Preface

Document Purpose

This document provides guidance for implementing Network Admission Control (NAC), an industry-wide collaboration sponsored by Cisco Systems. It describes deployment considerations and configuration procedures for Cisco IOS software devices acting as Network Access Devices (NADs). It provides installation guidelines for the Cisco Trust Agent (CTA) on Microsoft Windows client machines. It also provides configuration instructions for Cisco Secure ACS, including configuration with anti-virus software products.

Intended Audience

The audience for this document consists of system engineers and network administrators responsible for the implementation of NAC. This document assumes you are familiar with Microsoft Windows operating systems and client machines and with the configuration and operation of Cisco Secure Cisco Secure ACS. It also assumes you know how to configure Cisco IOS devices, and are familiar with certificate authorities and the trust models provided by digital certificates.

I

Introducing Network Admission Control

This chapter provides background information required to implement Network Admission Control (NAC), an industry-wide collaboration sponsored by Cisco Systems. It includes the following sections:

- Overview
- NAC Operational Detail
- Limitations and Guidelines
- Pre-Deployment Considerations
- System Components

Overview

This section describes the benefits of NAC and how it works, and includes the following topics:

- The Benefits of Network Admission Control
- How Network Admission Control Works

The Benefits of Network Admission Control

Virus infection on data networks has become an increasingly serious problem. The resources consumed during just one disinfection process are much greater than the resources necessary to implement an anti-virus feature in the network such as Network Admission Control.

Cisco NAC helps ensure the health of client workstations before they are granted network access. NAC works with anti-virus software to assess the condition, called the posture, of a client before allowing access to the network.

NAC helps ensure that a network client has an up-to-date virus signature set and has not been infected before gaining access to a data network. If the client requires a signature update, the NAC solution directs it to complete the update. If the client has been compromised or if a virus outbreak is occurring on the network, NAC places the client into a quarantined network segment until disinfection is completed.

How Network Admission Control Works

NAC implementation combines a number of existing protocols and Cisco products with some new products and features, including the following:

- Cisco Trust Agent (CTA) and plug-ins
- Cisco IOS Network Access Device (NAD)
- Extensible Authentication Protocol (EAP)
- Cisco Secure Access Control Server (ACS)/Remote Authentication Dial-In User Service (RADIUS)
- Posture validation/remediation server

CTA communicates with other software on the client computer over a published Application Program Interface (API) and answers posture queries from the NAD. CTA also implements the communication (EAP over UDP) necessary to implement NAC. The resident software includes a Posture Plug-In (PP) that interfaces with the CTA. The PP is an agent included with third-party software that reports on the policy and state of this software.

In the current implementation of NAC, the NAD is a Layer 3 Cisco IOS software device that queries client machines seeking network access using EAP over UDP (EOU). The way that the different components of the NAC solution interact is shown in Figure 1-1.

Figure 1-1 NAC Operation

NAC component interaction occurs as follows:

- 1. Client sends a packet through a NAC-enabled router.
- 2. NAD begins posture validation using EOU.
- 3. Client sends posture credentials using EOU to the NAD.
- 4. NAD sends posture to Cisco ACS using RADIUS.

- **5.** Cisco Secure ACS requests posture validation using the Host Credential Authorization Protocol (HCAP) inside an HTTPS tunnel.
- 6. Posture validation/remediation server sends validation response of pass, fail, quarantine, and so on.
- 7. To permit or deny network access, Cisco Secure ACS sends an accept with ACLs/URL redirect.
- 8. NAD forwards posture response to client.
- 9. Client is granted or denied access, redirected, or contained.

When the client sends a request for network access (1), the NAD starts the posture validation process (2). The identity it receives from the CTA is passed on to Cisco Secure ACS, which then initiates a protected EAP (PEAP) session with the CTA (the PEAP session is not shown).

CTA then sends its credential with any credentials it gets from PPs on the client machine to the NAD (3), which forwards them using the RADIUS protocol to Cisco Secure ACS (4). These credentials contain attributes that hold information about the current state of the client software.

Cisco Secure ACS checks and validates the credentials by comparing the attributes contained in the credentials against its policy database. Cisco Secure ACS can also be configured to pass these credentials and attributes to an external server for validation (5). This is done using HCAP over an HTTPS tunnel. This may be the preferred option when client software comes with a PP and an external posture validation server for credential evaluation.

Where there is an external posture validation server, the external server checks the credentials and attributes against its internal database and returns an application posture token (APT) to Cisco Secure ACS. Cisco Secure ACS then collects all APTs from any local or external policies. The most restrictive of these APTs becomes the system posture token (SPT).

Cisco Secure ACS then places the client in a group corresponding to its SPT. These groups correspond to the access rights granted by the SPT and may be Healthy, Checkup, Quarantine, Infected, or Unknown. Cisco Secure ACS then sends the appropriate access control list (ACL) for the group to the NAD to be applied against the client (8).

Cisco Secure ACS can optionally include an HTTP redirect in the returned policy sent to the NAD to force a client to visit a particular server for a mandatory update and to determine if remediation has occurred.

A posture agent can be developed to return information contained in its credential by the CTA that can be used in many ways, including assessment for host intrusion detection system (HIDS), host intrusion prevention system (HIPS), personal firewalls, operating system patch levels, and application version control.

NAC Operational Detail

This section provides additional details about the NAC process for those who want to understand the process at a more technical level. This level of understanding is not required to implement NAC, but is helpful for troubleshooting and fine-tuning the process.

NAC is dependent on a Layer 3 Cisco IOS software device for policy enforcement. The installation of CTA and any compatible client software has no effect until the required commands are configured on the Cisco IOS software enforcement device, called the NAD.

The admission control process is triggered by a Layer 3 packet entering a router interface with admission control configured. After the NAC process is triggered, the router sends an EOU hello message to which the client host answers with an EOU hello. When the NAD and client recognize each other, the NAD asks for the identity of the client. When received, this identify is passed to Cisco Secure ACS in the form of an EAP over RADIUS packet. Cisco Secure ACS then initiates a PEAP session with the client host.

Note that the router acts as a pass-through device at this point; it does not proxy any part of the PEAP session but merely re-encapsulates the PEAP packets from UDP to RADIUS.

After the PEAP session has been established, Cisco Secure ACS queries the client for the credentials from registered software on the client. This causes the CTA on the client to query the PPs that have been registered with CTA for their credentials and attributes. These credentials and attributes are collected and sent to Cisco Secure ACS in the PEAP session. During this initialization phase, the packets received on the router interface are subject to any access list applied on that interface. Some packets may be dropped during this initialization. Figure 1-2 shows the details of this process.

When Cisco Secure ACS receives the credentials from the CTA, it looks for a NAC external user database configured in ACS with the best match of the same mandatory credentials as those it received from the CTA. The NAC external user databases have one or more policies configured in them. When the Cisco Secure ACS finds a match, it checks the credentials and attributes against any local or external policies in the matched database. These policies specify the values that the attributes in the received credentials must have to meet the admissions policy for the configured network.

Each policy returns an APT in a single credential back to the client, along with any supported actions, which are unique to each posture agent. The most restrictive of the application posture tokens are used as the SPT. The SPT determines the group into which Cisco Secure ACS places the client and the overall posture of that client. The actual enforcement rules are configured in the Cisco Secure ACS group policy. Enforcement rules take the form of downloadable ACLs, URL redirection, and timer adjustments. These enforcement rules are sent to the NAD by ACS at the termination of a successful validation session.

The NAD periodically queries the host to determine whether the posture of the client has changed or whether the host is the same host that has gone through the validation process. The NAD can also enforce a URL redirection to cause a client to automatically go to an attribute-value (AV) server for updates when the client attempts web access. This URL redirection is configurable from Cisco Secure ACS for each posture state.

You can also configure Cisco Secure ACS to shorten the status query value or the re-validation time on the NAD by sending a Cisco IOS AV pair with the specific timer values to be applied for a particular client to help ensure that the client successfully completes the remediation process. As each application is remediated, the application APT returns to a healthy condition, and eventually a healthy SPT is achieved.

If there has been a change, such as a new DHCP address being assigned or a changed DHCP client, (the client holding that address has dropped off line and a new client has been assigned the same address), the status query process fails and the validation process is restarted. If no response is received from the client, the system can download a default enforcement policy to the NAD to limit the network access of the client, depending on the overall network security policy.

Limitations and Guidelines

NAC is a Layer 3 technology, and NAC posture validation and enforcement is currently restricted to Layer 3.

Because communication between Cisco Secure ACS and the CTA uses PEAP, the CTA must trust Cisco Secure ACS. This trust is established using X.509 certificates. If you already have a certification authority (CA), you can generate a certificate signing request from Cisco Secure ACS and send it to your CA for enrollment. The CA (root) certificate must be installed on each client taking part in admission control. CA certificate installation occurs automatically at installation time if the certificate is placed in the \certs directory located below the directory from which the program ctasetup.exe is run. For details, see the section on CTA installation.

Cisco Secure ACS can also generate a self-signed certificate. In this case, the certificate from Cisco Secure ACS is installed on each client taking part in the admissions control process. This also occurs automatically if the certificate is placed in the \certs directory located below the directory from which ctasetup.exe is run.

If you generate an external private key and certificate for use on Cisco Secure ACS, you must install the certificate and private key files on Cisco Secure ACS.

Pre-Deployment Considerations

Successful deployment of NAC requires some planning ahead of the deployment. The primary consideration is the handling of clients as they go through the NAC process. This includes enforcement action for clients without CTA installed yet. Consider using a phased enforcement policy initially to limit the enforcement action taken when a large number of clients do not yet have CTA installed. This significantly limits network disruption.

This section describes other issues to consider and includes the following topics:

- Access Restrictions for Postured Clients
- Non-Responsive Hosts Handling

Access Restrictions for Postured Clients

This section provides an overview of the access restrictions for postured clients and describes the various conditions for which NAC tests. It includes the following topics:

- Category and Token Assignment
- Healthy
- Checkup
- Quarantine
- Infected
- Unknown

Category and Token Assignment

During the admission control process, clients are placed into a particular category and are assigned a token. One token is assigned per policy configured in the Cisco Secure ACS NAC external user databases. The token assigned depends on the values of the attributes contained in the credential originated by the NAC-compliant software on the client. The assigned categories of these returned tokens give each client specific access rights.

