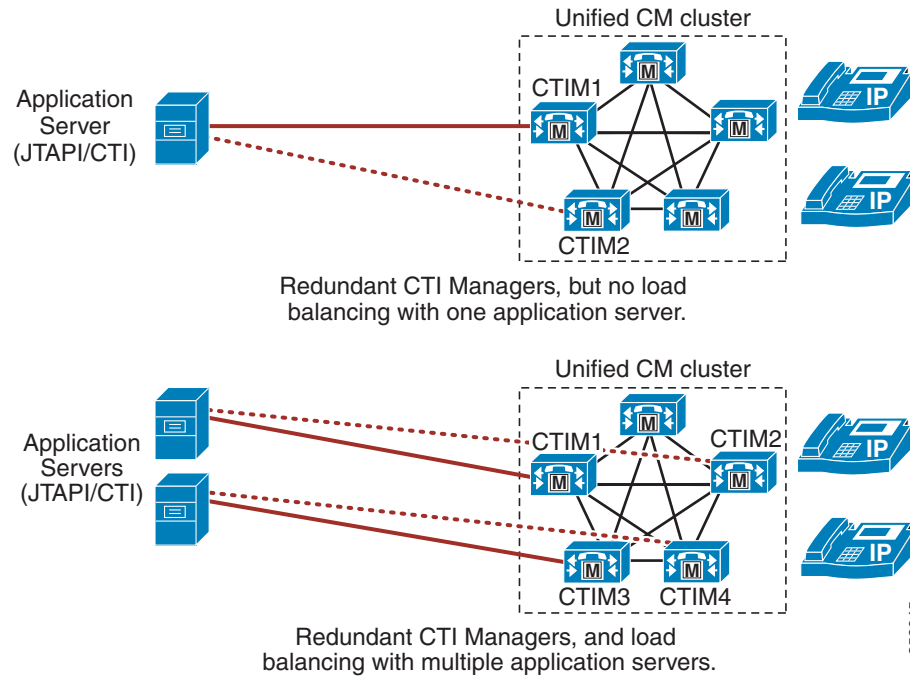

Figure 9-13 shows an example of this type of configuration for Cisco Unified Contact Center Enterprise (Unified CCE). This type of configuration has the following characteristics:

- Unified CCE uses two Peripheral Gateways (PGs) for redundancy.
- Each PG logs into a different CTI Manager.
- Only one PG is active at any one time.

**Figure 9-13** *CTI Redundancy with Cisco Unified Contact Center Enterprise*

271551

Figure 9-14 shows an example of this type of configuration for Cisco Unified Contact Center Express (Unified CCX). This type of configuration has the following characteristics:

- Unified CCX has two IP addresses configured, one for each CTI Manager.
- If connection to the primary CTI Manager is lost, Unified CCX fails-over to its secondary CTI Manager.

**Figure 9-14** CTI Redundancy with Cisco Unified Contact Center Express

## Implementation

For guidance and support on writing applications, application developers should consult the Cisco Developer Connection, located at

<http://developer.cisco.com/web/cdc/community>

# Interoperability of Unified CM and Unified CM Express

This section explains the requirements for interoperability and internetworking of Cisco Unified CM with Cisco Unified Communications Manager Express (Unified CME) using H.323 or SIP trunking protocol in a multisite IP telephony deployment. This section highlights the recommended deployments between phones controlled by Unified CM and phones controlled by Unified CME.

This section covers the following topics:

- [Overview of Interoperability Between Unified CM and Unified CME, page 9-42](#)
- [Unified CM and Unified CME Interoperability via SIP in a Multisite Deployment with Distributed Call Processing, page 9-44](#)
- [Unified CM and Unified CME Interoperability via H.323 in a Multisite Deployment with Distributed Call Processing, page 9-47](#)

## Overview of Interoperability Between Unified CM and Unified CME

Either H.323 or SIP can be used as a trunking protocol to interconnect Unified CM and Unified CME. When deploying Unified CM at the headquarters or central site in conjunction with one or more Unified CME systems for branch offices, network administrators must choose either the SIP or H.323 protocol after careful consideration of protocol specifics and supported features across the WAN trunk. Using H.323 trunks to connect Unified CM and Unified CME has been the predominant method in past years, until more enhanced capabilities for SIP phones and SIP trunks were added in Unified CM and Unified CME. This section first describes some of the features and capabilities that are independent of the trunking protocol for Unified CM and Unified CME interoperability, then it explains some of the most common design scenarios and best practices for using SIP trunks and H.323 trunks.

## Call Types and Call Flows

In general, Unified CM and Unified CME interworking allows all combination of calls from SCCP IP phones to SIP IP phones, or vice versa, across a SIP trunk or H.323 trunk. Calls can be transferred (blind or consultative) or forwarded back and forth between the Unified CM and Unified CME SIP and/or SCCP IP phones.

When connected to Unified CM via H.323 trunks, Unified CME can auto-detect Unified CM calls. When a call terminating on Unified CME is transferred or forwarded, Unified CME regenerates the call and routes the call appropriately to another Unified CME or Unified CM by hairpinning the call. Unified CME hairpins the call legs from Unified CM for the VoIP calls across SIP or H.323 trunks when needed. For more information on allowing auto-detection on a non-H.450 supported Unified CM network and for enabling or disabling supplementary services for H450.2, H450.3, or SIP, refer to the Unified CME product documentation available at

[http://www.cisco.com/en/US/products/sw/voicesw/ps4625/tsd\\_products\\_support\\_series\\_home.html](http://www.cisco.com/en/US/products/sw/voicesw/ps4625/tsd_products_support_series_home.html)

When connected to Unified CM via SIP trunks, Unified CME does not auto-detect Unified CM calls. By default, Unified CME always tries to redirect calls using either a SIP Refer message for call transfer or a SIP 302 Moved Temporarily message for call forward; if that fails, Unified CME will then try to hairpin the call.

## Music on Hold

While Unified CM can be enabled to stream MoH in both G.711 and G.729 formats, Unified CME streams MoH only in G.711 format. Therefore, when Unified CME controls the MoH audio on a call placed on hold, it requires a transcoder to transcode between a G.711 MoH stream and a G.729 call leg.

## Ad Hoc and Meet Me Hardware Conferencing

Hardware DSP resources are required for both Ad Hoc and Meet Me conferences. Whether connected via SIP, H.323, or PSTN, both Unified CM and Unified CME phones can be invited or added to an Ad Hoc conference to become conference participants as long as the phones are reachable from the network. When calls are put on hold during an active conference session, music will not be heard by the conference participants in the conference session.

For information on required and supported DSP resources and the maximum number of conference participants allowed for Ad Hoc or Meet Me conferences, refer to the Unified CME product documentation available at

[http://www.cisco.com/en/US/products/sw/voicesw/ps4625/tsd\\_products\\_support\\_series\\_home.html](http://www.cisco.com/en/US/products/sw/voicesw/ps4625/tsd_products_support_series_home.html)

Unified CM can communicate directly with Unified CME using a SIP interface. [Figure 9-15](#) shows a Cisco Unified Communications multisite deployment with Unified CM networked directly with Cisco Unified CME using a SIP trunk.

The diagram illustrates a Unified Communications Network Architecture across three sites:

- Unified CM Site:** This site contains a Voicemail server, an MTP/SDP (Media Termination Point/Session Description Protocol) component, a Directory Server, and a Unified CM (Unified Communications Manager) server. The Unified CM server is connected via SIP to several IP phones, some using SCCP (Session Control over Cloud Protocol) and others using SIP. It also connects to a central switch that manages the network for this site.
- Unified CM Express Site (Top):** This site features a Unified CM Express router connected via SIP to a central switch, which in turn manages a group of IP phones using both SCCP and SIP protocols.
- Unified CM Express Site (Bottom):** Similar to the top site, this one also has a Unified CM Express router connected via SIP to a central switch, managing a group of IP phones using both SCCP and SIP protocols.
- Inter-site Connectivity:** The sites are interconnected through two central clouds: a PSTN (Public Switched Telephone Network) cloud and a WAN (Wide Area Network) cloud. Both clouds are connected to the Unified CM Express routers in the Express sites and the Unified CM server in the main site via SIP.