Category assignment can also cause pop-up messages to appear on the client screen and redirect a web browser to a specific URL. Cisco Secure ACS can send configured actions to individual software applications taking part in NAC. The particular actions are not discussed in this document because they are specific to the different applications participating in NAC. These actions can include the triggering of a software update or some other type of software-specific action. See specific software documentation for more details about the configurable actions supported by your vendor software.

Healthy

The Healthy category is assigned when the information received from the client posture agent credentials are current with the policy defined in the NAC external user database on Cisco Secure ACS. In this case, the scanning engine and the signature files are considered current for an AV policy or the current policy for a personal firewall are current, and no further action needs to be taken by the user. Normally, no access restriction is placed on a client in this condition.

Checkup

The Checkup category is assigned when the client may have some files, either the AV signature file or the scanning engine or some other third party software that supports NAC, which is not completely current with the network admission policy. Users should upgrade their client software to maintain currency, but no access restrictions are normally placed on the client in this state. This state can trigger normal AV DAT file updates or other non-mandatory file upgrades. A pop-up message can be configured to alert the user of the available upgrade.

Quarantine

When a client is assigned to the Quarantine category, the user must take immediate action to update their anti-virus files. A client might be placed in this condition during a virus outbreak to prevent the spread of the virus or when a particular OS vulnerability has been discovered to force a personal firewall policy

upgrade. To enforce this policy, an ACL can be downloaded to the NAD that permits access only to the upgrade server, and a URL redirection can force the client to visit the upgrade server. This effectively blocks any other network access and forces the client to immediately come into compliance with the network access policy.

Infected

The Infected category can be assigned when the client has been actively infected with a virus. It is normally the job of the posture agent installed on the client to check for an infected condition. This condition triggers ACLs to be downloaded that prevent any network access by the infected client until a remediation process is completed. A pop-up message can notify the user of the state of the machine and indicate the required action that must be taken by that user. A URL re-direction is normally configured in this case.

Unknown

The Unknown category can be assigned when there is no CTA on the client or the host did not respond to the EOU queries by the NAD. This can occur with hosts that do not have the admission control software loaded, with hosts that have unsupported operating systems, or with IP devices that do not support NAC. A clientless exception policy can be configured that is applied to any clientless device present on an interface performing NAC by creating a "clientless user" in the IOS NAD configuration. The unknown group contains the access restrictions necessary for these devices. These exception policies can include the specific destination hosts with which the excepted devices are permitted to communicate.

Non-Responsive Hosts Handling

Generally speaking, a non-responsive host is a client without posture agent software loaded. These clients might be IP devices such as IP phones, network-attached printers, or other IP devices. Any PCs or workstations that do not have the CTA or posture agent software loaded are also considered non-responsive hosts. These workstations may be running MacOS, Solaris, or unsupported versions of Windows. This can also occur with a client that does not trust the Cisco Secure ACS that is performing the validation process. Non-responsive hosts may be handled in the following three ways:

- Static policy—This configuration is performed on the NAD device only. These devices can be statically excepted via IP address, MAC address, or by device type (such as a Cisco IP Phone).
- Clientless user—A clientless user name and password is configured on the NAD. The same
 username and password is configured on the Cisco Secure ACS, and the username is assigned to a
 particular group with the appropriate access restrictions configured. These access restrictions can
 include IP access lists and URL redirections. This method of handling non-responsive hosts is
 identical to the creation of a clientless user for the unknown category mentioned previously.
- Restricted access—This classification takes no action whatsoever. The interface ACL configured on the NAD provides the default access restrictions for all non-responsive hosts on that interface.

Static Policy

One way to handle a non-responsive host is to configure a static policy in Cisco IOS software, which includes the IP address of the host, the MAC address of the host, or the configured NAD host type; and building an ACL that identifies the IP addresses and networks with which an unknown host can communicate. To use a static policy for non-responsive host handling, certain information about the hosts must be known, and this information must remain static.

Clientless User

A second method of handling non-responsive hosts is to define a clientless user. A clientless user is simply a username and password that have been configured in the NAD to be used in a RADIUS authentication packet when no credentials have been received during the posture validation process. A corresponding user is created in Cisco Secure ACS with the appropriate access limitations. For example, the user is placed into the unknown group in Cisco Secure ACS or another group with specific access restrictions enforced by downloadable ACLs. This limits the access of non-responsive clients according to the security policy.

Default Access

A third way to handle non-responsive hosts is to allow them to fail the posture checking process without a static policy configured and without permitting a clientless user. This prevents any access other than what is expressly permitted by the interface ACL configured on the router interface on which the posture validation occurs.

System Components

NAC consists of components from Cisco and various third-party vendors. NAC requires a supported Cisco IOS software platform (a router) between the client undergoing the admissions process and the protected network. NAC also requires Cisco Secure ACS version 3.3 or later as an integral part of the admissions control process. The CTA is a client-side component provided by Cisco that resides on the client and provides an interface to supported third-party software.

This section provides some detailed information about the required system components and includes the following topics:

- Hardware Requirements
- Software Requirements

Hardware Requirements

This section describes the hardware requirements for NAC implementations and includes the following topics:

- Access Control Server Hardware Requirements
- Client Hardware Requirements
- Cisco IOS Software Platform Hardware Requirements

Access Control Server Hardware Requirements

Cisco Secure ACS requires an Intel workstation with the following minimum hardware requirements:

- Pentium III processor running at 550 Mhz or faster
- 256 MB of memory
- 250 MB of free disk space
- Minimum supported graphics resolution is 256 colors at 800 x 600 screen resolution

If a Cisco Secure ACS internal user database is running on the same computer running Cisco Secure ACS, more disk space is recommended.

Client Hardware Requirements

There are negligible additional requirements for the client machines other than the necessary memory and processor speed to run the anti-virus software and Cisco Security Agent. See the anti-virus vendor or CSA documentation for further details about client requirements.

Cisco IOS Software Platform Hardware Requirements

The Cisco hardware platforms that are supported as NADs in a NAC implementation are shown in Table 1-1. This table also summarizes the software images that support NAC, the amount of flash memory required, and the amount of dynamic RAM required for each platform.

Router Model	Image Name	DRAM Required	Flash Required
Cisco 83x Series Router	c831-k9o3sy6-mz c831-k9o3y6-mz	48 MB 48 MB	12 MB 8 MB

Table 1-1	Cisco IOS Software	Platform Hardware	Requirements	(continued)
-----------	--------------------	-------------------	--------------	-------------

Each successfully validated client consumes a fixed amount of about 6 Kb. In addition, each downloadable ACL applied as a dynamic entry uses an additional .8 Kb of memory.

Software Requirements

NAC requires the following software:

- Cisco Secure ACS
- CTA on each client
- PP provided by a supported third-party anti-virus vendor

A posture validation server, which can be obtained from the anti-virus vendor with the appropriate PP, is optional. Table 1-2 summarizes the specific requirements for each of these components.

Component	Software Requirement		
Access Control	• Any of the following:		
Server	 Windows 2000 Server or Advanced Server with Microsoft Service Pack 3 or 4 		
	- Windows 2003 Server Enterprise Edition		
	• Either of the following:		
	 Internet Explorer version 6.0 SP1 		
	 Netscape 7.0.2 for browser access 		
	English language versions only are supported at this time. For further details, see the latest release notes available at the following URL: http://www.cisco.com/univer-cd/cc/td/doc/product/access/acs_soft/csacs4nt/acs33/rnwin332.htm		
Cisco Trust	One of the following:		
Agent	Microsoft Windows 2000		
	Microsoft Windows XP		
	• Microsoft Windows NT version 4.0 with Service Pack 4 or later		
	• One or more posture plug-ins provided by a NAC-supported vendor		
Cisco IOS software images	Advanced security images or greater, beginning with version 12.3(8)T. IOS version 12.3(8)T5 is recommended.		

Table 1-2 Software Requiremen

Third Party Supported Software

A variety of third party Cisco partners provide software that participates in the NAC solution. A list of the supported software and the third-party vendors can be found at the following URL: http://www.cisco.com/en/US/partners/pr46/nac/partners.html

Implementing Network Admission Control

This chapter describes how to implement Network Admission Control (NAC) and includes the following sections:

- Network Topology
- Configuration Overview
- Installing and Configuring the Cisco Secure ACS Server
- Configuring Client Credentials and Type Length Value Data
- Configuration Tips
- Installing the Posture Agent and Remediation Server
- Configuring the Cisco IOS Software NAD

Network Topology

Figure 2-1 shows the network that is used for the deployment example in this chapter.

Figure 2-1 Network Topology for Test Setup

Configuration Overview

The installation of NAC components can be completed in any order because there are no installation dependencies between the various components. However, perform the configuration of the NAD last, because traffic through the router interface performing NAC is blocked until the CTA and Cisco Secure ACS installations and configuration have been completed. NAC consists of the following components:

- Cisco Secure ACS
- Cisco Trust Agent (CTA)
- Network Access Device (NAD), which is a Cisco IOS router that separates protected and unprotected networks
- Anti-virus vendor software, along with any remediation server software if that has been supplied by the AV vendor

Installing and Configuring the Cisco Secure ACS Server

The following sections detail the installation (where required) and configuration of the individual components that comprise the NAC feature, and include the following topics:

- Configuration Overview
- Installing Cisco Secure ACS
- Configuring the Administrator Interface to Cisco Secure ACS
- Allowing Administrator Access Via HTTP
- Installing the Cisco Secure ACS Server Certificate
- Generating Signing Request, Enrolling and Installing Certificate
- Using a Self-Signed Certificate
- Configuring Logging
- Configuring a NAD in Cisco Secure ACS
- Configuring Network Access Filters
- Configuring Downloadable IP ACLs
- Configuring Groups and Vendor Specific Attributes
- Clientless User Configuration (Non-Responsive Hosts)
- Setting Up and Enabling Global EAP Authentication
- Configuring External User Databases
- Configuring Token to User Group Mappings
- Configuring an Unknown User Policy to Check an External Database

Installing Cisco Secure ACS

To install Cisco Secure ACS version 3.3 software on a machine running a supported operating system, run the setup.exe program provided with the Cisco Secure ACS installation software. When you install Cisco Secure ACS, the Setup program uninstalls any previous version of Cisco Secure ACS before it installs the new version. If you have a previous version, you are given the option to save and reuse your existing configuration.

The following sections describe how to set up Cisco Secure ACS for NAC. User authentication and authorization using TACACS+ or RADIUS and configuration of Cisco Identity-Based Networking Services (IBNS) or 802.1X is not covered and may be found in the Cisco Secure ACS user guide located at the following URL:

http://www.cisco.com/univercd/cc/td/doc/product/access/acs_soft/csacs4nt/acs33/index.htm

You configure Cisco Secure ACS using a web interface. The Welcome window is shown in Figure 2-2.

Figure 2-2 Cisco Secure ACS Welcome Window

Use the buttons on the Cisco Secure ACS main menu, located on the left frame of this window, to select a specific configuration task. This guide describes only the specific configuration that is required for implementing NAC.

Configuring the Administrator Interface to Cisco Secure ACS

The Cisco Secure ACS administrator windows are missing some necessary options by default. This is done to un-clutter the administrator windows from options that are not normally used. For the NAC solution to work, some of these configuration windows need to be enabled. These windows are used by Cisco Secure ACS to send enforcement actions to the NAD. To enable the appearance of the enforcement action windows in the Cisco Secure ACS administrator interface, perform the following steps:

Step 1 Click Interface Configuration on the Cisco Secure ACS main menu.

The system displays the window shown in Figure 2-3.

Figure 2-3 Interface Configuration Main Menu

Step 2 Click **Advanced Options** in the middle frame in this window. The system displays the window shown in Figure 2-4.

Figure 2-4 Interface Configuration Advanced Options

Step 3 Enable the following options in this window:

- Group-Level Downloadable ACLs—This enables the appearance of the downloadable ACLs option in the Shared Profile Components and Group Setup windows. These are used to cause Cisco Secure ACS to send network access policies to the NAD to be applied on a client undergoing NAC.
- Network Access Filtering—This option enables the appearance of the network access filtering option under the Shared Profile Components window. This allows a network to have differing enforcement policies downloaded for application to a client in a particular state depending on where in the network the client is located. For instance, if multiple remediation servers are present in a network, it is best to send a client in a quarantined state to the closest remediation server for its software update.
- Step 4 After checking these check boxes, click Submit.

This adds the downloadable ACLs configuration option and the network access filters configuration option to the Shared Profile Components window. These options are necessary for the configuration of the enforcement actions taken by the NAD.

Allowing Administrator Access Via HTTP

To enable remote Cisco Secure ACS configuration through the web interface, you must configure at least one administrator username and password. To do this, perform the following steps:

Step 1 Click Administration Control on the Cisco Secure ACS main menu.

The system displays the window shown in Figure 2-5.

Installing the Cisco Secure ACS Server Certificate

Protected EAP and the NAC feature require the use of certificates on Cisco Secure ACS and on the clients running CTA. The certificate installation process must be completed and Cisco Secure ACS restarted before beginning the PEAP configuration.

Cisco Secure ACS uses the certificate store that is built into the Windows operating system. The server certificate may be installed in several ways. If the public and private key pair to be used for the server certificate are generated on an external server, the certificate is installed by copying the files to the Cisco Secure ACS server and completing a series of forms. This example uses a certificate and a private key from a certificate authority named "Stress". These consist of three files: a CA certificate file named "ca.cer", a server certificate named "server.cer" to be used with the Cisco Secure ACS, and a private key file to be used with the Cisco Secure ACS named "private.pvk". Your file names may vary.

To install a public/private key pair that are generated on an external server, perform the following steps:

- **Step 1** Copy the public/private key pair files to a directory accessible to the Cisco Secure ACS server.
- **Step 2** On the System Configuration menu, click **Cisco Secure ACS Certificate Setup**. The system displays the window shown in Figure 2-7.

- **Step 14** Ensure that the check box for the CA to be used is checked.
- **Step 15** Restart Cisco Secure ACS.
- Step 16 Click System Configuration on the Cisco Secure ACS main menu.
- Step 17 Click Service Control.

The system displays the window shown in Figure 2-12.

Figure 2-12 Services Log File Configuration

Step 18 Click Restart.

Wait until the browser refreshes. Cisco Secure ACS has been successfully restarted.

Generating Signing Request, Enrolling and Installing Certificate

To use a private CA for enabling PEAP between the CTA client and the Cisco Secure ACS server, the Cisco Secure ACS server needs to generate a signing request and have the resulting key enrolled in the CA. You then install the private CA certificate on the Cisco Secure ACS server using the procedure described in Installing the Cisco Secure ACS Server Certificate, page 2-7. Then configure Cisco Secure ACS to trust the private CA and install the CA certificate on all the client machines participating in NAC.

To use a certificate from a private CA, perform the following steps:

- **Step 1** In the Cisco Secure ACS Certificate Setup window, click **Generate Certificate Signing Request**.
- **Step 2** Fill in the blanks with the appropriate information according to your own installation.
- Step 3 Click Submit.

The system displays the window shown in Figure 2-13.

Figure 2-13 Generate Certificate Signing Request

The private key is stored in the subdirectory and file that you entered.

The right frame in this window is the actual signing request ready for pasting into the CA certificate request. This signing request should then be transferred to the CA and the steps for enrollment completed. Please see the documentation provided with your CA for specific details on the enrollment process.

Using a Self-Signed Certificate

Cisco Secure ACS version 3.3 also allows the generation of a self-signed certificate. A self-signed certificate is useful when no CA or other trust authority is required. The self-signed certificate from the Cisco Secure ACS server is required for installing CTA on each client.

To use a self-signed certificate, perform the following steps:

- Step 1 Click Generate Self-Signed Certificate in the Cisco Secure ACS Certificate Setup window.
- **Step 2** Fill in the blanks with the appropriate information according to your own installation.
- **Step 3** Ensure that you enable **Install generated certificate**.
- **Step 4** After completing the certificate setup process, restart Cisco Secure ACS.

After generating and installing the self-signed certificate, include the certificate file as part of the install process for each client installing CTA.

Configuring Logging

Logging configuration is crucial for monitoring, reporting, and troubleshooting a NAC implementation. In addition to the local logging being configured here, the fields that you select are sent by the Security Information Management Solution (SIMS) agent that resides on Cisco Secure ACS to the SIMS management tool.

To set up logging, perform the following steps:

Step 1 Click System Configuration on the Cisco Secure ACS main menu.

Click logging.

Click CSV Passed Authentications.

The system displays the window shown in Figure 2-14.

Figure 2-14 Logging Configuration

Aggress e http://172.2	26.181.246:3790/index2.htm	re a unis "

User Setup Setup Barred Profile Barred Profile Certification Certificati	Logging Configuration Use Local Logging Configuration CSV Failed Attempts CSV FALUES Accounting CSV TACACS+ A during stration CSV VolP Accounting CSV ViolP Accounting CSV ViolP Accounting Cast Tack CS+ A during stration CSV ViolP Accounting Cast Tack CS+ A during stration CSV ViolP Accounting 	 CSV Lag: CSV Failed Attempts CSV TACACS: Accounting CSV TACACS: Administration ODBSC Failed Attempts ODBSC TACACS: A Antonistration ODBSC TACACS: Administration ODBSC TACACS: Accounting ODBSC TACACS: Administration ODBSC TACACS: Accounting Tacatact Lag Tag Tacatact Lag Tag

Step 2 Click Log to CSV Passed Authentications.

The system displays the window shown in Figure 2-15.

Figure 2-15 Enable Logging

Step 3 Enable the Log to CSV Passed Authentications report.

Step 4 In the Select Columns To Log list, select the attributes (fields) that you wish to include in the log file.

Useful fields to include in the logs include Reason, Application Posture Token, and System Posture Token. These should be moved towards the top of the list of installed attributes for easy access.

You must include the AAA Server field for SIMS to correctly parse the log output from Cisco Secure ACS.

The NAS-IP-Address and User Name fields also provide valuable information during troubleshooting.

The SIMS agent that resides on Cisco Secure ACS sends these fields to the SIMS server, with the SIMS server providing correlation and alerting functions.

You can include other fields as you like.

During initial setup, include the attribute values from the credentials. This makes writing the rules much easier. You can remove the attribute fields after initial configuration and troubleshooting. However, if they are removed, these fields do not appear in SIMS logs.

All client instances successfully completing the posture validation process are logged in the passed authentications log even if the client has posture validated into a state other than healthy. The failed authentication attempts log contains entries for clients failing to complete the posture validation process.

- **Step 5** Scroll down the window and change the file management settings if desired.
- Step 6 Click Submit.
- Step 7 Click System Configuration again on the Cisco Secure ACS main menu.

Step 8 Click Service Control.

The system displays the window shown in Figure 2-16.

	💡 Back to Help	If you want to designate more than one AAA client with a single AAA client entry in Cisco Secure ACS, you can specify the IP address for each AAA client to be

Step 3 Click **add entry** under the AAA clients table.

- **Step 4** Add the name of the NAD, the IP address from which the RADIUS packets will be sourced on that device, and the RADIUS key that was (or will be) used in the devices configuration. In the Authenticate Using window, select RADIUS (Cisco IOS/PIX).
- Step 5 Click Submit.

If there are multiple NADs, complete Step 2 through Step 4 for each NAD.

Step 6 After configuring the last NAD, restart AAA services.

To restart, click **Submit + Restart** or click **System Configuration** from the Secure ACS main menu, then click **Service Control**, and finally click **Restart** at the bottom of the window.

Configuring Network Access Filters

You can vary a downloadable ACL based on the NAD to which it is being downloaded. You might do this when remediation servers have been placed throughout the network and you want clients to connect to the closest remediation server. To do this, use Network Access Filtering (NAF). This feature allows you to control access easily by NAD and ensure that the client connects to the closest remediation server.

To configure a NAF, complete the following steps:

Step 1 In the Shared Profile Components window, click Network Access Filters.The system displays the window shown in Figure 2-18.

Type an explanation of the network access restriction. To specify that the restriction should permit or deny access to a specified AAA client or specified ports on a AAA client, follow these steps:
Submit Cancel	Select the Define IP-based access restrictions check box. From the Table Defines list, select either Permitted

Figure 2-18 Network Access Filtering

Step 2 Enter an appropriate name and description for the purpose of this instance of NAF.

An appropriate name might be east-coast or something similar that defines the portion of the network to which this NAF applies.