- Configure a SIP Trunk Security Profile with **Accept Replaces Header** selected.
- Configure a SIP trunk on Unified CM using the SIP Trunk Security Profile created, and also specify a ReRouting CSS. The ReRouting CSS is used to determine where a SIP user (transferor) can refer another user (transferee) to a third user (transfer target) and which features a SIP user can invoke using the SIP 302 Redirection Response and INVITE with Replaces.
- For SIP trunks there is no need to enable the use of media termination points (MTPs) when using SCCP endpoints on Unified CME. However, SIP endpoints on Unified CME require the use of media termination points on Unified CM to be able to handle delayed offer/answer exchanges with the SIP protocol (that is, the reception of INVITEs with no Session Description Protocol).

- Route calls to Unified CME via a SIP trunk using the Unified CM dial plan configuration (route patterns, route lists, and route groups).
- Use Unified CM device pools and regions to configure a G.711 codec within the site and the G.729 codec for remote Unified CME sites.
- Configure the **allow-connections sip to sip** command under **voice services voip** on Unified CME to allow SIP-to-SIP call connections.
- For SIP endpoints, configure the **mode cme** command under **voice register global**, and configure **dtmf-relay rtp-nte** under the **voice register pool** commands for each SIP phone on Unified CME.
- For SCCP endpoints, configure the **transfer-system full-consult** command and the **transfer-pattern .T** command under **telephony-service** on Unified CME.
- Configure the SIP WAN interface voip dial-peers to forward or redirect calls, destined for Unified CM, with **session protocol sipv2** and **dtmf-relay [sip-notify | rtp-nte]** on Unified CME.

## Design Considerations

This section first covers some characteristics and design considerations for Unified CM and Unified CME interoperability via SIP in some main areas such as supplementary services for call transfer and forward, presence service for busy lamp field (BLF) notification for speed-dial buttons and directory call lists, and out-of-dialog (OOD-Refer) for integration with partner applications and third-party phone control for click-to-dial between the Unified CM phones and Unified CME phones. The section also covers some general design considerations for Unified CM and Unified CME interoperability via SIP.

### Supplementary Services

SIP Refer or SIP 302 Moved Temporarily messages can be used for supplementary services such as call transfer or call forward on Unified CME or Unified CM to instruct the transferee (referee) or phone being forwarded (forwardee) to initiate a new call to the transfer-to (refer-to) target or forward-to target. No hairpinning is needed for call transfer or call forward scenarios when the SIP Refer or SIP 302 Moved Temporarily message is supported.

However, **supplementary-service** must be disabled if there are certain extensions that have no DID mapping or if Unified CM or Unified CME does not have a dial plan to route the call to the DID in the SIP 302 Moved Temporarily message. When **supplementary-service** is disabled, Unified CME hairpins the calls or sends a re-invite SIP message to Unified CM to replace the media path to the new called party ID. Both signaling and media are hairpinned, even when multiple Unified CMEs are involved for further call forwards. The **supplementary-service** can also be disabled for transferred calls. In this case, the SIP Refer message will not be sent to Unified CM, but the transferee (referee) party and transfer-to party (refer-to target) are hairpinned.

#### Note

Supplementary services can be disabled with the command **no supplementary-service sip moved-temporarily** or **no supplementary-service sip refer** under **voice service voip** or **dial-peer voice xxxx voip**.

The following examples illustrate the call flows when supplementary services are disabled:

- Unified CM phone B calls Unified CME phone A, which is set to call-forward (all, busy, or no answer) to phone C (either a Unified CM phone, a Unified CME phone on the same or different Unified CME, or a PSTN phone).

Unified CME does not send the SIP 302 Moved Temporarily message to Unified CM, but hairpins the call between Unified CM phone B and phone C.

- Unified CM phone B calls Unified CME phone A, which transfer the call to phone C (either a Unified CM phone, a Unified CME phone, or a PSTN phone).

Unified CME does not send the SIP Refer message to Unified CM, but hairpins the call between Unified CM phone B and phone C.

### General Design Considerations for Unified CM and Unified CME Interoperability via SIP

- Disable **supplementary-service** if SIP 302 Moved Temporarily or SIP Refer messages are not supported by Unified CM, otherwise Unified CM cannot route the call to the transfer-to or forward-to target.
- In a SIP-to-SIP call scenario, a Refer message is sent by default from the transferor to the transferee, the transferee sets up a new call to the transfer-to target, and the transferor hears ringback tone by default while waiting for the transfer at connect. If **supplementary-service** is disabled on Unified CME, Unified CME will provide in-band ringback tone right after the call between the transferee and transfer-to target is connected.
- Presence service is supported on Unified CM and Unified CME via SIP trunk only.
- The OOD-Refer feature allows third-party applications to connect two endpoints on Unified CM or Unified CME through the use of the SIP REFER method. Consider the following factors when using OOD-Refer:
  - Both Unified CM and Unified CME must be configured to enable the OOD-Refer feature.
  - Call Hold, Transfer, and Conference are not supported during an OOD-Refer transaction, but they are not blocked by Unified CME.
  - Call transfer is supported only after the OOD-Refer call is in the connected state and not before the call is connected; therefore, call transfer-at-alert is not supported.
- Control signaling in TLS is supported, but SRTP is not supported over the SIP trunk.
- SRTP over a SIP trunk is a gateway feature in Cisco IOS for Unified CM. SRTP support is not available with Unified CM and Unified CME interworking via SIP trunks.

#### Note

When multiple PSTN connections exist (one for Unified CM and one for Unified CME), fully attended transfer between a Unified CM endpoint and a Unified CME endpoint to a PSTN endpoint will fail. The recommendation is to use blind transfer when using multiple PSTN connections, and it is configured under **telephony-service** as **transfer-system full-blind**.

#### Note

Cisco Unified CME supports video calls across SIP trunks between multiple Unified CMEs. This capability applies in distributed call processing deployments that use Unified CMEs only. Video calls between Unified CM and Unified CME over SIP trunks are not supported. For configuration details, refer to the *Cisco Unified Communications Manager Express System Administrator Guide*, available at [http://www.cisco.com/en/US/products/sw/voicesw/ps4625/products\\_installation\\_and\\_configuration\\_guides\\_list.html](http://www.cisco.com/en/US/products/sw/voicesw/ps4625/products_installation_and_configuration_guides_list.html).

## Unified CM and Unified CME Interoperability via H.323 in a Multisite Deployment with Distributed Call Processing

There are two deployment options to achieve interoperability between Unified CM and Unified CME via H.323 connections in a multisite WAN deployment with distributed call processing. The first option is to deploy a Cisco Unified Border Element as a front-end device of Unified CM, which has a peer-to-peer H.323 connection with a remote Unified CME system. The Cisco Unified Border Element performs dial plan resolution between Unified CM and Unified CME, and it also terminates and re-originates call signaling messages between the two. The Cisco Unified Border Element acts as a proxy device for a system that does not support H.450 for its supplementary services, such as Unified CM, which uses Empty Capability Sets (ECS) to invoke supplementary services. The Cisco Unified Border Element can also act as the PSTN gateway for the Unified CM cluster so that a separate PSTN gateway is not needed.

The second option is to deploy a via-zone gatekeeper. Unified CM, Unified CME, and the Cisco Unified Border Element all register with the via-zone gatekeeper as VoIP gateway devices. The via-zone gatekeeper performs dial plan resolution and bandwidth restrictions between Unified CM and Unified CME. The via-zone gatekeeper also inserts a Cisco Unified Border Element in the call path to interwork between ECS and H.450 to invoke the supplementary services. For detailed information on the via-zone gateway and Cisco Unified Border Element, see the chapter on [Call Admission Control](#), page 13-1.

These two deployment options have the following differences:

- With the first option, the Cisco Unified Border Element registers with Unified CM as an H.323 gateway device; with the second option, it registers with via-zone gatekeeper as a VoIP gateway device.
- With the first option, the Cisco Unified Border Element performs dial plan resolution based on the VoIP dial-peer configurations on the Cisco Unified Border Element; with the second option, the via-zone gatekeeper performs dial plan resolution based on the gatekeeper dial plan configuration.
- With the first option, there is no call admission control mechanism that oversees both call legs; with the second option, the via-zone gatekeeper performs gatekeeper zone-based call admission control.
- With the second option, the via-zone gatekeeper can also act as an infrastructure gatekeeper for Unified CM, to manage all dial plan resolution and bandwidth restrictions between Unified CM clusters, between a Unified CM cluster and a network of H.323 VoIP gateways, or between a Unified CM cluster and a service provider's H.323 VoIP transport network.

[Figure 9-16](#) shows H.323 integration between Unified CM and Unified CME using a via-zone gatekeeper and Cisco Unified Border Element.