- **Step 3** Add the NADs, or if you are using network device groups in your configuration, add the appropriate network device groups.
- **Step 4** Click **Submit** to save your configuration.

The configuration of Downloadable IP ACLs differs slightly when you use NAFs in your configuration.

Configuring Downloadable IP ACLs

The enforcement action taken by the NAD is configured through Downloadable IP ACLs. Each category into which a client is validated must have a matching downloadable ACL associated with it. The access control entries contained in each ACL depend on your own network configuration and the access policy put in place by the network administrator. To configure downloadable IP ACLs, complete the following steps:

- Step 1 Click Shared Profile Components on the Secure ACS main menu.
- Step 2 Click Downloadable IP ACLs from the resulting menu.

The system displays the window shown in Figure 2-19.

Figure 2-20 Defining the Downloadable IP ACL Type

After creating the downloadable ACLs for each condition, define the ACLs that are actually sent to the individual NADs for enforcement action. The ACL elements vary depending on the policy set by the individual network administrator.

Step 5 Click the title of each downloadable ACL and enter a name for each ACL particular condition.

If NAFs are not being used in your network, the name of the ACL can be the same as the name of the condition for which this ACL is associated.

The system displays the window shown in Figure 2-21.

Figure 2-21 Defining an Access Control Entry

An example of the syntax for the ACL is **permit ip** *any any*. The first "any" in the ACL entry is replaced with the IP address of the host undergoing admission control to which this ACL is being applied. These ACLs are applied "over" the interface ACL. The downloadable IP ACL takes precedence over the interface ACL because the client source IP address is matched first.

- **Step 6** Click **Submit** after completing the entries in an ACL.
- **Step 7** Click **Submit** in the resulting window to save the downloadable ACL.

The system displays the window shown in Figure 2-22.

Figure 2-22 Completed ACL

Repeat this process for each ACL. Generally, ACLs should become more restrictive as the token returned in the credential drops in postured condition.

The next example for the quarantine ACL permits access only to the AV remediation server. NAFs are used to cause hosts in one section of the network to contact the closest remediation server.

- Step 8 Click quarantine previously created from the Downloadable IP ACLs window.
- Step 9 Enter a descriptive name for the instance of this ACL; for example, "east coast quarantine".

The system displays the window shown in Figure 2-23.

Figure 2-23 Adding a Quarantine IP ACL

Step 10 Enter the individual lines for the ACL being written.

Step 11 Click Submit after completing each window.

Do not use the buttons on the Cisco Secure ACS main menu to go to another section, because your entries are not saved unless you click **Submit** after completing each window.

The system displays the window shown in Figure 2-24.

Figure 2-24 Selecting the Filter List

Because the quarantine example uses NAFs, select the set of devices to which this ACL applies.

- **Step 12** Pick the appropriate filter list from the drop-down list.
- Step 13 If NAFs are not being used, select All-AAA-Clients.

These ACLs are "inserted" over the top of the interface ALC that is configured and applied to the router interface that participates in the posturing process to block traffic.

Configuring Groups and Vendor Specific Attributes

The group configuration section of Cisco Secure ACS is where actions and attributes are sent to the NAD. This causes any configured enforcement action to be taken by the NAD.

To configure groups and vendor specific attributes, complete the following steps:

- Step 1 Click Group Setup on the Cisco Secure ACS main menu.
- **Step 2** Choose the group numbers that correspond to the following conditions: Healthy, Checkup, Quarantine, Infected, and Unknown.

The system displays the window shown in Figure 2-25.

For example, RADIUS settings appear only if you have configured a AAA client that uses RADIUS.

Figure 2-26 Defining an Attribute-Value Pair

Step 7 In the [009/001] cisco-av-pair window, check the associated check box and enter an appropriate string for the group condition. For example, for the Healthy condition, enter posture-token=*Healthy*. A corresponding posture token must be entered for each group being configured. The Cisco IOS NAD receives this posture token as the only indication of the validated state of the client being posture checked.

The name of the actual AV pair is case-sensitive; for example, the posture token must be all in lower case. The strings for the values are not case-sensitive.

Note

The posture-token AV pair is the only way that Cisco Secure ACS notifies the AAA client of the SPT returned by posture validation. Therefore, it is important to type and format the AV name correctly and to identify the correct value for the posture-token attribute. Errors can result in the incorrect SPT being sent. If the AV pair name is mistyped, the AAA client does not receive the SPT.

The system displays the window shown in Figure 2-27.

Figure 2-27 Downloadable ACL and Attribute Configuration for the Quarantine Group

If a client machine is in a quarantined state and its access has been restricted to the AV remediation server, it is helpful to shorten the status query timeout. After the client has been through the upgrade process, a shorter timeout ensures that the client spends a minimal amount of time with restricted access.

Step 8 To change the status query timeout, use the string status-query=*timeout in seconds* where the value is between 30 and 1800 seconds.

Step 9 To configure URL redirection, use the following string: url-redirect=*http://172.30.2.10/*

This URL redirection is enforced by the NAD.

Note

If the interface ACL in the NAD does not contain an access line allowing access to the IP address where the redirection takes place, then a line must be added in the ACL that is paired with the group that has the URL redirection configured.

It may be desirable to change the revalidation timer for a particular group. This accomplished by checking the [027 Session-Timeout] check box in the IETF RADIUS Attribute section. Enter the number of seconds for the revalidation period under the IETF RADIUS Attributes section as shown in Figure 2-28 where the value is between 300 and 86400 seconds.

Clientless User Configuration (Non-Responsive Hosts)

A clientless user is one that does not have the CTA installed. Examples include printers, IP phones, or any other IP-connected appliance that does not support CTA. Workstations without supported OS versions are also considered clientless. PCs that have not yet been through the CTA installation process are also clientless.

There are two methods to provide access for clientless users or devices:

• Configuring a username and password combination on Cisco Secure ACS and in the Cisco IOS software NAD—When this method of allowing for clientless devices is used, the NAD constructs an ordinary RADIUS packet on behalf of the clientless device. This packet is sent to the access control server for validation, with the resulting access restrictions applied to all users authenticating with this method.

This username can be anything, but in the example shown in this section, the username "clientless" is used.

Configuring the clientless user exception policy with Cisco IOS software commands only—This
method can be used only for devices with known IP addresses or MAC addresses. This method does
not involve sending a RADIUS packet to Cisco Secure ACS. The configuration of this method is
shown in Configuring Clientless User Policy, page 2-51.

In the example shown in this section, the clientless user configuration is used with Cisco IOS software configuration to assign a user ID of "clientless" to the RADIUS packets that are returned by a host with no posture agent loaded.

If the user ID clientless is configured on the Cisco IOS software NAD, the user ID clientless must be added to the appropriate group in Cisco Secure ACS. This can be any group with the appropriate restrictions (usually the Unknown group) and downloadable ACL assigned.

To configure access for clientless users, complete the following steps:

Step 1 Click User Setup on the Cisco Secure ACS main menu.

The system displays the window shown in Figure 2-29.

Configuring External User Databases

The external user database configuration is the heart of the NAC configuration process. Here you define the policies to which the clients must adhere for network access. This section describes these configuration steps and provides some background information. It includes the following topics:

- Overview
- Preliminary Configuration
- Configuring Local Policy Verification

Overview

The rules that comprise a posture policy may be stored on Cisco Secure ACS in the form of policies in a NAC external user database, or may be stored where they are checked on an external posture validation server. As part of the query process, CTA forwards its own posture credential to Cisco Secure ACS, as well as any posture credentials it has received from other posture plug-ins. There is normally one credential per posture plug-in, with each credential having one or more attributes. A few posture agents send multiple credentials.

The particular set of credentials forwarded from CTA causes Cisco Secure ACS to select the appropriate NAC external database to use for the posture validation. When the NAC database is initially created, you configure a set of mandatory credentials. Cisco Secure ACS uses these mandatory credentials as the minimum requirement to pick the best matching instance of the NAC external user database to use for credential validation.

If all of the clients in your network have the same set of posture agents loaded, they all forward the same set of credentials to Cisco Secure ACS. In this case, you need only one instance of the NAC external user database. If different clients are returning different sets of credentials because you use more than one AV vendor or some clients have different posture agents loaded, then you may need one instance of the NAC external user database for each set of received client credentials.

Each external user database has a different set of mandatory credentials uniquely identifying the minimum set of received client credentials necessary for that external user database instance to be chosen for the validation session. The received credentials are compared against the list of NAC external user databases in the order in which the external user database names appear in the Cisco Secure ACS configuration. If a NAC external user database with a small number of mandatory credentials (or only a single mandatory credential) appears ahead of a database instance with a larger number of credentials, and the mandatory credential set of the first database matches the received credentials, the first database instance is used for validation of the NAC posture of that particular client. For this reason, the ordering of the databases in the Cisco Secure ACS configuration is important.

The attributes forwarded to Cisco Secure ACS in each credential are evaluated by one or more policies in the NAC external user database. When there are multiple policies present, each policy in the database instance is evaluated. After the attributes in the credentials are checked against the rules in a policy, Cisco Secure ACS assigns an application posture token (APT) for each policy. This APT is returned to the client in a credential specified in the configured action for the policy.

If multiple policies are configured, multiple application posture tokens are sent to the client. Each APT must send a unique credential; if two APTs are returned in the same credential by two different policies, an error occurs. The most restrictive of these APTs becomes the system posture token (SPT). The client is placed in a particular group based on this most restrictive token. Cisco Secure ACS then takes the configured action based on that group. This can include sending an ACL to a NAD for enforcement actions on that host or forcing a URL redirection.

If a particular combination of mandatory credentials are not received from a specific client, Cisco Secure ACS looks for a different NAC external user database with the correct minimum set of mandatory credentials. If a match of the minimum credentials is not found, the posture validation fails, and the client is denied any access except that expressly permitted by the interface ACL configured on the NAD.

You can configure a policy for each mandatory credential in the received packet. Each of these policies includes at least one rule for each posture state that is checked. Each rule is made up of one or more rule elements and each rule element checks the value of a particular attribute in a received credential. A rule returns an APT in a credential if all the rule elements test true. Every rule element in a particular rule must test true for the rule to evaluate true and for the resulting action (returned token and credential) to occur. The first rule that matches in a local policy is the rule that returns the APT configured for that policy.