**Figure 9-16** Multisite Deployment with Unified CM and Unified CME Using a Cisco Unified Border Element or Via-Zone Gatekeeper

## Best Practices

This section discusses configuration guidelines and best practices when using the deployment model illustrated in [Figure 9-16](#) with the second deployment option (via-zone gatekeeper):

- Configure a gatekeeper-controlled H.225 trunk between Unified CM and the via-zone gatekeeper. Media termination point (MTP) resources are required over the trunk only when Unified CME tries to initiate an outbound H.323 fast-start call.
- The **Wait For Far End H.245 Terminal Capability Set (TCS)** option must be unchecked to prevent stalemate situations from occurring when the H.323 devices at both sides of the trunk are waiting the far end to send TCS first and the H.245 connection times out after a few seconds.
- Configure the Unified CM service parameter **Send H225 user info message to H225 info for Call Progress Tone**, which will make Unified CM send the H.225 Info message to Unified CME to play ringback tone or tone-on-hold.
- Use the Unified CM dial plan configuration (route patterns, route lists, and route groups) to send calls destined for Unified CME to the gatekeeper-controlled H.225 trunk.
- Register Unified CME and the Cisco Unified Border Element as H.323 gateways with the via-zone gatekeeper.

- Configure the **allow-connection h323 to h323** command on the Cisco Unified Border Element to allow H.323-to-H.323 call connections. This command is optional to configure on Unified CME. Configure **allow-connection h323 to sip** if Cisco Unity Connection is used on Unified CME.
- Supplementary services such as transfer and call forward will result in calls being media hairpinned when the two endpoints reside in the same Unified CME branch location.

**Note**

The only configuration difference between the two deployment options is that the first option requires configuring the Cisco Unified Border Element as an H.323 gateway device in Unified CM. The rest of the configuration guidelines listed above are the same for both options.

**Note**

When multiple PSTN connections exist (one for Unified CM and one for Unified CME), fully attended transfer between a Unified CM endpoint and a Unified CME endpoint to a PSTN endpoint will fail. The recommendation is to use blind transfer when using multiple PSTN connections, and it is configured under **telephony-service** as **transfer-system full-blind**.

## Design Considerations

In an H.323 deployment, Unified CME supports call transfer, call forward with H.450.2, and H.450.3 as part of the H.450 standards. However, Unified CM does not support H.450, and supplementary services such as call transfer, call forward, call hold or resume are done using the Empty Capabilities Set (ECS). Therefore, when calls are transferred or forwarded between Unified CM and Unified CME, they are hairpinned and routed with a Cisco Unified Border Element and with or without a gatekeeper, as described as the two deployment models in the previous section. This section lists some of the design considerations and best practices for Unified CM and Unified CME interoperability via H.323.

### Supplementary Services Such as Call Transfer and Call Forward

Unified CME can auto-detect Unified CM, which does not support H.450, by using H.450.12 protocol to automatically discover the H.450.x capabilities. Unified CME uses VoIP hairpin routing for calls between Unified CM and Unified CME. When the call is terminated, Unified CME hairpins the call from the Unified CM phone by re-originating and routing the call as appropriate.

**Note**

When Unified CME detects that Unified CM does not support H.450, Unified CME hairpins the calls by hairpinning both signaling and media at Unified CME. This causes double the amount of bandwidth to be consumed when calls are transferred or forwarded across the WAN. (For example, if a Unified CM phone calls a Unified CME phone and the Unified CME phone transfers the call to a second Unified CM phone, Unified CME hairpins both the signaling and media even though the call is between two Unified CM phones.) To avoid this double bandwidth consumption on the WAN, Cisco recommends using the Cisco Unified Border Element to act as an H.450 tandem gateway and to allow for H.450-to-ECS mapping for supplementary services such as call transfer or call forward.

### Supported Call Flows

Unified CME is a back-to-back user agent (B2BUA), thus call flows work from SCCP phone to SCCP phone and from SCCP phone to SIP phone. SIP phone calls work over H.323 trunks, but supplementary features are not supported.

### Security

Unified CME provides secure signaling with TLS and media encryption with SRTP. Unified CM also supports secure signaling via TLS and secure media via SRTP. However, interworking between secure Unified CM and secure Unified CME is not supported.