Preliminary Configuration

To configure the NAC external user database(s), you must complete the following tasks:

1. Determine the number of unique combinations of posture agents present on the clients in your network.

For example, if a client has a supported anti-virus package and CTA, that is one combination. A client with the same supported anti-virus package and CTA plus CSA is another unique combination.

- 2. During the configuration of Cisco Secure ACS, create an instance of a NAC database in the External User Database section of Cisco Secure ACS for each unique combination of posture agents.
- **3.** For each database instance, configure a set of mandatory credential types that matches the credentials returned by the posture agents loaded on the client machines. If an exact match is not found, the Cisco Secure ACS picks the best match of mandatory credentials. Under the Unknown User Policy database configuration, order the External User Databases properly so that the proper database is matched first; that is, the least desirable database appears last. For example, if you have configured a database with only the Cisco:PA as the mandatory credential type; this matches all incoming NAC validations. This database should be the last database to be checked.

Configuring Local Policy Verification

When configuring the APTs to be returned by local policies, never configure two policies to return an APT in the same credential, because this results in a failure. If a large number of clients are going to be posture checked, and you expect them to return with a healthy token each time, you should configure and order the rules in the local policies to check for the healthy condition first. This reduces the number of rules Cisco Secure ACS checks and reduces the processing load.

To configure Cisco Secure ACS for using external user databases, complete the following steps:

- Step 1 To configure Cisco Secure ACS, click External User Databases on the Cisco Secure ACS main menu.
- **Step 2** Click **Database Configuration** from the resulting menu.
- Step 3 Click Network Admission Control.

The system displays the window shown in Figure 2-31.

Figure 2-31 External User Databases

Step 4 Click Create New Configuration.

Step 5 Enter a name for this instance of the NAC database.

If multiple different AV vendor products are present and participating in the admission control process, one instance of the external user database for each AV vendor combination needs to be created.

- **Step 6** Enter a unique name for the database instance and click **Submit**.
- **Step 7** If multiple instances of the NAC external user database have been created, as you begin the configuration process make sure that the database name appears in the External Database Configuration window and click **Configure**.

If there is only a single instance of the NAC database, the name of that database is the only option to configure and no drop-down list is present.

Two windows are displayed; one asking for any mandatory credential types, and the other where you configure the local (or external) policies for the credential validation.

- **Step 8** Click **Edit List** in the Mandatory Credential Types window.
- Step 9 Add the credential types to be returned from your client for this instance of the NAC database by highlighting the desired credential type and clicking the right arrow. If the returned credentials are not an exact match to one of the external user databases, the best match is used. If there are no instances of external user database with matching mandatory credentials returned by a client, that client validation process fails. The mandatory credential set acts as a minimum requirement for the instance of the external user database to be used for validation.

The system displays the window shown in Figure 2-32.

Figure 2-33 Mandatory Credential Types

In this example, the client to which this instance of NAC database applies is loaded with CTA and with CSA.

- Step 11 Click Local Policies, and click New Local Policy from the Local Policy Selection window.
- **Step 12** Enter a name and a description for this policy and a description if desired.
- Step 13 Click New Rule from the Configurable Rules window.
- **Step 14** Select the attribute that you wish to validate for this rule element and select the appropriate operator for validation. Each of these becomes a rule element.

Rule element values are case-sensitive. Although it is not mandatory, in most cases only attributes from a single credential type should be checked in a single policy.

The system displays the window shown in Figure 2-34.

To do so, select the bottom to the left of a rule and use the Up and Down buttoms to arrange it as needed. Define the default rule. To do so, under Default Rule, select a freshult redential Type and a Token, and if needed, type an Action. Click Salwait
P Back to Help	(Backto Top)
E Done	S Internet

Figure 2-35 Local Policy Configuration

This completes entering the criteria for a single rule. Directly below the display of the rule elements are several scroll windows and a text window. These define the action Cisco Secure ACS takes on a successful test for this rule. These actions include the return of a token in one of the credentials that contained the tested attributes.

Specific actions may also be entered into the Action window below the configured rule.

Actions are specific to the posture plug-in to which the APT is being returned. See the documentation supplied with the posture plug-in for specific details on these actions.

Step 16 To configure the order in which a rule is checked, highlight the radio button to the left of the rule and click **Up** or **Down**.

The last rule in the policy is the default rule. This rule is matched and the credential result and action returned if no other rules evaluate true for this particular policy. This result token is normally set to a token type such as quarantine or infected.

- Step 17 Make configuration changes as needed to the default rule and click Submit in this window and click Submit again in the next window.
- Step 18 To make the changes permanent, click Save Configuration in the last window.

Configuring External Policy Verification

Credentials may also be verified by an external posture validation server. A particular instance of the NAC external users database may contain both local and external policies. In these cases, credentials are sent to an external server over a protected connection with the Host Credentials Authorization Protocol

(HCAP). After the credentials and action are checked, the external server returns a token reflecting the current state of the client. The Cisco Secure ACS then puts the client in the corresponding group, with the configured ACLs of the group and Cisco IOS software AV pairs.

To configure Cisco Secure ACS for external policy verification, complete the procedure in Configuring Local Policy Verification, page 2-33 through Step 10. Then complete the following steps:

Step 1 Click New External Policy.

The system displays the window shown in Figure 2-36.

Figure 2-36 External Policy Configuration

sends the credential types in the Selected Credentials has		Rack-to-Help	the left and right arrow buttons to move highlighted credential types to the applicable list. Cisco Secure ACS sends the credential types in the Selected Credentials list

Figure 2-37 Selecting Forwarding Credential Types

Step 9 Scroll down the window and select the credentials to be passed to the external server.

If a particular credential is to be checked on an external policy server, there is no need to create a policy to check that credential locally.

Ensure that no local policies return an APT in the same credential that is being checked by an external policy server.

Step 10 Click **Submit** to complete the configuration process.

Configuring Token to User Group Mappings

To force a client with CTA into a policy with a particular ACL applied, place the clients with a particular returned token into a specific user group. Multiple sets of user groups may be configured, each with a different downloadable IP ACL, configured URL redirection and so on. This permits different enforcement actions for different instances of the external user databases. To create the token to user group mappings, complete the following steps:

Step 1 Click External User Databases on the Cisco Secure ACS main menu.

Step 2 Click Database Group Mapping.

The system displays the window shown in Figure 2-38.

Figure 2-38 Unknown User Group Mappings

For each instance of a configured database, perform the following steps.

Step 3 Click on the name of the configured database.

The system displays the window shown in Figure 2-39.

Figure 2-39 Token to User Group Mappings

- **Step 4** For each token, select the appropriate user group in which to place the client that has that token returned.
- **Step 5** Optionally, enter a message to be displayed on the client in a pop-up window after the initial posturing process has completed.

If a particular token does not have a user group associated with it, clients returning those tokens are given default access.

Step 6 Click Submit to save your configuration.

Configuring an Unknown User Policy to Check an External Database

EAP packets received with posture AV pairs are processed with the Unknown user policy. These packets do not contain conventional username password combinations like standard RADIUS authentication packets. To cause these packets to be checked against the policies contained in the external user databases that you have just configured, complete the following steps.

Step 1 From the External User Databases on the Cisco Secure ACS main menu, click Configure Unknown User Policy.

The system displays the window shown in Figure 2-40.

Applet started	S Internet

Figure 2-40 Configure Unknown User Policy

- **Step 2** For each external user database you wish to check, add the external user database name to the Selected Databases window with the arrow. Order the databases in the sequence in which you wish to have them compared against the received credential set.
- **Step 3** Click the Check the following external user databases radio button.
- Step 4 Click Submit.

Configuring Client Credentials and Type Length Value Data

This section describes the attributes with which the CTA responds to the querying process, and includes the following topics:

- Attributes Overview
- Client Installation Tasks
- Certificate Placement
- Using the ctad.ini File
- Using the ctalogd.ini File
- Installation

Attributes Overview

These attributes set the policy to which clients accessing the network must adhere. Various posture agents reside on a host, each of which responds with a credential containing attributes that reflect the condition of the associated software.

It is the duty of the Cisco Secure ACS or the external policy server to verify the attributes and to match the client to the preconfigured policy. This policy can include an ACL, URL redirection, or other action, which is passed back to the NAD and/or the CTA for enforcement. The attributes available in the returned credentials from different posture plug-ins are summarized in the following tables.

Attribute Type	Attribute Name	Data Type	Data Format	Example
PA	OS-Type	String		Windows 2000 Professional
PA	OS-Version	Version	X.X.X.X	5.0.2195.0
PA	PA-Name	String		Cisco Trust Agent
PA	PA-Version	Version	X.X.X.X	1.0.51.0

Table 2-1	Cisco	Trust	Agent
-----------	-------	-------	-------

Table 2-2 Cisco Security Agent

Attribute Type	Attribute Name	Data Type	Data Format	Example Values
Host	HostFQDN	String		client.cisco.com
Host	ServicePacks	String		Service Pack 4
Host	HotFixes	String		KB87232
HIP	CSAMCName	String		Not supported
HIP	CSAStatus	String		Not supported
HIP	LastSuccessfulPoll	Unsigned integer	Х	Not supported
HIP	OperationalState	Unsigned integer	Х	Not supported
HIP	CSAVersion	Version	X.X.X.X	4.0.2.611

Table 2-3	Anti-virus	Vendor	Attributes
-----------	------------	--------	------------

Attribute Type	Attribute Name	Data Type	Data Format	Example Values
AV	Dat-Date	Time		2/28/2004 07:00
AV	Dat-Version	Version	X.X.X.X	5.0.4697.0
AV	Protection-Enabled	Unsigned integer	X	0 or 1
AV	Scan-Engine-Version	Version	X.X.X.X	2.9.567.0
AV	Software-ID	Unsigned integer	X	
AV	Software-Name	String		Anti-virus software
AV	Software-Version	Version	X.X.X.X	5.0.2345.0

The specific data values to be tested for and returned from the posture agents can be found in the documentation from the vendor of the posture agent. In addition, there may be other credential types and attribute names returned by your posture agent vendor. Consult the posture agent documentation for details.

Client Installation Tasks

The Cisco Trust Agent is currently compatible with the following Microsoft operating systems:

- Windows 2003 Server
- Windows XP
- Windows 2000
- Windows NT version 4.0 SP4

The way you install CTA depends on the AV vendor participating in the admission control process. Some AV vendor installation processes include CTA installation and others do not. Consult your vendor documentation to determine the method of installation to use. This section describes how to install CTA manually. Complete the CTA installation before installing any application software participating in admission control.

The client needs administrator privileges to complete the installation of CTA. If the user does not have administrator privileges on the client, then Windows installer (MSI) elevated privileges must be enabled on the host. For specific information on the anti-virus software installation, see the documentation supplied with the specific product.

To install CTA on a Windows workstation, run the ctasetup.exe installation file. This setup program is compatible with all supported versions of Windows.

Directory Structure

During installation, ctasetup.exe creates folders in the following directories:

- Two folders in %CommonProgramFiles%\Cisco Systems
 - %CommonProgramFiles%\Cisco Systems\CiscoTrustAgent

This folder contains the CTA program files.

- %CommonProgram Files%\Common Files\Cisco Systems\CiscoTrustAgent\Plugins

This folder contains the posture plug-in files for the Cisco:PA credential ctapp.dll and ctapp.inf.

Any files required by the posture plug-ins are placed into the Install folder below the previous directory by the posture plug-in installer. These are moved to %CommonProgram Files%\Common Files\Cisco Systems\CiscoTrustAgent\Plugins automatically when CTA registers the posture plug-in.

If logging is enabled, log files are written to the following directory:

%ALLUSERPROFILES%\Application Data\Cisco Systems\CiscoTrustAgent\Logs

Certificate Placement

Using PEAP during the admission control process requires that the CTA trust the PEAP initiator, which is Cisco Secure ACS. This trust is established with an x.509 certificate. You must add the certificate of the CA that issued the Cisco Secure ACS server certificate (or the self-signed certificate from the Cisco Secure ACS) to the \certs folder located in the directory from where the ctasetup.exe file runs before installation.

During installation, the CA certificate is automatically added to the proper store inside the client machine and installed into the CTA. If multiple CA certificates are used, each one should be placed into the \certs subdirectory.

If a certificate needs to be added after the installation has been completed, use the ctacert.exe program, with the following options:

ctacert /add c:\certificate_file_location\ca.cer /store root

Using the ctad.ini File

To change the default behavior of the CTA, you can manually create an initialization file (ctad.ini). Place this file in the directory where the ctasetup.exe file is located before the installation is performed. The installation process automatically copies the ctad.ini file into the proper directory. The format of the ctad.ini file is as follows:

```
ctad.ini template
[UserNotifies]
; prevent user from doing anything else when message displayed
SvsModal=0/1
                 {default=1}
;
; these control the messages on the users' desktop
EnableNotifies=0/1 {default=1}
MsgTimeout=<seconds> {Default=300, Min=30, Max=0 (infinite)}
;
; These control the behavior for logon desktop. If message comes in on the
; logon desktop and logon desktop messages are disabled, then the message
; will appear on the user's desktop when the user logs in.
EnableLogonNotifies=0/1
                             {default=0}
LogonMsgTimeout=<seconds>
                             {Default=0 (infinte), Min=30, Max=0}
;
   This section can be used to adjust the port and behavior of the communication
   with the NAD. It may be omitted.
[EAPOUDP]
LocalPort=21862
MaxSession=3
SessionIdleTimeout=600
```

Using the ctalogd.ini File

To configure the logging process, manually configure the ctalogd.ini file before installation. This file should be placed in the directory with the ctasetup.exe program before installation. The logging level legend is as follows; 1 = low, 2 = medium, 3 = high, and 15 = everything.

An example ctalogd.ini file is included with the readme file for the ctasetup.exe program. This example file is as follows:

PEAP=3 EAPTLV=3 EAPSQ=3 PPMgr=3

This sample file enables the logging daemon and sets the logging level to high for each of the individual CTA subsystems.

Installation

During installation, a log of the installation is placed in the same directory from where ctasetup.exe was launched. This file should be saved for troubleshooting.

After CTA installation is complete, there are two new processes running as Windows services:

- Cisco Trust Agent
- Cisco Trust Agent Logging Services

Both services are configured to automatically start on system boot. See the readme file supplied with CTA for the latest information.

Additional Information

Additional information regarding the Cisco Trust Agent can be found in the administrator guide at the following URL:

http://www.cisco.com/en/US/partner/products/ps5923/products_administration_guide_book09186a008 023f7a5.html

Configuration Tips

This section describes some important configuration tips. It includes the following topics:

- Status Query Timeout Values
- Revalidation Timer
- External User Database Local Policy Rule Ordering

Status Query Timeout Values

The status query process ensures that a particular client remains in compliance with the policies configured in the Cisco Secure ACS or the external policy server. You can configure Cisco Secure ACS to set the status query timer for a lower value if a client has been assigned to checkup or a quarantine state. This may be helpful if access restrictions are placed on the client in these posture states. Lowering the status query timeout in these states reduces the amount of time the client spends with restricted access.

Revalidation Timer

The revalidation timer is the time for which the posture check remains valid. It can be set lower if a virus outbreak is detected and an update needs to be pushed to all clients. Revalidation can also be initiated via the Cisco IOS command **eou revalidate all**. This causes all clients to be revalidated.

External User Database Local Policy Rule Ordering

The order in which rules are checked can have a significant impact on the load placed on the Cisco Secure ACS server. For example, if the Cisco Secure ACS server checks first for non-compliant clients and most clients are compliant, the Cisco Secure ACS server must process many more rules than if the rules are ordered so that it checks for a healthy state first.

Installing the Posture Agent and Remediation Server

The specific installation procedures required to install the posture agent and the optional remediation server vary depending on the software in use. Consult the AV vendor documentation for complete details.

The CSA system attributes are validated by the Cisco Secure ACS server at this time. External policy servers are not used. Currently the supported attribute from the CSA is the CSA version.

Configuring the Cisco IOS Software NAD

This section describes how to configure the Cisco IOS software device acting as the NAD. It includes the following topics:

- Overview
- Configuring AAA EOU Authentication Protocols and Authentication Proxy Authorization Protocols
- Configuring AAA Setup, RADIUS Server Host, and Key
- Configuring Admission Control EOU
- Configuring an Exception List Configuration for Clientless Hosts
- Configuring Clientless User Policy
- Configuring EAP over UDP Timers
- Configuring the Interfaces and Intercept ACL
- Configuring the HTTP Server
- Enabling EOU Logging

Overview

Because the Cisco IOS software NAD is the enforcement device in NAC, you configure it last, especially if some clients do not have CTA installed. This causes less disruption to network operations. You can remove the Cisco IOS software enforcement commands that turn on NAC if problems occur. The Cisco IOS software NAC functions are built on top of authentication proxy (auth-proxy) code. Some of the commands are familiar if you have configured auth-proxy.

You must complete the following configuration tasks:

- 1. Configuring AAA server communication
- 2. Configuring the EOU authentication method
- 3. Enabling the Cisco IOS software http server
- 4. Creating an ACL to block interface traffic until the client has successfully completed the admission control process
- **5.** Optionally, building an intercept access list to define the traffic that triggers the admission control process
- 6. Configuring auth-proxy banner and timers
- 7. Configuring eou timers and the interface configuration necessary to enable NAC

You can optionally configure a policy for unknown devices with specific IP addresses to bypass the posture checking process. These devices may be subject to specific access limitations on a device-by-device basis if desired. For more information, see the Cisco IOS Software Release 12.3(8)T new features documentation specific to NAC.

To configure a clientless method of handling users with a RADIUS username and password, see Clientless User Configuration (Non-Responsive Hosts), page 2-29.

Configuring AAA EOU Authentication Protocols and Authentication Proxy Authorization Protocols

Enter the following commands to enable AAA services for EOU authentication:

aaa new-model aaa authentication eou default group radius aaa session-id common

RADIUS server groups may be used to send user authentication to different server sets than the posture validation authentication packets.

Configuring AAA Setup, RADIUS Server Host, and Key

Enter the RADIUS host IP address and RADIUS server key information with the following commands in global configuration mode:

radius-server host 172.30.1.10 auth-port 1645 acct-port 1646 radius-server key *secret*

Replace the word *secret* with the shared key you entered in the Cisco Secure ACS during the installation and configuration of that server. Also configure the source IP address interface for the RADIUS packets that was configured in Cisco Secure ACS server network configuration.

The source IP address of the transmitted RADIUS packets is configured with the following command:

ip radius source-interface FastEthernet0/0

This is the IP address from which Cisco Secure ACS receives RADIUS packets.

The following command allows non-standard attributes to be sent to RADIUS:

radius-server vsa send authentication

Configuring Admission Control EOU

The following command enables the EOU posture validation process. Any packet received on the interface to which this policy is applied triggers the admission control process.

ip admission name AVERT eapoudp

Optionally, you can exempt traffic from triggering the admission control process by applying an ACL to the NAC policy statement in the configuration. The following example causes traffic with a destination of port 53 (domain) or port 80 (www) to be exempted from the admission control process:

ip admission name AVERT eapoudp list 102

access-list 102 deny udp any host 10.10.30.10 eq domain access-list 102 deny tcp any host 10.10.20.10 eq www access-list 102 permit ip any any

These packets need a corresponding entry in the interface ACL to be successfully forwarded without a prior posture validation taking place. No posture validation triggering occurs if only deny statements are present in the intercept ACL.

Configuring an Exception List Configuration for Clientless Hosts

If hosts with a statically-configured IP address and no posture agent installed (non-responsive hosts) are located on the network where posturing is taking place, they may be exempted from the posturing process. The following commands configure a policy that allows a host with a static IP address access defined by an access list:

```
identity profile eapoudp
device authorize ip-address 172.30.40.32 policy NACless
identity policy NACless
access-group clientException
redirect url http://172.30.2.10/update
ip access-list extended clientException
permit ip any host 172.30.1.10
```

This configuration allows a host with an IP address of 172.30.40.32 to communicate with the host 172.30.1.10 and no other hosts. This configuration is useful for IP-connected printers or IP telephony devices.

In the case of networks where only web clients exist, URL redirection can point those clients to a server where the appropriate software can be obtained.

Note

The use of the exception list method of exempting individual hosts from the admission control process requires the use of named access-lists in the Cisco IOS software configuration.