### Video

Observe the following design considerations when implementing video functionality with Unified CME:

- All endpoints on Unified CM and Unified CME must be configured as video-capable endpoints. The video codec and formats for all the video-capable endpoints must match.
- Unified CM and Unified CME support basic video calls; however, supplementary services such as call transfer and call forward are not supported for video calls between Unified CM and Unified CME. To support supplementary services with Unified CME, H.450 must be enabled on all Unified CMEs and voice gateways. Because Unified CM does not support H.450, video calls will revert to audio-only calls when supplementary services are needed between Unified CM phones and Unified CME phones.
- Conference calls revert to audio only.
- WAN bandwidth must meet the minimum video bit rate of 384 kbps for video traffic to traverse the WAN.

### H.320 Video via ISDN

Observe the following design considerations when implementing H.320 video functionality via ISDN:

- When directly connected to an H.320 endpoint via a PRI or BRI interface, Unified CME and Cisco IOS routers currently support only 128 kbps video calls.
- When H.320 is enabled on Unified CME and PSTN gateways to interwork with Unified CM, use a separate dial-peer for video calls to differentiate them from voice-only calls. Configure **bear-cap speech** under the **voice-port** configuration on Unified CME.
- H.320 does not support supplementary services.

### General Design Considerations for Unified CM and Unified CME Interoperability via H.323

- Configure Unified CME to auto-detect Unified CM by using H.450.12 to hairpin the calls between Unified CM and Unified CME phones.
- For SCCP-to-SCCP calls or SCCP-to-SIP calls, an H.323 trunk can be deployed between Unified CM and Unified CME.
- While Unified CME supports secure signaling with TLS and secure media with SRTP, conferencing call flows cannot be secured. Further, security interoperability is not supported between Unified CM and Unified CME phones.
- Deploy video only for SCCP phones (with support of basic calls), and not for SIP phones.
- MTP functionality is not compatible with video; for video calls to work, the MTP feature must be disabled (unchecked).
- Make sure that IP connectivity between Unified CM and Unified CME works properly.
- Make sure the local video setup works correctly for each Unified CME local zone and Unified CM location (local SCCP).
- Use the existing voice dial-plan infrastructure.

- Observe the following guidelines for video traffic shaping:
  - Mark the video and audio channels of a video call with CoS 4 to preserve lip-sync and to separate video from audio-only calls.
  - Place voice and video traffic in different queues.
  - Use Priority Queuing (PQ) for voice and video traffic. Two different policies are required for voice-only calls and video (voice stream + video stream) calls based on Classifications. Voice calls are protected from video calls because the voice stream in a video call is marked the same as the video stream in the video call.
- Video should not be deployed in links with less than 768 kbps of bandwidth.
- With link speeds greater than 768 kbps and with proper call admission control to avoid oversubscription, placing video traffic in a PQ does not introduce a noticeable increase in delay to the voice packets.
- There is no need to configure fragmentation for speeds greater than 768 kbps.
- cRTP is not recommended for video packets. (Because video packets are large, cRTP is of no help with video.)
- Voice and video traffic should occupy no more than 33% of the link capacity.
- When calculating video bandwidth, add 20% to the total video data rate of the call to account for overhead.

For more details on integrating Unified CME with Unified CM through H.323, refer to the *Cisco Unified CME Solution Reference Network Design Guide*, available at

[http://www.cisco.com/en/US/products/sw/voicesw/ps4625/products\\_implementation\\_design\\_guides\\_list.html](http://www.cisco.com/en/US/products/sw/voicesw/ps4625/products_implementation_design_guides_list.html)

## Interoperability of Cisco TelePresence VCS with Unified CM

It can be beneficial to deploy both Cisco Unified CM and Cisco VCS and integrate them. For example, in a deployment with Unified CM as the main call processing agent, Cisco VCS can be added to provide full-featured interoperability with H.323 telepresence endpoints and interworking with SIP, integration with third-party video endpoints, alternate solutions for telepresence conferencing, and external communication using NAT or firewall traversal when combined with the VCS Expressway.

Unified CM and VCS clusters are joined by one or more connections, called trunks in Unified CM and zones in VCS. A trunk or zone is the fundamental connection between two call processing agents in different clusters, exchanging signaling protocols and call routing information. Cisco recommends using the SIP protocol for the trunks and zones.

Figure 9-17 illustrates a Unified CM cluster connected to the VCS cluster with a SIP trunk.