Configuring Clientless User Policy

This section describes a different exception method for hosts without a posture agent installed. The **eou clientless username** command configures the Cisco IOS software NAD to insert a username of *clientless* for clientless end stations in the RADIUS protocol.

```
eou clientless username clientless
eou clientless password password
eou allow clientless
```

The eou clientless password command configures the password *cisco123* to be returned.

The **eou allow clientless-host** command enables the return of the previous username/password combination for all hosts the NAD attempts to posture without receiving a valid EOU response.

The Cisco Secure ACS then issues a token according to the group in which a user with the clientless username is placed. This configuration is useful for PCs and workstations that receive their IP addresses through DHCP and do not have the posture agents installed.

Configuring EAP over UDP Timers

The following commands configure the timers for the EOU posturing processes. These timers are shown with their default settings.

```
eou timeout hold-period 60
eou timeout revalidation 1800
eou timeout status-query 300
ip auth-proxy inactivity-timer 10
```

The **eou timeout hold-period** command ignores packets from a host that has just unsuccessfully authenticated for the hold period in seconds. The **eou timeout revalidation** command sets the global revalidation period for all clients. This may be overridden by a RADIUS AV pair from the Cisco Secure ACS. The **eou timeout status-query** command sets the global status query period. This may also be overridden by an AV pair received from the Cisco Secure ACS.

Configuring the Interfaces and Intercept ACL

The interface configuration consists of two commands that must be configured on the interface facing the hosts to be posture validated.

```
interface FastEthernet0/0
ip address 172.30.40.1 255.255.255.0
ip access-group 101 in
ip admission AVERT
access-list 101 permit udp any host 172.30.40.1 eq 21862
```

The **ip access-group 101 in** command places an ACL on the interface in the inbound direction that blocks all traffic entering the interface except for that which is expressly permitted. This ACL, called the interface ACL, is useful for creating pin holes that allow certain kinds of inbound traffic before subjecting that device to the posturing process. For example, an access control element (ACE) permitting UDP packets equal to domain allows for DNS queries to be successfully sent without being postured. The interface ACL at a minimum must permit inbound UDP communication destined to port 21862. The first permit ACE allows this UDP traffic into the NAD. This is necessary for the EOU communications. The **ip admission AVERT** command applies the previously configured NAC policy to the interface.

The traffic specifically permitted by access list 102 is subject to the posturing process.

Configuring the HTTP Server

Enabling the HTTP server is necessary for URL redirection. When URL redirection is configured in the group configuration section, these URL redirections are sent to the Cisco IOS software NAD.

```
ip http server
ip http authentication aaa
no ip http secure-server
```

Enabling EOU Logging

Enable logging from the Cisco IOS software NAD with the following commands:

```
eou logging
logging 172.30.1.20
```

This enables syslog messages at an informational level (syslog level 6) from the posturing process.

Additional Information

Additional information may be found in the *Cisco IOS Configuration Guide and Command Reference* for Network Admission Control found at the following URL:

http://www.cisco.com/univercd/cc/td/doc/product/software/ios123/123newft/123t/123t_8/gt_nac.htm

Managing and Troubleshooting NAC

This chapter describes how to manage and troubleshoot NAC and includes the following sections:

- Management and Reporting
- Troubleshooting and Logging

Management and Reporting

The Cisco Security Information Management System (SIMS) is an integral part of a NAC deployment. SIMS is an important tool for monitoring the condition of the network where admission control is implemented. This section describes how to use SIMS for monitoring and reporting NAC activity, and includes the following topics:

- SIMS Hardware Requirements
- Monitoring and Reporting

SIMS Hardware Requirements

The recommended hardware requirements for a SIMS installation are a dual Xeon processor class machine with 2 GB of memory and 50 GB of disk space.

This machine requirement is for a system that receives 1,000 messages per second. If the load on the server is different, the characteristics of the system may be adjusted accordingly. To obtain installation procedures for the host operation system, RedHat Linux Enterprise v2.1, and the SIMS software, see the documentation provided with SIMS at the following website:

http://www.cisco.com/univercd/cc/td/doc/product/rtrmgmt/cw2000/cw2000_b/sims/3_1_1/

Monitoring and Reporting

SIMS provides several features for monitoring and reporting NAC network activity. The NAC dashboard shown in Figure 3-1 provides a consolidated view of the state of the application software being monitored by the NAC system.

Figure 3-1 netForensics SIM Desktop

This window displays the percentage of compliant and non-compliant hosts, and average remediation times. Other available reports list the hosts subject to posture checking and summarize overall network compliance.

For information about using SIMS, see the *netForensics User's Guide* at the following URL:

http://www.cisco.com/univercd/cc/td/doc/product/rtrmgmt/cw2000/cw2000_b/sims/3_1_1/user.pdf

Troubleshooting and Logging

NAC helps ensure that connected client machines are submitted to an access policy that specifies criteria for applications that must be met before the client machine is allowed network access.

By examining the various logs from CTA, the Cisco IOS software NAD, and Cisco Secure ACS, you can obtain a fairly accurate picture of the NAC activity on your network.

The SIMS server correlates the log messages from Cisco IOS software and from Cisco Secure ACS. The Cisco IOS software NAD also provides Cisco IOS software **debug** and **show** commands for monitoring and troubleshooting purposes.

Overview of Operational Checks

When a client in the healthy condition accesses the network, the posturing process takes place transparently. No user notification of the admission control process takes place unless a pop-up message has been configured in the Cisco Secure ACS database mapping section. If network access is not allowed but the client should have been assigned a Healthy condition, make sure that the client CTA services are currently in a started state in the Microsoft Services windows in the control panel, and that the CTA has successfully started a PEAP session with the Cisco Secure ACS. This can be determined by examining the CTA log file.

If PEAP does not start properly, check the certificate installation in both Cisco Secure ACS and CTA. If PEAP starts but an unexpected EAP type is shown in the CTA log file, make sure that the Allow CNAC check box has been checked under the Global Authentication Setup menu in Cisco Secure ACS System Configuration and that the Unknown user policy has been properly configured under the External User Database section of ACS. If a PEAP session is successfully started and the expected results are still not achieved, check the external user database policy configuration and rule sets. The received attribute values may be found in the logging and reporting section of the ACS Administrators screen.

CTA Logging

To start CTA logging, run the **ctalogd enable** command from the command-line interface (CLI) in the directory where CTA is installed. After running this command, ctalogd writes a trace of its current activity into the following directory:

C:\Documents and Settings\All Users\Application Data\Cisco Systems\CiscoTrustAgent\Logs

For sample output from a CTA logging session, see CTA Logging Output, page A-4.

Cisco Secure ACS Logs and Troubleshooting

The passed and failed authentication .csv files log files, which are created by Cisco Secure ACS, are of particular interest to NAC administrators. If properly configured, these logs contain the attribute values that are present in the clients.

Cisco Secure ACS Passed Authentication Log

During the configuration process, Cisco Secure ACS is set up to log passed and failed authentications to comma-separated values (CSV) files. To access these files, use the **Reports and Activity** option from the Secure ACS main menu. During the rule configuration, view these files frequently to verify the attribute values being sent to Cisco Secure ACS in the received credentials.

To view the Reports and Activity window, complete the following steps:

- Step 1 Click Reports and Activity from the Cisco Secure ACS main menu.
- **Step 2** Click **CSV Passed Authentications** in the window that is displayed. The system displays the window shown in Figure 3-2.

Figure 3-2 Reports and Activity

The current admission control session appears in the passed authentications file even if the client was posture checked into an unhealthy state. This is because the posturing process has completed successfully.

Pay special attention to the Reason field in the log file, because this shows the particular instance of the NAC external user database, the policy, and the specific rule in the policy that was matched to produce the SPT.

Cisco Secure ACS Failed Authentication Log

Some useful information may not be written to the failed log file because of the unknown state that a client may be in when the authentication for NAC fails. This information might include the credentials Cisco Secure ACS was expecting to receive as well as the attribute values contained in the credentials.

Some of the reasons a client admission control attempt appears in the failed attempts log include the following:

- The set of NAC external user databases configured may not have a set of mandatory credentials that matches the set of received credentials from that client.
- The NAD may not have been configured properly in Cisco Secure ACS.

Cisco IOS Software Commands

Cisco IOS software contains **show**, **clear**, and **debug** commands useful for verifying and troubleshooting NAC processes.

Cisco IOS Software Log Output

The following shows the console output from a router taking part in the admission control process with the **eou logging** command configured:

```
nac1751#
May 13 13:05:16: %EOU-6-SESSION: IP=172.30.40.16| HOST=DETECTED| Interface=FastEthernet0/0
May 13 13:05:16: %EOU-6-CTA: IP=172.30.40.16| CiscoTrustAgent=DETECTED
May 13 13:05:18: %EOU-6-POLICY: IP=172.30.40.16| TOKEN=healthy
May 13 13:05:18: %EOU-6-POLICY: IP=172.30.40.16| ACLNAME=#Cisco Secure
ACSACL#-IP-healthy-40a00ae9
May 13 13:05:18: %EOU-6-POSTURE: IP=172.30.40.16| HOST=AUTHORIZED|
Interface=FastEthernet0/0
May 13 13:05:18: %EOU-6-AUTHTYPE: IP=172.30.40.16| AuthType=EAP
May 13 13:10:18: %EOU-6-SQ: IP=172.30.40.16| STATUSQUERY|VALIDATED
```

The last line shows a single successful status query. These are informational level messages and are not normally seen by any logging device.

Cisco IOS Software Show Commands

nag1751#gh oou all

The show eou all command displays a list of the currently detected hosts and their posture states if any.

naci/ji#sh eou	a11			
Address	Interface	AuthType	Posture-Token	Age(min)
172.30.40.16	FastEthernet0/0	EAP	healthy	13

This command may also be run with an IP address substituted for the **all** keyword to show the state of a single host.

show ip auth-proxy cache posture

The **show ip access-list** command displays the currently downloaded ACLs at the end of the output.

```
nac1751#sh ip access-lists
Standard IP access list access
   10 deny 192.168.0.1
   20 permit 192.168.0.0, wildcard bits 0.0.255.255
   30 permit 172.30.0.0, wildcard bits 0.0.255.255
    40 permit 172.31.0.0, wildcard bits 0.0.255.255
   50 deny any
Extended IP access list 101
    permit ip host 172.30.40.16 any (12 matches)
    10 permit ip any host 172.30.40.1 (1227 matches)
Extended IP access list clientException
   10 permit ip any host 172.30.1.10
Extended IP access list sl_def_acl
   10 deny tcp any any eq telnet log
   20 deny tcp any any eq www log
   30 deny tcp any any eq 22 log
   40 permit ip any any log
Extended IP access list xCisco Secure ACSACLx-IP-healthy-40a00ae9
   10 permit ip any any
```

nac1751#

In this example, the last access list is named xCisco Secure ACSACLx-IP-healthy-40a00ae9. This ACL has a single line, **permit ip any any**.

The first **any** in this ACL has been replaced by the IP address of the posture-checked client and the result has been placed over the top of the ACL (ACL 101 in this case) applied to the interface on the Cisco IOS software device taking part in the admission control process.

Correcting a Blank or Incorrect Posture

If the results of the **show eou all** or **show eou ip address** commands include postures that do not match the actual result of posture validation or display "------" instead of a posture, the posture-token AV pair may be misconfigured in one or more groups in Cisco Secure ACS, or the group mapping may be misconfigured in the NAC database that processed the posture validation request.

If the posture displayed is "------," the AAA client (the NAD) is not receiving the posture-token AV pair within a Cisco IOS/PIX RADIUS cisco-av-pair vendor-specific attribute (VSA). If the posture displayed does not correspond to the actual result of posture validation, the AAA client is receiving an incorrect value in the posture-token AV pair.

Check group mappings in the NAC database to verify that the correct user groups are associated with each system posture token (SPT). In the user groups configured for use with NAC, be sure that the Cisco IOS/PIX RADIUS cisco-av-pair VSA is configured correctly.

For example, in a group configured to authorize NAC clients receiving a Healthy SPT, be sure the [009\001] cisco-av-pair check box is checked and that the following string appears in the [009\001] cisco-av-pair text box:

posture-token=Healthy

EOU Commands

The following commands may be used to cause a re-initialization or a revalidation of any or all hosts on a network being subject to admission control:

```
eou initialize all
eou initialize ip x.x.x.x
eou revalidate all
eou revalidate ip x.x.x.x
```

These commands are useful if a virus outbreak is detected and a new signature file is available. Client hosts that had already been successfully validated can be revalidated to immediately get the new signature file.

When a host is initialized, all previous state information about that host is deleted and the admission control process for that host starts with no state. When a host is revalidated, state information about that host is retained so that the host still has its current access during the revalidation process.

Cisco IOS Software Clear Commands

The Cisco IOS software **clear eou** command removes the state information regarding admission control about any or all hosts detected. This command can be used for specific IP addresses or for all the sessions on a specific router.

```
nac1751#clear eou all
nac1751#
```

May 13 13:18:47: %EOU-6-SESSION: IP=172.30.40.16 | HOST=REMOVED | Interface=FastEthernet0/0

Cisco IOS Software Debug Commands

The following debug commands are available for the various admission control components:

nac1751#debu e	ou ?	
all	All EA	APoUDP debugging messages turned on
eap	Debug	EAP packets
errors	Debug	Errors
events	Debug	Events
obj-create	Debug	EAPoUDP Session Creation

obj-unlink	Debug	EAPoUDP session removal from hash table
packets	Debug	EAPoUDP packets
ratelimit	Debug	Ratelimit Events
sm	Debug	EAPoUDP State Machine Events
debug eap		

For sample debug output, see Admission Control Session Debug Output, page A-1.

Debug Output and CTA Logs

This appendix provides sample output form debugging and CTA logs and includes the following sections:

- Admission Control Session Debug Output
- debug eou events Output
- EOU State Machine Debug Output
- CTA Logging Output

Admission Control Session Debug Output

The following shows debug output during a successful admission control session and during the clearing of that session.

```
nac1751#show debug
eou:
  EAPoUDP Session Creation debugging is on
  EAPoUDP Session Destroy debugging is on
  EAPoUDP Session Removal from Hash Table debugging is on
  EAPoUDP Session Addition to Hash Table debugging is on

May 13 13:20:32: eou-obj_link:172.30.40.16: EAPOUDP Session added to Hash table
nac1751#clear eou all
nac1751#
May 13 13:20:56: eou-obj_destroy:(172.30.40.16): Session Timedout
May 13 13:20:56: eou-obj_unlink:172.30.40.16: EAPoUDP Session removed from hash table
May 13 13:20:56: eou-obj_destroy:172.30.40.16: Session Destroyed
nac1751#
```

debug eou events Output

The **debug eou events** command shows the timers being reset during successful communication between a client with CTA and a NAD.

EOU logging has also be enabled in this trace to show when the host is validated. These informational messages begin with EOU-6.

```
nac1751#deb eou events
Events debugging is on
nac1751#

CTA Logging Output

To start CTA logging, run the **ctalogd enable** command from the CLI in the directory where CTA is installed. After executing this command, **ctalogd** writes a trace of its current activity into the following directory:

C:\Documents and Settings\All Users\Application Data\Cisco Systems\CiscoTrustAgent\Logs

The following shows a trace from a successful posture validation session:

Cisco Trust Agent Version 1.0.48.0 Copyright © 2003 Cisco Systems, Inc. All Rights Reserved. Trust Agent Type(s): Windows, WinNT Running on: 5.1.2600

Reference Information

This appendix provides a list of acronyms and definitions of terms used in Network Admission Control (NAC). It provides sources of further information about NAC and includes the following sections:

- Acronyms
- Definitions
- Related Documentation

Acronyms

Acronyms	Definition
AAA	Authentication, Authorization, and Accounting
ACE	Access Control Element
ACL	Access Control List
Cisco Secure ACS	Access Control Server
APT	Application Posture Token
AV	Anti Virus
AVP	Attribute Value Pair
CA	Certificate Authority
СТА	Cisco Trust Agent
EAP	Extensible Authentication Protocol
FW	Firewall
НСАР	Host Credential Authorization Protocol
HTTPS	Secure Hyper Text Transfer Protocol
IDS	Intrusion Detection Systems
NAC	Network Admission Control
NAD	Network Access Device
PA	Posture Agent
PB	Posture Broker

Table B-1 Acronyms

Acronyms	Definition
PEAP	Protected Extensible Authentication Protocol
RADIUS	Remote Access Dial In User Service
SPT	System Posture Token
TACS+	Terminal Access Controller Access Control System Plus
TLS	Transport Layer Security
TLV	Type Length Value
UDP	User Datagram Protocol
VPN	Virtual Private Network

Table B-1 Acronyms (continued)

Definitions

Table	B-2	Definitions
IUNIC		Dennitions

Term	Definition
AAA Server	Evaluates credentials from peer and determines network access policy for enforcement by Authenticator. May use back-end servers for credential evaluation, such as vendor-specific posture servers such as the NAI AV Server. Also supports access policies for "cli- entless hosts".
Access Accept	AAA Server returns Access Accept to Authenticator to indicate that the peer has had its credentials evaluated successfully and (option- ally) that a new access policy is to be enforced as a result. Success- ful evaluation means that the Authenticator must keep state that the Peer has had its credentials checked so that the Peer is not checked again until it is time to re-validate the Peer.
Access Reject	AAA Server returns Access Reject to indicate that the credentials have not been evaluated successfully, and no (new) access is to be provided to the peer. Unsuccessful evaluation means that the Au- thenticator does not maintain state about the peer; that is, the peer credentials need to be checked again after some configurable hold period. The default access policy continues to apply to rejected peers.
Accounting	The process of collecting quantitative data about sessions for the purposes of troubleshooting, capacity planning, or auditing.
Association	A single instance of the L3 access control protocol (Apocope) between peer and authenticator. Represented by state of conversa- tion, IP address of other party, active timers, keys used in status query.

Term	Definition
Authentication	In the case of identity, the use of credentials to establish that a principal is who he or she claims to be. In the case of posture, the use of credentials to establish that the posture of the end-system is what the principal says it is.
Authenticator	Logical entity in the gateway that initiates the exchange of EAP cre- dentials, relays EAP credential requests and responses between peer and AAA server, and enforces network access policy on a particular port or interface based on the results from the AAA server. Same functionality as authenticator in EAP or 802.1X, but does not include any AAA server functionality. In addition to acting as an EAP "pass-through" for EAP methods that require a AAA server, the authenticator implements EAP methods that do not require AAA server functionality, in particular, the EAP status query method.
Authorization	The act of determining what part of the network a principal is permitted to access based on identity or posture or both.
Cisco Trust Agent	Cisco software that implements peer functionality
Clientless host	A TCP/IP host that does not have the posture agent installed
Credential	A piece of information presented by a principal in support of a claim of identity or posture. Includes identity and posture information itself. Examples include username, password, and AV signature file version.
Default Access Policy	Access policy applied to a peer when the policy has not been updated as a result of an Access Accept
End-system	A TCP/IP host; for example, desktop, server, IP phone, printer
Gateway	L3 network device that has authenticator functionality. May be one or more hops from peer
Identity	A unique name associated with a principal.
IP Intercept ACL	A special type of access control list (ACL) that indicates which packets on an interface trigger validation of the peer (source IP address of the packet)
Network Access Device	First hop network device (as measured from peer) that has authen- ticator functionality
Network Access Filtering	A method of changing the downloadable access list depending on which network access device is receiving the download.
Network Device	L2 or L3 networking equipment such as switches, routers, wireless access points, and VPN concentrators
Peer	Logical entity in end-system that responds to requests for creden- tials from authenticator for the purposes of gaining access to re- stricted network. Referred to as supplicant in 802.1x. Same as peer in EAP.
Posture	The state of a device; for example, set of applications loaded on desktop; AV scan engine version and signature file version; FW version and rules file

Table B-2	Definitions	(continued)
		(continuou)

Term	Definition
Posture Agent	The software implementing the posturing process on a client machine. This includes, but is not limited to, the Cisco Trust Agent.
Posture Client	Cisco or third-party software that resides on the peer and responds to requests from posture agent for posture credentials.
Posture Server	Cisco or third-party back-end server that responds to requests from AAA server to validate vendor-specific posture credentials from posture client.
Principal	Something with an identity; for example, a user or a device.
Provisioning	Configuration of network devices and servers needed to deliver services for a principal.
User	A human being using a device.