**Figure 9-17 Cisco Unified CM Integrated with Cisco VCS by Means of a SIP Trunk**

P0060

To integrate Unified CM with Cisco TelePresence VCS, on Unified CM configure a SIP trunk across an IP network. If the VCS has multiple VCS peers, you can use a DNS SRV record for the VCS cluster. Alternatively, you can specify a list of VCS peers in the SIP trunk configuration using the hostnames or IP addresses of the VCS peers. Also run the **vcs-interop** normalization script on the Unified CM SIP trunk configuration. For more information on this normalization script, refer to the latest version of the *Cisco Unified Communications Manager System Guide*, available at

[http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod\\_maintenance\\_guides\\_list.html](http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html)

For more details on the Unified CM SIP trunk design, refer to the chapter on [Cisco Unified CM Trunks](#), page 6-1.

On Cisco TelePresence VCS, to configure a connection to a cluster of Unified CM nodes, use any of the following methods:

- Configure a single neighbor zone in VCS, with the Unified CM nodes listed as location peer addresses.
- Use DNS SRV records and a Cisco VCS DNS zone.
- Set up multiple zones, one per Unified CM node. Then configure a set of prioritized search rules to route calls to each of the zones in the preferred order.

Cisco recommends the first and second configuration methods listed above because they ensure that the VCS-to-Unified CM call load is shared across Unified CM nodes. The third method provides only redundancy and not load balancing.

For more information, refer to the latest version of the *Cisco TelePresence Video Communication Server Cisco Unified Communications Manager Deployment Guide*, available at

[http://www.cisco.com/en/US/products/ps11337/products\\_installation\\_and\\_configuration\\_guides\\_list.html](http://www.cisco.com/en/US/products/ps11337/products_installation_and_configuration_guides_list.html)

## Dial Plan Integration

Dial plan integration between Unified CM and VCS is simpler if it is based on a numeric dial plan. Therefore, for new deployments, use a numeric dial plan across Unified CM and VCS whenever possible. However, in situations where a partially URI-based deployment already exists or is chosen for a new deployment, alphanumeric URIs can be used.

The simplest way to route directory URI calls from a supported endpoint on Unified CM to an endpoint on a Cisco TelePresence Video Communication Server (VCS) is to configure a domain-based SIP route pattern. For example, you can configure a SIP route pattern of *cisco.com* to route calls addressed to the *cisco.com* domain out a SIP trunk that is configured for the VCS.

When deploying multiple Unified CM clusters and VCS clusters using the same domain, configure Intercluster Lookup Service (ILS) to provide URI dialing interoperability. For each VCS, manually create a csv file with the directory URIs that are registered to that call control system. On a Unified CM cluster that is set up as a hub cluster in an ILS network and that could also be performing a Session Management Edition (SME) role, create an Imported directory URI catalog for each VCS, and assign a unique route string for each catalog. After you import the csv files into their corresponding imported directory URI catalog, ILS replicates the imported directory URI catalog and route string to the other clusters in the ILS network.

On each Unified CM cluster, configure SIP route patterns that match the route string assigned to each imported directory URI catalog in order to allow Unified CM to route directory URIs to an outbound trunk that is destined for the VCS.

For more information, refer to the latest version of the *Cisco Unified Communications Manager System Guide*, available at

[http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod\\_maintenance\\_guides\\_list.html](http://www.cisco.com/en/US/products/sw/voicesw/ps556/prod_maintenance_guides_list.html)

## Design Considerations

- Both Unified CM and VCS can perform call admission control. However, bandwidth information is not exchanged between Unified CM and VCS.
- The integration between VCS and Unified CM clusters can also be done through Cisco Unified Communications Manager Session Management Edition (SME). For details, see the chapter on [Collaboration Deployment Models, page 10-1](#).
- In general, Cisco recommends SIP Delayed Offer because no MTPs are required during call setup. SIP Early Offer using **SIP Early Offer for Voice and Video (Insert MTP if needed)** can also be used, but bear in mind that if an MTP is inserted, then only voice is supported during the initial call setup. For more information, see the chapter on [Cisco Unified CM Trunks, page 6-1](#).
- The best practice for integrating dial plans between Unified CM and VCS clusters is to normalize the dial plan (with a flat domain, and separate and unique DN ranges) in either call agent through careful planning during the deployment and by using the following available mechanisms in the call processing applications:
  - Transforms and search rules on VCS
  - Route patterns, translations, and transformation patterns in Unified CM
